14 Archives 2543
14.1 Migrate from TrackMe V1 to TrackMe V2 . . . 2543

TrackMe has transitioned to a new licensing model.

- The Free Community Edition has been discontinued.
- What this means for you:
  - Existing licensed customers are not impacted. Your current license continues unchanged.
  - Community users are automatically upgraded to a Foundation Edition trial for 90 days, with full functionality enabled.
- After the trial period:
  - TrackMe remains active and fully usable for monitoring
  - The platform enters read-only mode
  - You can continue to view data, dashboards, alerts, and history
  - Creation of new tenants, trackers, or entities will be disabled
  - To continue using TrackMe with full capabilities after the trial, a Foundation license is required.

Buy Foundation Edition: https://trackme-solutions.com/get-foundation/

The PDF version of this documentation is available here. For a nine-page overview of the product, see the `product brochure (PDF)`.

TrackMe for Splunk is the ideal companion for your Splunk deployment, no matter the size of your environment. Its unique capabilities help you on a daily basis to get the best value from your Splunk investments:

- Discover and maintain Splunk entities at scale, track availability and quality of any kind of data in Splunk
- Virtual tenancy is a key concept in TrackMe which allows creating on the fly knowledge objects in a repeatable way: create and scope tenants, experiment, destroy and restart as needed
- TrackMe allows tracking your local Splunk deployment, or transparently any number of Splunk remote deployments (subject to licensing restrictions)
- TrackMe's unique workflow combines best Splunk capabilities, from a comprehensive user interface to notable events generation, SLA tracking and many more
- Get the best from TrackMe components, using splk-feeds components provide deep Splunk feed tracking, splk-vol (Volume Outliers) detects abnormal drops and spikes of the licensed volume of every index, splk-cim provides Common Information Model (CIM) compliance tracking, splk-flx (FLEX) adapts to any kind of Splunk magic query, and the dedicated tenant types raise findings: splk-uam (User Activity Monitoring) tells you who is doing what on your Splunk, the Cribl Stream tenant monitors your Cribl Stream deployment from its own metrics, the Cribl Edge tenant follows your Cribl Edge Fleets and Edge Nodes at any fleet size, and the Splunk HEC tenant monitors your HTTP Event Collector endpoints, pools and tokens from Splunk's own telemetry! (components are subject to license restrictions)
- Extend the visibility at any point in time with Hybrid and Elastic trackers, use Machine Learning outliers detection with deep and easy control, TrackMe is incredibly rich in features

CHAPTER

TWO

USE CASES:

2.1 Quickstart — hands-on walkthroughs

Guided walkthroughs of TrackMe, captured live on the product: every page is a slide deck with a description of what each slide shows — read it top to bottom, present it, or download it.

Suggested order for a first contact with the product: the introduction, then the three parts of the series (a first tenant, classification, alerting), then the walkthroughs of the components you plan to use.

Product introduction What TrackMe watches — your data, the people, the forwarders, the HEC endpoints and the Cribl pipelines around it — how it decides and how it tells you: the vocabulary before the live product. *29 slides · 25 min.*

Product introduction Part 1 — Your first DSM tenant Create a Virtual Tenant, let the hybrid tracker discover the feeds, read the first entity in alert and why. *16 slides · 20 min.*

Part 1 — Your first DSM tenant Part 2 — Classify with policies Priority and tags from a CMDB lookup, simulated before saving; the on-call and ownership views. *12 slides · 15 min.*

Part 2 — Classify with policies Part 3 — Stateful alerting One alert scoped to critical and high; the incident lifecycle, the email with charts and the AI report. *16 slides · 20 min.*

Part 3 — Stateful alerting Topology Studio A map generated from a tenant, one authored from scratch, Topology Alerts, and a map built with AI. *39 slides · 40 min.*

Topology Studio Field Quality Monitoring CIM and custom dictionaries, sampling, the field-quality advisors. *35 slides · 40 min.*

Field Quality Monitoring Volume Outliers Licensed volume per index, verified figures, ML outliers on drops and spikes, the ML Advisor. *43 slides · 35 min.*

Volume Outliers User Activity Monitoring Who is doing what on your Splunk: Finding groups, privileged users, knowledge objects, custom policies, emails to the account concerned, and which data is read. *48 slides · 48 min.*

User Activity Monitoring Cribl Stream A Cribl Stream deployment from its own metrics: Finding groups and triage, traffic ML models and their tuning, Workers and data paths, the AI Agent. *33 slides · 35 min.*

Cribl Stream Cribl Edge The Fleets and Edge Nodes of a Cribl Edge Leader at any size: connectivity, rollouts, version drift, any node up close, and the AI Agent. *30 slides · 30 min.*

Cribl Edge Splunk HEC The HTTP Event Collector of a deployment: endpoints from their heartbeats, pools per data centre, tokens by name, a heavy forwarder stopped, and the AI Agent. *32 slides · 30 min.*

Splunk HEC Splunk S2S The receiving side of a deployment: an indexer cluster as one pool per site, the heavy forwarder tier as an automatic pool, what is blocked, the data path, a heavy forwarder stopped, and the AI Agent. *26 slides · 30 min.*

Splunk S2S Splunk UF Fleet The forwarding agents of a deployment at any fleet size: Deployment Server accounts, CMDB enrichment, groups, expected agents, a site gone dark, and the AI Agent. *26 slides · 30 min.*

Splunk UF Fleet

2.1.1 Product introduction

What TrackMe is and what it watches, from your data to the licensed volume, the people, the forwarders and receivers, the HTTP Event Collector endpoints and the Cribl pipelines around it; the two ways of watching — entities and findings — how it decides and how it tells you: the vocabulary and the mental model before the live product.

`Download the deck (PDF) · PowerPoint`

about 25 minutes · 29 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

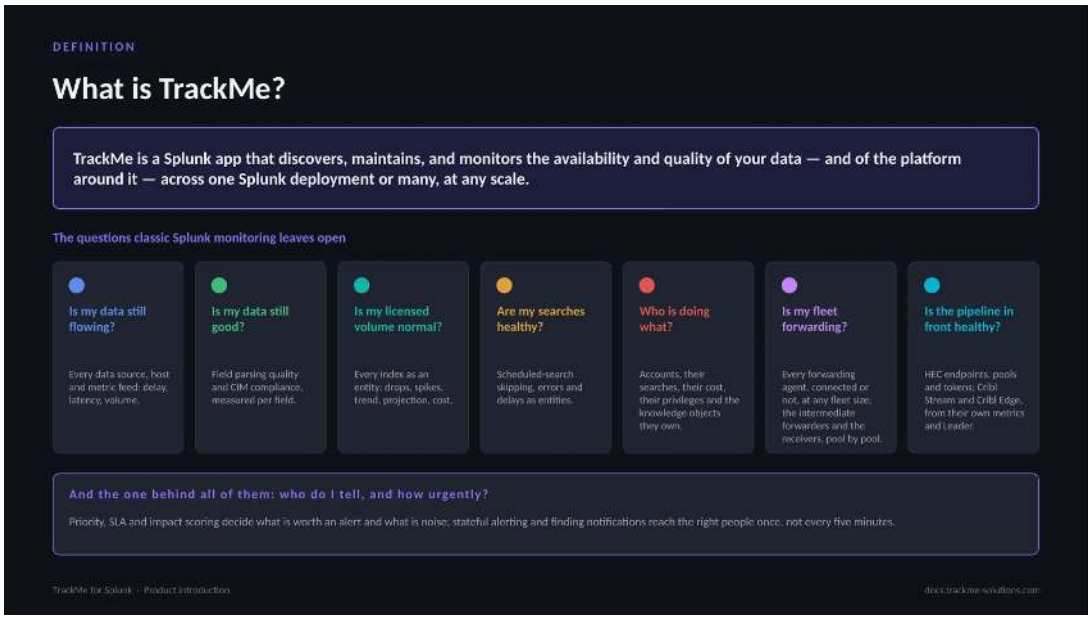
Overview

This introduction sets the vocabulary and the mental model of TrackMe 2.4.22. Everything here maps one to one to the Product Guide on docs.trackme-solutions.com. TrackMe started with the data — is it arriving, is it good — and today it covers the platform around it too: the licensed volume of every index, the people and service accounts using Splunk, the forwarders and receivers carrying the data, the HTTP Event Collector endpoints receiving it, and the Cribl pipelines in front of it.

What breaks silently

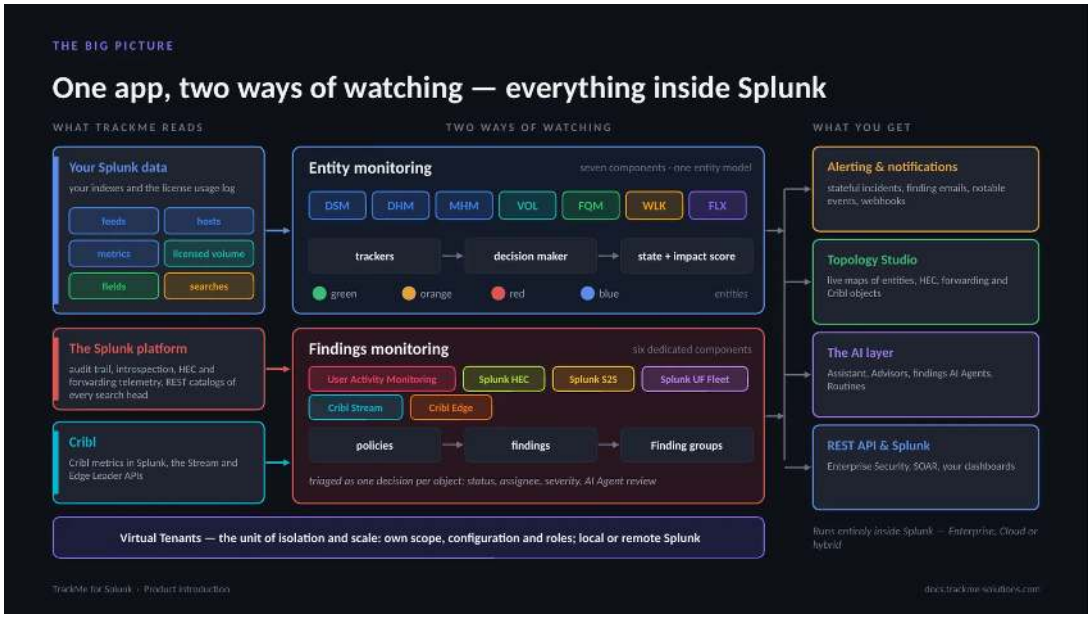
Most teams come to TrackMe because of one specific pain: a critical feed died hours ago and nobody noticed; a host went silent while the index still looked busy; a field extraction drifted and a detection stopped firing; scheduled searches started skipping. And the platform around the data fails just as quietly: an index doubling its licensed volume, an account running all-time searches on a schedule nobody owns, two hundred forwarders dropping at once behind a receiver tier, an intermediate forwarder whose output pauses and holds every sender behind it, a HEC token gone silent behind a load balancer that still answers, a Cribl Destination in backpressure in front of Splunk. One root cause: Splunk does not monitor itself, and you cannot watch or classify all of it by hand.

What TrackMe is



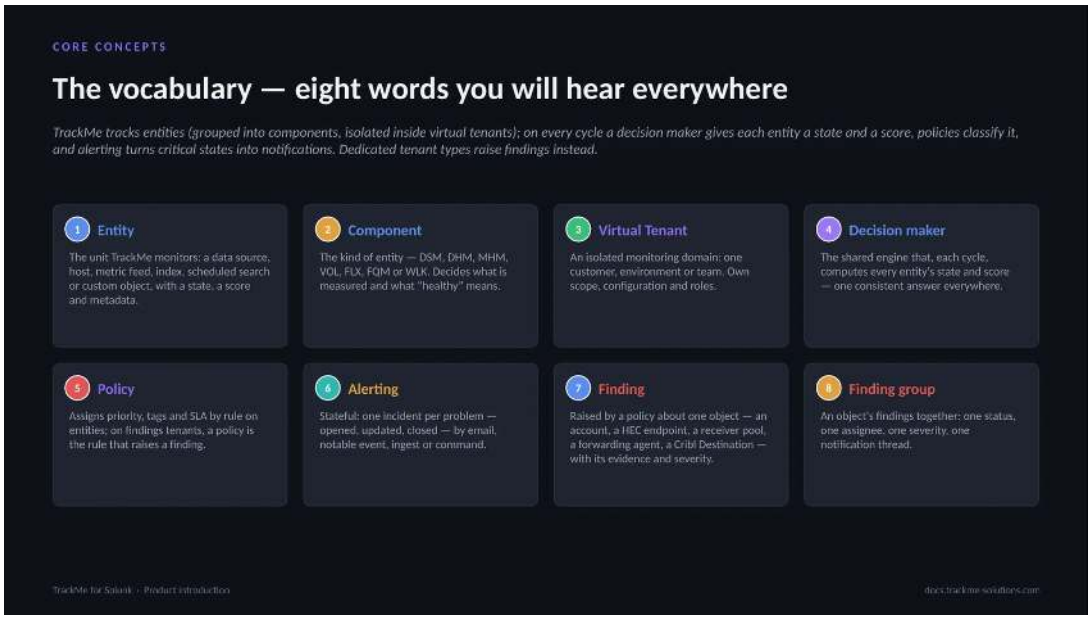
One sentence: TrackMe discovers, maintains and monitors the availability and quality of your data. It is a control plane on top of Splunk that runs entirely inside Splunk — on-premises, Splunk Cloud or hybrid — with no outbound SaaS. It answers the questions classic Splunk monitoring leaves open, from the data itself to the platform around it: is the data flowing, is it good, is the licensed volume normal, are the searches healthy, who is doing what, is my fleet forwarding, is the pipeline in front healthy, from the HEC endpoints to Cribl Stream and Cribl Edge. Who it is for: Splunk administrators proving the platform is healthy, SOC and detection engineers who depend on complete, well-parsed data, platform owners who answer for the licence and the usage, service owners reporting SLA attainment, and managed service providers.

The big picture



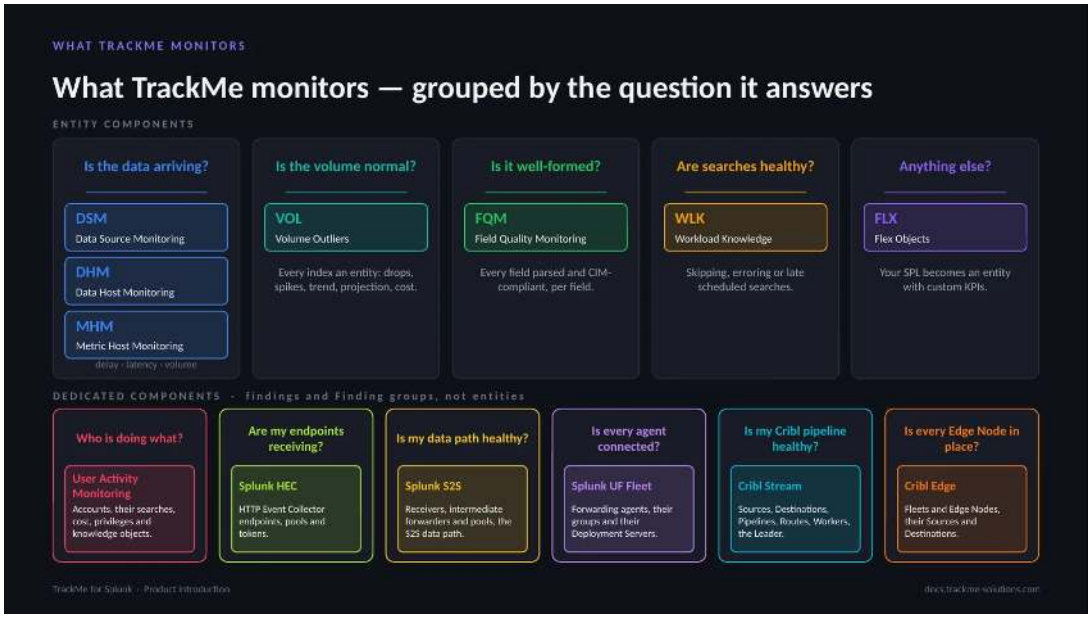
On the left, what TrackMe reads: your Splunk data, the Splunk platform itself, and Cribl. In the middle, two ways of watching. Entity monitoring is the historical core: seven components turn data feeds, hosts, metrics, the licensed volume of each index, field quality, scheduled searches and any SPL into entities with a state and an impact score. Findings monitoring is the second model, used by six dedicated components — User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge: policies raise findings, grouped per object into Finding groups that you triage. Both live in Virtual Tenants. On the right, what you get from both: alerting and notifications, live maps in Topology Studio, the AI layer, and the REST API.

The vocabulary



TrackMe has a small, consistent vocabulary that appears on every page of the guide and in the UI. Entity monitoring: an entity belongs to a component, lives in a virtual tenant, gets its state from the decision maker; policies classify it and alerting turns critical states into notifications. Findings monitoring adds two words: a finding, raised by a policy about one object — an account, a HEC endpoint, a receiver pool, a forwarding agent, a Cribl Destination — and the Finding group that gathers an object's findings into one decision. There is no global list of entities: everything lives inside exactly one tenant.

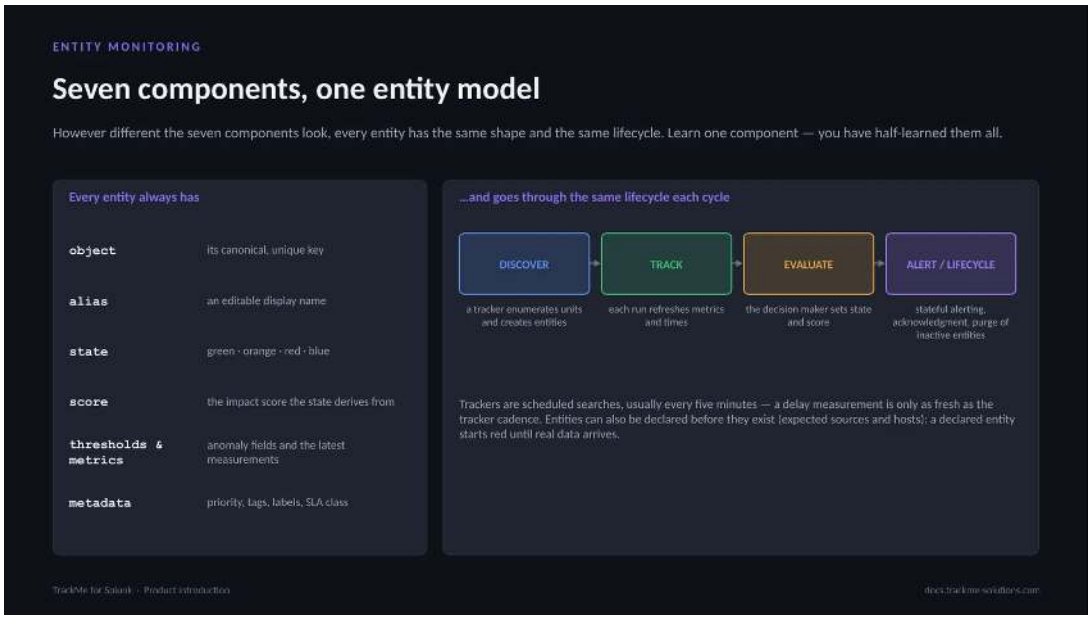
What TrackMe monitors



TrackMe monitors two families, grouped by the question each answers. Seven entity components: DSM, DHM and MHM answer whether the data is arriving, VOL whether the licensed volume of each index is normal, FQM whether the data is well-formed, WLK whether the scheduled searches are healthy, and FLX monitors anything else from the SPL you write.

Beside them, six dedicated components raise findings and Finding groups instead of tracking entities: User Activity Monitoring answers who is doing what on Splunk, Splunk HEC whether every HTTP Event Collector endpoint, pool and token is receiving, Splunk S2S whether the receivers and the intermediate forwarders accept and keep up, pool by pool, Splunk UF Fleet whether every forwarding agent is connected and its Deployment Servers are healthy, Cribl Stream whether the Cribl pipeline in front of Splunk is healthy, and Cribl Edge whether every Edge Node is where it should be. Almost every deployment starts with DSM.

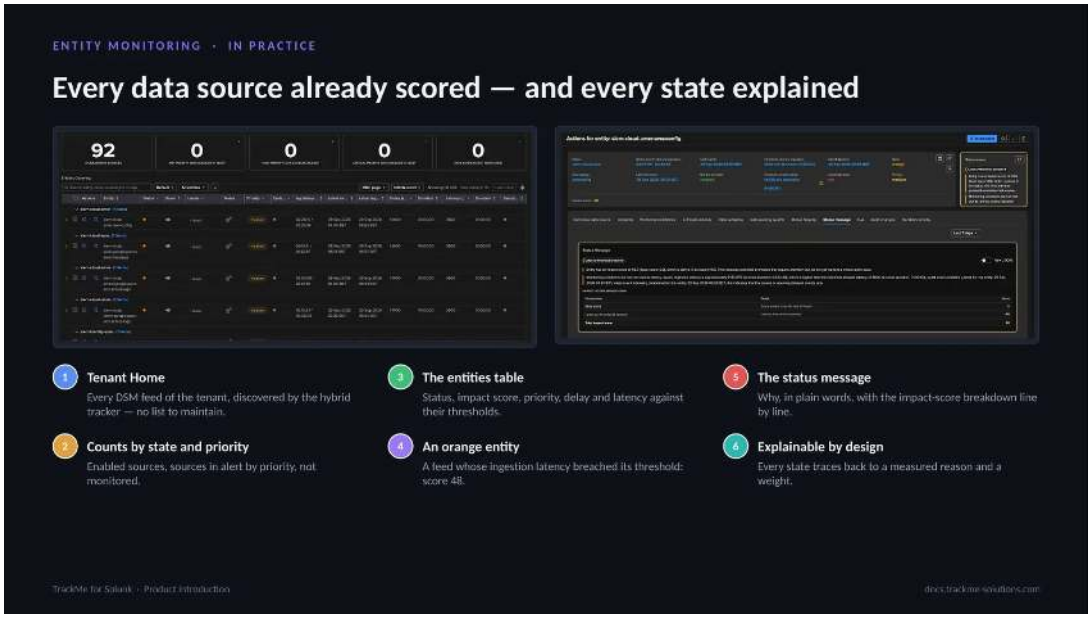
One entity model



The shared entity model is what makes TrackMe consistent: the same object, alias, state and score shape, the same lifecycle. Classification, protection, stateful alerting, scoring and ML outliers are documented once and apply to all seven components. Where they differ: variable delay and lagging classes are DSM and DHM; data sampling and

elastic sources are DSM; dynamic thresholds are FLX and FQM; versioning and orphan detection are WLK; VOL has one entity per index, fed incrementally from the license usage log, with ML outliers as its state.

Entity monitoring in practice



Tenant Home lists every data source the hybrid tracker discovered, already scored: the counts by state and priority on top, then the entities with their status, impact score, priority, delay and latency against their thresholds. Here several feeds are orange with a score of 48.

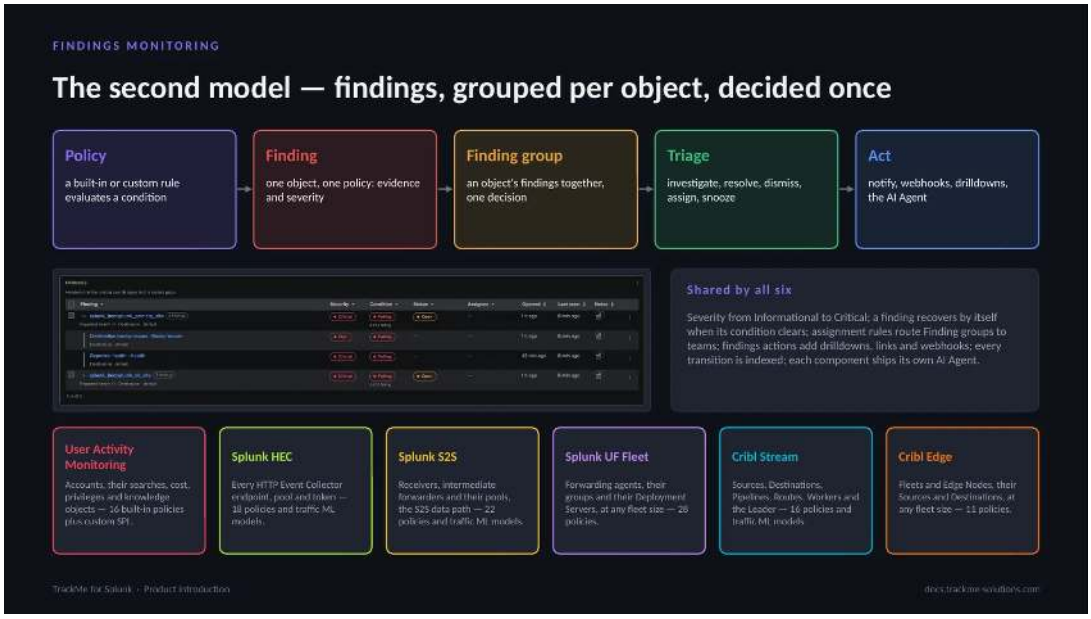
The status message of one of them explains why in plain words: its ingestion latency breached the threshold, which adds 48 to the impact score, above zero and below 100, so orange. The breakdown lists every contribution line by line: every state traces back to a measured reason and a configurable weight.

Volume Outliers

Volume detection has always been part of TrackMe — DSM volume outliers, FLX licence-usage use cases. VOL is its standardised, first-class form at scale: one entity per Splunk index, the licensed volume read incrementally from the license usage log with one search over a single source every five minutes, never a 24-hour rescan; ML outliers on drops and spikes, one model per index; trend and month projection. The Global license usage view answers the

licence questions people otherwise build dashboards for: who consumes, the trend, days over quota, working-day averages, costs and chargeback. VOL is part of the Foundation edition.

The findings model



Some things are not entities with a health score: an account that runs all-time searches, a HEC token gone silent, a receiver pool with a member silent, a fleet of forwarders disconnecting together, a Cribl Destination in backpressure, an Edge Fleet left on an old version. For those, six dedicated components — User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge — share one findings model. A policy evaluates a condition and raises a finding about one object, with its evidence and a severity on the TrackMe scale from Informational to Critical. All findings about one object form a Finding group: one status, one assignee, one severity, one notification thread. Findings recover by themselves when the condition clears; a person decides the rest. The same model brings assignment rules, webhooks and notifications, every component ships its own AI Agent, and nothing is installed on the platforms being watched.

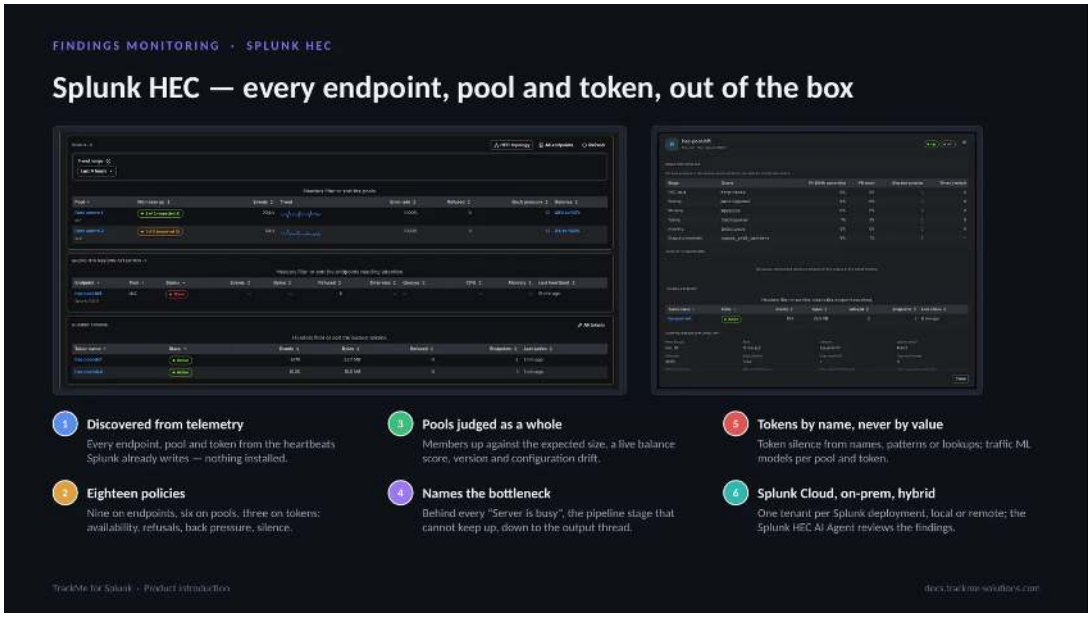
User Activity Monitoring

User Activity Monitoring is a dedicated tenant type for one indexing layer seen through one to ten search head tiers. The Findings tab groups the findings about an account and the saved searches it owns into one Finding group; the

account view in front shows one person's activity over the last 24 hours, its executions by search type, run time and the apps used, next to the catalogs of what the account owns.

Sixteen built-in policies in four families — inventory, activity, resources and privileged users — and custom policies in SPL raise the findings; a Privileged users tab shows which accounts hold high privileges and why. UAM can email the account concerned, the UAM AI Agent reviews findings on demand or on a schedule, and nothing is ever changed on the platform.

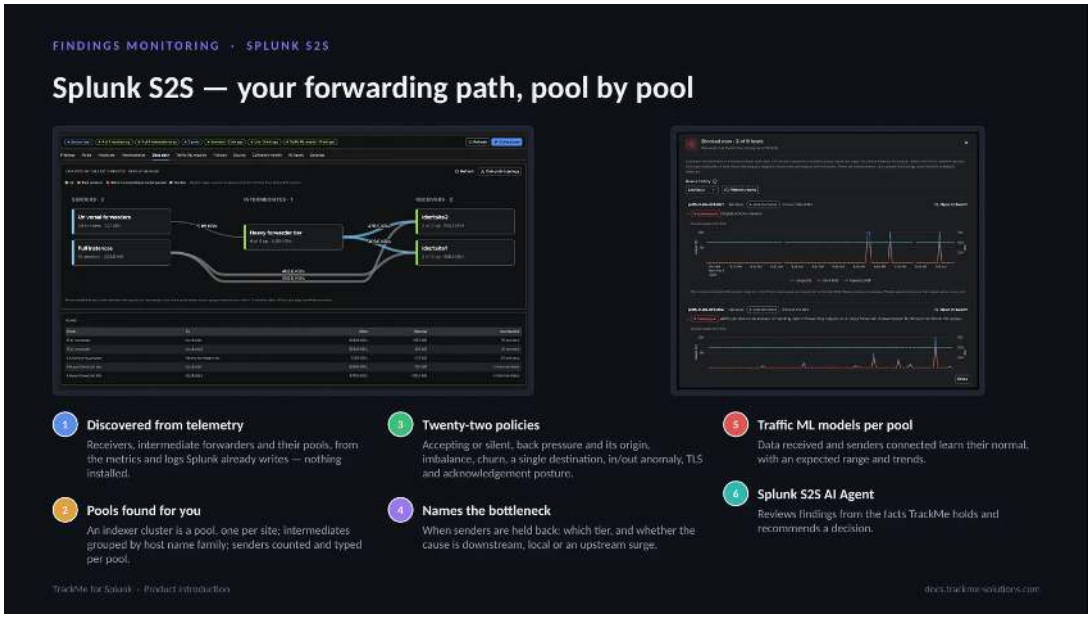
Splunk HEC



A Splunk HEC tenant watches the HTTP Event Collector of one Splunk deployment, Splunk Cloud included, from the telemetry Splunk already writes: every HEC instance logs a heartbeat to _introspection every minute. Endpoints are discovered automatically and grouped into pools, the hosts behind one load balancer, judged as a whole: members up against the expected size, a live balance score, version and configuration drift. Tokens are known by name only, never by value.

Eighteen built-in policies raise findings — availability, senders refused, back pressure naming the pipeline stage that cannot keep up, pool imbalance, token silence — and traffic ML models learn every pool and token. On the left, the pools with one member gone silent; on the right, one endpoint's ingestion pipeline, every queue with its fill. Nothing is installed on the endpoints.

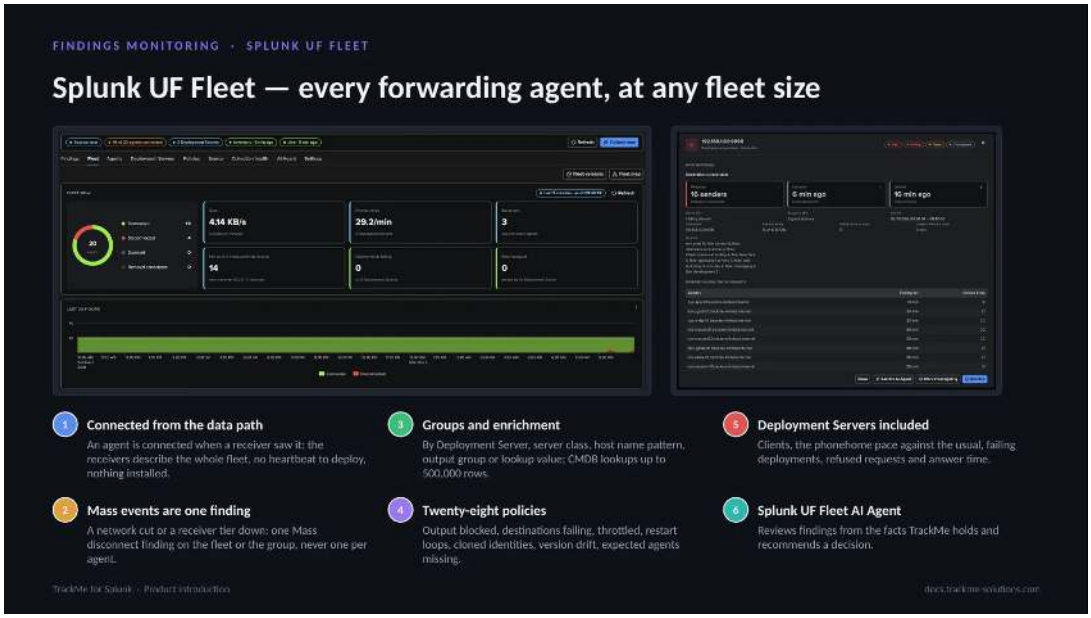
Splunk S2S



A Splunk S2S tenant watches the receiving side of forwarding for one Splunk deployment: the receivers, the intermediate forwarders and the pools they form, from the metrics.log connection lines, queues and throughput, the splunkd.log messages and the health report Splunk already writes. An indexer cluster is a pool, one per site of a multisite cluster; intermediate forwarders are grouped by host name family; senders are counted and typed per pool. On the left, the data path of the last five minutes with the rate on every edge; on the right, Blocked now names the queue that cannot keep up on each host.

Twenty-two built-in policies raise findings: a receiver that stops accepting or goes silent, back pressure and its origin, imbalance, churn, a single destination, TLS and acknowledgement posture. Traffic ML models learn every receiver pool, and the Splunk S2S AI Agent reviews the findings. Nothing is installed on any Splunk instance.

Splunk UF Fleet

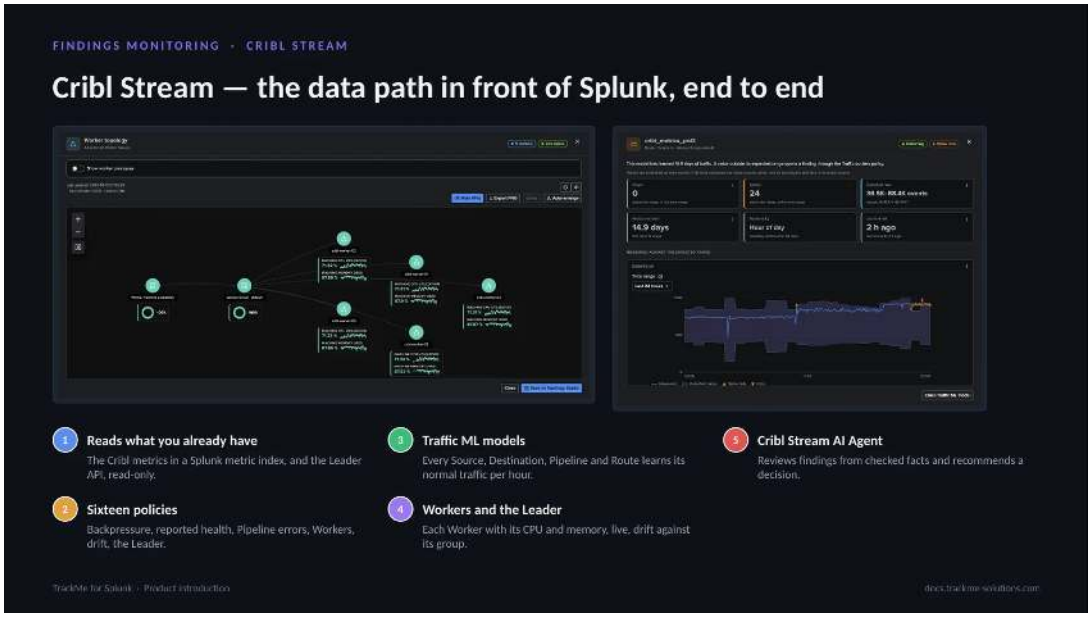


A Splunk UF Fleet tenant follows the forwarding agents of one Splunk deployment and the Deployment Servers that manage them. An agent is connected when a receiver saw a connection from it within the connected window: the receivers describe the whole fleet, whatever its size, with no heartbeat to deploy. On the left, the fleet now: connected, disconnected and dormant agents, versions, Deployment Servers and the last 24 hours; on the right, a

Destination unreachable finding with its sixteen failing senders listed by group.

Mass events are one finding: when many agents disconnect together, one Mass disconnect finding on the fleet or on the group says it. Groups come from the Deployment Servers, server classes, host name patterns, output groups or lookup values; enrichment lookups carry the CMDB onto every agent. Twenty-eight built-in policies cover the agents, the fleet and the Deployment Servers; the Splunk UF Fleet AI Agent reviews the findings.

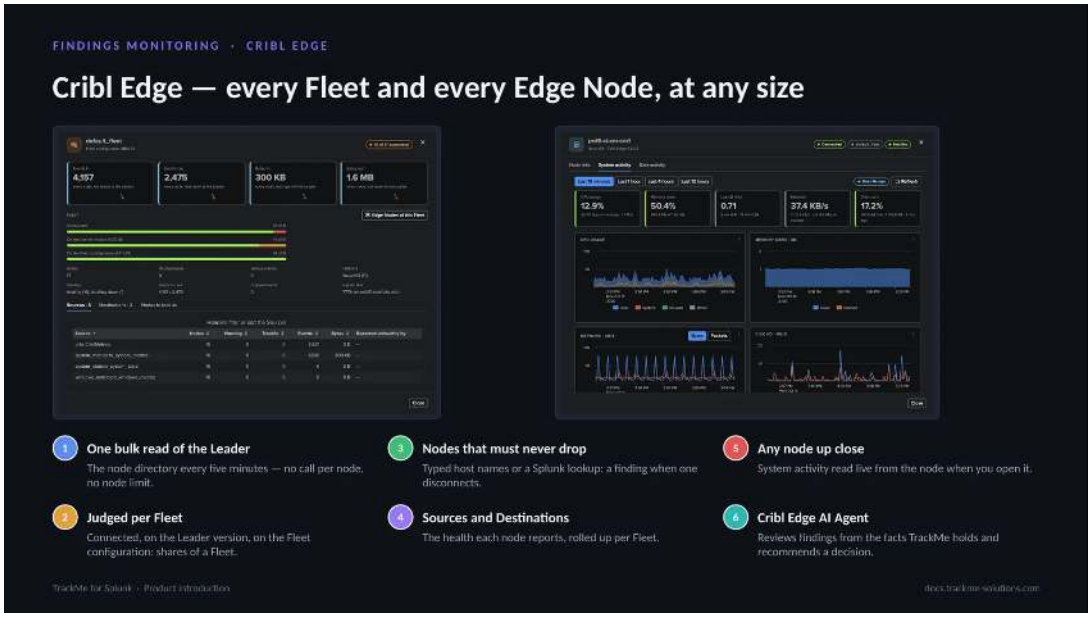
Cribl Stream



A Cribl Stream tenant watches one Cribl Stream deployment end to end, from the metrics the Workers already send to a Splunk metric index and from the Leader API, read-only within a shared request budget. On the left, the Worker topology of a self-managed deployment, each Worker with its CPU and memory, live. On the right, a traffic ML model of a Route: what it learned over two weeks, its expected band and the spikes above it.

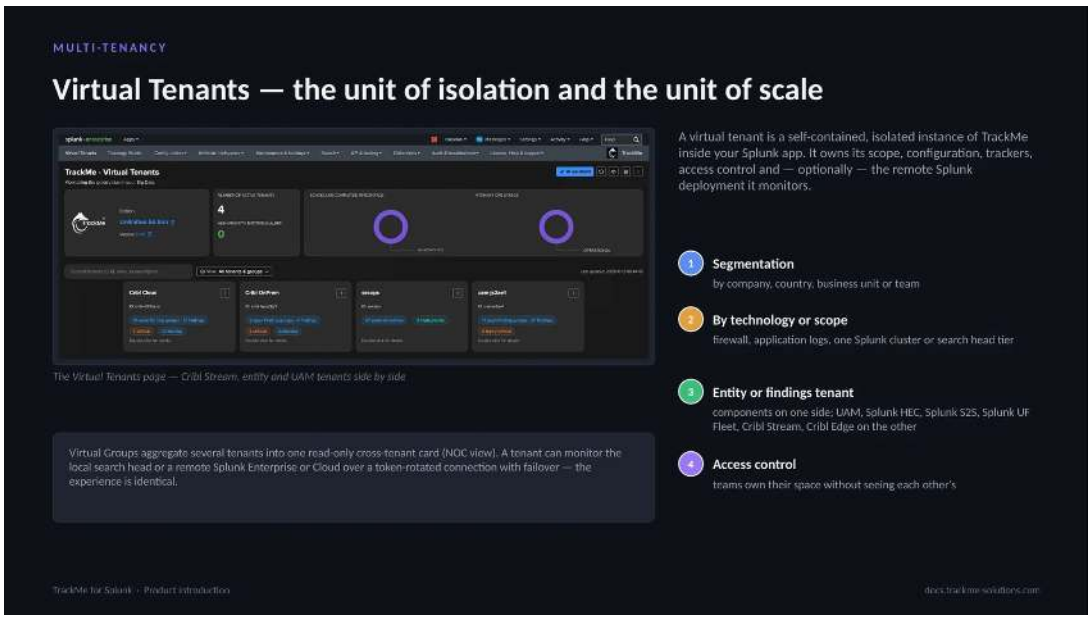
Sixteen built-in policies raise findings: backpressure, reported health, Pipeline errors, Workers that stop or drift. The Cribl Stream AI Agent reviews findings from checked facts. TrackMe never changes anything in Cribl.

Cribl Edge



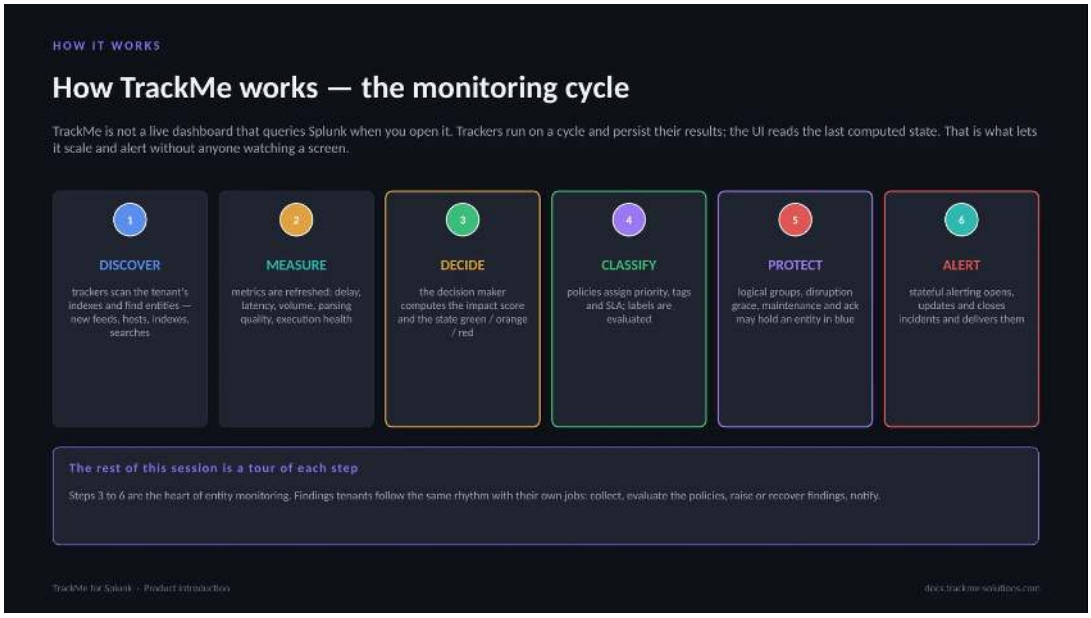
A Cribl Edge tenant follows the Fleets of one Cribl Edge Leader, the Edge Nodes enrolled in them and the Sources and Destinations they run. It reads the Leader's node directory in bulk, so its cost does not grow with one call per node and there is no node limit. Fleets are judged as a share of their nodes: one laptop going to sleep opens nothing, a fifth of a Fleet dropping does. Version drift after a rollout, configuration drift after a deploy, failing inputs and outputs and full disks become findings. Any node opens with its system activity read live through the Leader. Edge has no machine learning by design; its AI Agent reviews the findings.

Virtual Tenants



A single flat monitoring space does not survive contact with a real Splunk estate. Tenants carve the estate into domains that match how the organisation works. Everything — entities or findings, policies, thresholds, alerts — is scoped to a tenant. An entity tenant enables one or more components: splk-feeds for DSM, DHM and MHM, splk-vol, splk-wlk, splk-flx, splk-fqm. User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge are dedicated tenant types. RBAC is per tenant through Splunk roles, Virtual Groups aggregate several tenants into one read-only card, and Saved Views let a team land on its own tenants.

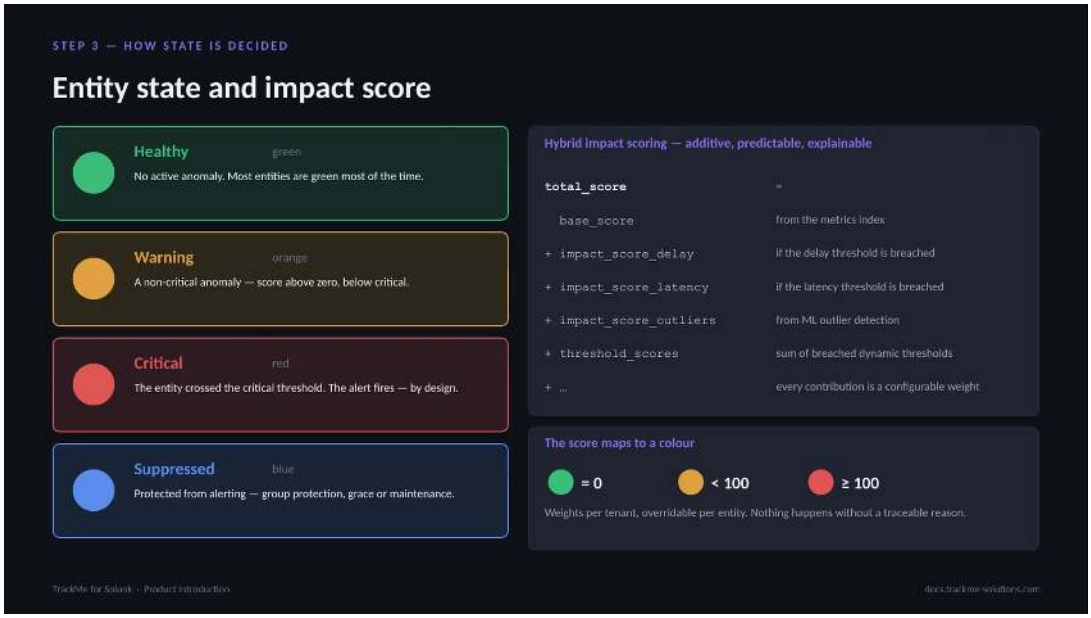
The monitoring cycle



Each cycle, for every tenant: discover, measure, decide, classify, protect, alert. The deliberate separation between

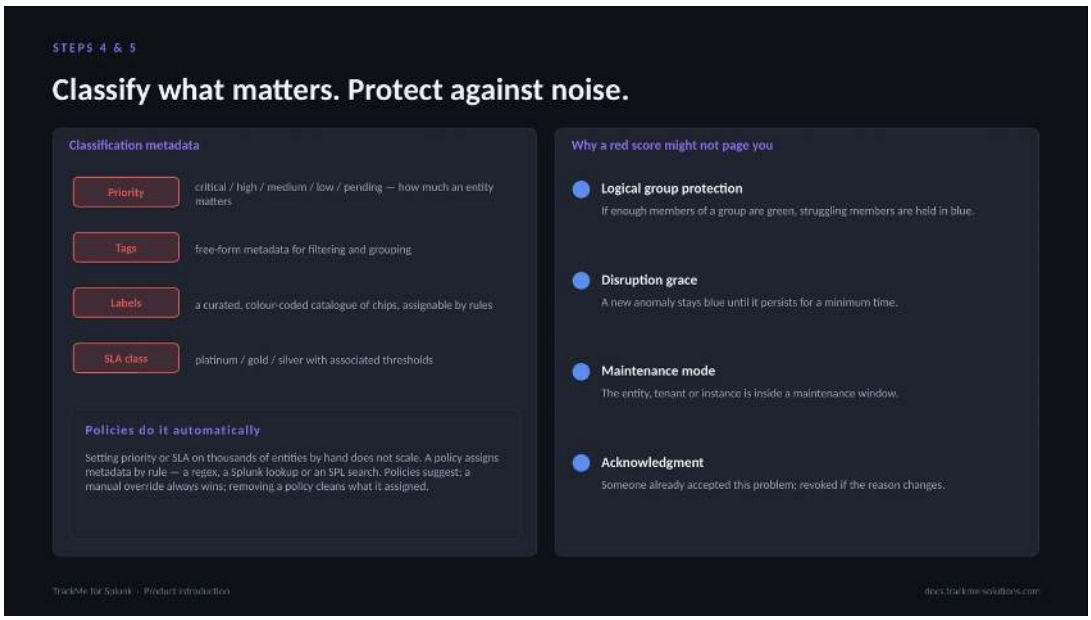
what state an entity is in, step 3, and whether to tell you, steps 5 and 6, is why TrackMe is quiet in practice despite tracking so much. Findings tenants run the same idea with their own jobs: collect, evaluate the policies, raise or recover findings, notify. Trackers are scheduled searches, typically every five minutes.

State and impact score



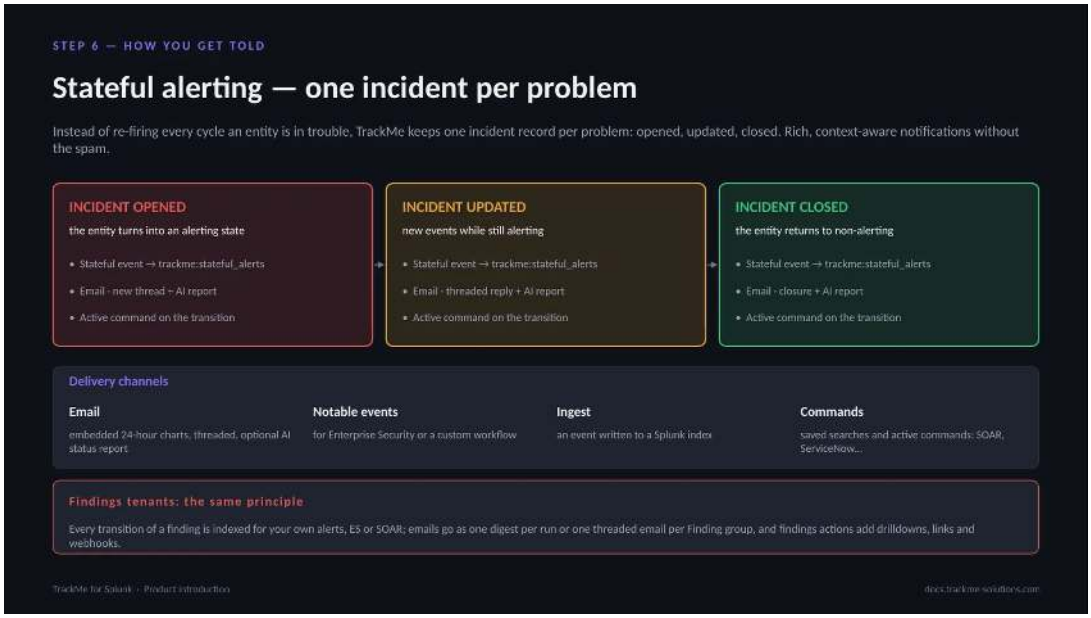
Every cycle each entity gets one of four colours. The state derives from a numeric impact score: TrackMe adds up everything currently wrong with an entity into one total score — 0 is green, below 100 orange, 100 and above red. Because every contribution is a number with a configurable weight, you control exactly what makes an entity critical: one major breach trips red, several small ones accumulate. Blue is not a fifth severity — it means "I see this, but I am not waking you up".

Classification and protection



Step 4, classification: priority, tags, labels and SLA are the four kinds of metadata attached to entities. Tags are free-form strings, labels come from a managed coloured catalogue. Three policy families assign them by rule — priority, tags and SLA. Step 5, protection: four mechanisms can hold an entity in blue instead of red. This separation between what state and whether to tell you is deliberate.

Stateful alerting



Instead of re-firing every cycle, TrackMe keeps one incident record per problem: it opens when the entity first goes into alert, updates while the problem persists, and closes when the entity recovers. On those transitions it can deliver an email with embedded charts and optionally an AI-written status report, write a notable event, ingest an event and run a command. Findings tenants follow the same principle: every transition of a finding is indexed, and email notifications go one per run or one thread per Finding group.

Topology Studio

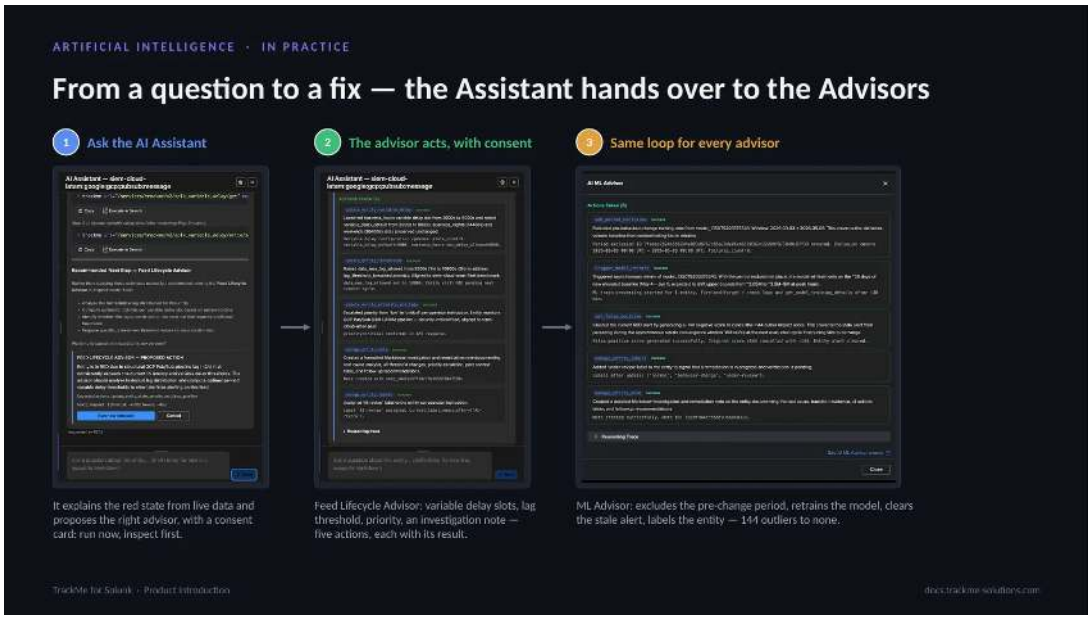
Topology Studio is the canvas for a view of the environment: a payment flow, a data centre, an ingestion pipeline, a business service. On the left, a map of web services built from TrackMe entities, feeds, hosts and heartbeat checks, with their live state and KPIs. On the right, the flow topology of a Cribl Stream deployment filtered on its nginx Routes, with three Destinations coloured by their findings, ready to save as a live view.

A Splunk HEC tenant generates its own map in one click: pools, endpoints and tokens with live status and sparkline KPIs; a Splunk S2S tenant saves its data path and a Splunk UF Fleet tenant its fleet map the same way. Views are shared under RBAC, aggregates roll many objects into one node, Topology Alerts notify on the health of a whole map, and the AI Assistant can build a view from a sentence. Available in every edition.

The AI layer

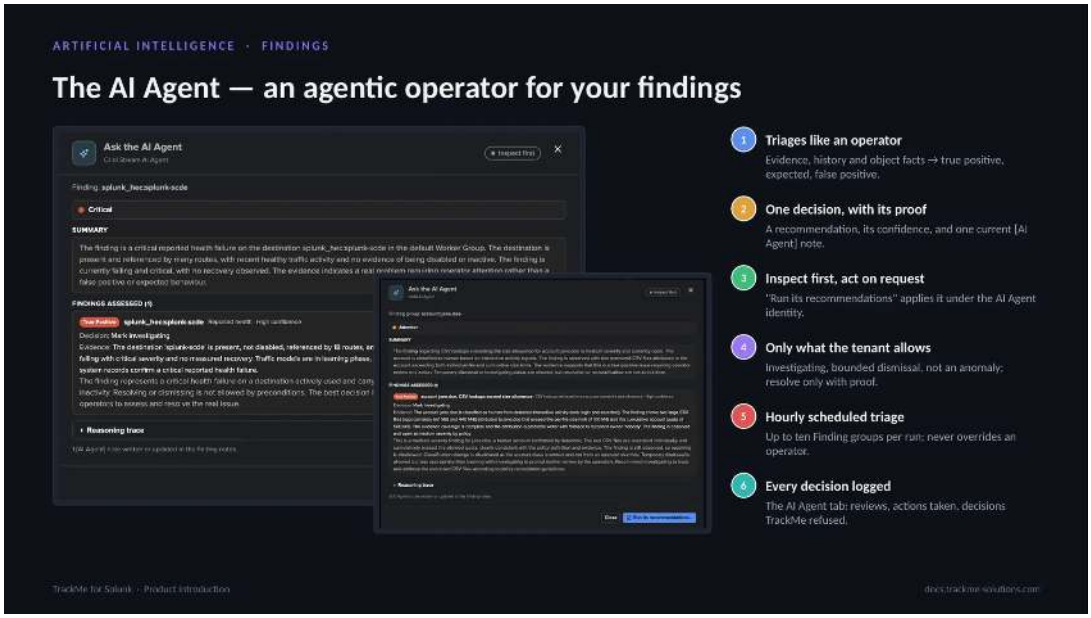
The AI layer helps operators understand and resolve what TrackMe detects, grounded in the live state of the environment and keeping the operator in the loop. It grew in four levels: the AI Assistant on every page; the AI Advisors and the Concierge, which inspect and, with consent, act; AI Agents automation, running the advisors unattended within guardrails; and AI Routines, your own standing instructions. For findings, User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge share the AI Agent, an agentic operator that triages findings, applies the decisions the tenant allows and follows custom instructions. The whole layer is opt-in and inert until an administrator configures a provider.

From a question to a fix



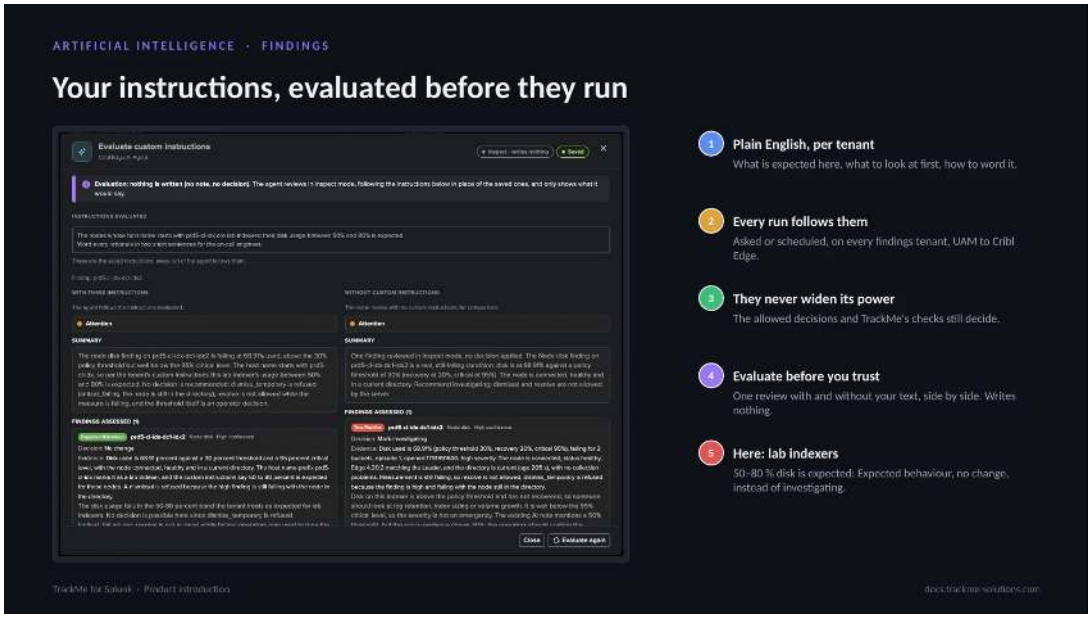
A feed is red and the operator asks the AI Assistant why. The Assistant reads the entity, explains the lag and, rather than guessing values, proposes the Feed Lifecycle Advisor with a consent card. The advisor inspects first; on request it acts: it widens the variable delay slots, raises the lag threshold, escalates the priority and documents everything in a note. Every advisor follows the same loop. The ML Advisor, facing a permanent change of baseline, excludes the old period, retrains the model, cancels the stale alert and labels the entity under review: 144 outliers become none. Each action is a typed tool call with its result, audited.

The AI Agent for findings



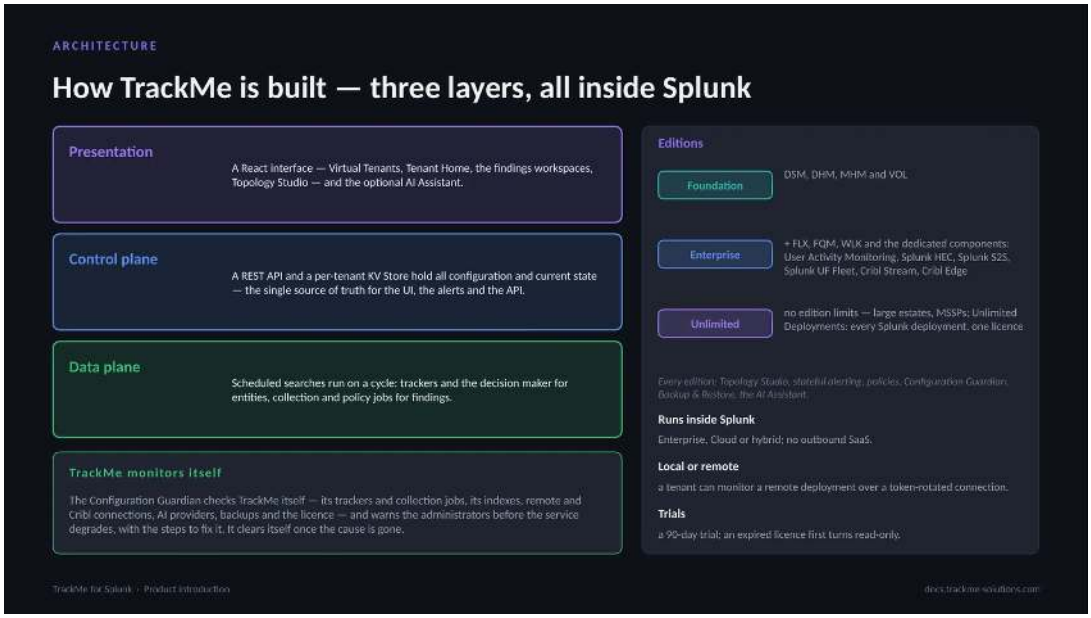
User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge share one AI Agent. Asked about a finding, or during its hourly scheduled triage, it reads the evidence, the history and the facts about the object, assesses the finding and recommends one decision with its confidence. On the left, the Cribl Stream agent confirms a real health failure on a busy Destination; on the right, the UAM agent confirms oversized CSV lookups on a human account. In act mode it applies only what the tenant allows, resolves only with proof, never overrides an operator, keeps one [AI Agent] note per finding and logs every decision.

Custom instructions, evaluated



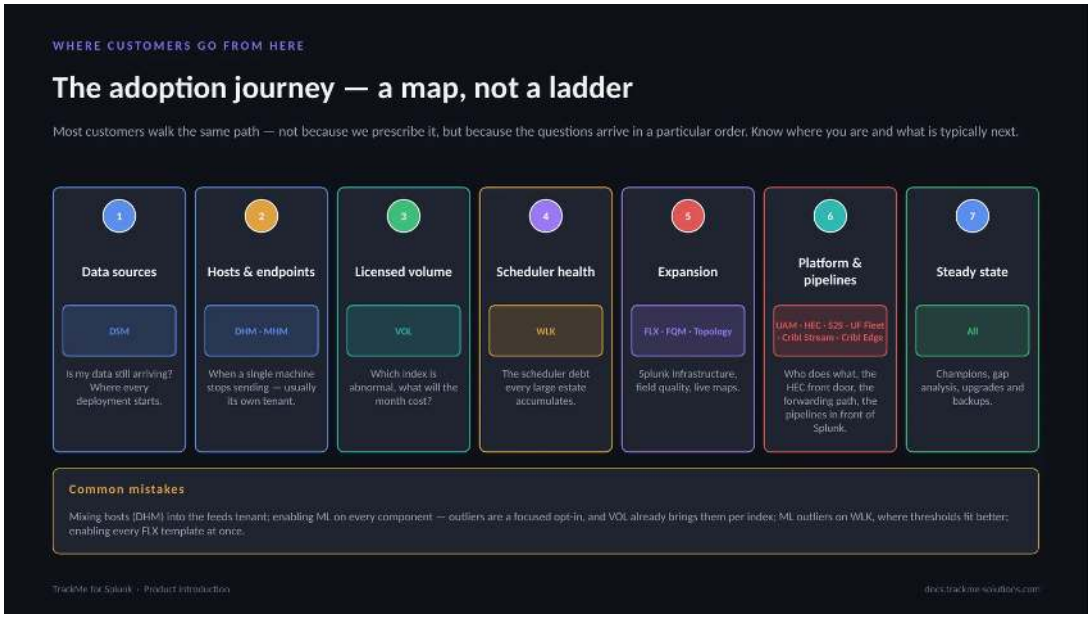
Administrators give the AI Agent of a findings tenant custom instructions in plain English: what to treat as expected, what to look at first, how to word its recommendations. Every run follows them, asked or scheduled, for all six components, and they never widen what the agent may do. Evaluate runs the agent in inspect mode with the text, saved or not, and shows the same review with and without it, side by side, writing nothing. Here the Cribl Edge agent learns that lab indexers between 50 and 80 percent disk are expected: the same finding reads Expected behaviour instead of a true positive to investigate.

Architecture and editions



Three layers: the data plane, trackers and the decision maker or the findings jobs; the control plane, a REST API and per-tenant KV Store; the presentation, a React interface and the AI Assistant. Everything runs inside the Splunk environment, and TrackMe monitors itself: the Configuration Guardian checks its own trackers, connections, indexes and licence and warns the administrators before the service degrades. Editions: Foundation covers DSM, DHM, MHM and VOL. Enterprise adds FLX, FQM and WLK and the dedicated components: User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge. Unlimited removes the edition limits; Unlimited Deployments covers every Splunk deployment under one licence. Topology Studio, stateful alerting, policies, the Configuration Guardian, Backup & Restore and the AI Assistant are in every edition. An expired licence first switches to read-only while monitoring keeps running.

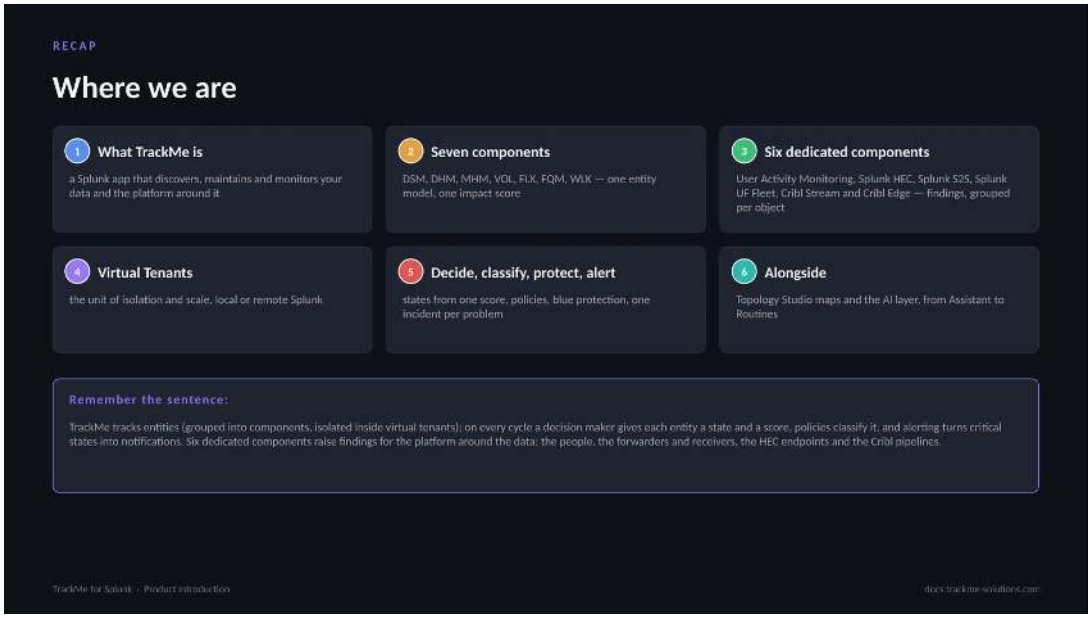
The adoption journey



This journey is a map, not a ladder: the questions arrive in a particular order and most teams are in several phases at once. Phase 1, data sources with DSM, is where every deployment starts. Phase 2 covers hosts and endpoints with DHM and MHM, usually in a dedicated tenant. Phase 3 is the licensed volume of every index with VOL. Phase 4 is the scheduler with WLK. Phase 5 expands with FLX, FQM and Topology Studio. Phase 6 goes beyond the data: who does what on the platform with User Activity Monitoring, the HTTP Event Collector with Splunk HEC, the

forwarding path with Splunk S2S and Splunk UF Fleet, and the Cribl pipelines with Cribl Stream and Cribl Edge. Phase 7, the steady state, is a continuous practice.

Where we are



TrackMe is a Splunk app that discovers, maintains and monitors the availability and quality of your data and of the platform around it. Entity monitoring: seven components — DSM, DHM, MHM, VOL, FLX, FQM and WLK — share one entity model, with a state from one impact score, policies that classify, protection that holds noise in blue and stateful alerting. Findings monitoring: six dedicated components — User Activity Monitoring, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge — raise findings, grouped per object and decided once. Everything is isolated in virtual tenants, with Topology Studio and the AI layer alongside.

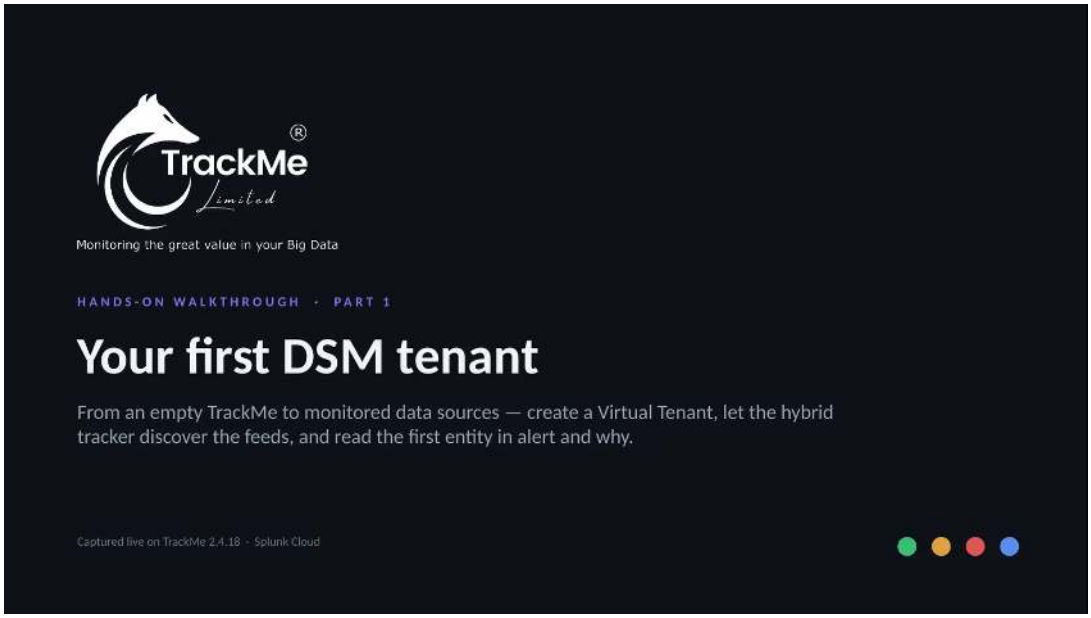
2.1.2 Part 1 — Your first DSM tenant

From an empty TrackMe to monitored data sources: create a Virtual Tenant, let the hybrid tracker discover the feeds, and read the first entity in alert and why.

`Download the deck (PDF) · PowerPoint`

about 20 minutes · 16 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

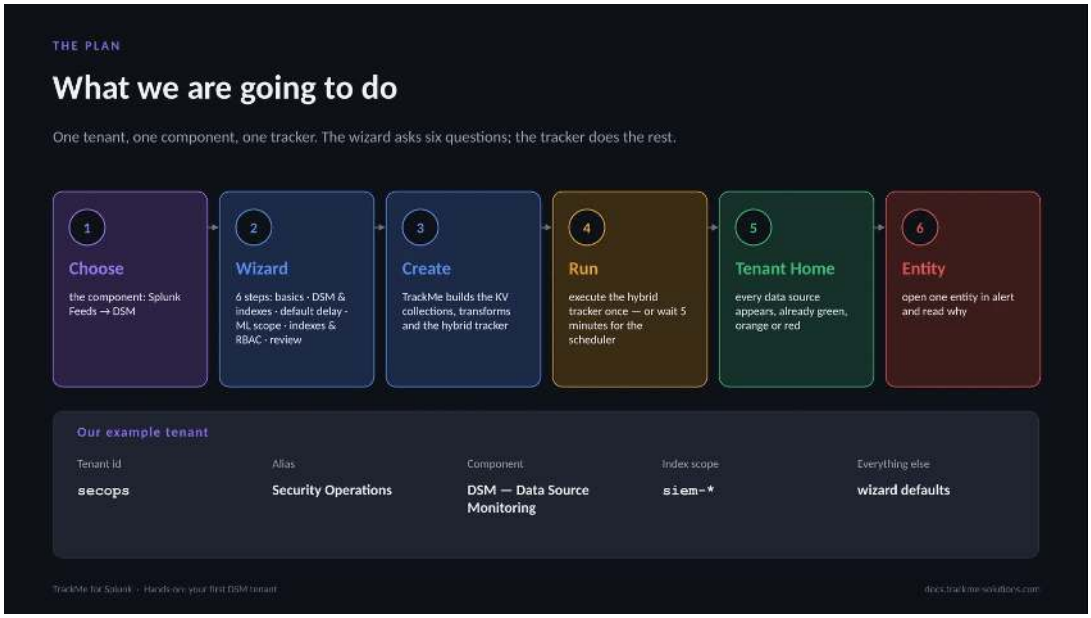
Overview



This walkthrough goes from an empty TrackMe to monitored data sources: a Virtual Tenant is created, the hybrid tracker discovers the feeds, and the first entity in alert is read together with the reason for its state. Everything shown was captured on TrackMe 2.4.18 on Splunk Cloud, starting from a tenant that did not exist.

The aim is to show the product doing what the introduction described, discover, measure and decide, on a fresh tenant with no configuration beyond an index pattern.

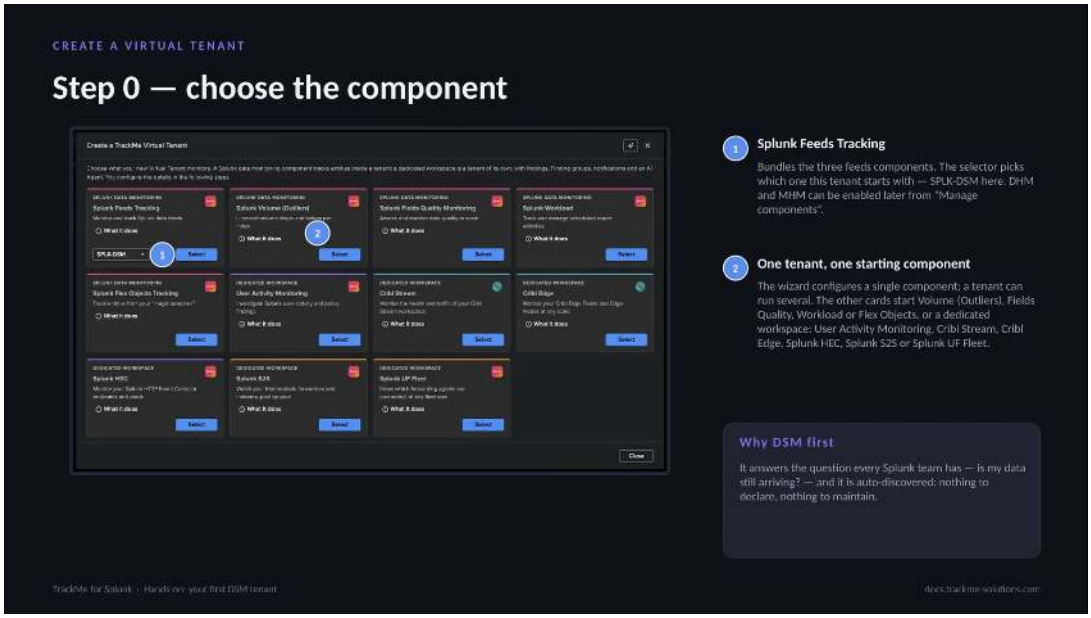
Six steps and the example tenant



One tenant, one component, one tracker. Callouts 1 to 6 lay out the path: Choose the component (Splunk Feeds, then DSM); Wizard, six steps covering basics, DSM and indexes, default delay, ML scope, indexes and RBAC, and review; Create, where TrackMe builds the KV collections, transforms and the hybrid tracker; Run, executing the tracker once or waiting 5 minutes for the scheduler; Tenant Home, where every data source appears already green, orange or red; and Entity, opening one entity in alert to read why.

The example tenant uses the id secops, the alias Security Operations, the component DSM (Data Source Monitoring) and the index scope siem-*. Everything else keeps the wizard defaults, each revisitable from the Tenant Home later.

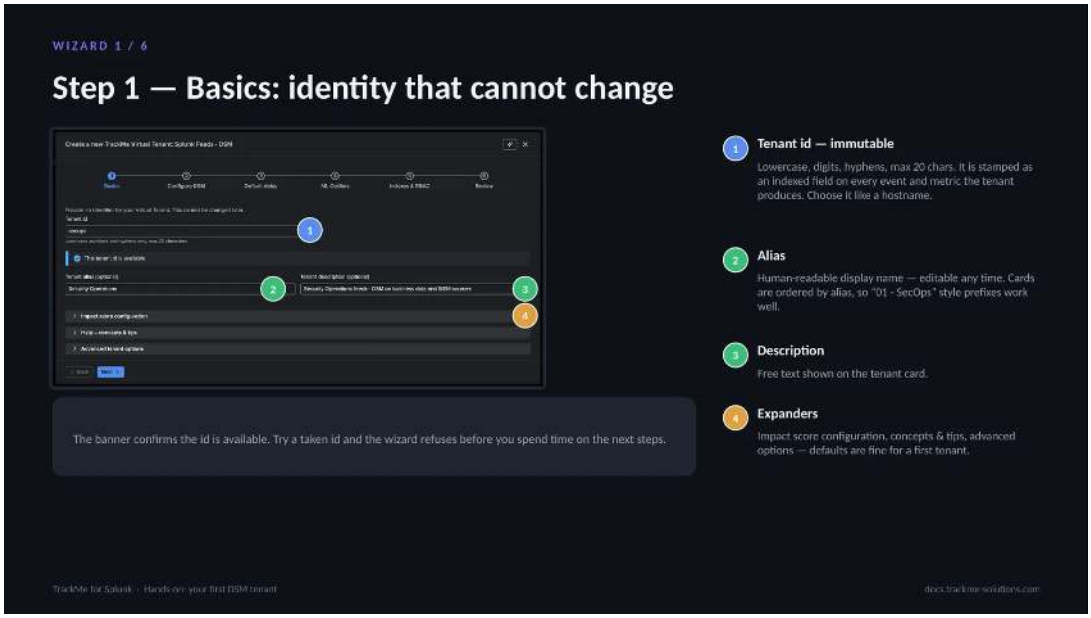
The tenant type chooser



The chooser opens from Virtual Tenants, Actions, Create a tracking tenant, with eleven cards: the Splunk data monitoring components, then the dedicated workspaces. Splunk Feeds Tracking (callout 1) bundles the three feeds components, DSM (index and sourcetype), DHM (host and sourcetype) and MHM (metric hosts); its selector picks the starting component, SPLK-DSM here, and DHM and MHM can be enabled later from Manage components. The other cards start Volume (Outliers), Fields Quality, Workload or Flex Objects tenants, or a dedicated workspace: User Activity Monitoring, Cribl Stream, Cribl Edge, Splunk HEC, Splunk S2S or Splunk UF Fleet.

The wizard configures a single component, although a tenant can run several (callout 2). DSM comes first because it answers whether the data is still arriving and is auto-discovered: nothing to declare, nothing to maintain. The AI icon at the top right opens the AI Assistant in context.

Tenant id, alias and description

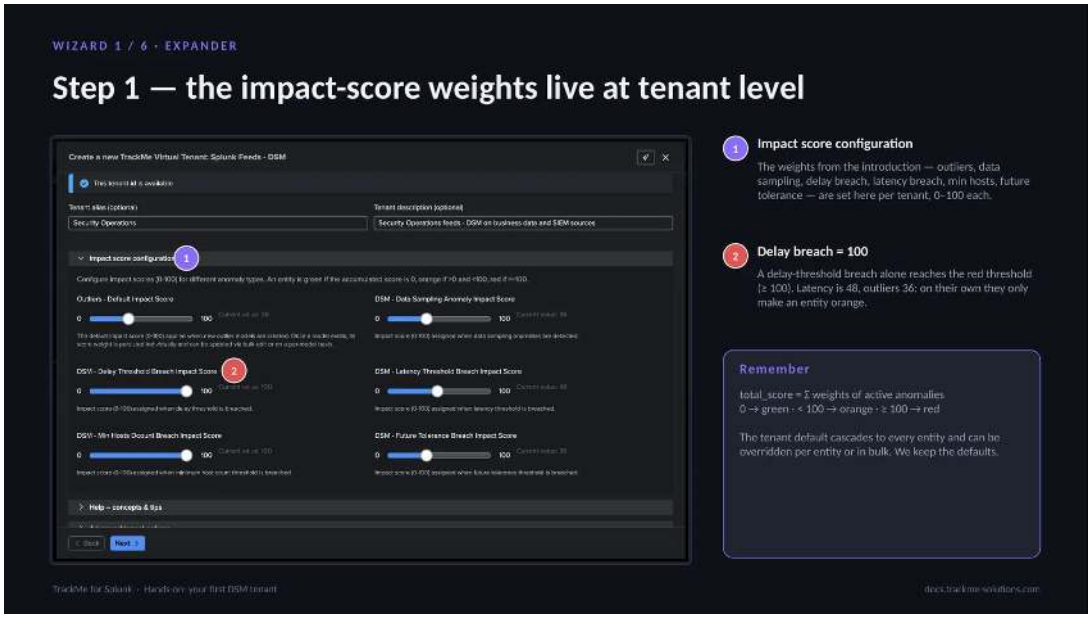


Step 1 of 6 sets identity. The Tenant id (callout 1) is immutable: lowercase, digits and hyphens, 20 characters at most. It is stamped as an indexed field on every event the tenant produces and is part of every KV collection and report name, so it should be chosen like a hostname. A banner confirms the id is available; a taken id is refused immediately.

The Alias (callout 2) is a human-readable display name, editable any time; cards are ordered by alias, so prefixes like

01 - SecOps work well. The Description (callout 3) is free text shown on the tenant card. The Expanders (callout 4) hold Impact score configuration, concepts and tips, and advanced options.

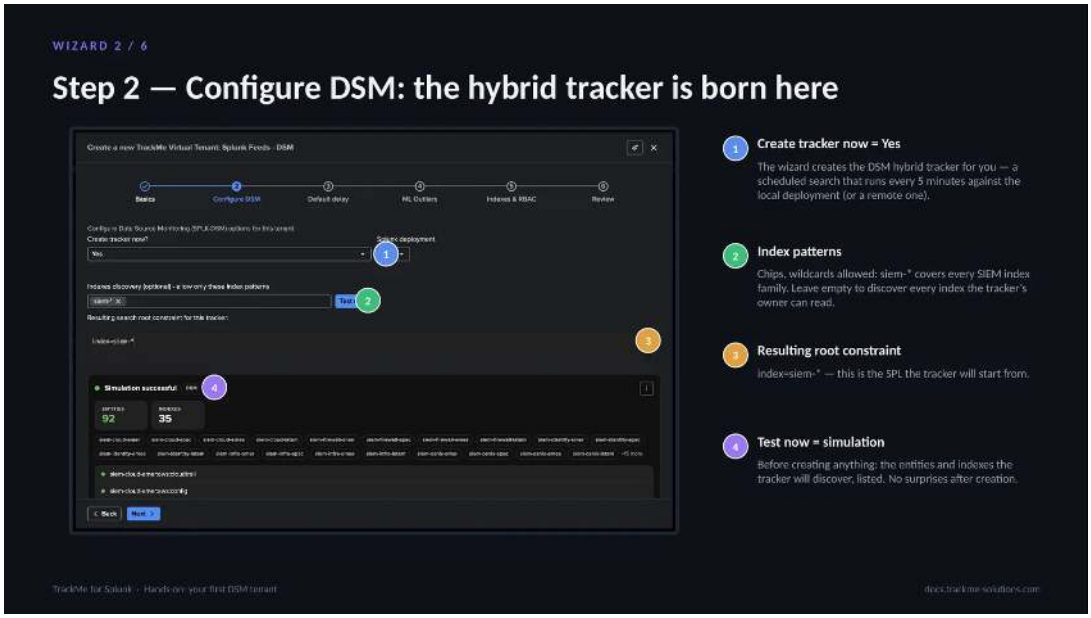
Impact score weights per tenant



The Impact score configuration expander (callout 1) sets the weights of the scoring model, outliers, data sampling, delay breach, latency breach, min hosts and future tolerance, per tenant, from 0 to 100 each.

Delay breach carries 100 (callout 2), so a delay-threshold breach alone reaches the red threshold: a feed that stopped is by definition critical. Latency is 48 and outliers 36; on their own they only make an entity orange. The rule is total_score equals the sum of the weights of active anomalies: 0 is green, below 100 orange, 100 and above red. The tenant default cascades to every entity and can be overridden per entity or in bulk.

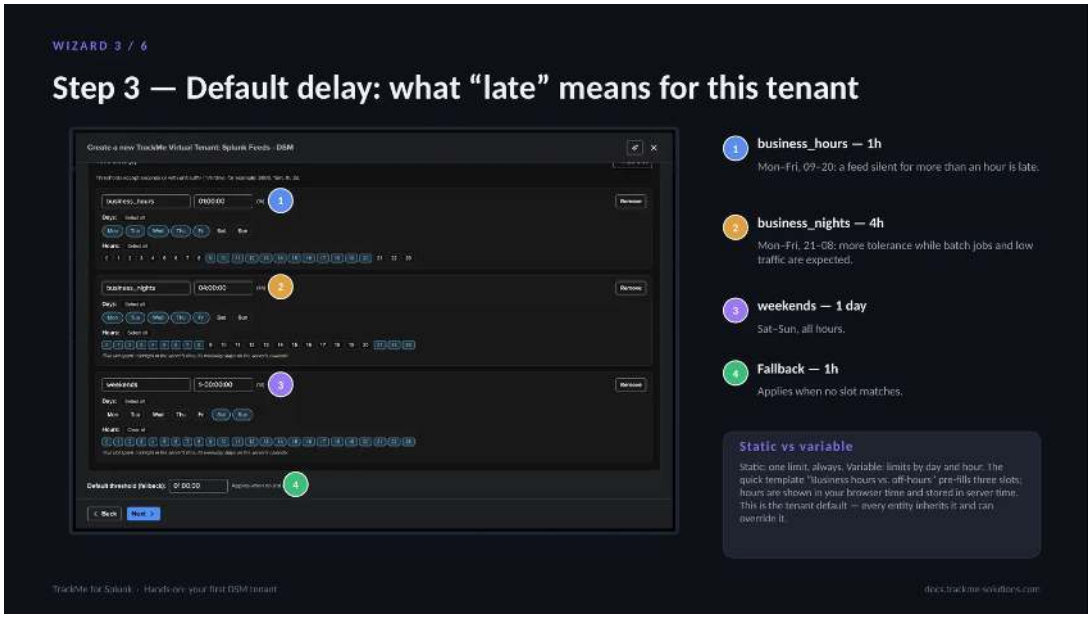
Discovery scope and tracker creation



Step 2 of 6 scopes discovery and creates the tracker. Create tracker now set to Yes (callout 1) makes the wizard create the DSM hybrid tracker, a scheduled search that runs every 5 minutes against the local deployment or a remote one. Index patterns (callout 2) are chips with wildcards allowed: siem-* covers every SIEM index family, and an empty list discovers every index the tracker's owner can read.

The Resulting root constraint (callout 3) shows the SPL the tracker starts from, index=siem-*. Test now (callout 4) runs the discovery search as a simulation before anything is created, listing the entities and indexes the tracker would discover. It is the fastest way to validate index patterns and permissions before committing.

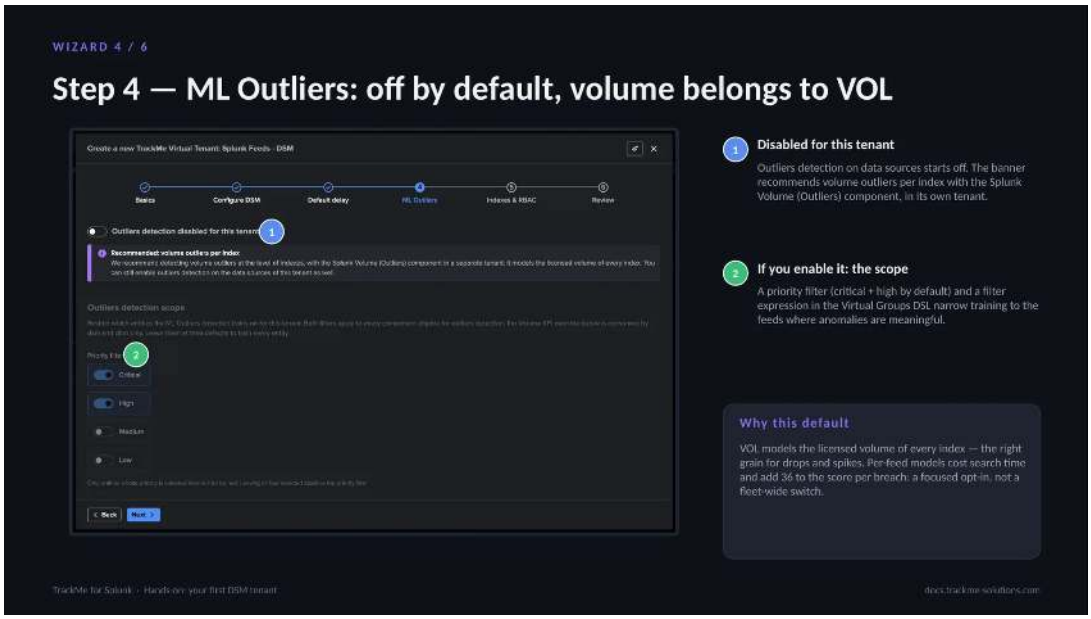
Variable delay slots



Delay is the core DSM metric: the time since the last event was indexed, compared to a threshold. A static threshold is one limit always; a variable one sets limits by day and hour. The quick template Business hours vs. off-hours pre-fills three slots: business_hours (callout 1), Monday to Friday 09 to 20, 1h; business_nights (callout 2), Monday to Friday 21 to 08, 4h; weekends (callout 3), Saturday and Sunday, 1 day. The Fallback (callout 4), 1h, applies when no slot matches.

Hours are shown in browser time and stored in server time. Every entity inherits this tenant default and can override it, which keeps TrackMe quiet at night and on weekends without a rule per feed.

ML outliers scope and the VOL recommendation

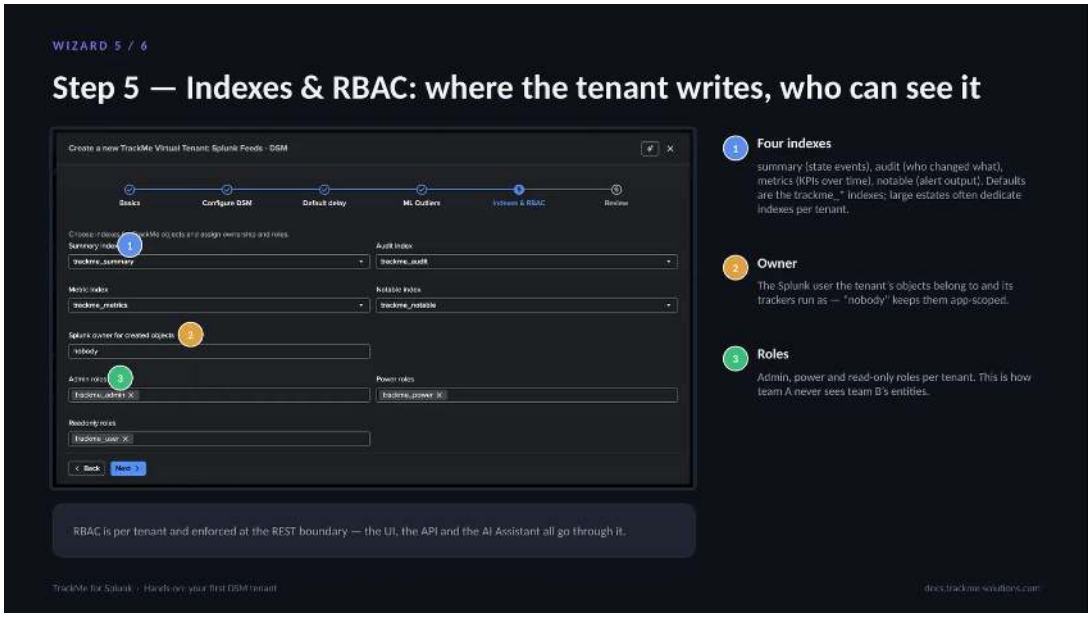


Step 4 of 6 covers ML outliers. Outliers detection on data sources starts disabled for the tenant (callout 1), and the banner recommends volume outliers per index with the Splunk Volume (Outliers) component in its own tenant.

Nothing needs changing for a first tenant.

When enabled, the scope (callout 2) narrows training to the feeds where anomalies are meaningful: a priority filter, critical and high by default, and a filter expression in the Virtual Groups DSL. VOL models the licensed volume of every index, the right grain for drops and spikes, whereas per-feed models cost search time and add 36 to the score per breach. Outliers are a focused opt-in, not a fleet-wide switch.

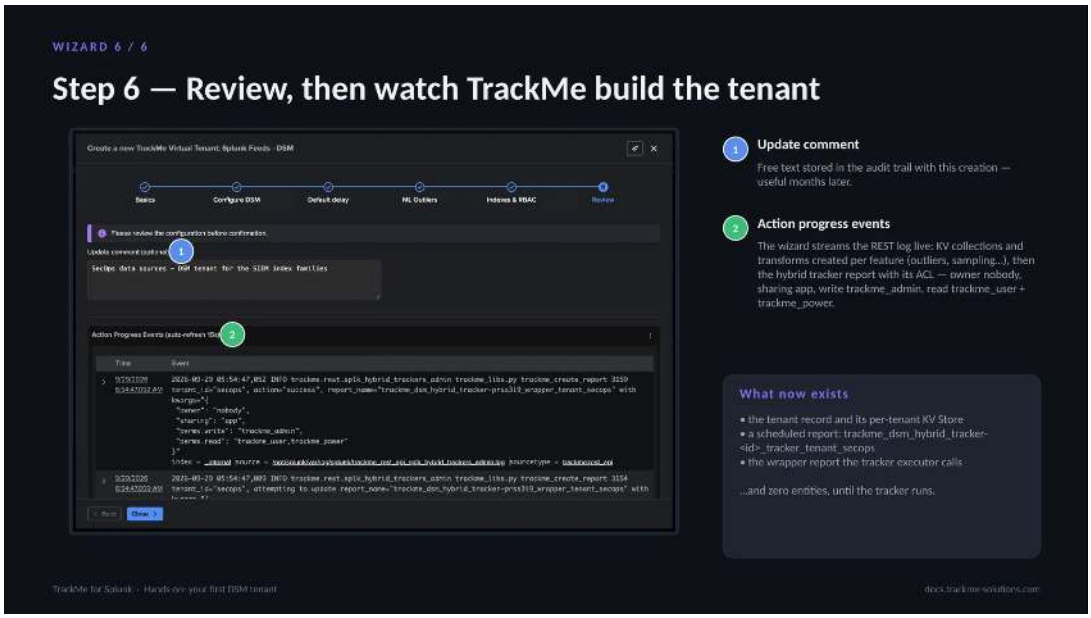
Tenant indexes, owner and roles



Step 5 of 6 sets where the tenant writes and who sees it. Four indexes (callout 1) receive its output: summary for state events, audit for who changed what, metrics for KPIs over time and notable for alert output. The defaults are the trackme_* indexes; large estates often dedicate indexes per tenant.

The Owner (callout 2) is the Splunk user the tenant's objects belong to and its trackers run as; nobody keeps them app-scoped. Roles (callout 3) assign admin, power and read-only Splunk roles per tenant, so one team never sees another's entities. RBAC is per tenant and enforced at the REST boundary: the UI, the API and the AI Assistant all go through it.

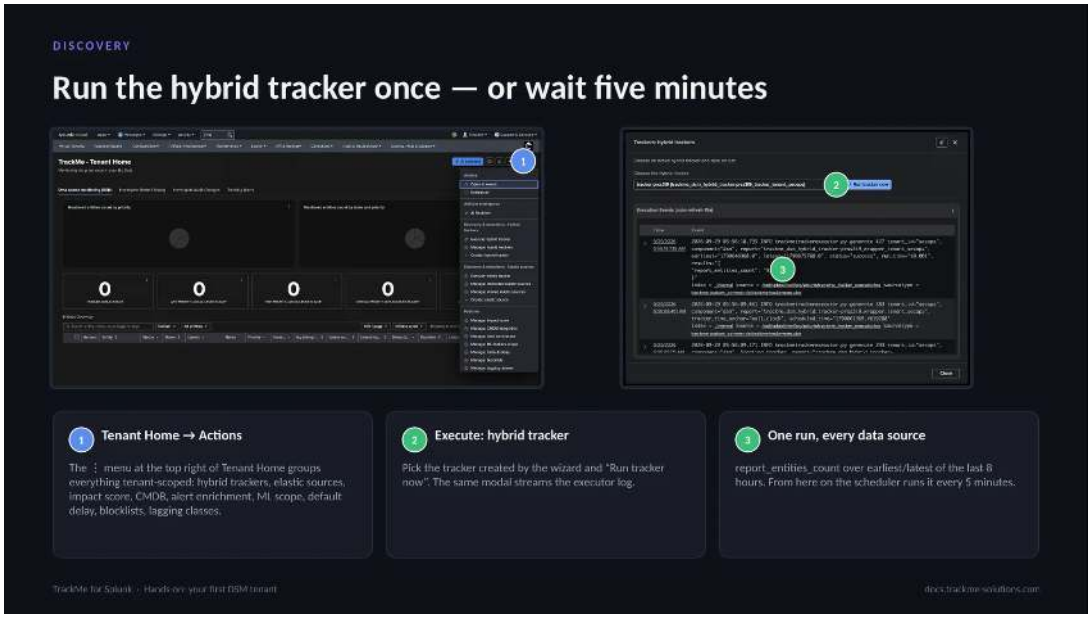
Creation log and resulting objects



Step 6 of 6 reviews and creates the tenant. The Update comment (callout 1) is free text stored in the audit trail with this creation. The Action progress events panel (callout 2) streams the REST log live, the same log an administrator would read in the TrackMe REST API logs: KV collections and transforms created per feature (outliers, sampling and so on), then the hybrid tracker report with its ACL, owner nobody, sharing app, write trackme_admin, read trackme_user and trackme_power. Creation takes seconds.

What now exists: the tenant record and its per-tenant KV Store, a scheduled report named trackme_dsm_hybrid_tracker-<id>_tracker_tenant_secops, and the wrapper report the tracker executor calls. There are zero entities until the tracker runs.

Executing the tracker from Tenant Home



Nothing appears in Tenant Home until a tracker has run, because TrackMe is not a live dashboard. Rather than waiting for the 5-minute schedule, the tracker is executed from Tenant Home, Actions (callout 1): the menu at the top right groups everything tenant-scoped, hybrid trackers, elastic sources, impact score, CMDB, alert enrichment, ML scope, default delay, blocklists and lagging classes.

Execute: hybrid tracker (callout 2) picks the tracker created by the wizard and offers Run tracker now; the same modal streams the executor log. One run covers every data source (callout 3): the panel reports report_entities_count over the last 8 hours. From here on the scheduler runs it every 5 minutes.

Health strip, donuts and entities table

Four tabs run across the top of Tenant Home: the component view, status flipping, audit changes and tracking alerts. The Health strip (callout 1) counts entities per state, computed by the decision maker on the tracker run just made. The State by priority donut (callout 2) shows everything at medium priority: discovery does not yet know what matters, which is what policies bring.

The Single-stat drilldowns (callout 3) and every state in the health strip filter the table on click; every number on the page is a filter. The Entities table (callout 4) has one row per (index, sourcetype) with state, score, labels, priority, lag (delay and latency), last event, last ingest, thresholds, outliers and sampling.

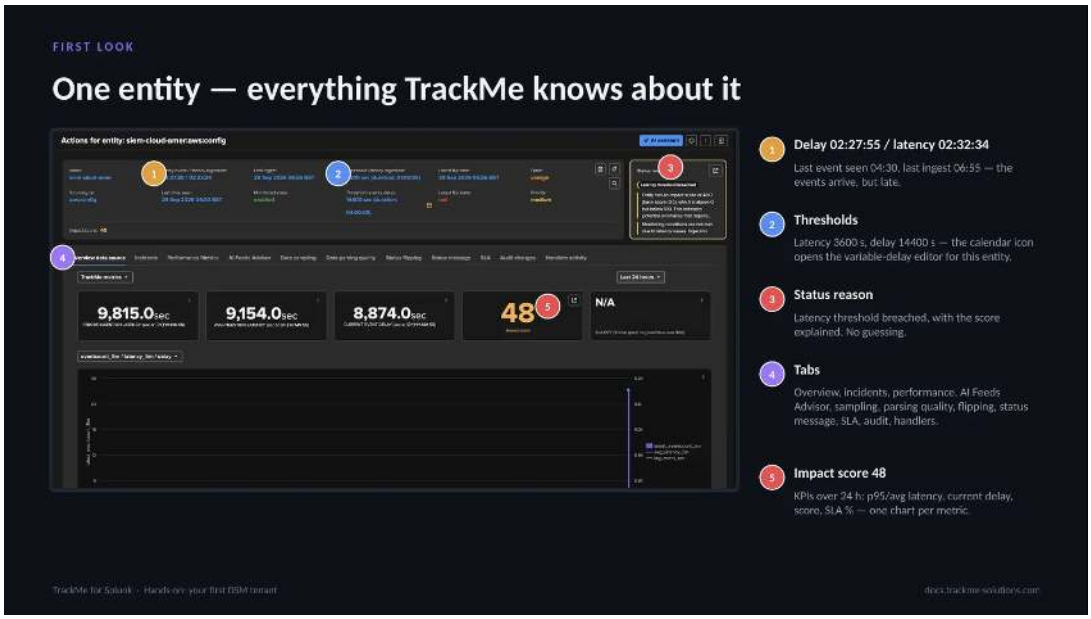
Score, lag and thresholds in a row

With the table filtered on orange from the health strip and grouped by index (callout 4), one row reads siem-cloud-amer:aws:config, orange, score 48, medium. Score 48 (callout 1) means latency only: 48 is below 100, hence orange. Adding a delay breach (100) would turn the same entity red at 148, additive exactly as configured in step 1. Sorting by score shows at a glance how many anomalies overlap.

The lag column (callout 2) shows delay and latency, 02:26:19 / 02:32:34: the last event is 2h26 old and was indexed 2h32 after its timestamp, so latency is what breached. The inline thresholds (callout 3) show Delay 14400 with

duration 04:00:00, the business_nights slot applied at run time, and Latency 3600.

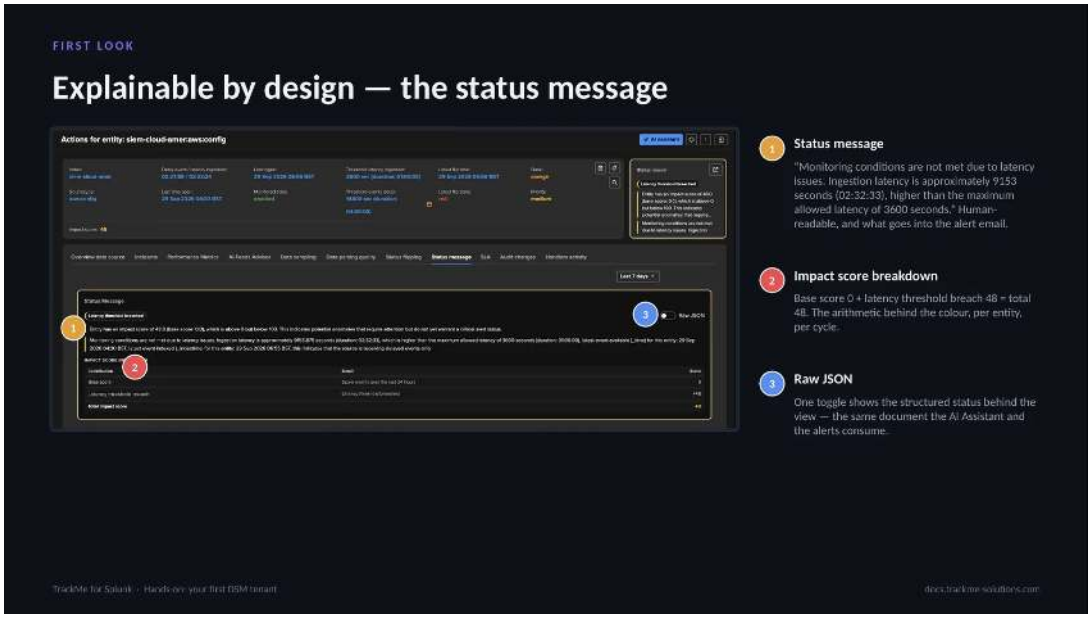
The entity view



The view is the same for every component; only the KPIs differ. The header (callout 1) is the decision maker's output: Delay 02:27:55 and latency 02:32:34, last event seen at 04:30, last ingest at 06:55, so the events arrive, but late. Thresholds (callout 2) show Latency 3600 s and delay 14400 s; the calendar icon opens the variable-delay editor. The Status reason (callout 3) states that the latency threshold is breached.

The Tabs (callout 4) are Overview, incidents, performance, AI Feeds Advisor, sampling, parsing quality, flipping, status message, SLA, audit and handlers. Impact score 48 (callout 5) heads the KPIs over 24 h, p95 and average latency, delay, score and SLA %, one chart per metric.

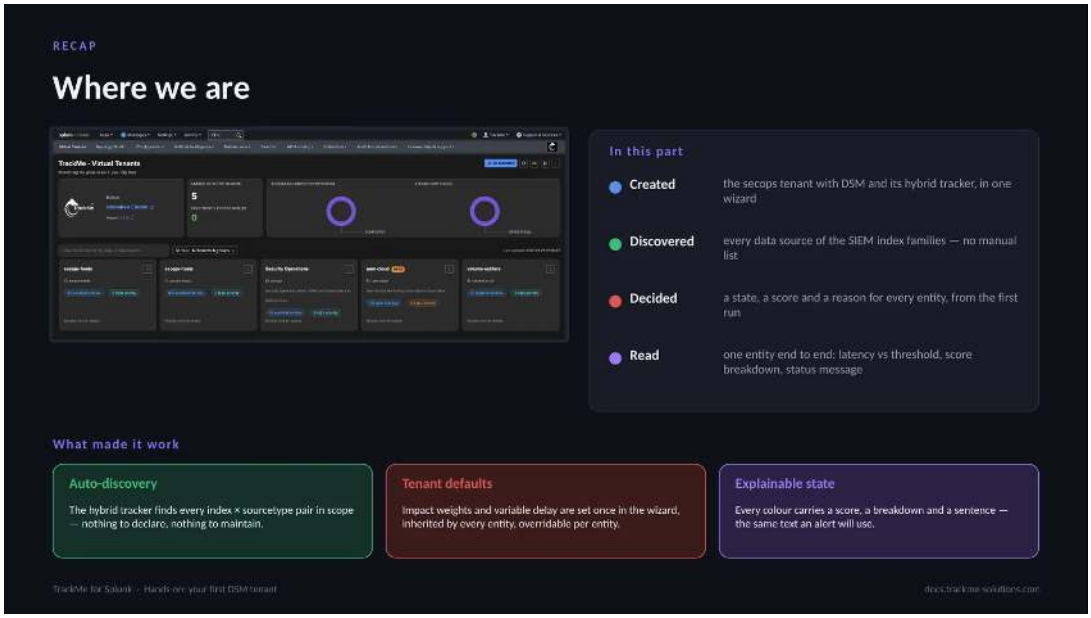
Status message and score breakdown



The Status message (callout 1) is human-readable and is the text that goes into the alert email: Monitoring conditions are not met due to latency issues. Ingestion latency is approximately 9153 seconds (02:32:33), higher than the maximum allowed latency of 3600 seconds. The Impact score breakdown (callout 2) gives the arithmetic behind the colour: base score 0 plus latency threshold breach 48 equals total 48.

The Raw JSON toggle (callout 3) shows the structured status behind the view, the same document the AI Assistant and the alerts consume. Nothing in TrackMe changes state without a reason string and a score breakdown. The 7-day timeline below is how flapping is spotted over weeks.

Where we are



In this part the secops tenant was created with DSM and its hybrid tracker in one wizard, every data source of the SIEM index families was discovered without a manual list, and every entity received a state, a score and a reason from the first run.

Three things made it work. Auto-discovery: the hybrid tracker finds every index and sourcetype pair in scope, nothing to declare or maintain. Tenant defaults: impact weights and variable delay are set once in the wizard, inherited by every entity and overridable. Explainable state: every colour carries a score, a breakdown and a sentence, the same text an alert uses. Every entity is still medium priority; classification is what policies bring.

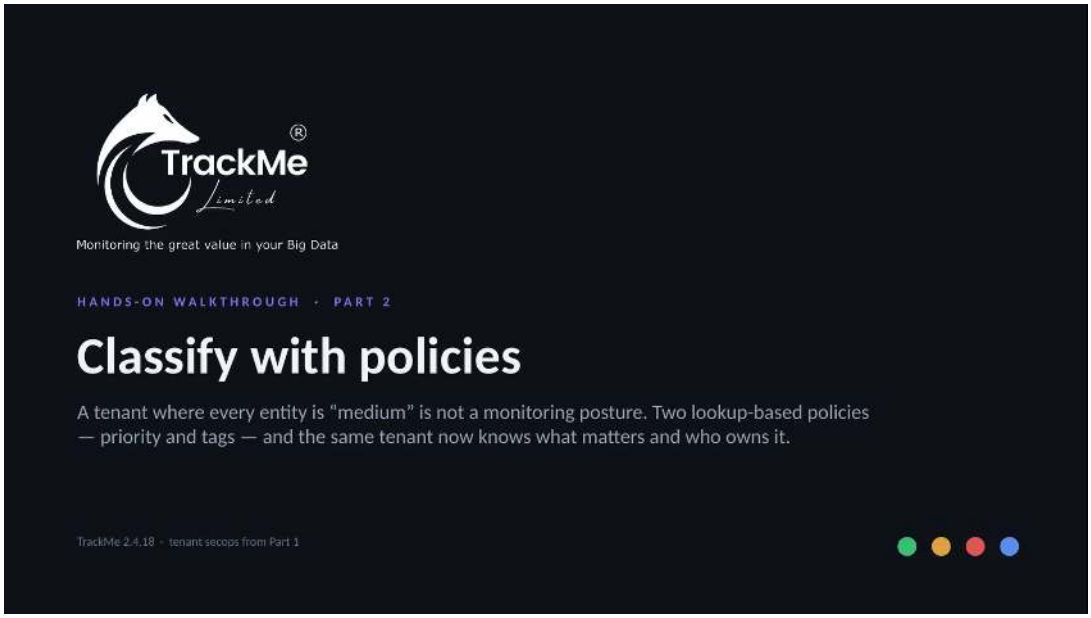
2.1.3 Part 2 — Classify with policies

Two lookup-based policies — priority and tags — simulated before saving, and the same tenant now knows what matters and who owns it.

`Download the deck (PDF) · PowerPoint`

about 15 minutes · 12 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

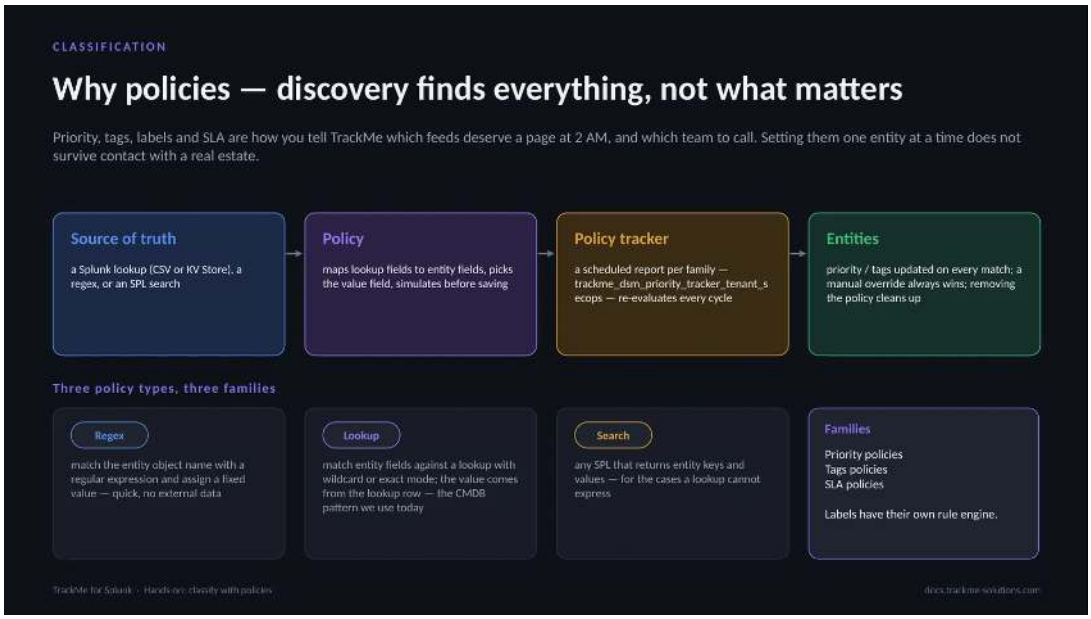
Overview



Part 2 of the hands-on walkthrough starts where Part 1 stopped: the secops tenant has its DSM entities, every one of them at medium priority and none tagged. A tenant where every entity is medium is not a monitoring posture — TrackMe cannot yet tell which feeds matter or who owns them.

This part covers step 4 of the cycle, CLASSIFY, done the way it scales: two lookup-based policies, priority and tags, driven by a CMDB-style lookup rather than set one entity at a time. Once applied, the same tenant knows what matters and which team to call. Captured on TrackMe 2.4.18.

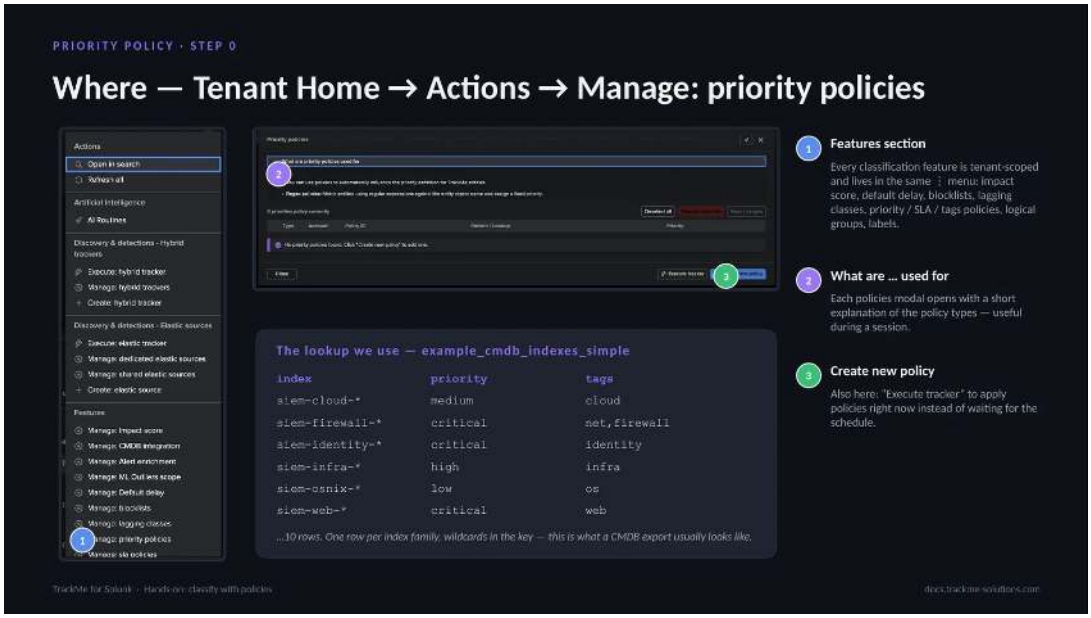
Policy types and policy families



Priority, tags, labels and SLA tell TrackMe which feeds matter and which team to call; setting them one entity at a time does not scale. A policy assigns them by rule: a source of truth (a Splunk lookup in CSV or KV Store, a regex, or an SPL search) feeds a policy that maps lookup fields to entity fields, picks the value field and simulates before saving; a policy tracker, one scheduled report per family such as trackme_dsm_priority_tracker_tenant_secops, re-evaluates every cycle.

Three types (Regex, Lookup, Search) serve three families (Priority, Tags, SLA); labels have their own rule engine. A manual override always wins, removing a policy cleans up, and the higher priority wins when several match.

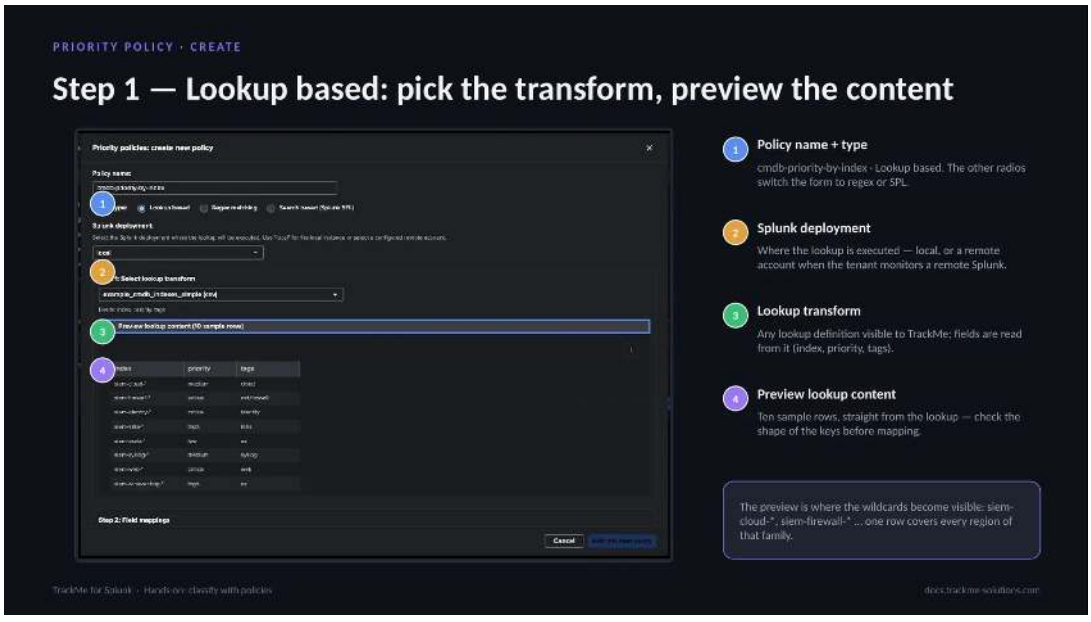
Locating the policies in Tenant Home



Every classification feature is tenant-scoped and sits in the Features section of the ⋮ Actions menu on Tenant Home (callout 1): impact score, default delay, blocklists, lagging classes, priority / SLA / tags policies, logical groups and labels. Each policies modal opens with a "What are … used for" explanation (callout 2). Create new policy starts the wizard; Execute tracker applies the policies immediately, without waiting for the schedule (callout 3).

The lookup used here, example_cmdb_indexes_simple, ships with TrackMe and is shaped like a CMDB export: an index pattern with wildcards, a priority and comma-separated tags. Ten rows, one per index family. A deployment replaces it with its own CSV or KV Store without changing the policy definition.

Choosing the lookup transform

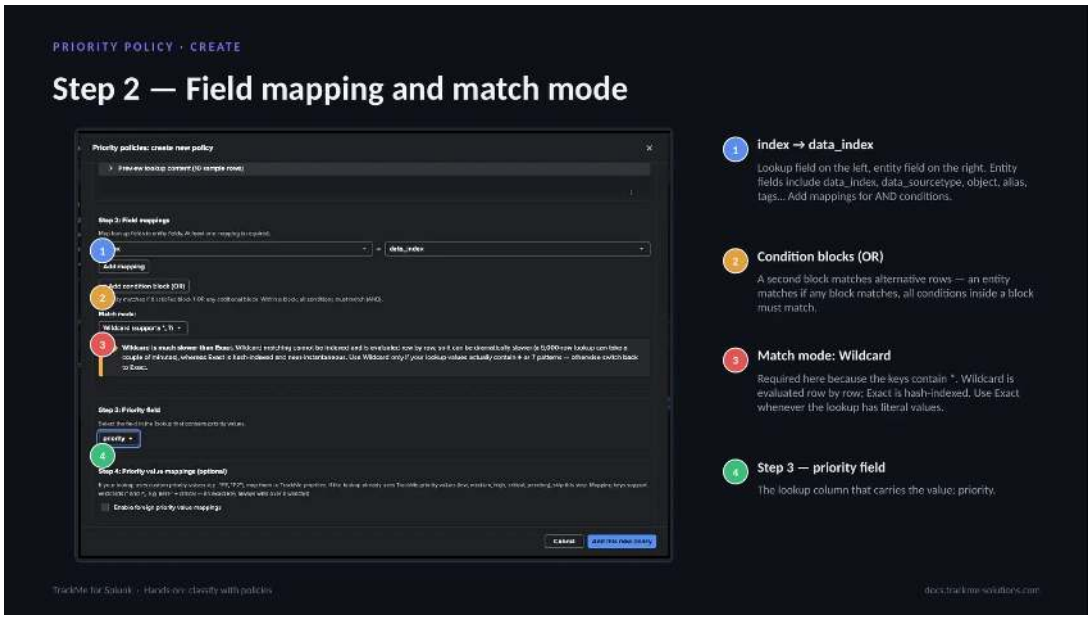


Step 1 of the wizard. Callout 1 names the policy, cmdb-priority-by-index, and selects the type, Lookup based; the other radio buttons switch the form to regex or SPL. Callout 2, Splunk deployment, sets where the lookup runs — local, or a remote account when the tenant monitors a remote Splunk. Callout 3, Lookup transform, lists every lookup definition visible to TrackMe and reads its fields (index, priority, tags); the filter box narrows a long list.

Callout 4, Preview lookup content, shows ten sample rows straight from the lookup. The preview reveals whether the key column contains wildcards such as siem-cloud-*, one row covering every region of a family, which decides the

match mode on the next step.

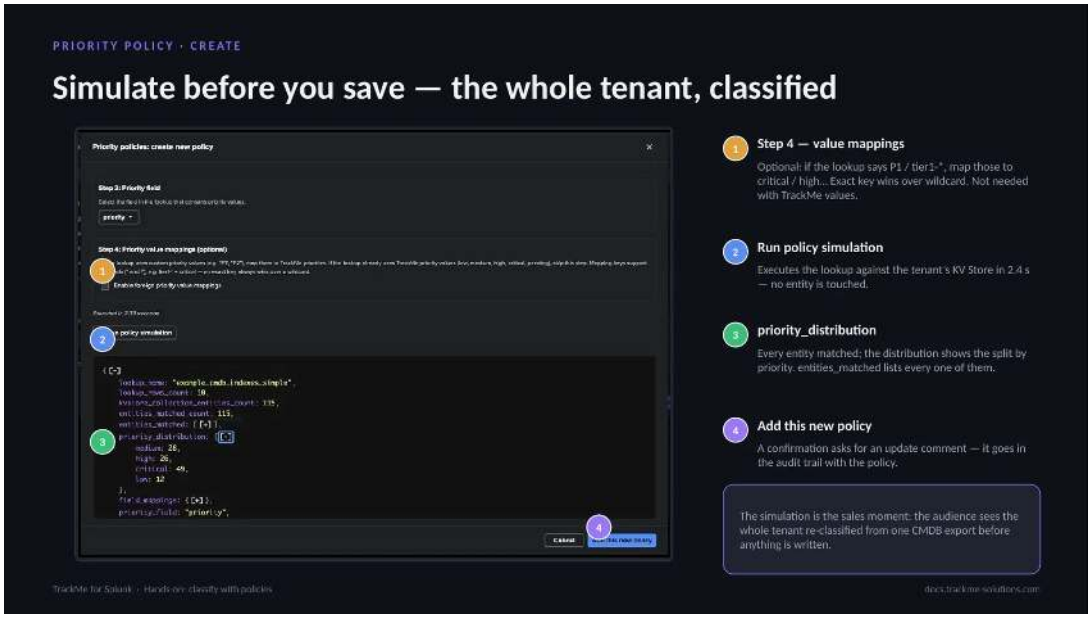
Mapping lookup fields to entity fields



The mapping decides which lookup column is compared with which entity attribute. Callout 1 maps index → data_index; entity fields include data_index, data_sourcetype, object, alias and tags, and additional mappings form AND conditions. Callout 2, Condition blocks (OR), adds a block for alternative rows: an entity matches if any block matches, all conditions in a block must match.

Callout 3 sets Match mode: Wildcard, required because the keys contain *. Wildcard is evaluated row by row while Exact is hash-indexed; a 5,000-row lookup checked this way against tens of thousands of entities takes minutes, so Exact is preferred whenever the lookup holds literal values. Callout 4, Step 3, selects priority as the lookup column carrying the value.

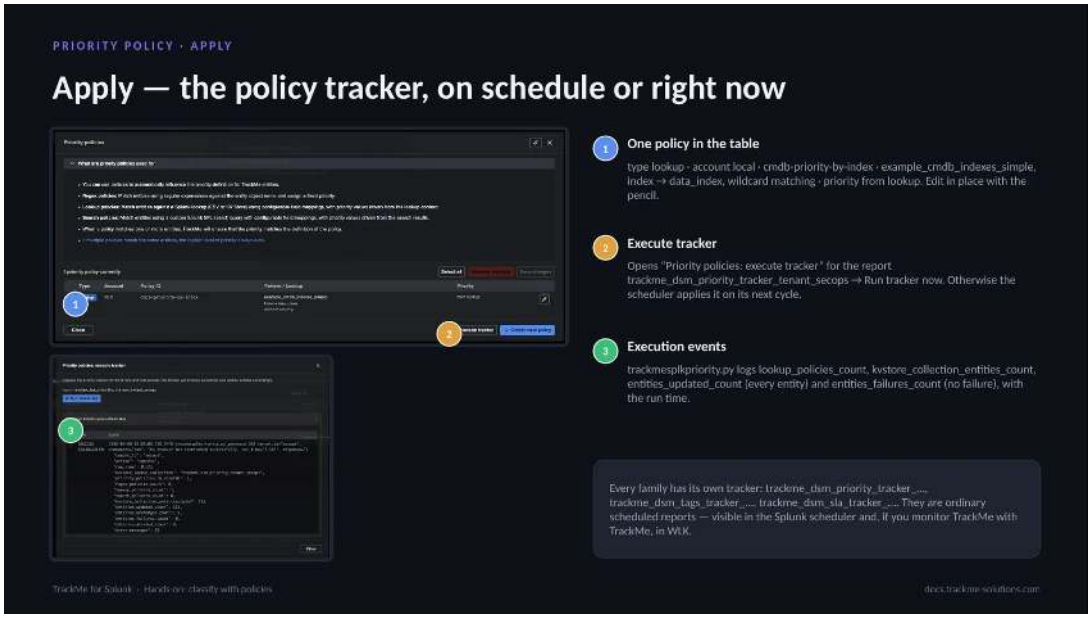
Running the policy simulation



Step 4, value mappings (callout 1), is optional: foreign lookup values (P1, tier1-*) are mapped onto TrackMe priorities, an exact key winning over a wildcard; it is not needed with TrackMe values. Run policy simulation (callout 2) executes the lookup against the tenant's KV Store — 2.4 s here — without touching any entity.

The result (callout 3) is the JSON structure the policy tracker applies: priority_distribution shows the split by priority and entities_matched lists every entity. Every entity matched; a split that looked wrong, such as everything medium, would point at the value field or the match mode. Add this new policy (callout 4) asks for an update comment, recorded in the audit trail with the policy.

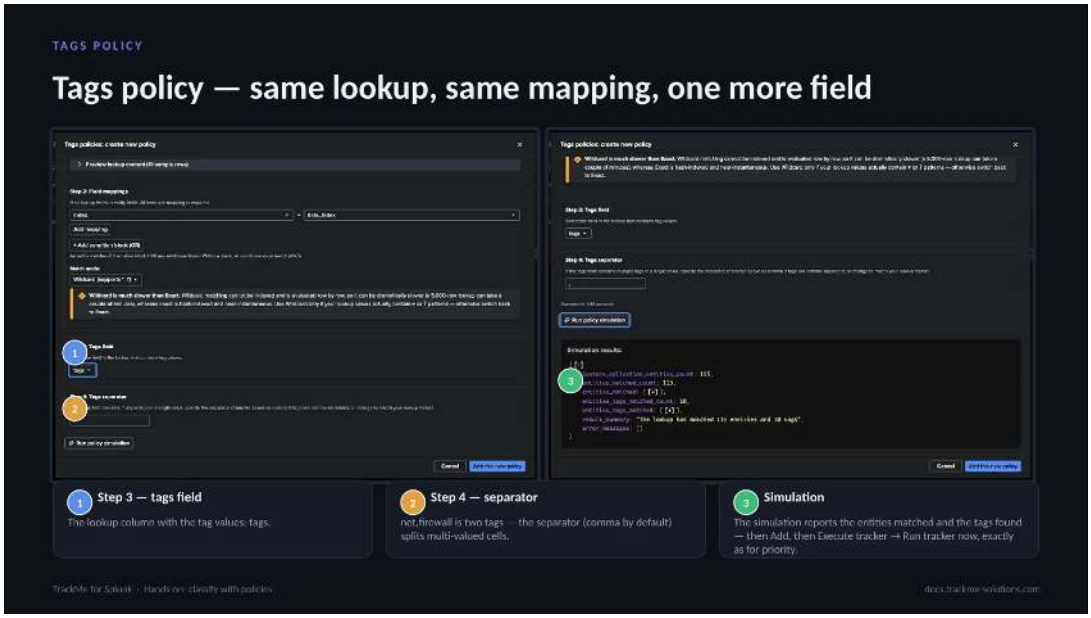
Applying the policy with the tracker



A policy changes nothing by itself; the policy tracker does, on its schedule. The policies table (callout 1) holds one row — type lookup, account local, cmdb-priority-by-index, example_cmdb_indexes_simple, index → data_index, wildcard matching, priority from lookup — editable in place with the pencil. Execute tracker (callout 2) opens "Priority policies: execute tracker" for the report trackme_dsm_priority_tracker_tenant_secops; Run tracker now applies it immediately rather than on the next scheduled cycle.

The execution events (callout 3) come from trackmesplkpriority.py: lookup_policies_count, kvstore_collection_entities_count, entities_updated_count (every entity), entities_failures_count (none) and the run time — the place to check when a policy seems not to apply. Each family has its own tracker; they are ordinary scheduled reports, visible in the Splunk scheduler and in WLK.

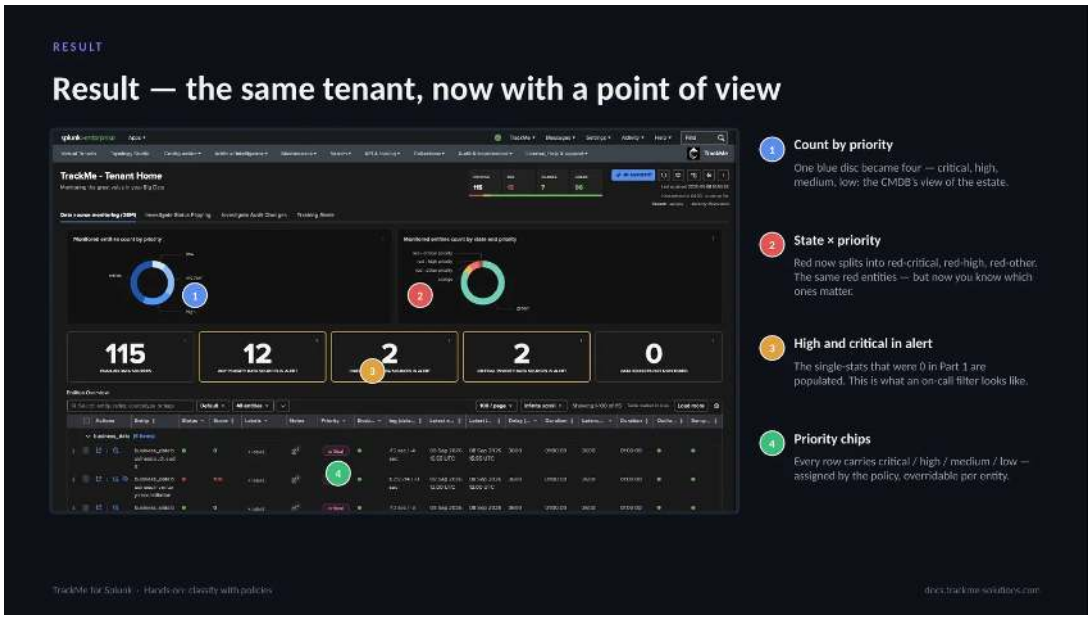
Creating the tags policy



The tags policy is a copy of the priority one: same lookup, same index → data_index mapping, with two different choices. Step 3 (callout 1) selects tags as the lookup column carrying the values. Step 4 (callout 2) sets the separator, comma by default, which splits multi-valued cells — net,firewall becomes two tags. The simulation (callout 3) reports the entities matched and the tags found; then Add, then Execute tracker → Run tracker now, exactly as for priority.

Tags are free-form strings that become a filter and a grouping axis in the entities table, in Virtual Groups, in ML outlier scope filters and in Topology Studio aggregates. Labels are different: a managed, coloured catalogue with its own rule engine.

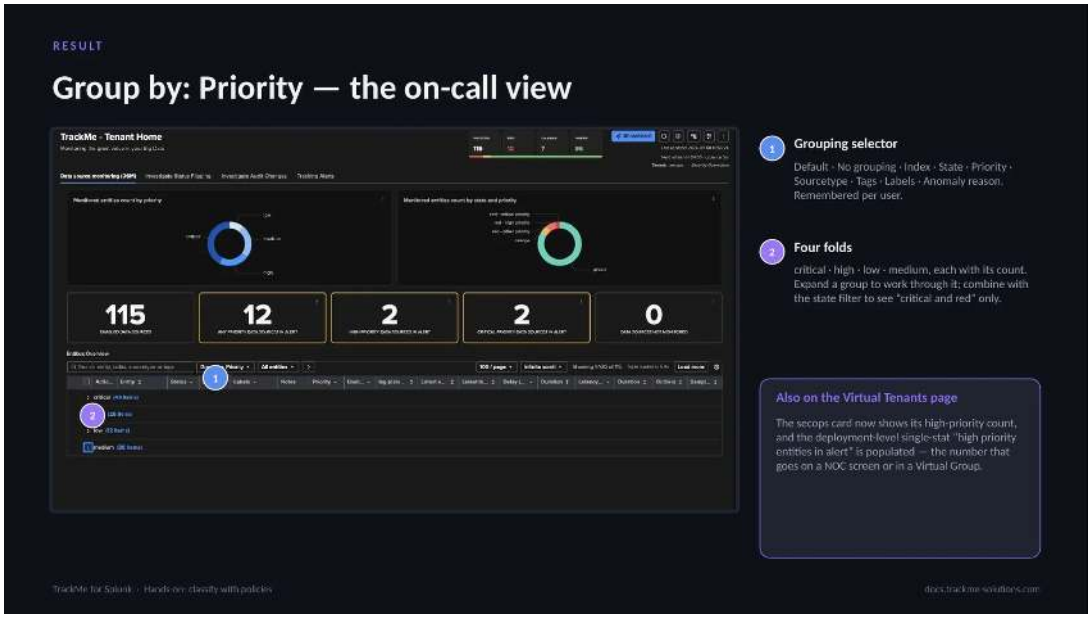
Priority across the tenant summary



Same entities and the same red ones, but now ranked. Count by priority (callout 1) shows one blue disc turned into four — critical, high, medium, low — the CMDB's view of the estate. State × priority (callout 2) splits red into red-critical, red-high and red-other, so the red entities that matter stand out. The single-stats for high and critical in alert (callout 3), which read 0 in Part 1, are populated: this is what an on-call filter looks like.

Every row of the entities table carries a priority chip (callout 4) — critical, high, medium or low — assigned by the policy and overridable per entity. Priority feeds the alerting model: alert on critical and high, watch the rest.

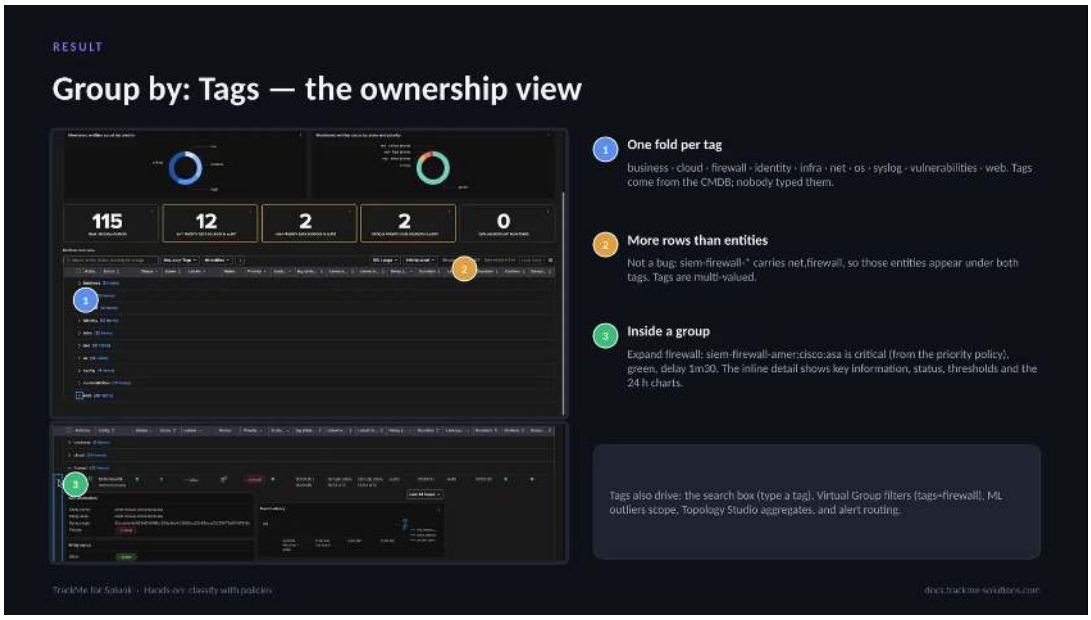
Grouping the entities table by priority



Group by is a per-user display setting on the entities table. The grouping selector (callout 1) offers Default, No grouping, Index, State, Priority, Sourcetype, Tags, Labels and Anomaly reason. Grouped by Priority, the table shows four folds (callout 2) — critical, high, low, medium — each with its count; combined with the state filter it shows "critical and red" only. The critical group contains the business_data inventory feed from Part 1, now critical because business_data is critical in the CMDB.

The Virtual Tenants page reflects the change too: the secops card shows its high-priority count, and the deployment-level single-stat "high priority entities in alert" is populated — the number for a NOC screen or a Virtual Group.

Grouping the entities table by tag

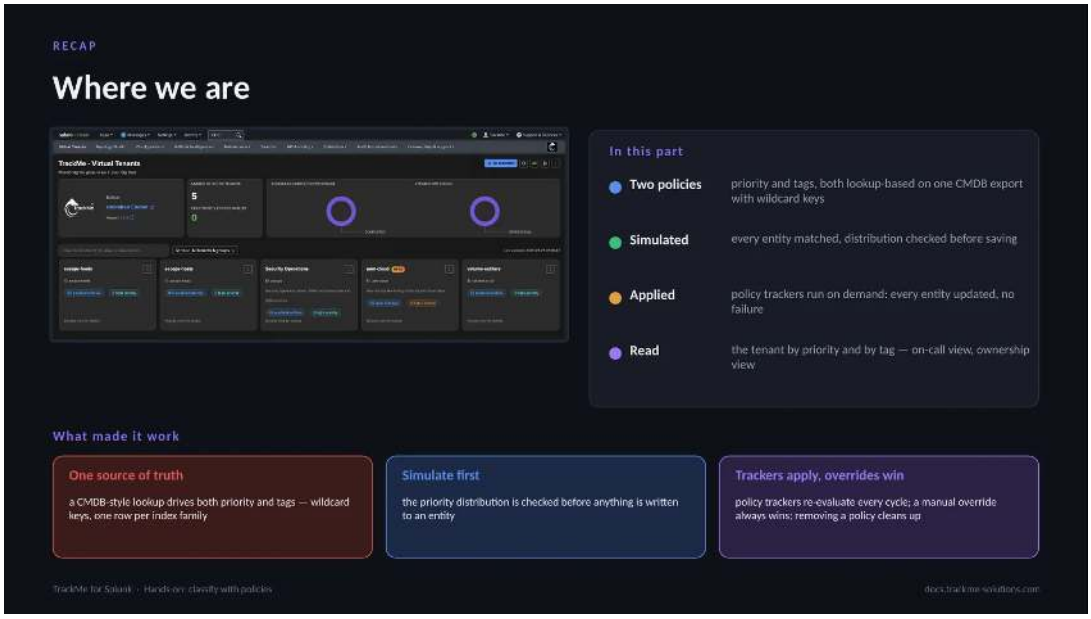


Grouped by Tags, the table shows one fold per tag (callout 1): business, cloud, firewall, identity, infra, net, os, syslog, vulnerabilities, web — all from the CMDB. The table has more rows than entities (callout 2); expected, since siem-firewall-* carries net,firewall and those entities appear under both tags. Tags are multi-valued.

Inside the firewall group (callout 3), siem-firewall-amer:cisco:asa is critical from the priority policy, green, delay 1m30; the inline detail shows key information, status, thresholds and the 24 h charts. Tags are the ownership axis —

the firewall team sees firewall, the identity team sees identity — and also drive the search box, Virtual Group filters (tags=firewall), ML outliers scope, Topology Studio aggregates and alert routing.

Where we are



Classification, step 4 of the cycle, is a policy problem, not a data-entry problem. Two lookup-based policies, priority and tags, run on one CMDB export with wildcard keys. Both were simulated first, the distribution checked before anything was written, then applied by the policy trackers on demand: every entity updated, no failure. The tenant now reads by priority (on-call view) and tag (ownership view).

What makes it work: one source of truth for both families, simulation before saving, and trackers that re-evaluate every cycle while a manual override always wins and a removed policy cleans up. Alert scoping relies on priority: an alert restricted to critical and high pages for the firewall and identity feeds, not the low-priority ones.

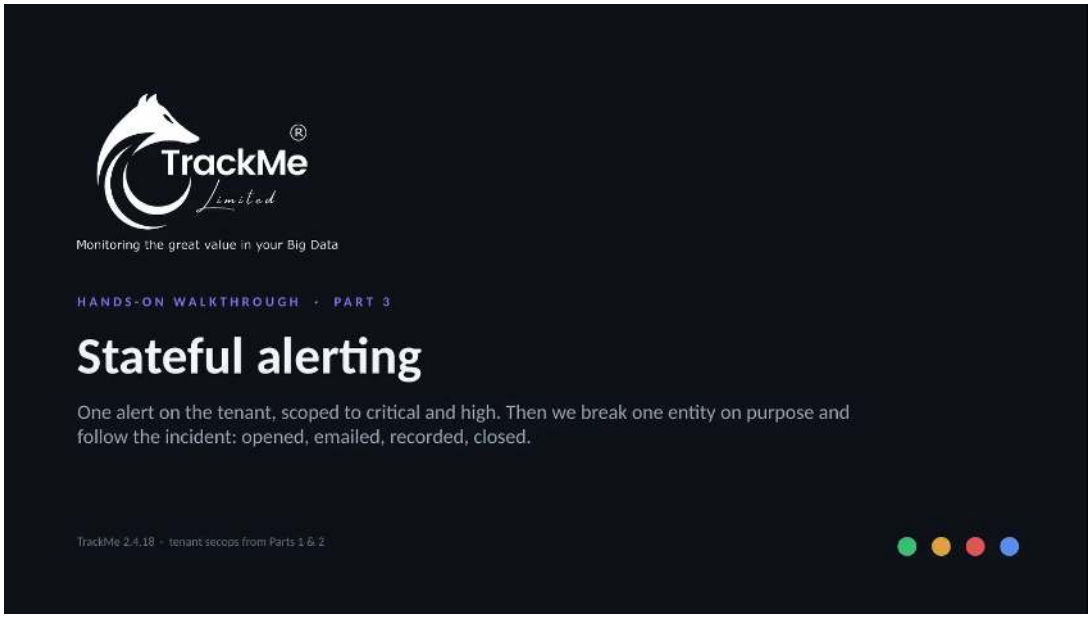
2.1.4 Part 3 — Stateful alerting

One alert on the tenant, scoped to critical and high; then an entity is broken on purpose and the incident is followed: opened, emailed, recorded, closed.

`Download the deck (PDF) · PowerPoint`

about 20 minutes · 16 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

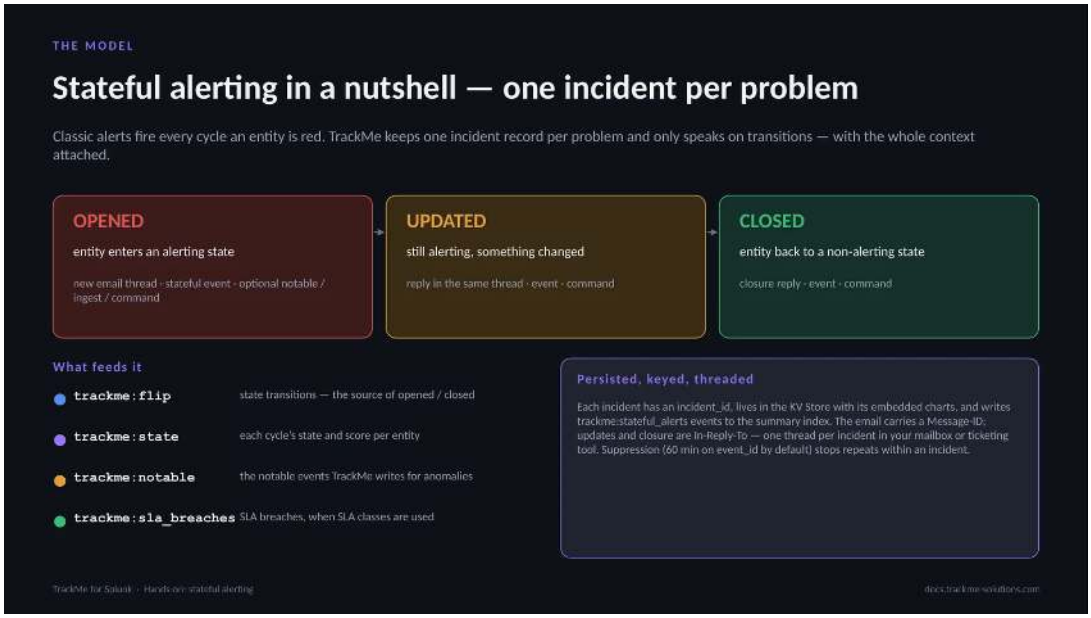
Overview



Part 3 of the hands-on walkthrough covers step 6 of the cycle, ALERT, on the secops tenant classified in Part 2. One stateful alert is created on the tenant, with emails restricted to critical and high priority entities. A healthy critical entity is then forced into red with a manual score influence, and the resulting incident is followed end to end: opened, emailed, recorded and closed.

Every screen in this part was captured live on TrackMe 2.4.18.

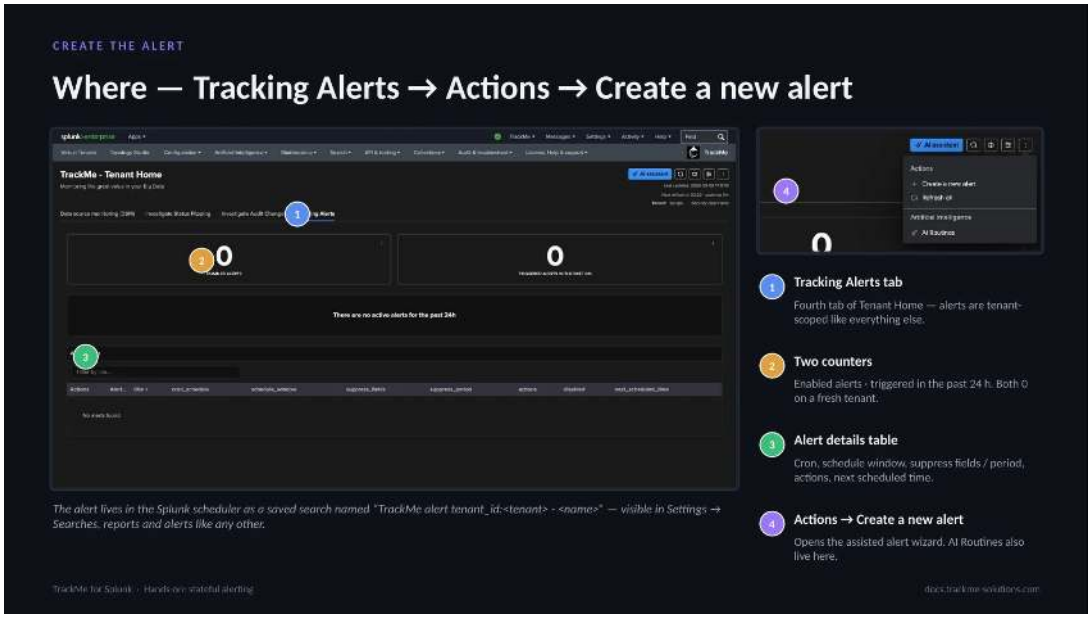
Incident lifecycle and its inputs



Classic alerts fire every cycle an entity is red. TrackMe keeps one incident record per problem and only speaks on transitions. An incident is OPENED when the entity enters an alerting state (new email thread, stateful event, optional notable / ingest / command), UPDATED when it is still alerting and something changed, and CLOSED when it returns to a non-alerting state.

Each incident has an incident_id, lives in the KV Store with its charts, and writes trackme:stateful_alerts events to the summary index. The email carries a Message-ID; updates and closure are In-Reply-To, one thread per incident. Suppression, 60 min on event_id by default, stops repeats within an incident. Inputs: trackme:flip (the source of opened and closed), trackme:state, trackme:notable, trackme:sla_breaches.

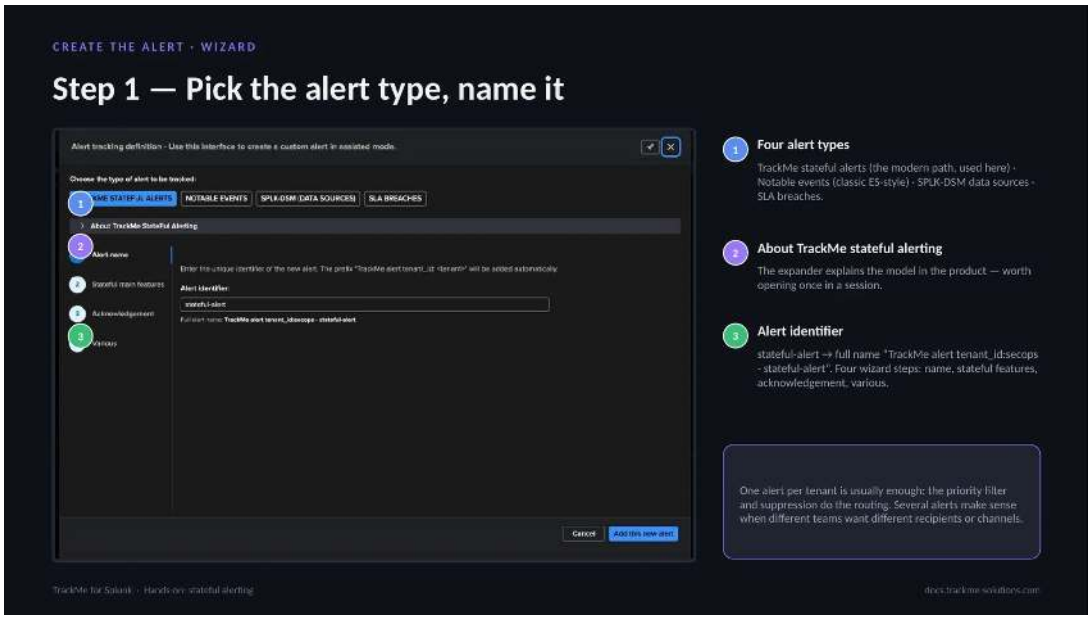
The Tracking Alerts tab



Alerts are created per tenant from the Tracking Alerts tab, the fourth tab of Tenant Home (callout 1). Two counters (callout 2) show enabled alerts and alerts triggered in the past 24 h, both 0 on a fresh tenant. The alert details table (callout 3) lists cron, schedule window, suppress fields and period, actions and next scheduled time. Actions → Create a new alert (callout 4) opens the assisted wizard; AI Routines also live here.

The wizard produces a normal Splunk saved search named "TrackMe alert tenant_id:<tenant> - <name>", visible in Settings → Searches, reports and alerts, with TrackMe alert actions attached — nothing proprietary in the scheduler, which matters where saved searches are managed through CI/CD.

Alert type and identifier

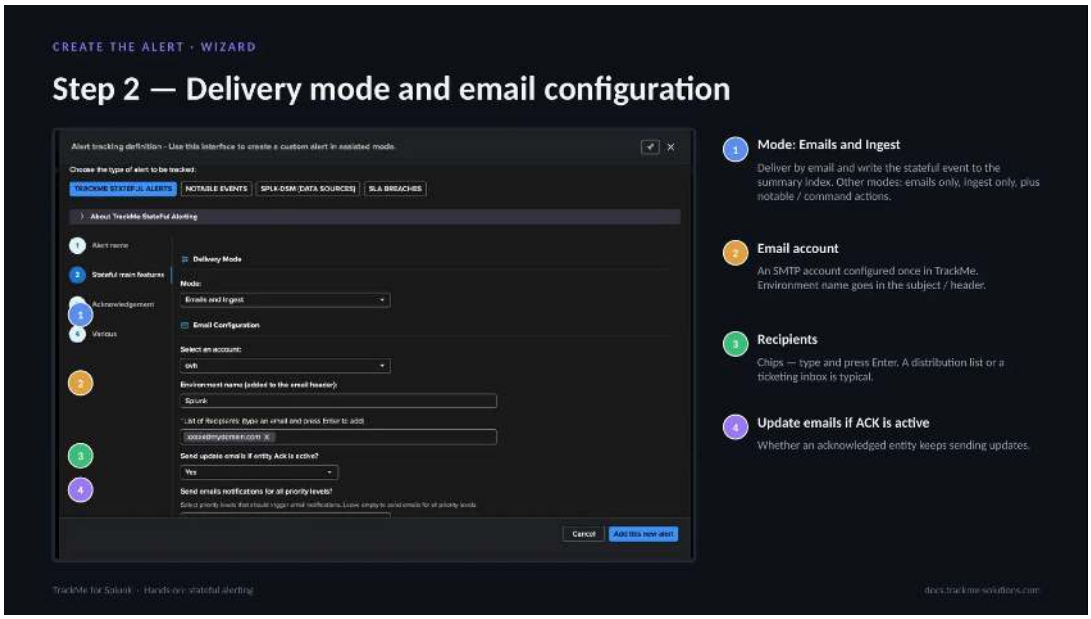


Step 1 offers four alert types (callout 1): TrackMe stateful alerts, the modern path used here; Notable events, the classic ES-style path where TrackMe writes notables and Enterprise Security correlates them; SPLK-DSM data sources; and SLA breaches. The About TrackMe stateful alerting expander (callout 2) explains the model inside the product. The alert identifier (callout 3), stateful-alert, is prefixed automatically with the tenant id, giving "TrackMe alert tenant_id:secops - stateful-alert". The wizard has four steps: name, stateful features, acknowledgement, various.

One alert per tenant is usually enough, because the priority filter and suppression do the routing; several alerts make

sense when different teams want different recipients or channels.

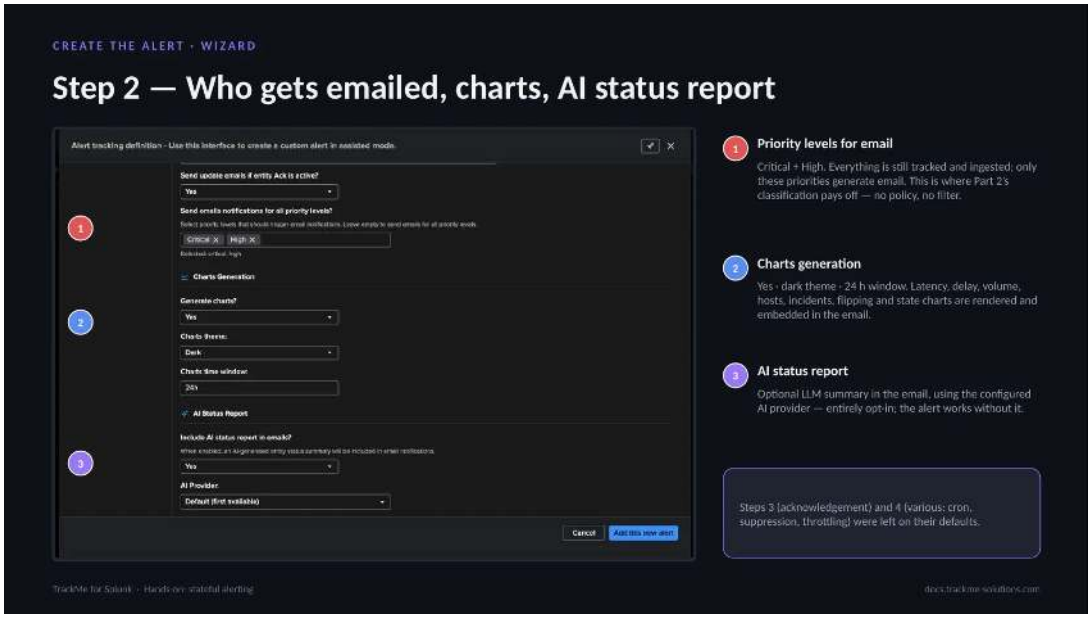
Delivery mode and email account



The mode (callout 1), Emails and Ingest, delivers by email and writes the stateful event to the summary index — the usual choice, since people get the thread and Splunk keeps the record; other modes are emails only, ingest only, plus notable and command actions. The email account (callout 2) is an SMTP account configured once under Configuration; the wizard only selects it, and its environment name goes in the subject and header, separating prod from preprod in a shared inbox.

Recipients (callout 3) are entered as chips, one per Enter; a distribution list or a ticketing inbox is typical. Update emails if ACK is active (callout 4) decides whether an acknowledged entity keeps sending updates.

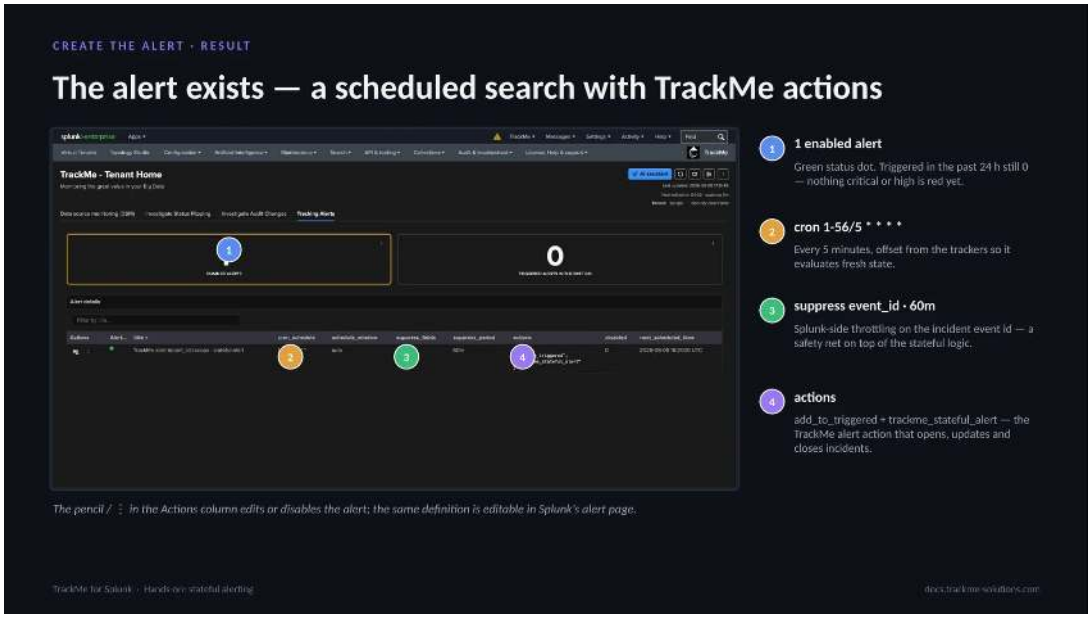
Priority filter, charts and AI report



Priority levels for email (callout 1) is set to Critical + High: everything is still tracked and ingested, but only these priorities generate email. This is where the classification from Part 2 pays off and the key setting for a quiet on-call: low and medium feeds still get their incidents recorded, but nobody is paged for them.

Charts generation (callout 2) is Yes, dark theme, 24 h window: latency, delay, volume, hosts, incidents, flipping and state charts are embedded, giving the recipient 24 hours of context without opening Splunk. AI status report (callout 3) adds an opt-in LLM summary from the configured AI provider. Steps 3 (acknowledgement) and 4 (cron, suppression, throttling) keep their defaults.

The saved search behind the alert



The Tracking Alerts tab now shows 1 enabled alert with a green dot (callout 1); triggered in the past 24 h is still 0, as nothing critical or high is red. The cron is 1-56/5 * * * * (callout 2): every 5 minutes, one minute after the trackers so it evaluates fresh state. Suppression is on event_id for 60m (callout 3), Splunk-side throttling on the incident event id, a safety net over the stateful logic.

The actions (callout 4) are add_to_triggered, keeping Splunk's triggered-alerts list in sync, and trackme_stateful_alert, the TrackMe alert action that opens, updates and closes incidents. The pencil and ⋮ in the Actions column edit or disable the alert, also editable from Splunk's alert page.

Adding a manual score influence

The entity ⋮ menu (callout 1) lists: manually influence the score, false positive, disruption queue, lagging classes,

priority, maintenance. Callout 2 shows a healthy critical entity, siem-firewall-amer:cisco:asa — green, score 0, priority critical from the policy. Add 100 to the score (callout 3), with a comment: audited as a manual_score event; a score_breached anomaly is recorded.

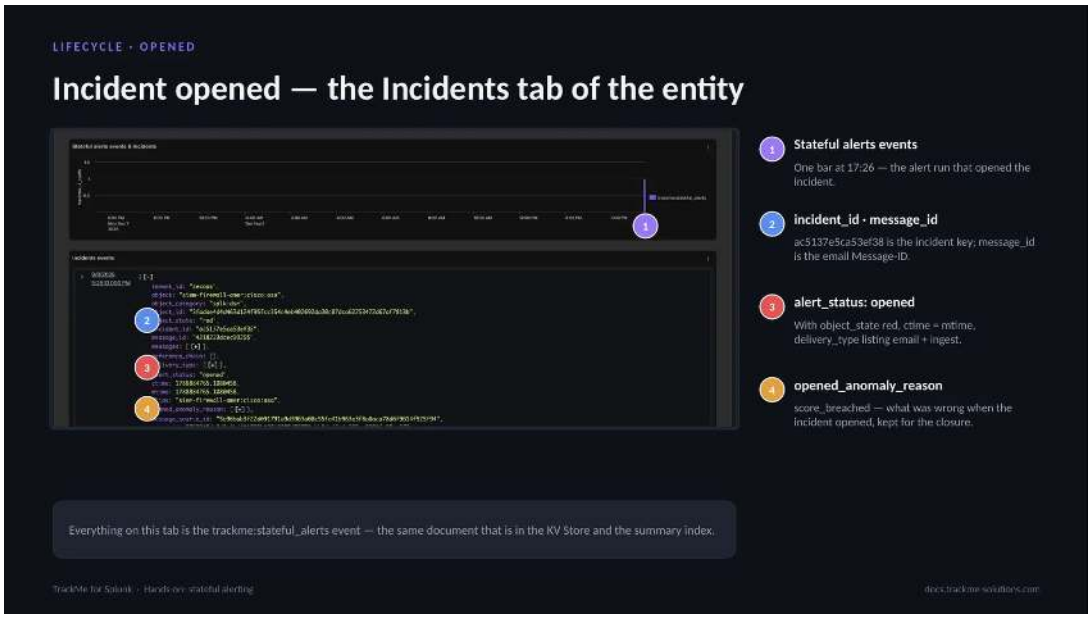
Manual score influence adds or subtracts a value from the impact score; operators use it to force attention on an entity or soften one. Here it produces a deterministic red state on a healthy feed without touching data or thresholds. Being critical, the entity passes the alert's email filter; the AI status report will name the manual override as the cause.

The entity header after the influence

The metrics are still healthy (callout 1): delay 02:59, latency 01:50, thresholds 3600 — nothing wrong with the feed. The state is red (callout 2), latest flip at 16:24 UTC, priority critical. anomaly_reason is score_breached (callout 3): the status reason names the manual influence rather than telling a false delay story. Impact score is 100 (callout 4), entirely the manual component, and score_definition in the Status message tab shows it.

This is the honesty of the scoring model — the reason is always the real one. The next alert run, every 5 minutes, sees a critical entity in red with no open incident and opens one.

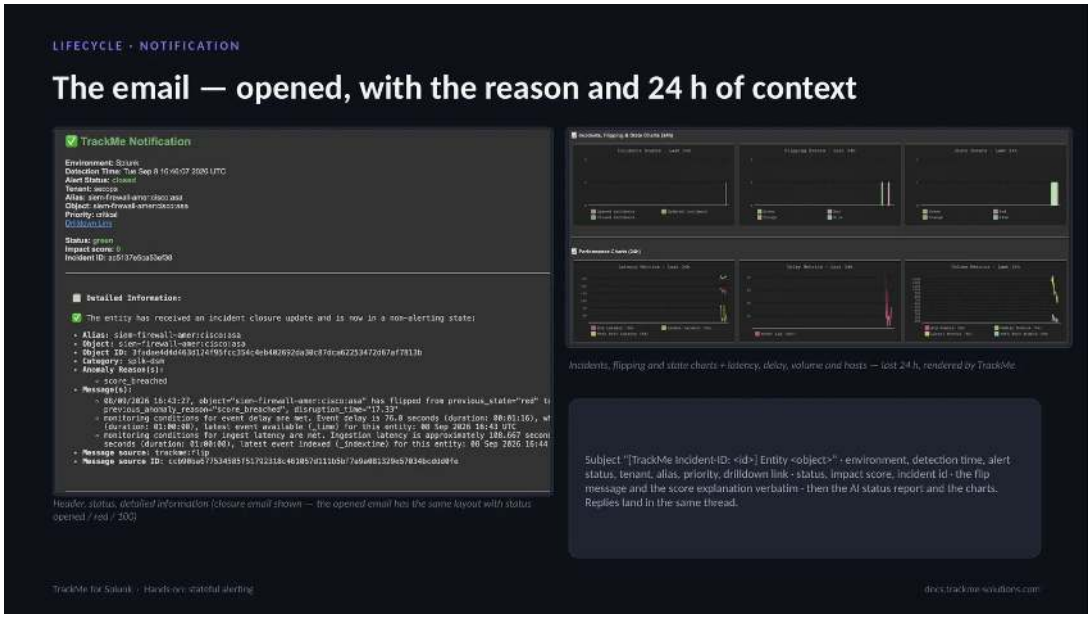
The incident record on the entity



The Incidents tab of the entity shows the incident record as TrackMe stores it. The stateful alerts events chart (callout 1) has one bar at 17:26, the alert run that opened the incident. incident_id ac5137e5ca53ef38 is the incident key and message_id is the email Message-ID (callout 2); message_source_id points at the flip event that caused the incident. alert_status is opened (callout 3), with object_state red, ctime equal to mtime and delivery_type listing email and ingest. opened_anomaly_reason (callout 4) is score_breached — what was wrong when the incident opened, kept for the closure.

Everything on this tab is the trackme:stateful_alerts event, the same document held in the KV Store and in the summary index.

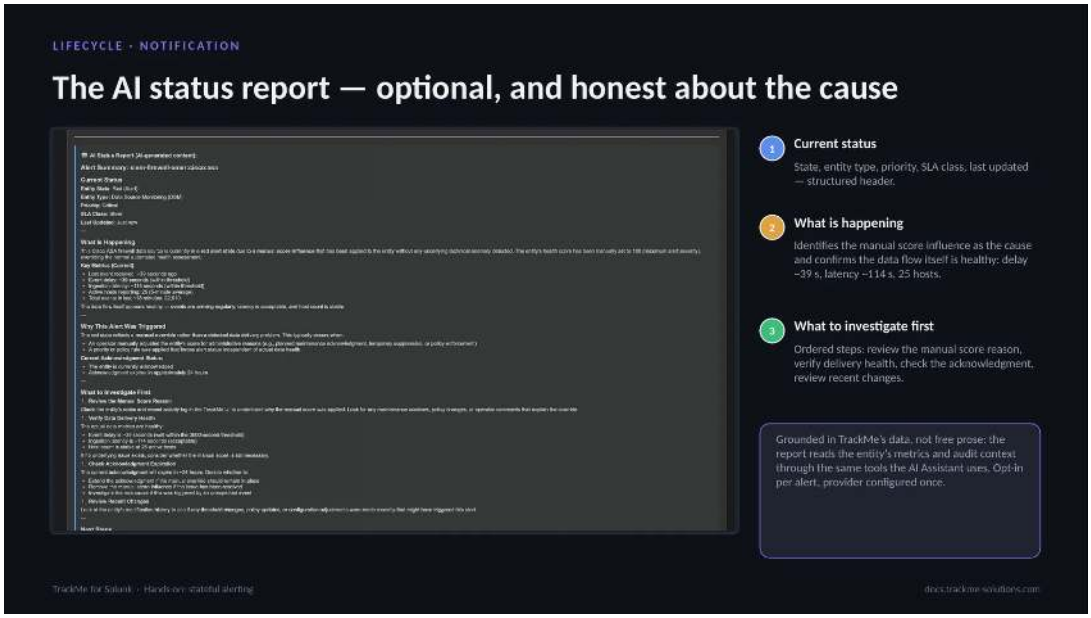
Anatomy of the notification email



The email reads top to bottom: who, what, why, how bad, link to the entity. The subject is "[TrackMe Incident-ID: <id>] Entity <object>". The header carries environment, detection time, alert status, tenant, alias, priority and the drilldown link; the status block gives status, impact score and incident id; detailed information quotes the flip message and score explanation verbatim. Then the AI status report, when enabled, and the 24 h charts rendered by TrackMe: incidents, flipping and state, plus latency, delay, volume and hosts.

The closure email is shown; the opened email has the same layout with status opened, red and impact score 100. Replies land in the same thread, and recipients need no Splunk access.

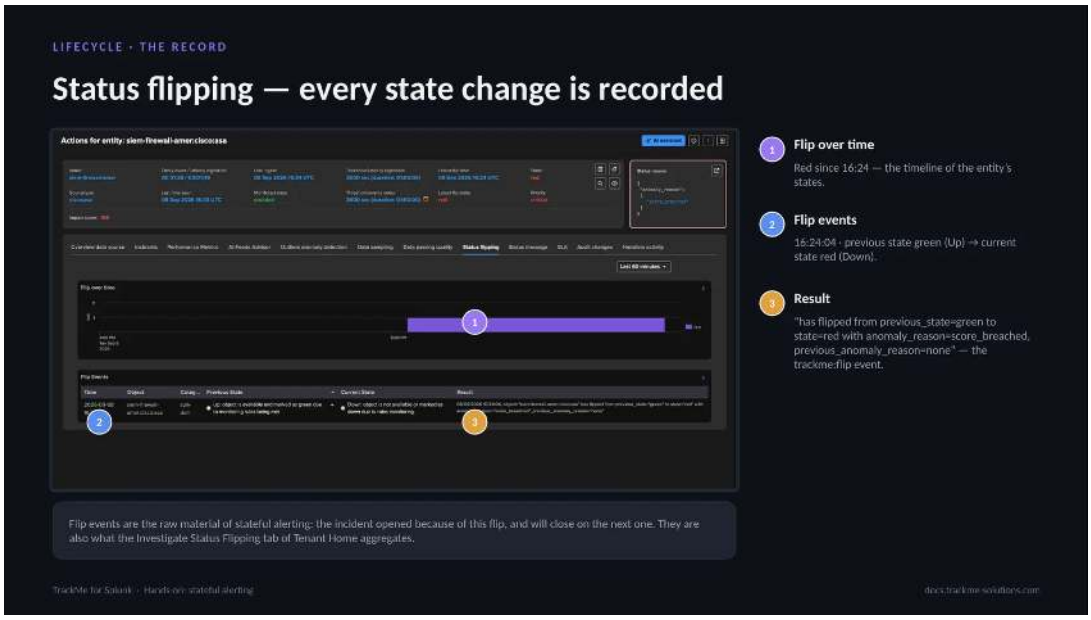
Reading the AI status report



Current status (callout 1) is a structured header: state, entity type, priority, SLA class, last updated. What is happening (callout 2) names the manual score influence as the cause and confirms the data flow is healthy — delay ~39 s, latency ~114 s, 25 hosts. What to investigate first (callout 3) gives ordered steps: review the manual score reason, verify delivery health, check the acknowledgement, review recent changes.

The report is grounded in TrackMe's data rather than free prose: it reads the entity's metrics and audit context through the same tools the AI Assistant uses, hence the correct verdict of a manual override on a healthy feed. Opt-in per alert, provider configured once; the email is complete without it.

Flip events behind the incident

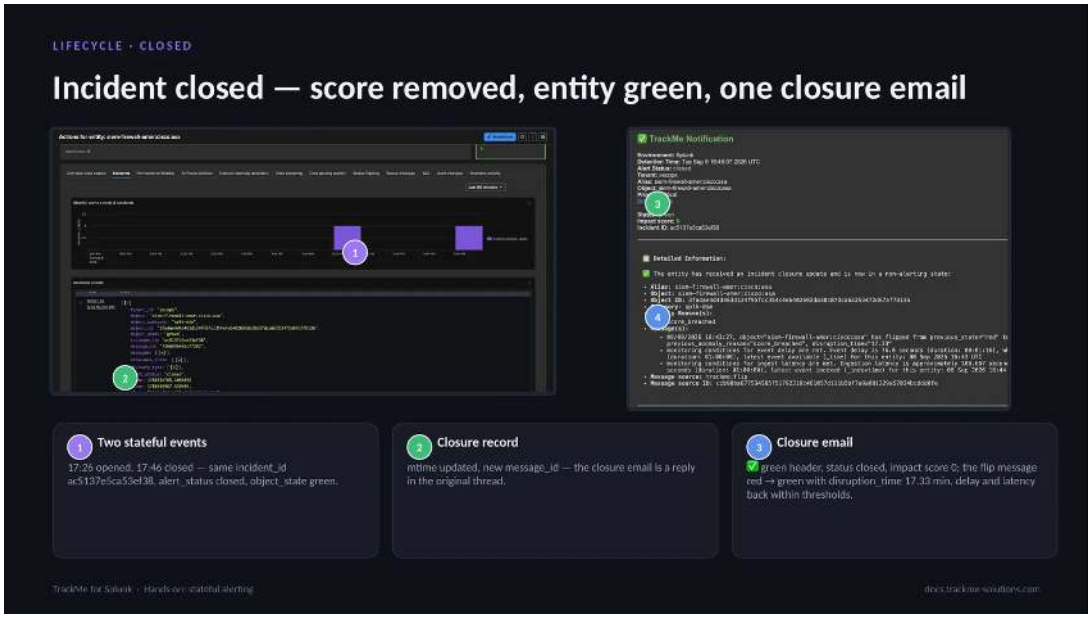


The Status flipping tab records every state change as an event with a history. Flip over time (callout 1) is the timeline of the entity's states, red since 16:24. The flip events list (callout 2) shows 16:24:04, previous state green (Up) to current state red (Down). The result (callout 3) is the trackme:flip event itself: "has flipped from previous_state=green to state=red with anomaly_reason=score_breached, previous_anomaly_reason=none" — the same sentence quoted in the email.

Flip events are the raw material of stateful alerting: the incident opened because of this flip and closes on the next

one. They are also what the Investigate Status Flipping tab of Tenant Home aggregates, which is how flapping entities are found later.

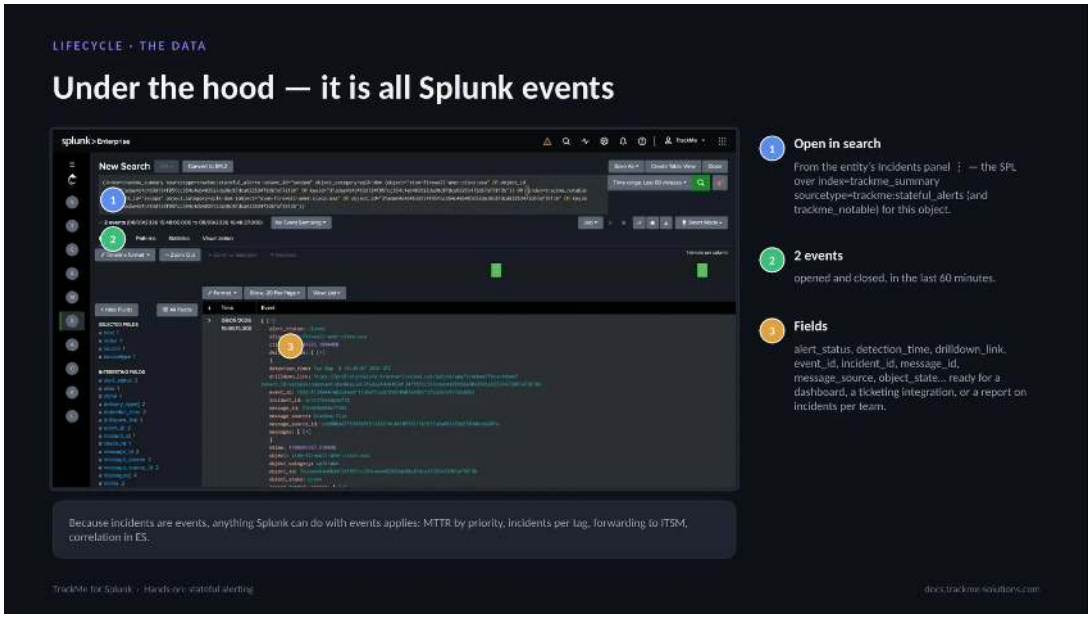
Closure record and closure email



Removing the 100 points turns the entity green on the next tracker run; the alert's next run finds an open incident and closes it. The Incidents tab shows two stateful events (callout 1): 17:26 opened, 17:46 closed, same incident_id ac5137e5ca53ef38, alert_status closed, object_state green. The closure record (callout 2) has an updated mtime and a new message_id, so the closure email is a reply in the original thread.

The closure email (callout 3) has a green header, status closed, impact score 0; it quotes the recovery flip red → green with disruption_time 17.33 min, delay and latency back within thresholds. SLA reporting uses the same disruption time; the AI recovery summary confirms the entity is healthy.

Searching the incident events

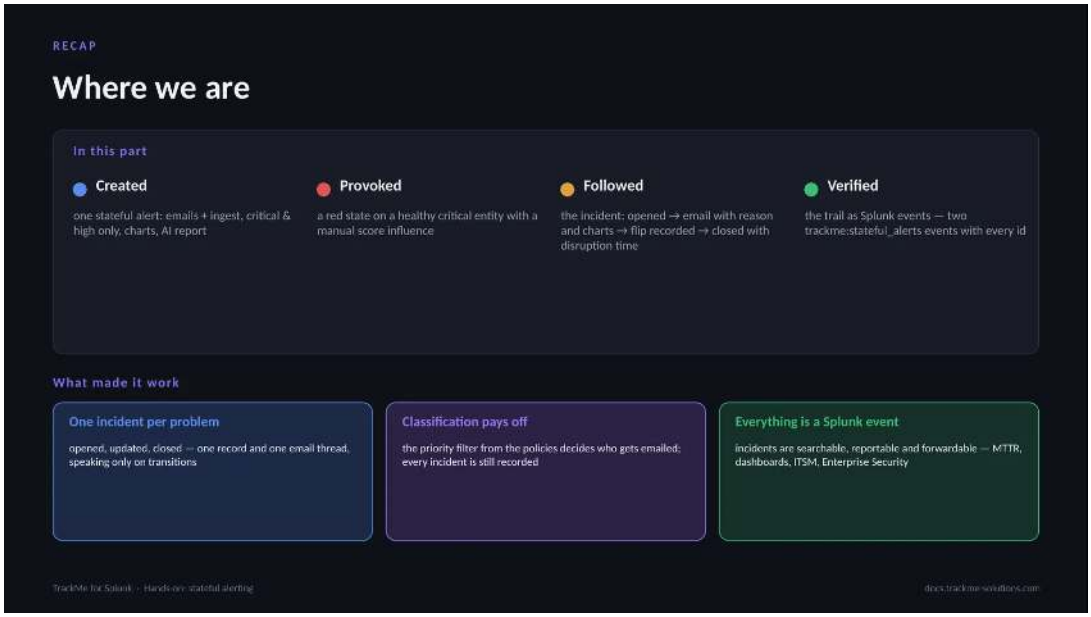


Open in search (callout 1), from the ⋮ of the entity's Incidents panel, runs the SPL over index=trackme_summary sourcetype=trackme:stateful_alerts (and trackme_notable) for this object. It returns 2 events in the last 60 minutes (callout 2): opened and closed. The fields (callout 3) — alert_status, detection_time, drilldown_link, event_id, inci-

dent_id, message_id, message_source, object_state and more — are ready for a dashboard, a ticketing integration or a report on incidents per team.

Because incidents are events, anything Splunk can do with events applies: MTTR by priority, incidents per tag, forwarding to ITSM, correlation in Enterprise Security. There is no black box: one event per transition, with every id needed, and the drilldown_link brings a ticket back to the entity.

Where we are



Discover, classify, alert: the cycle is complete. One stateful alert was created — emails and ingest, critical and high only, charts, AI report — and a red state provoked on a healthy critical entity by score influence. The incident was followed from opened, through the email with reason and charts, the recorded flip, to closed with its disruption time, verified as two trackme:stateful_alerts events with every id.

Key points: one incident per problem — opened, updated, closed, one record and one email thread, speaking only on transitions; the priority filter from the policies decides who is emailed while every incident is recorded; and everything is a Splunk event — searchable, reportable, forwardable to dashboards, ITSM or Enterprise Security.

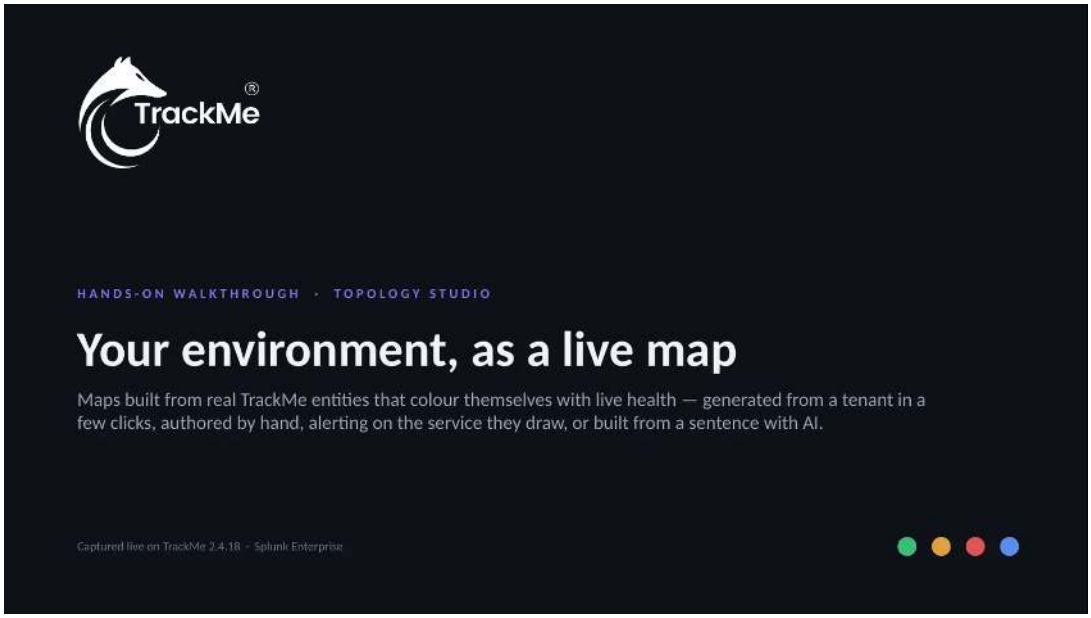
2.1.5 Topology Studio

Maps built from real entities that colour themselves with live health — generated from a tenant, authored by hand, alerting on the service they draw, or built from a sentence with AI.

`Download the deck (PDF) · PowerPoint`

about 40 minutes · 39 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

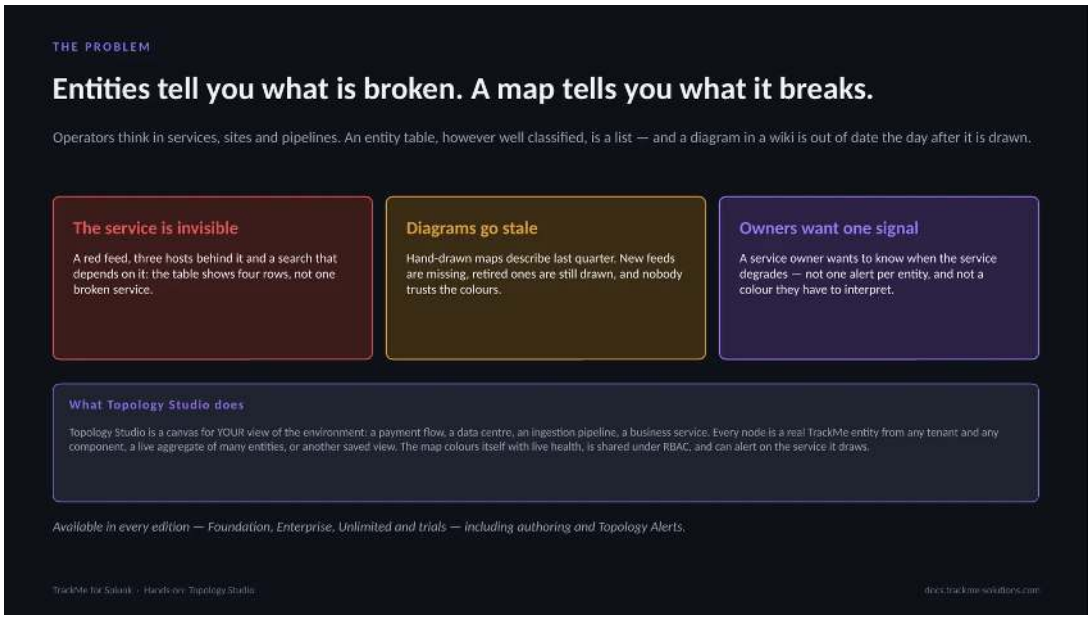
Overview



Topology Studio draws maps from real TrackMe entities, and every node colours itself with live health. A map can be generated from a tenant in a few clicks, authored by hand, made to alert on the service it draws, or built from a sentence with AI. Every screen was captured on TrackMe 2.4.18 running on Splunk Enterprise, against a production-like deployment with several tenants.

The walkthrough has four parts: generating a map from a tenant, building one from an empty canvas with aggregates and auto-generated members, alerting on the map, and building one from a sentence with AI. It closes with a few maps that run in production every day.

Why an entity list is not enough



An entity table is a list: a red feed, three hosts behind it and a search that depends on it show as four rows, not one broken service. Hand-drawn diagrams go stale within a week. A service owner wants one signal when the service degrades, not one alert per entity.

Topology Studio is a canvas for the operator's own view of the environment, such as a payment flow or a business service. Every node is a real TrackMe entity from any tenant and component, a live aggregate of many entities, or

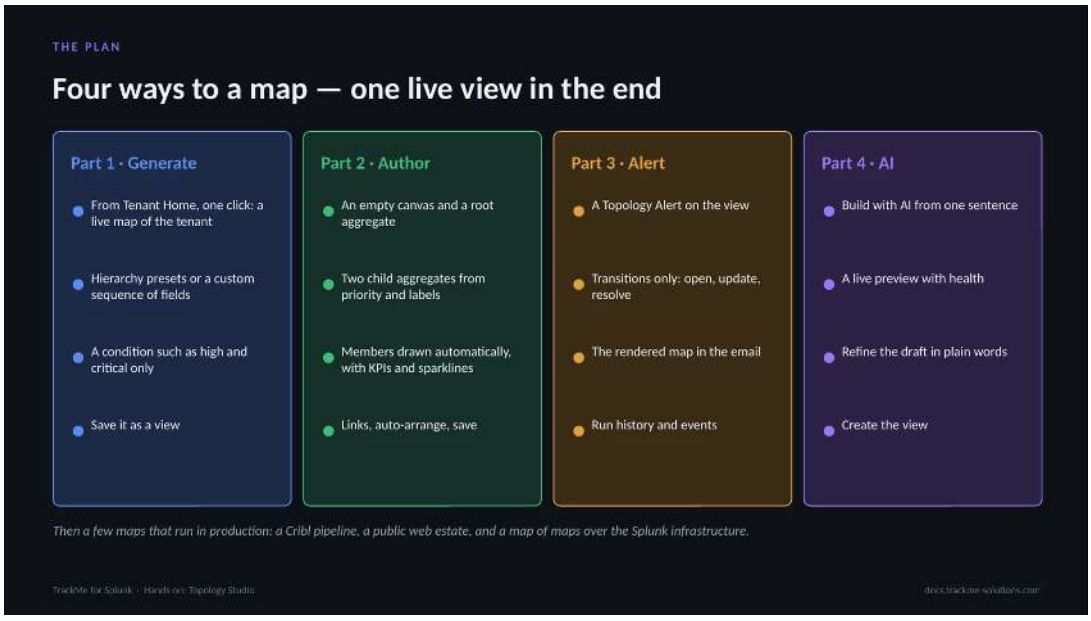
another saved view. The map colours itself with live health, is shared under RBAC, can alert on the service it draws, and is available in every edition, including trials.

Views, node types and live health

A view is one map: an id, a display name, a category and two role lists, Can view and Can edit. An Entity node is one monitored entity with up to five KPIs. A Scoped aggregate rolls up tenants × components plus an optional filter, with worst-member or healthy-percentage health and dynamic membership. An Auto aggregate is a parent whose members are the nodes linked to it. A View node folds another saved view into one health node. Labels and decorations carry no health.

Every node polls every 60 seconds. Incomplete data reads unavailable and a deleted entity reads missing, never green by default. Tenant masking is enforced per node on the server, and every save is a restorable version.

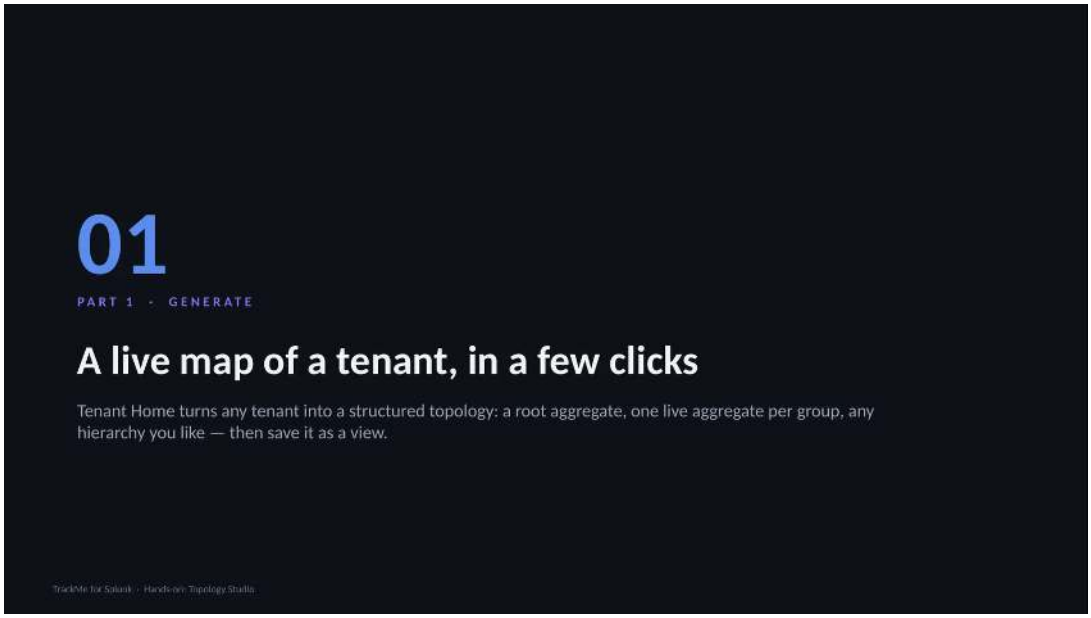
Four routes to a live map



The four parts are not steps of one procedure; each is a way to obtain a live map. Part 1 generates a map from Tenant Home in one click, with a chosen hierarchy and an optional condition. Part 2 authors a map from an empty canvas: a root aggregate, two child aggregates from priority and labels, members drawn automatically with KPIs and sparklines.

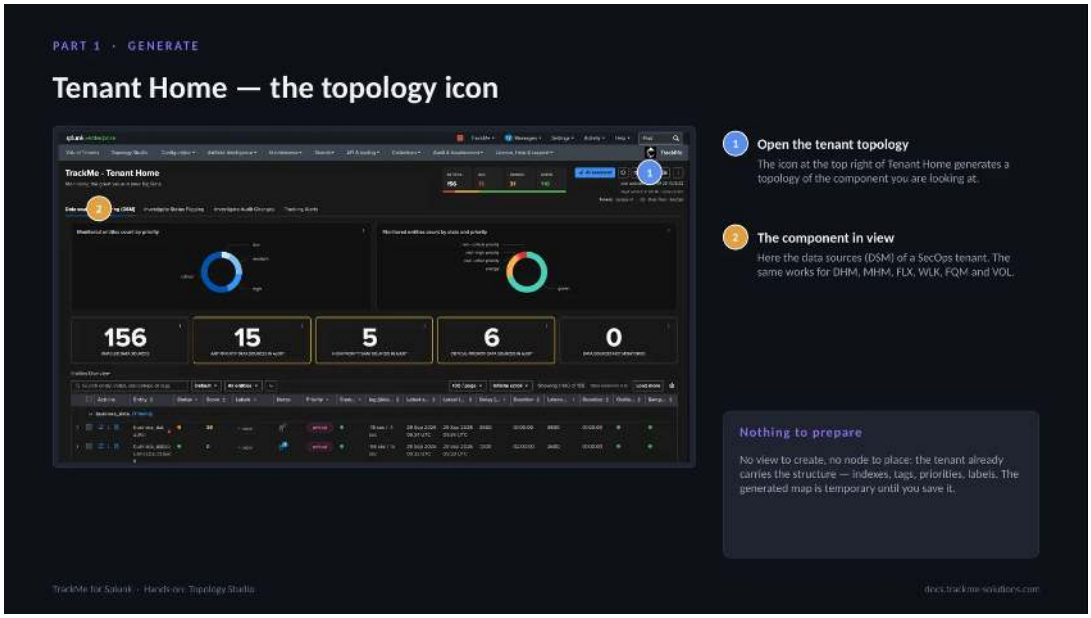
Part 3 attaches a Topology Alert to the view, notifying on transitions only with the rendered map in the email. Part 4 builds a map with AI from one sentence and refines it in plain words. In production follows: a Cribl pipeline, a web estate and a map of maps.

Part 1 — Generate



The fastest way to a map starts from a tenant that already knows its own structure: indexes, tags, priorities and labels. Tenant Home turns any tenant into a structured topology, with a root aggregate and one live aggregate per group, in any hierarchy. The operator picks the hierarchy, narrows it with a condition and saves it as a view once it is right. The generated map is temporary until it is saved.

Opening the topology from Tenant Home



The topology icon at the top right of Tenant Home (callout 1) generates a topology of the component in view; callout 2 marks that component. Here it is the data sources (DSM) of a SecOps tenant tracking a few hundred data sources; the same works for DHM, MHM, FLX, WLK, FQM and VOL. The icon opens a full-screen panel with three tabs, Topology Studio, Link graph and Network graph; the Topology Studio tab is the one used here.

Nothing needs preparing: no view to create and no node to place, because the tenant already carries the structure in

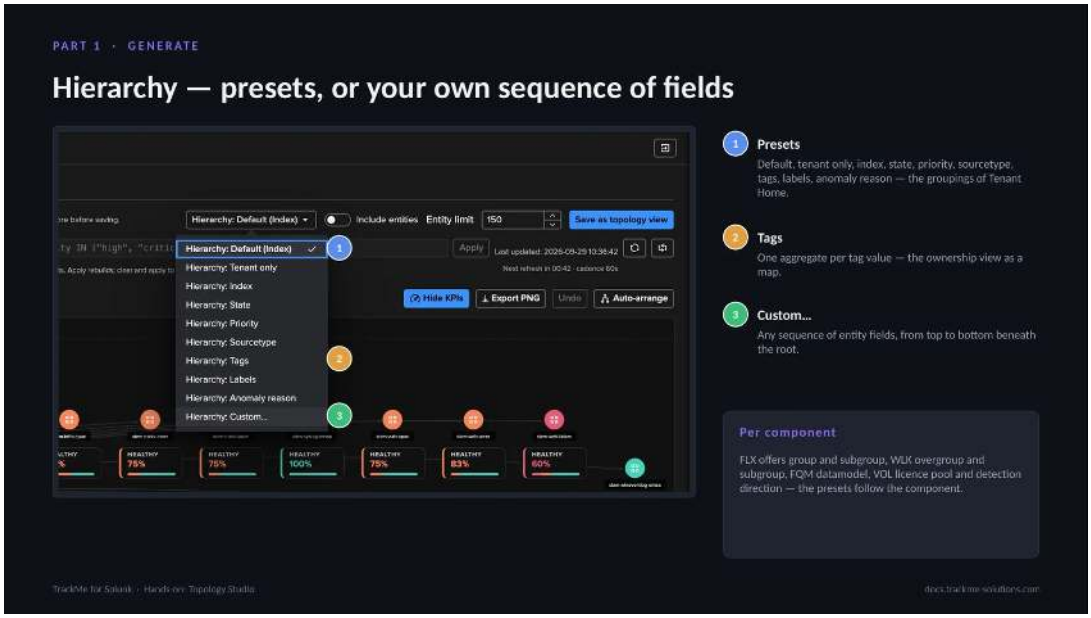
its indexes, tags, priorities and labels. The generated map stays temporary until it is saved.

The temporary topology and its controls

The generated map opens as a temporary topology (callout 1): nothing is saved yet, and the banner says how many entities are represented. Hierarchy (callout 2) is one selector, defaulting per component: index for DSM, group for FLX, overgroup for WLK, datamodel for FQM, the tenant root for DHM and MHM. Include entities and Entity limit (callout 3) add individual entity nodes on demand, within a limit; aggregates only is the default. Condition (callout 4) is an optional filter applied to every generated aggregate.

The Root aggregate (callout 5) is the tenant itself with its live healthy percentage; only monitored entities are included. Save as topology view (callout 6) freezes membership and layout while health stays live.

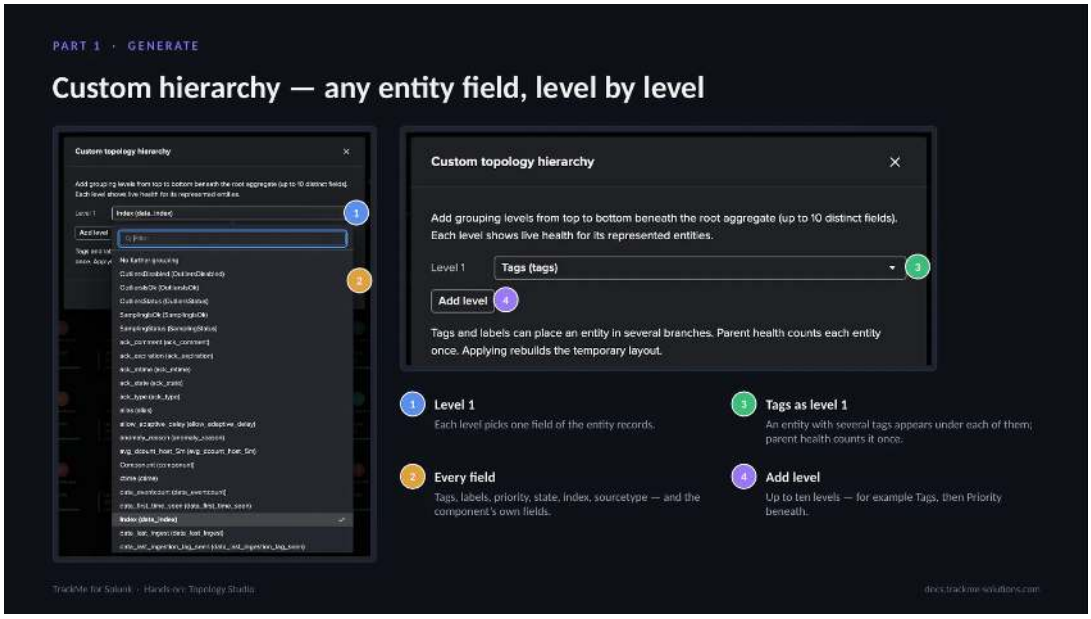
Hierarchy presets per component



The hierarchy selector lists Presets (callout 1): Default, tenant only, index, state, priority, sourcetype, tags, labels and anomaly reason, the same groupings as the Tenant Home table. Choosing Tags (callout 2) gives one aggregate per tag value, the ownership view as a map. Custom… (callout 3) opens a dialog to choose any sequence of entity fields, from top to bottom beneath the root.

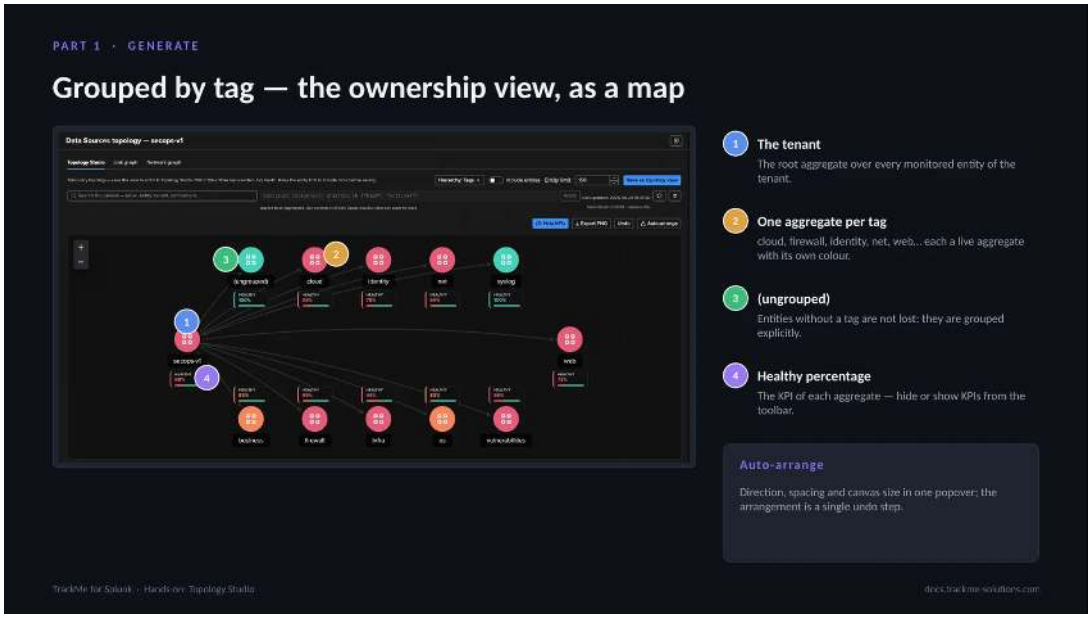
The presets follow the component: FLX offers group and subgroup, WLK overgroup and subgroup, FQM datamodel, and VOL licence pool and detection direction.

Building a custom hierarchy



The custom hierarchy dialog defines grouping levels from top to bottom beneath the root aggregate. Each level (callout 1) picks one field of the entity records; here Tags is the single level. Every field (callout 2) of the records is offered: tags, labels, priority, state, index, sourcetype and the component's own fields. An entity with several tags appears under each of them, while the parent health still counts it once (callout 3). Add level (callout 4) adds up to ten distinct levels, for example Tags with Priority beneath. Applying rebuilds the temporary layout.

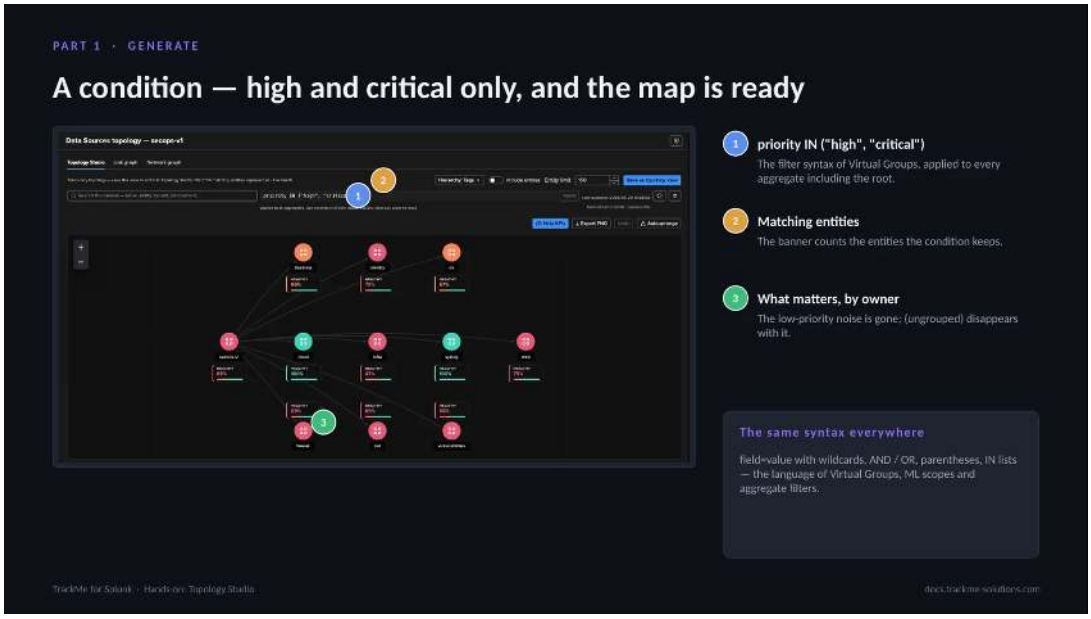
One aggregate per tag



With Tags as the hierarchy, the map shows the tenant as its owners see it. The root aggregate (callout 1) covers every monitored entity of the tenant. Beneath it sits one aggregate per tag (callout 2): cloud, firewall, identity, net, web and so on, each a live aggregate with its own colour. Entities without a tag are not lost; the (ungrouped) node (callout 3) collects them explicitly. The healthy percentage (callout 4) is the KPI of each aggregate; KPIs can be hidden or shown from the toolbar.

Auto-arrange lays the map out from one popover, with direction, spacing from compact to spacious and canvas size; the arrangement is a single undo step.

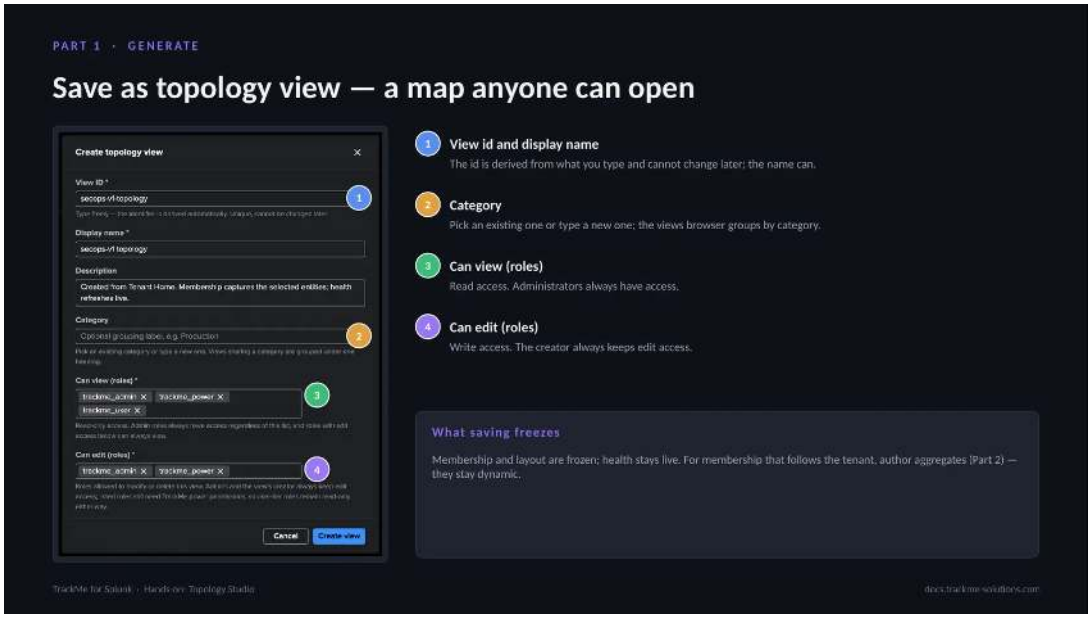
Narrowing the map with a condition



A condition narrows the whole map. The expression priority IN ("high", "critical") (callout 1) uses the filter syntax of Virtual Groups and is applied to every aggregate, including the root. The banner (callout 2) counts the matching entities the condition keeps. The result (callout 3) is what matters, by owner: the low-priority noise is gone, and the (ungrouped) node disappears with it. This is the on-call view a SecOps lead would put on a screen; clearing the condition and applying resets the map.

The same syntax is used everywhere in TrackMe: field=value with wildcards, AND / OR, parentheses and IN lists, the language of Virtual Groups, ML scopes and aggregate filters.

Saving the generated map as a view

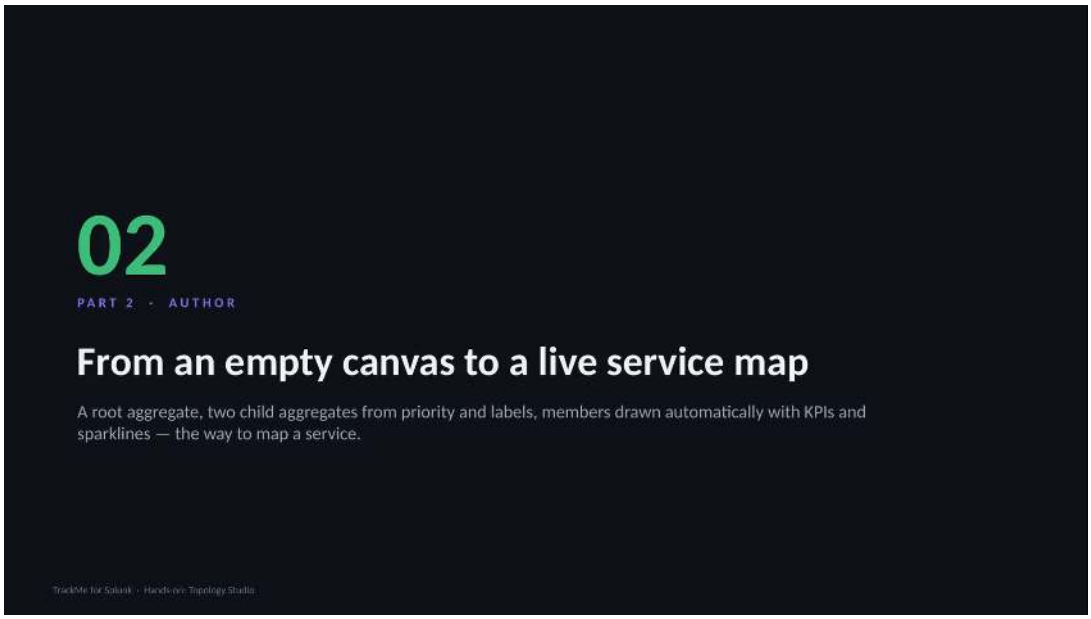


Save as topology view opens the create dialog. View id and display name (callout 1): the id is derived from what is typed and cannot change later, while the name can. Category (callout 2) accepts an existing value or a new one; the views browser groups views by category. Can view (callout 3) lists the roles with read access; administrators always

have access. Can edit (callout 4) lists the roles with write access; the creator always keeps edit access. A description can also be entered.

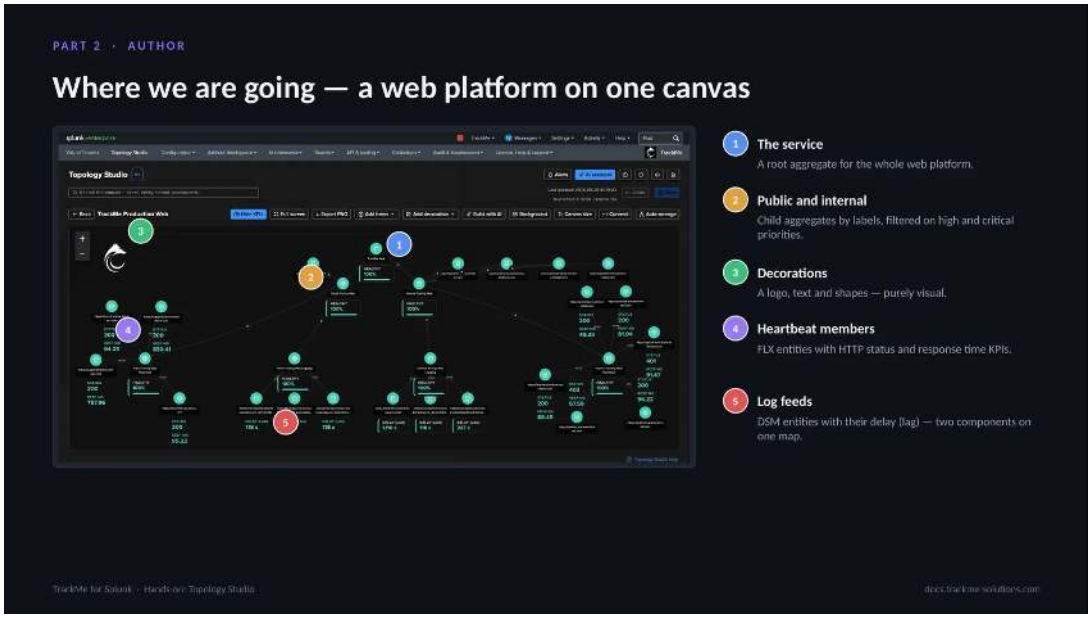
Saving freezes membership and layout while health stays live. For membership that follows the tenant as new entities appear, authored aggregates (Part 2) stay dynamic.

Part 2 — Author



Authoring by hand is the way most service maps are built: start from the service, describe its parts with aggregates, and let the members draw themselves. From an empty canvas, this part creates a root aggregate, two child aggregates built from priority and labels, and members drawn automatically with KPIs and sparklines, then links, arranges and saves the result as a live service map.

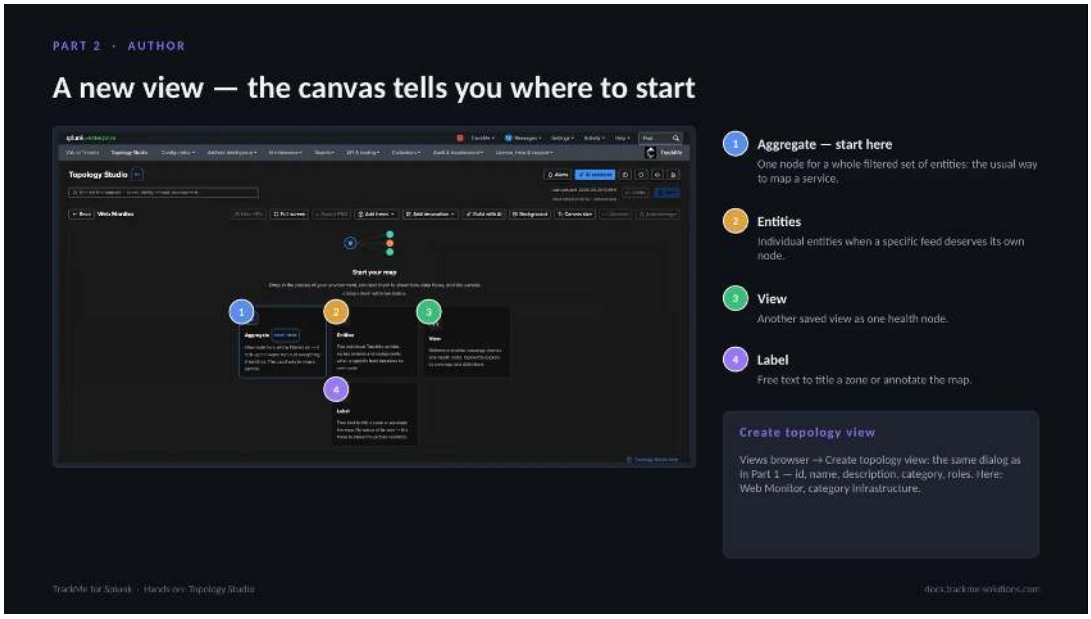
The target: a web platform map



The target is a map that runs in production, the web platform of TrackMe itself, rebuilt as a skeleton from an empty canvas in a few minutes. The service (callout 1) is a root aggregate for the whole web platform. Public and internal (callout 2) are child aggregates by labels, filtered on high and critical priorities. Decorations (callout 3), a logo, text

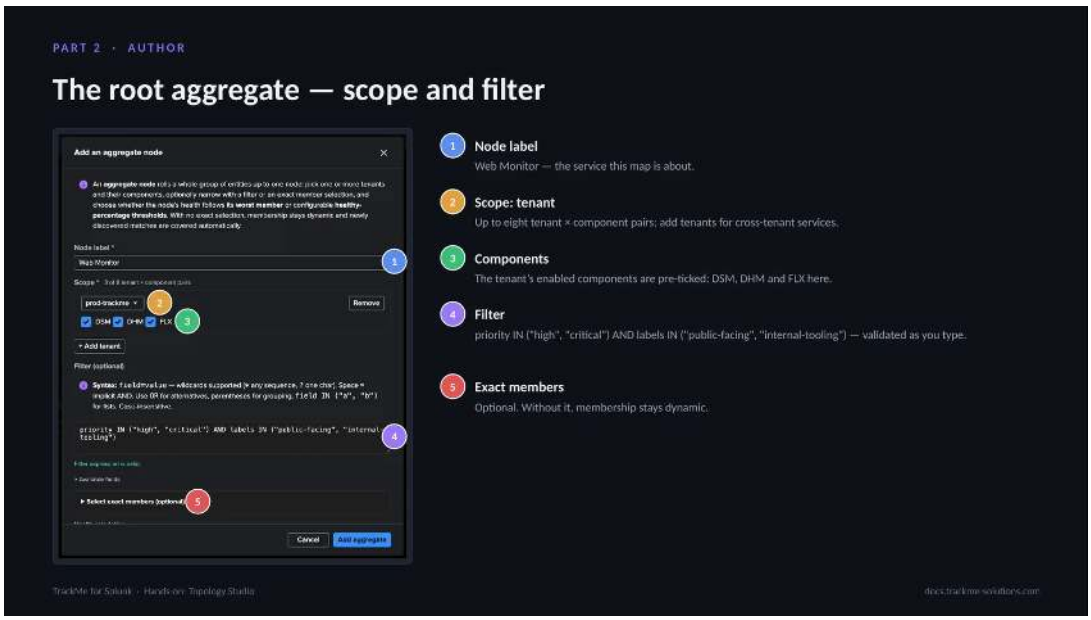
and shapes, are purely visual. Heartbeat members (callout 4) are FLX entities with HTTP status and response time KPIs. Log feeds (callout 5) are DSM entities with their delay (lag), so two components share one map.

Starting an empty view



A view called Web Monitor, category Infrastructure, is created from the views browser with Create topology view, the same dialog as in Part 1: id, name, description, category and roles. An empty view opens on the Start your map guide with four starting points. Aggregate (callout 1) is one node for a whole filtered set of entities, the usual way to map a service and the guide's recommendation. Entities (callout 2) adds individual entities when a specific feed deserves its own node. View (callout 3) adds another saved view as one health node. Label (callout 4) is free text to title a zone or annotate the map.

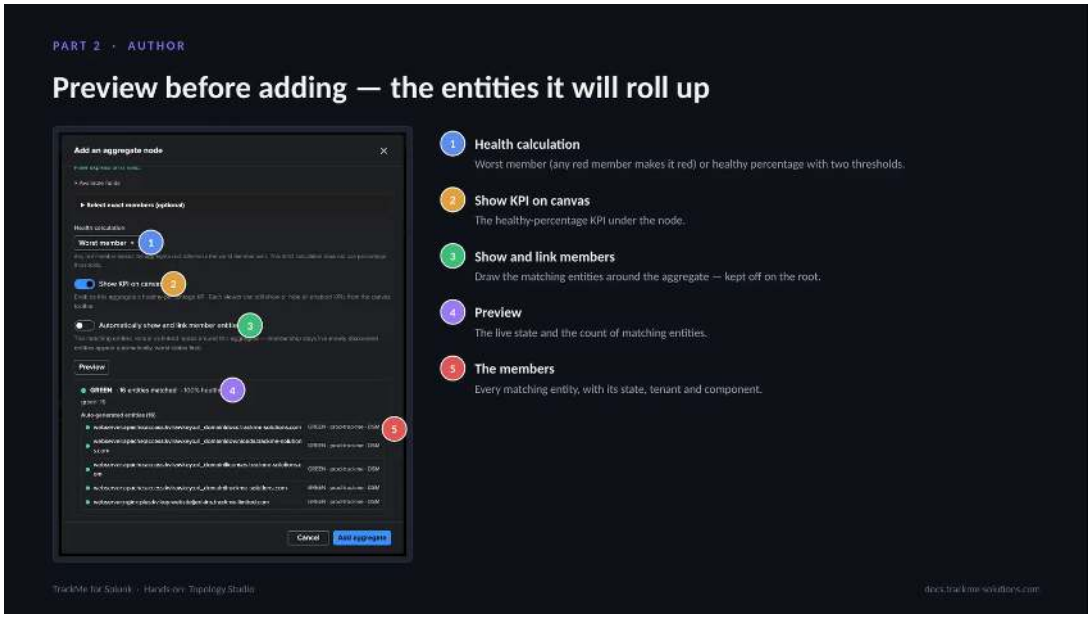
Defining the root aggregate



In the aggregate dialog, Node label (callout 1) is Web Monitor, the service the map is about. Scope: tenant (callout 2) takes up to eight tenant × component pairs; more tenants can be added for cross-tenant services. Components (callout 3) pre-ticks the tenant's enabled components, DSM, DHM and FLX here. Filter (callout 4) uses the same syntax as Part 1, validated as it is typed: priority IN ("high", "critical") AND labels IN ("public-facing", "internal-tooling"). The

labels come from the TrackMe label rules and the priorities from the policies. Exact members (callout 5) is optional; without it, membership stays dynamic and entities that start matching later join the aggregate by themselves.

Health calculation and member preview



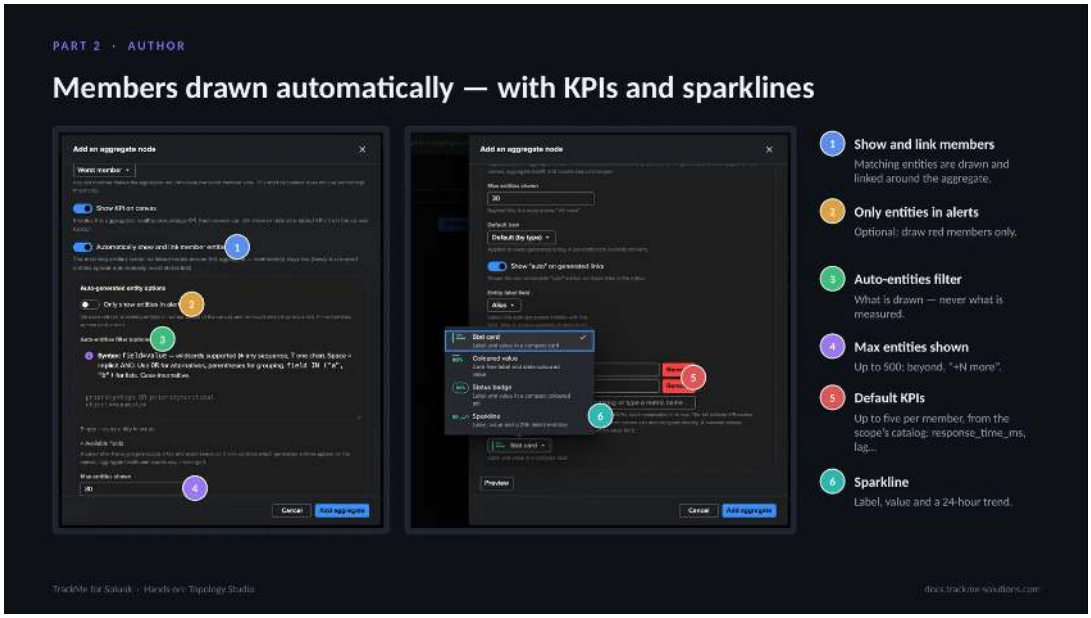
Health calculation (callout 1) is either worst member, where any red member makes the aggregate red, or healthy percentage with two thresholds, by default green from 90 percent and orange from 75. Show KPI on canvas (callout 2) displays the healthy-percentage KPI under the node. Show and link members (callout 3) draws the matching entities around the aggregate; it is kept off on the root. Preview (callout 4) shows the live state and the count of matching entities, and the members list (callout 5) names every matching entity with its state, tenant and component, so the aggregate's coverage is known before anything is added to the canvas.

Adding the two child aggregates

The root aggregate Web Monitor (callout 1) sits on the canvas, green, with its healthy percentage. Its KPI (callout 2) reads HEALTHY 100%: every member is green. Add items (callout 3) offers entities, aggregate, auto aggregate, view and label. The Inspector (callout 4) shows aggregate details, live status and a members map for the selected node.

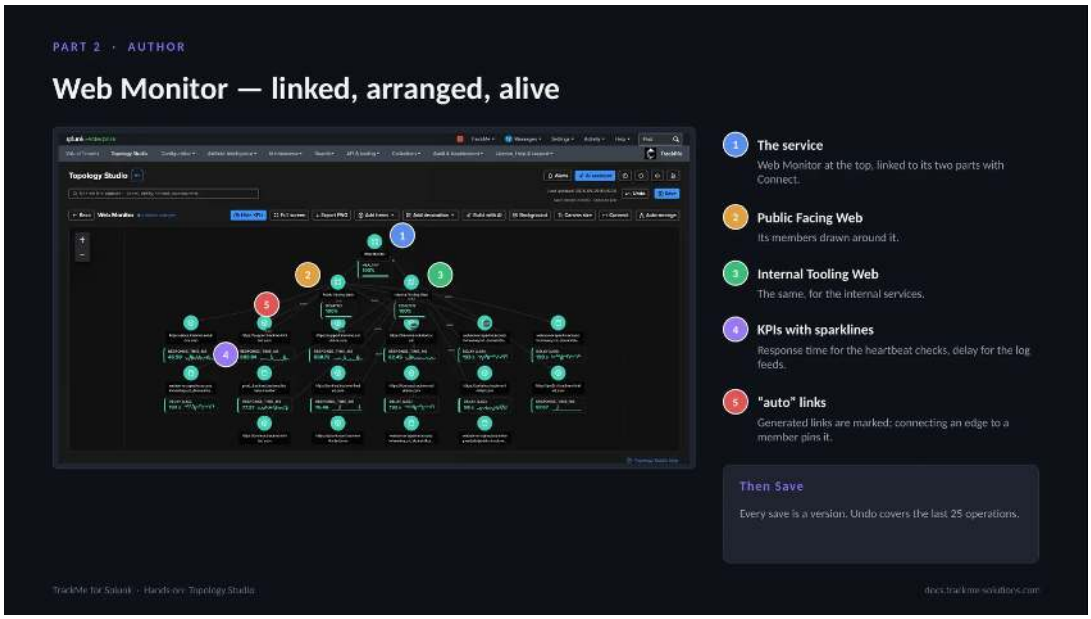
Two children are added with Add items → Add aggregate: Public Facing Web with labels IN ("public-facing") and Internal Tooling Web with labels IN ("internal-tooling"), each with the same scope and priority filter as the root and its own label. On the children, automatic members are switched on.

Automatic members, KPIs and sparklines



Show and link members (callout 1) draws the matching entities around the aggregate and links them; membership stays live, worst states first. Only entities in alerts (callout 2) draws red members only and removes them when they recover. The Auto-entities filter (callout 3) decides what is drawn, never what is measured. Max entities shown (callout 4) goes up to 500; beyond that the node shows "+N more". Default KPIs (callout 5) allows up to five per member from the scope's catalog, here response_time_ms for the heartbeat checks and lag for the log feeds. The Sparkline style (callout 6) shows label, value and a 24-hour trend on every member.

Linking, arranging and saving



Web Monitor (callout 1) sits at the top, linked to its two parts with Connect: toggle it, click the source, then the target. Public Facing Web (callout 2) and Internal Tooling Web (callout 3) each have their members drawn around them. KPIs with sparklines (callout 4) show response time for the heartbeat checks and delay for the log feeds, with a

24-hour trend. Generated links are marked “auto” (callout 5); connecting an edge to a member pins it. Auto-arrange lays out the tree.

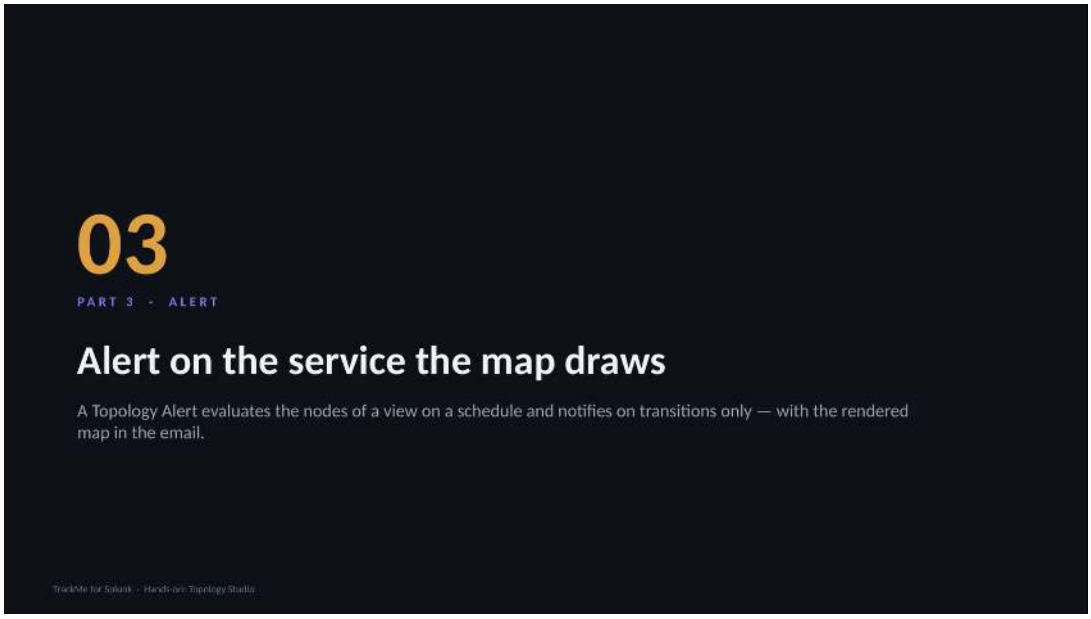
Nothing is stored until Save is clicked; every save becomes a version that can be restored, and Undo covers the last 25 operations.

Inspecting a member node

Selecting a generated member (callout 1), one of the heartbeat checks of Public Facing Web, opens the inspector. Entity details (callout 2) give the entity, tenant and component, here an FLX entity. View status, View details and Open in Tenant Home (callout 3) lead from the map to the status message, the entity and its tenant. Live status (callout 4) shows the state and the current value of each KPI.

The inspector is where the map becomes operational: the status is the same status message and score breakdown as in Tenant Home, and the entity can be opened directly in its tenant.

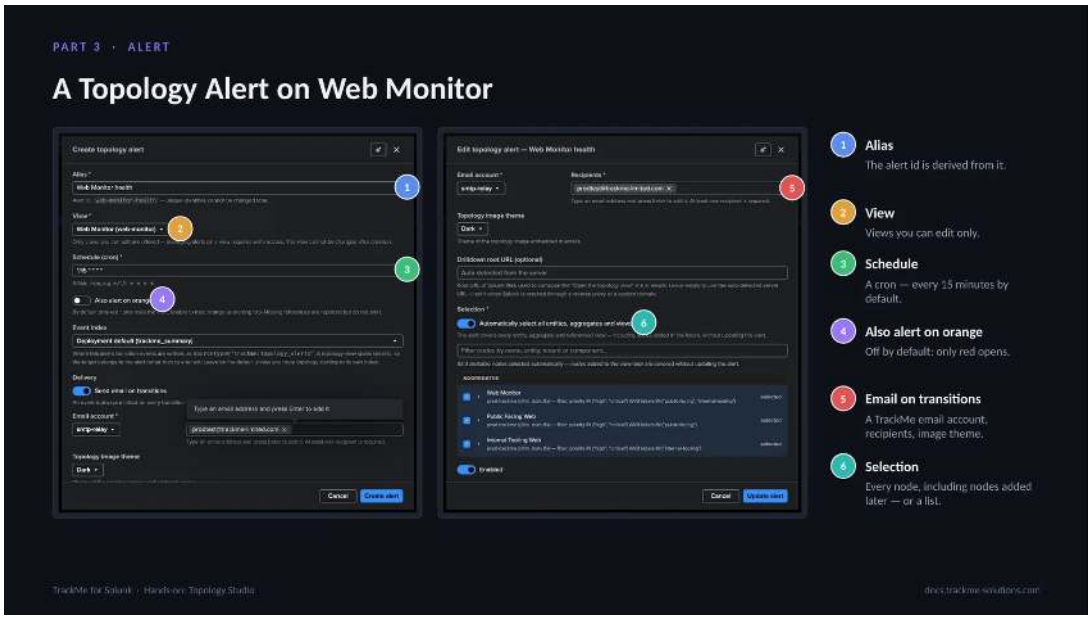
Part 3 — Alert



A map worth watching is a map worth alerting on. A Topology Alert is attached to a view, evaluates the nodes of that view on a schedule and notifies on transitions only: open, update and resolve. It speaks only when the set of unhealthy

items changes, and the email carries the rendered map.

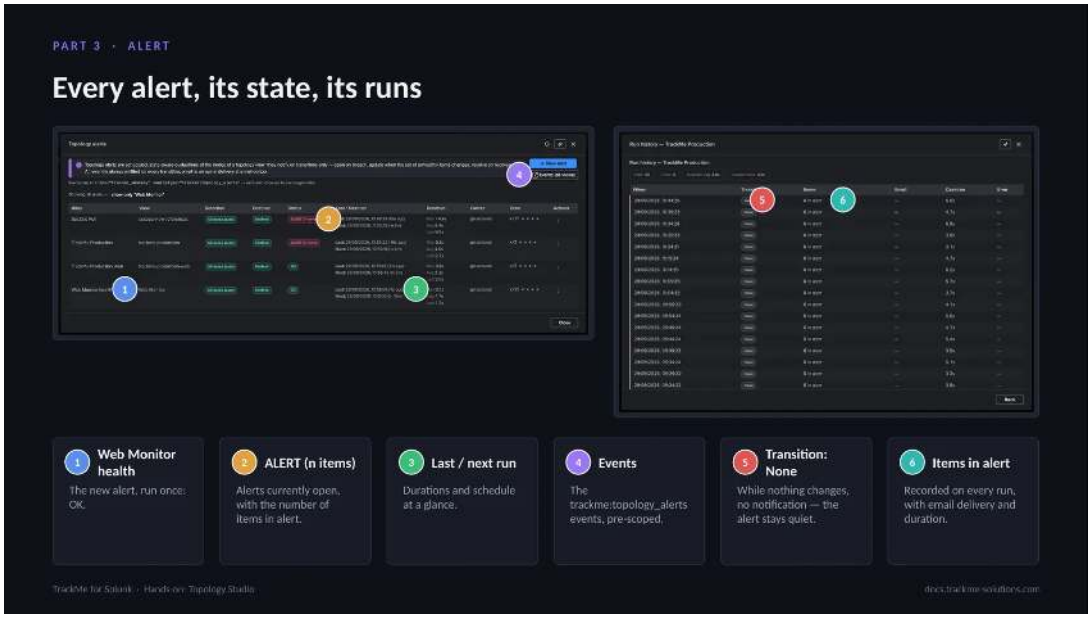
Creating a Topology Alert



From the Alerts button in the view header, New alert opens the alert form. Alias (callout 1): the alert id is derived from it. View (callout 2) lists only views the user can edit. Schedule (callout 3) is a cron, every 15 minutes by default. Also alert on orange (callout 4) is off by default, so only red opens an alert. Email on transitions (callout 5) takes a TrackMe email account, recipients and an image theme, dark or light, with the rendered topology embedded. Selection (callout 6) covers every entity, aggregate and referenced view of the map, including nodes added later, or an explicit list.

Every run writes a trackme:topology_alerts event on each transition; email is an extra channel.

Alert list and run history

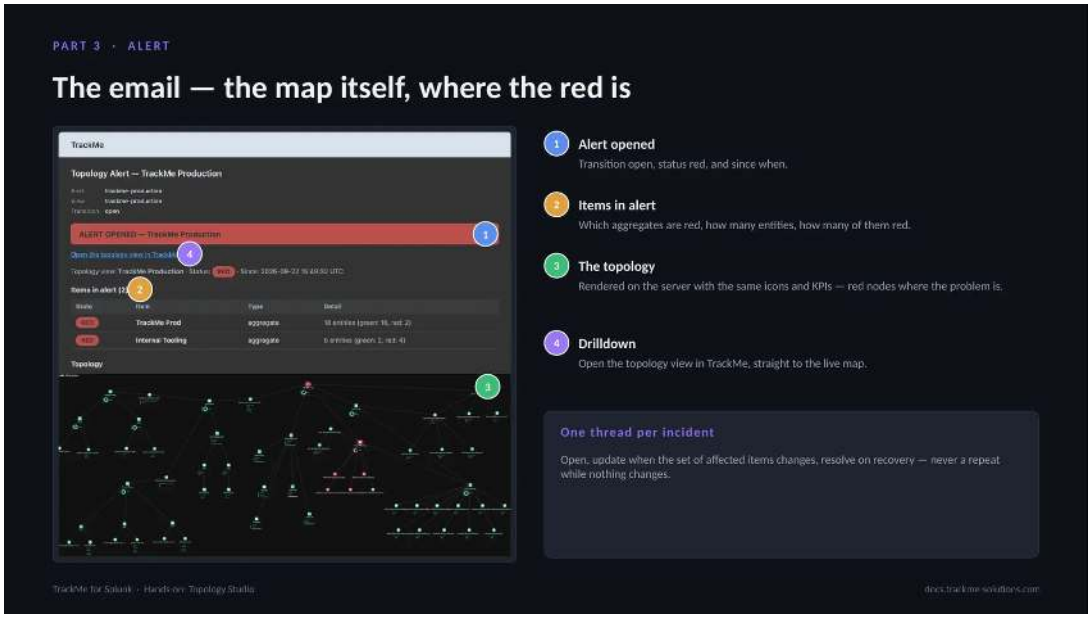


The alerts list covers every view. Web Monitor health (callout 1) is the new alert, run once: OK. ALERT (n items) (callout 2) marks alerts currently open with the number of items in alert; here two alerts are open, one with seven items. Last / next run (callout 3) shows durations and schedule. Events (callout 4) opens the trackme:topology_alerts events, pre-scoped. Transition: None (callout 5) is the key property of an open alert: while the set of affected items

does not change, no notification is sent. Items in alert (callout 6) is recorded on every run, with email delivery and duration.

Row actions include Run now, Alert events, Logs, History and Ask AI.

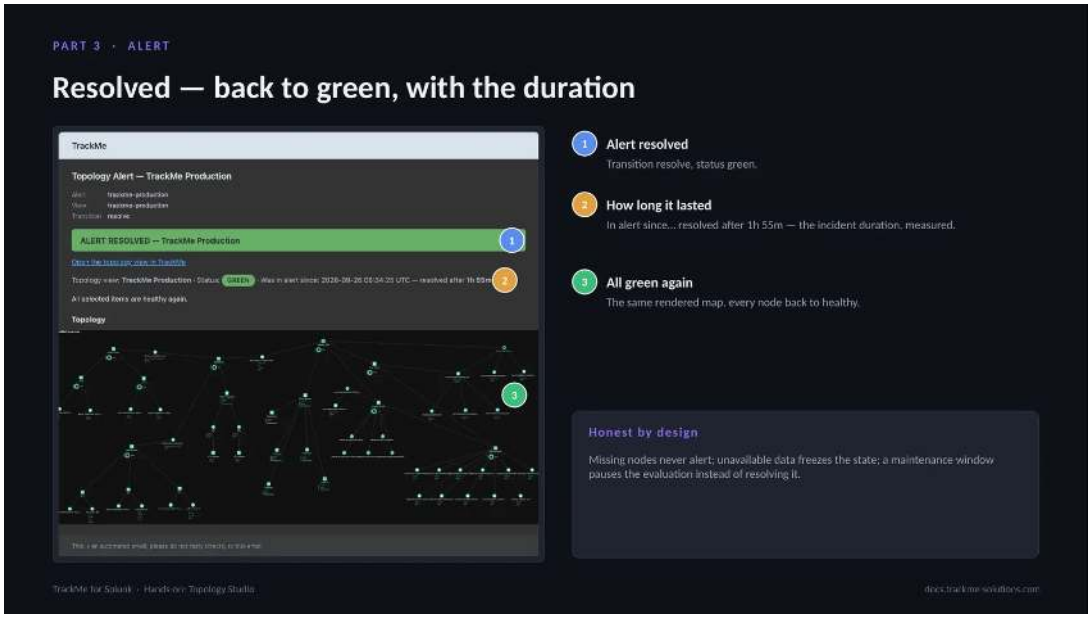
The alert-opened email



The email of a Topology Alert on the TrackMe Production view. Alert opened (callout 1) states the transition open, the status red and since when. Items in alert (callout 2) lists which aggregates are red, how many entities they hold and how many of those are red; when this alert opened, two aggregates were red. The topology (callout 3) is rendered on the server with the same icons and KPIs as the canvas, red nodes where the problem is. Drilldown (callout 4) opens the topology view in TrackMe, straight to the live map.

Each incident is one thread: open, update when the set of affected items changes, resolve on recovery, never a repeat while nothing changes.

The resolution email

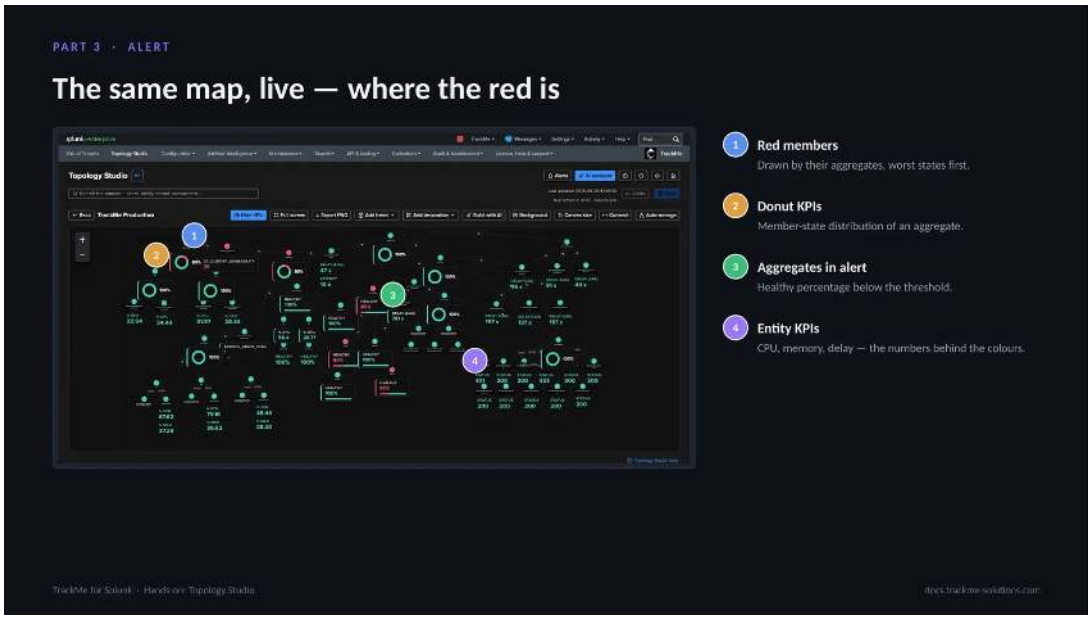


The resolution email of the same alert. Alert resolved (callout 1) states the transition resolve and the status green. How long it lasted (callout 2) reads “in alert since… resolved after 1h 55m”, the measured incident duration. All

green again (callout 3) is the same rendered map with every node back to healthy.

The alert state is honest by design: missing nodes never alert, unavailable data freezes the state, and a maintenance window pauses the evaluation instead of resolving it. An alert is never resolved by a data gap or a maintenance window.

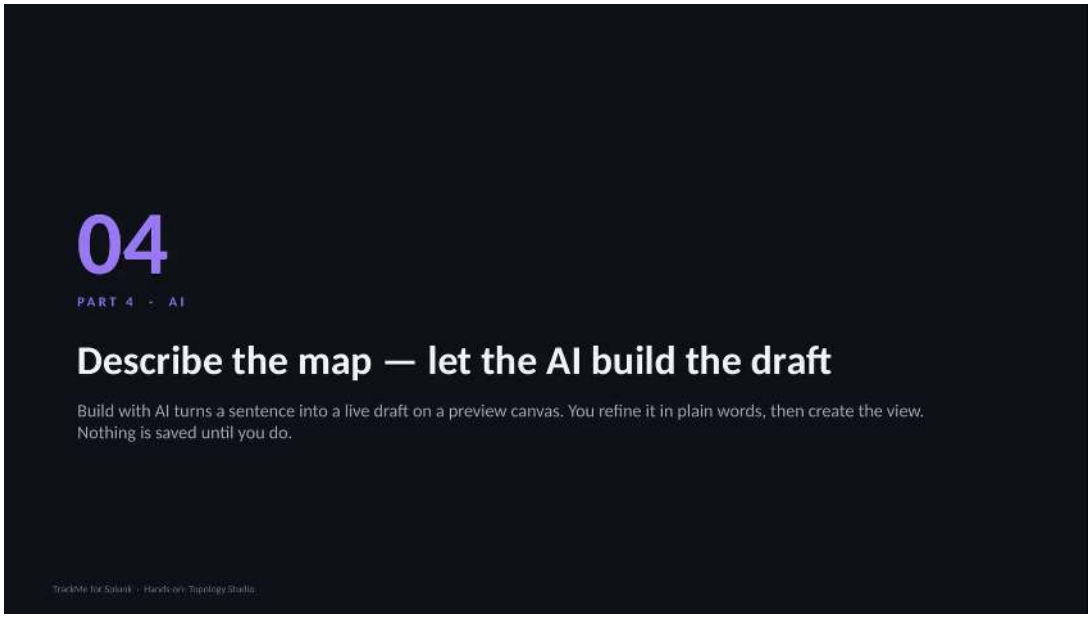
The live view during an alert



The TrackMe Production view while its alert is open: thirty-five nodes over several tenants and components. Red members (callout 1) are drawn by their aggregates, worst states first. Donut KPIs (callout 2) show the member-state distribution of an aggregate. Aggregates in alert (callout 3) have a healthy percentage below the threshold. Entity KPIs (callout 4), CPU, memory and delay, are the numbers behind the colours.

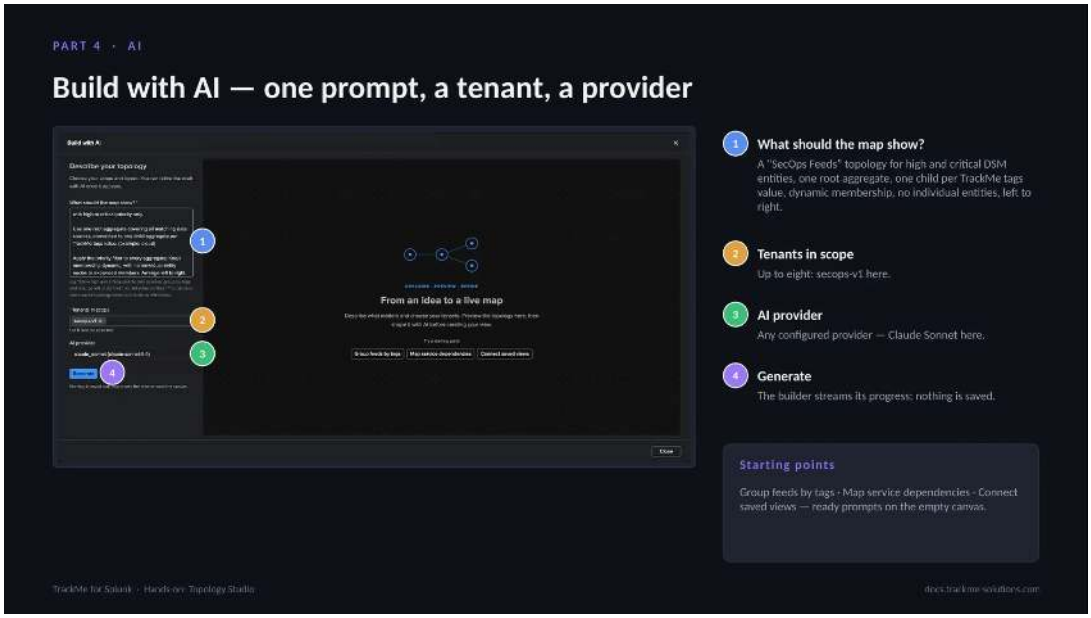
The red is where the email placed it: the live map and the email tell the same story because they are the same map.

Part 4 — AI



Build with AI turns a sentence into a live draft on a preview canvas. A dedicated AI builder agent reads the inventory of the selected tenants and proposes a draft, compiled and validated like a manual save. The draft is refined in plain words and then created as a view; nothing is saved until that point.

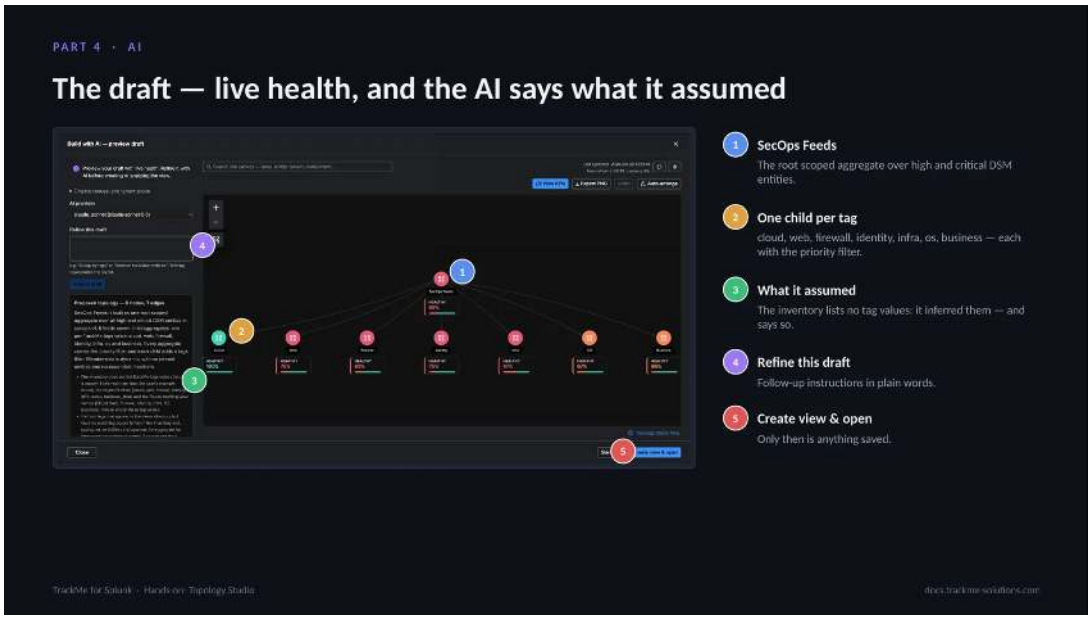
Prompt, tenants and provider



The prompt (callout 1) asks for a "SecOps Feeds" topology for high and critical DSM entities: one root aggregate, one child aggregate per TrackMe tags value, the priority filter on every aggregate, dynamic membership, no individual entities, laid out left to right. Tenants in scope (callout 2) accepts up to eight tenants, secops-v1 here. AI provider (callout 3) is any provider configured in TrackMe, Claude Sonnet in this case. Generate (callout 4) starts the builder, which streams its progress; nothing is saved.

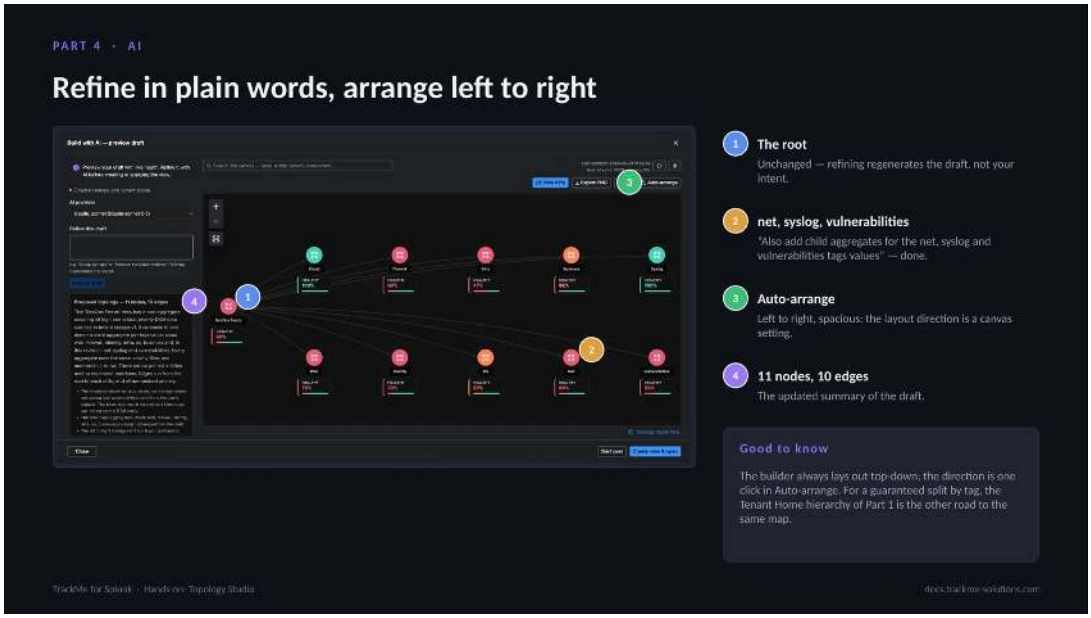
The empty canvas offers ready prompts as starting points: Group feeds by tags, Map service dependencies and Connect saved views.

Reading the first draft



The first draft arrives in about twenty seconds on a live preview canvas with real health. SecOps Feeds (callout 1) is the root scoped aggregate over high and critical DSM entities. One child per tag (callout 2): cloud, web, firewall, identity, infra, os and business, each carrying the priority filter. What it assumed (callout 3): the inventory the builder receives carries priorities and labels but no tag values, so it inferred them from the data source families, left out three tags it could not confirm, and says so in its summary. Refine this draft (callout 4) takes follow-up instructions in plain words. Create view & open (callout 5) is the only step that saves anything.

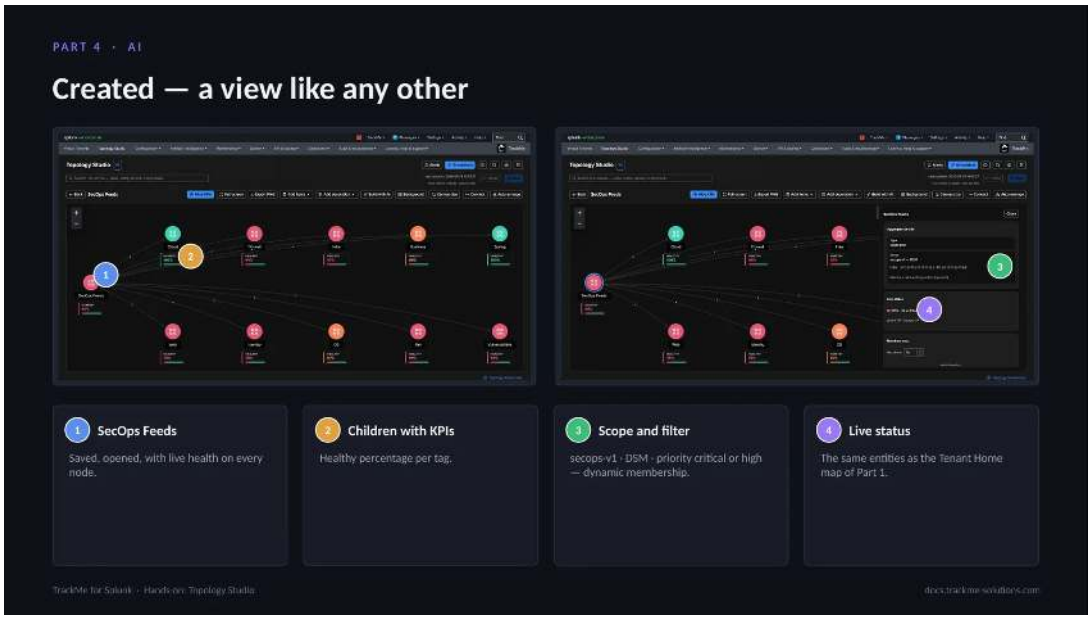
Refining the draft



One refinement adds the missing tags: "Also add child aggregates for the net, syslog and vulnerabilities tags values". The root (callout 1) is unchanged, because refining regenerates the draft, not the intent. The three new children (callout 2) appear; the draft updates in place, and a failed refinement would keep the previous draft. Auto-arrange (callout 3) switches the layout to left to right, spacious: the builder always lays out top-down, and the direction is a canvas setting, one click away. The summary (callout 4) now reads 11 nodes, 10 edges.

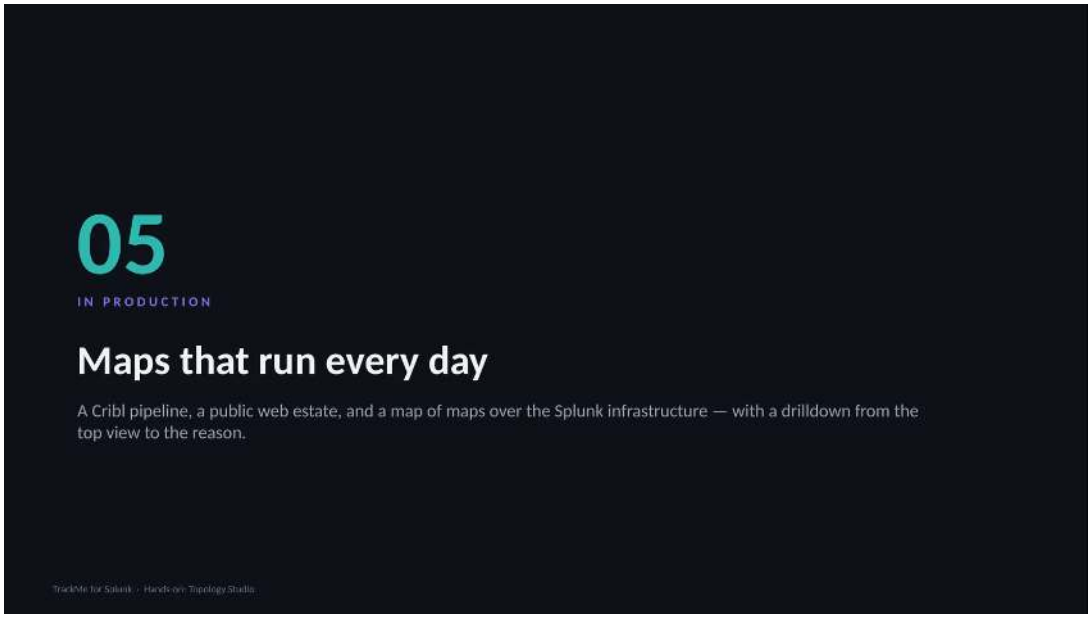
For a guaranteed split by tag, the Tenant Home hierarchy of Part 1 produces the same map: two roads to the same destination.

The created view



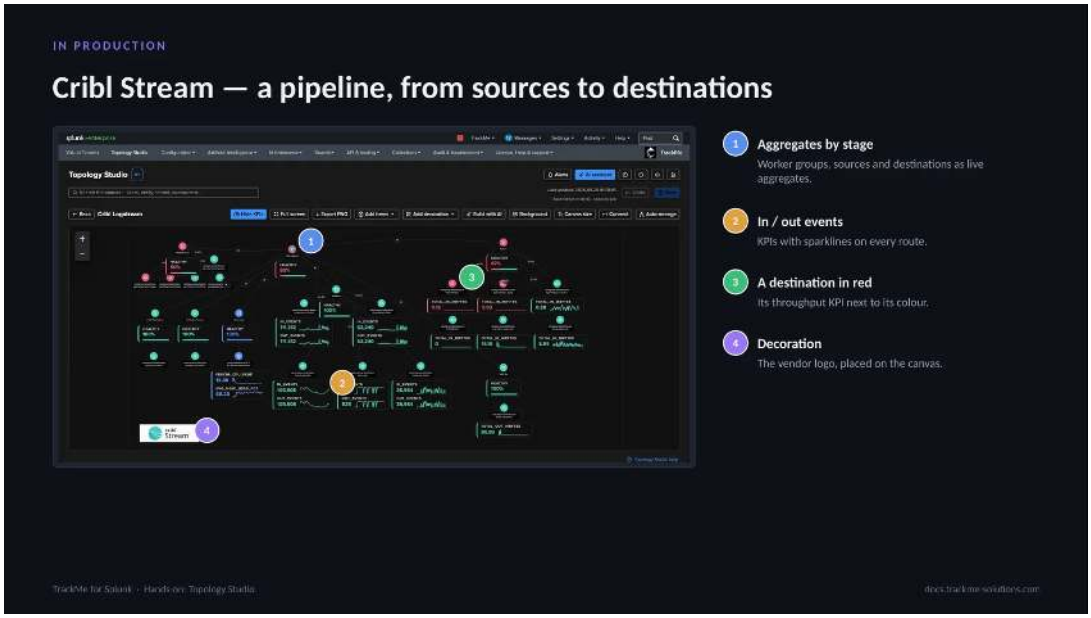
Create view & open saves the draft as a regular view: editable, versioned, shareable and alertable. SecOps Feeds (callout 1) is saved and opened, with live health on every node. Children with KPIs (callout 2) show the healthy percentage per tag. Scope and filter (callout 3) in the root's inspector read secops-v1 · DSM · priority critical or high, with dynamic membership, exactly as the AI wrote them. Live status (callout 4) covers the same entities as the Tenant Home map of Part 1.

In production



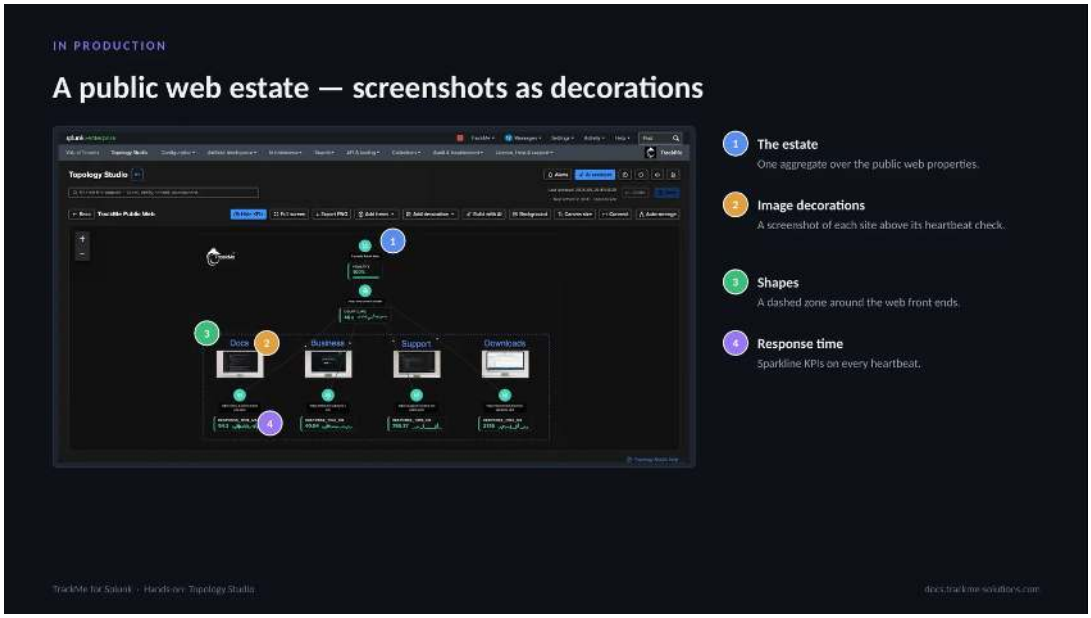
Three maps run every day on the deployment the screens were captured from: a Cribl pipeline mapped from sources to destinations, a public web estate with screenshots as decorations, and a map of maps over the Splunk infrastructure, with a drilldown from the top view to the reason for a red node.

A Cribl Stream pipeline map



A Cribl Stream pipeline mapped from TrackMe entities. Aggregates by stage (callout 1) represent worker groups, sources and destinations as live aggregates. In / out events (callout 2) are KPIs with sparklines on every route. A destination in red (callout 3) shows its throughput KPI next to its colour. The decoration (callout 4) is the vendor logo, placed on the canvas. With events in and out and throughput as KPIs, the map reads like the pipeline itself.

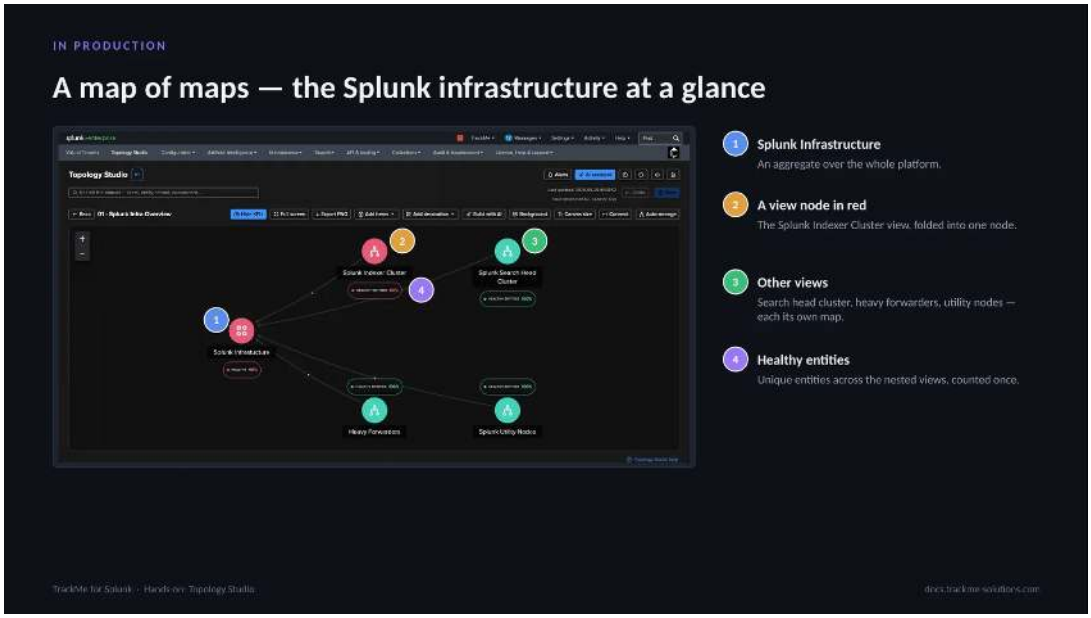
Decorations on a web estate map



The estate (callout 1) is one aggregate over the public web properties. Image decorations (callout 2) place a screenshot of each site above its heartbeat check. Shapes (callout 3) draw a dashed zone around the web front ends. Response time (callout 4) is a sparkline KPI on every heartbeat.

Decorations turn a map into a picture people recognise. They never affect health, and they appear in PNG exports and in alert emails.

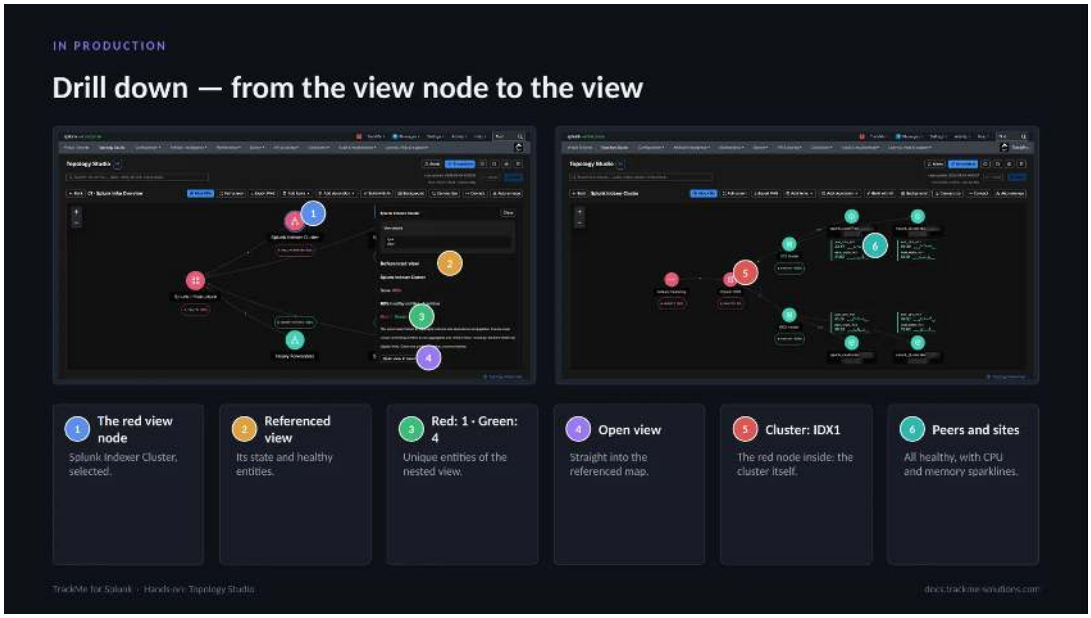
Nesting views: the Splunk infrastructure



The top view of the Splunk infrastructure. Splunk Infrastructure (callout 1) is an aggregate over the whole platform. A view node in red (callout 2) is the Splunk Indexer Cluster view, folded into one node. Other views (callout 3), search head cluster, heavy forwarders and utility nodes, are each their own map. Healthy entities (callout 4) counts unique entities across the nested views, each counted once.

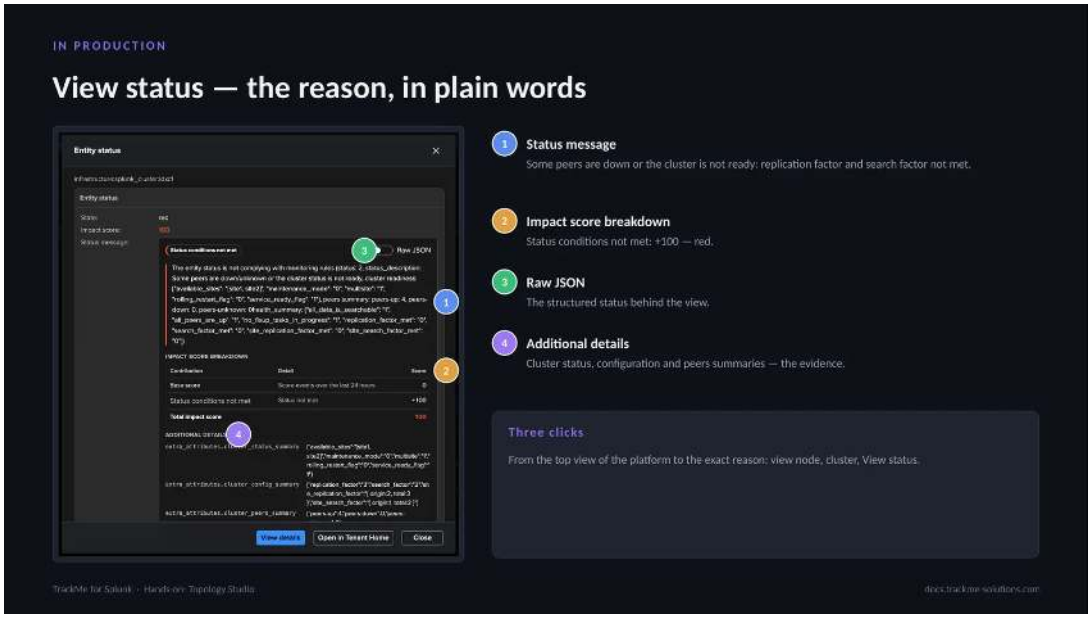
A view node counts the unique underlying entities across nested views and follows their policies; one of the nested views is red at the time of capture.

Drilling into a view node



The drilldown starts by selecting the red view node (callout 1), Splunk Indexer Cluster. Referenced view (callout 2) shows its state and healthy entities. Red: 1 · Green: 4 (callout 3) counts the unique entities of the nested view: one red entity out of five. Open view (callout 4) leads straight into the referenced map. Inside, Cluster: IDX1 (callout 5) is the red node, the cluster itself. Peers and sites (callout 6) are all healthy, with CPU and memory sparklines. The red belongs to the cluster entity, not to any peer.

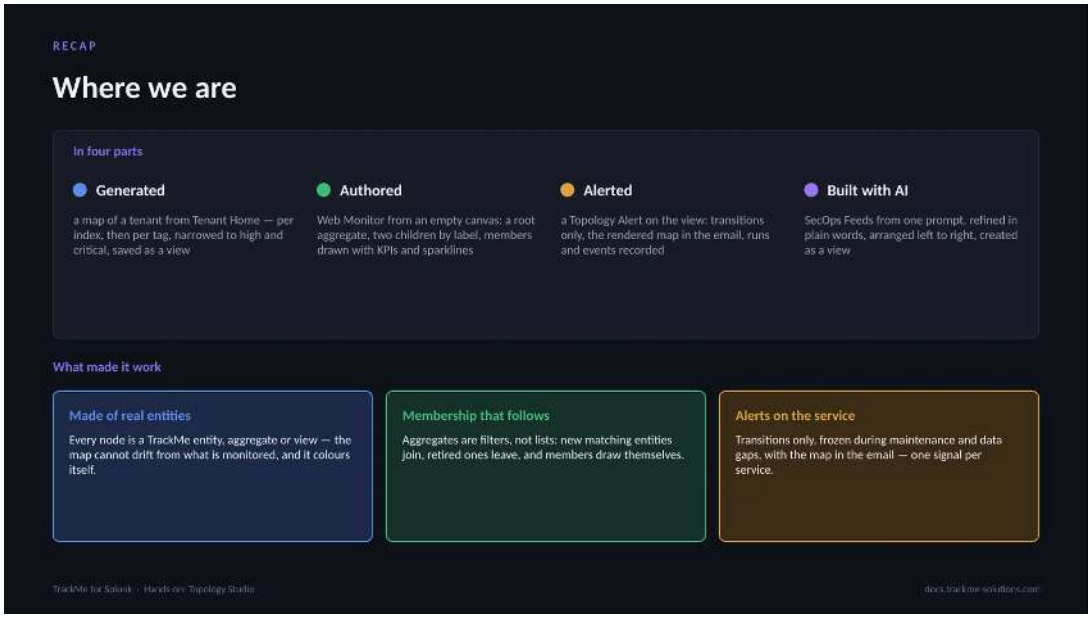
Reading the entity status



View status on the red member opens the entity status. The Status message (callout 1) reads that some peers are down or the cluster is not ready: replication factor and search factor not met. The Impact score breakdown (callout 2) shows Status conditions not met: +100, which makes the entity red. Raw JSON (callout 3) is the structured status behind the view. Additional details (callout 4) hold the cluster status, configuration and peers summaries, the evidence.

From the top view of the platform to the exact reason takes three clicks: view node, cluster, View status. This is the same status message the alert and the AI Assistant use.

Where we are



Four ways to a live map. Generated: a map of a tenant from Tenant Home, per index then per tag, narrowed to high and critical. Authored: Web Monitor from an empty canvas, a root aggregate, two children by label, members with KPIs and sparklines. Alerted: a Topology Alert on the view, transitions only, the rendered map in the email. Built with AI: SecOps Feeds from one prompt, refined in plain words.

What made it work: maps are made of real entities, aggregates or views, so they cannot drift from what is monitored. Aggregates are filters, not lists: matching entities join, retired ones leave. Alerts fire on transitions only, frozen during maintenance and data gaps: one signal per service.

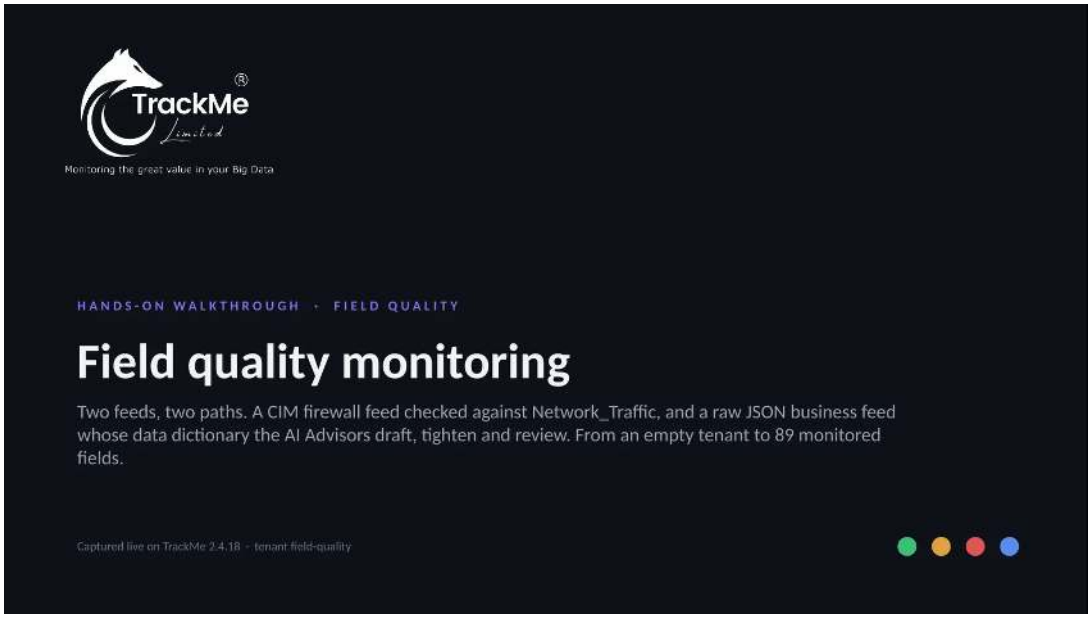
2.1.6 Field Quality Monitoring

Field extraction success and CIM compliance measured per field: CIM data models, AI-generated dictionaries for custom sourcetypes, sampling, and the field-quality advisors.

`Download the deck (PDF) · PowerPoint`

about 40 minutes · 35 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

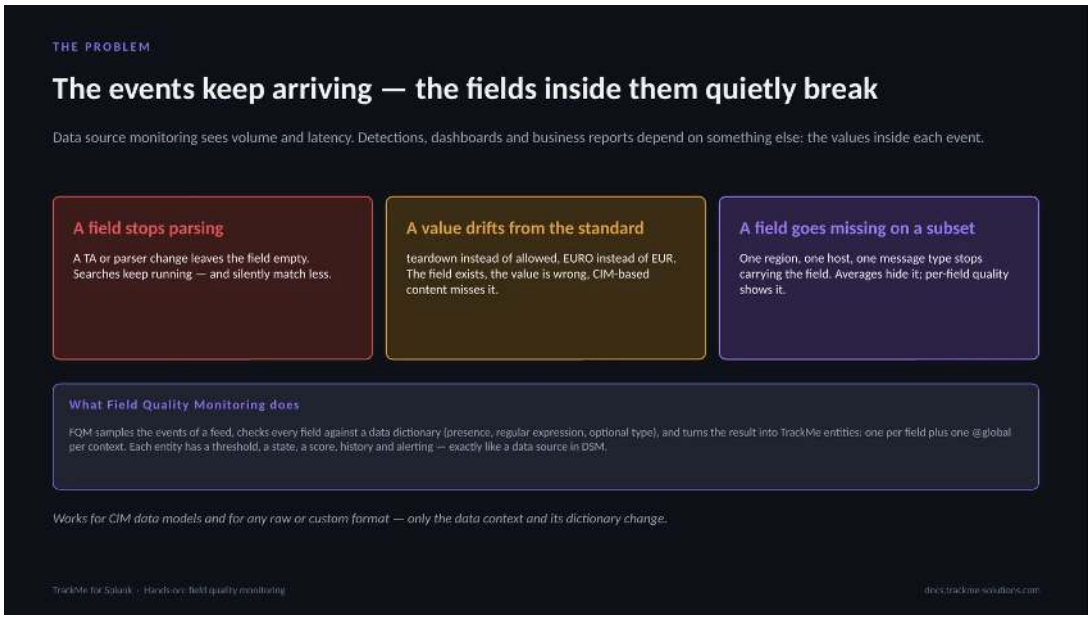
Overview



Field Quality Monitoring (FQM) follows two feeds down two paths. A CIM firewall feed, Cisco ASA logs, is checked against the Network_Traffic data model with a dictionary generated from CIM. A raw JSON business feed, e-commerce orders, has no CIM model: its data dictionary is drafted, tightened and reviewed by the AI Advisors. Both start from a brand new tenant, field-quality, and end with 89 monitored fields.

Every screen was captured on TrackMe 2.4.18. The walkthrough closes with what a mature FQM tenant looks like after several months of history.

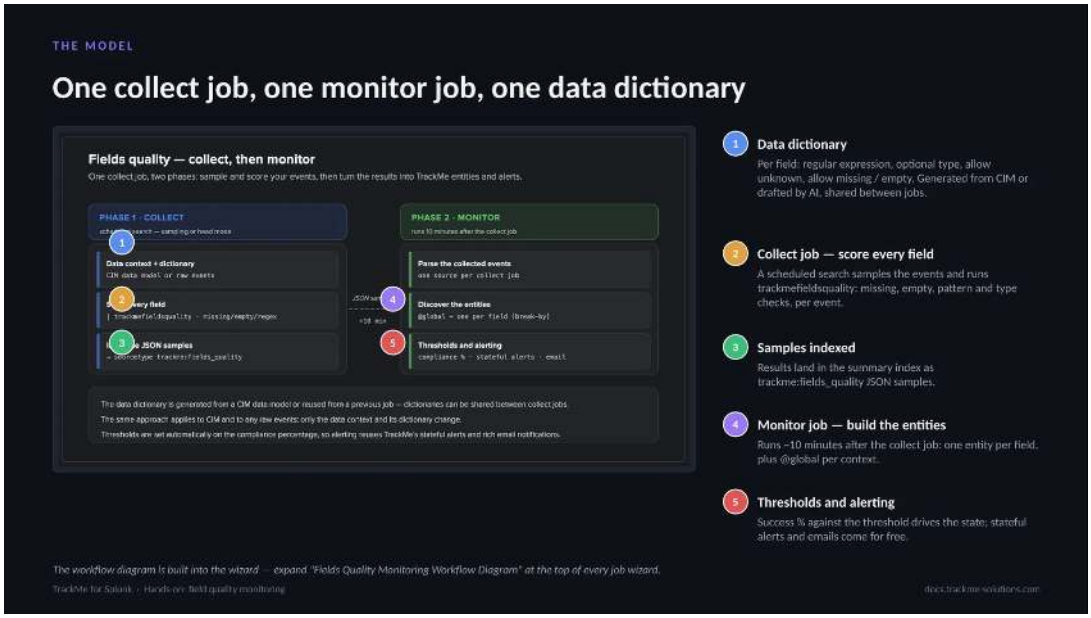
Why availability monitoring is not enough



Data source monitoring sees volume and latency; detections, dashboards and business reports depend on the values inside each event. A field stops parsing when a TA or parser change leaves it empty. A value drifts from the standard, EURO instead of EUR: the field exists, the value is wrong. A field goes missing on one region or one message type; averages hide it, per-field quality shows it.

FQM samples the events of a feed, checks every field against a data dictionary (presence, regular expression, optional type) and turns the result into TrackMe entities: one per field plus one @global per context, each with a threshold, a state, a score, history and alerting.

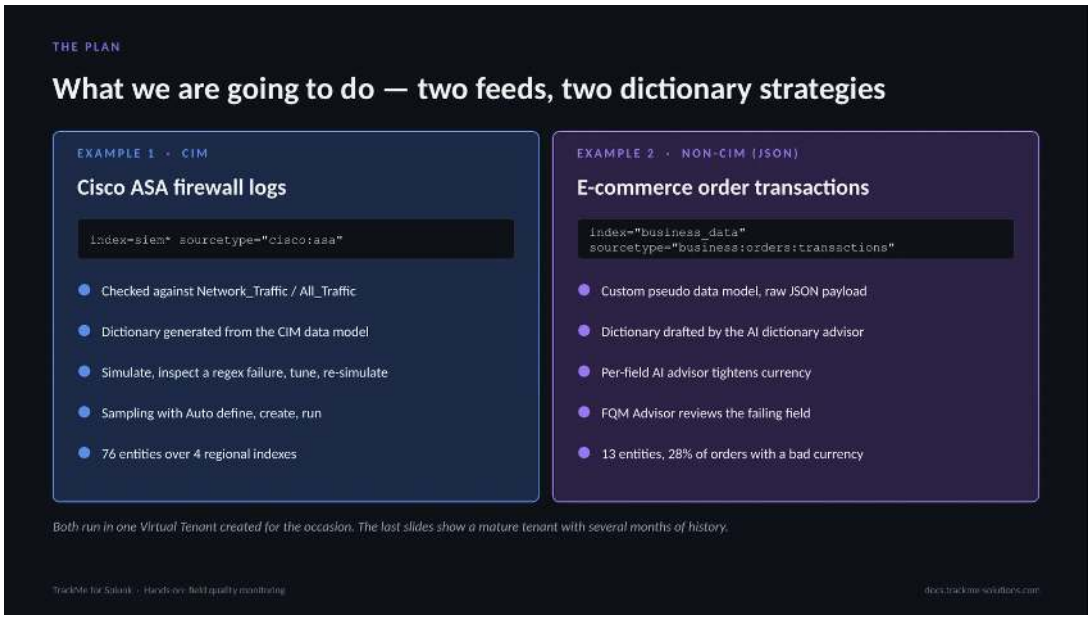
Dictionary, collect job and monitor job



The Data dictionary (callout 1) holds, per field, a regular expression, an optional type, allow unknown and allow missing / empty; it is generated from CIM or drafted by AI. The Collect job (callout 2) is a scheduled search that samples the events and runs trackmefieldsquality against the dictionary. The samples (callout 3) land in the summary index as trackme:fields_quality JSON. The Monitor job (callout 4) runs about 10 minutes later and builds one entity per field plus @global per context. Thresholds and alerting (callout 5): the success % against the threshold drives the state; stateful alerts and emails follow.

Both jobs are created and scheduled by the wizard; the dictionary is reusable across trackers that share a format.

Two feeds, two dictionary strategies

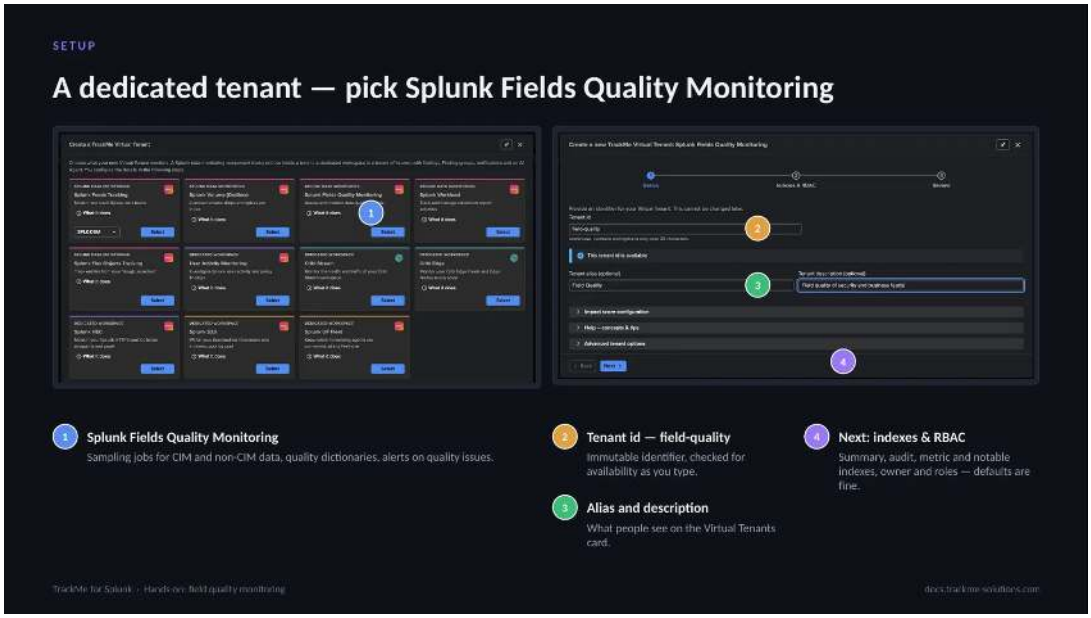


Example 1 is the CIM path: Cisco ASA firewall logs, index=siem* sourcetype="cisco:asa", checked against Network_Traffic / All_Traffic. The dictionary is generated from the CIM data model; the flow is simulate, inspect a regex failure, tune, re-simulate, then sampling with Auto define, create and run. The result is 76 entities over 4 regional indexes.

Example 2 is the non-CIM path: e-commerce order transactions, index="business_data" sourcetype="business:orders:transactions", a custom pseudo data model over a raw JSON payload. The AI dictionary

advisor drafts the dictionary, a per-field AI advisor tightens currency, and the FQM Advisor reviews the failing field. The result is 13 entities, with 28% of orders carrying a bad currency. Both run in one Virtual Tenant created for the occasion.

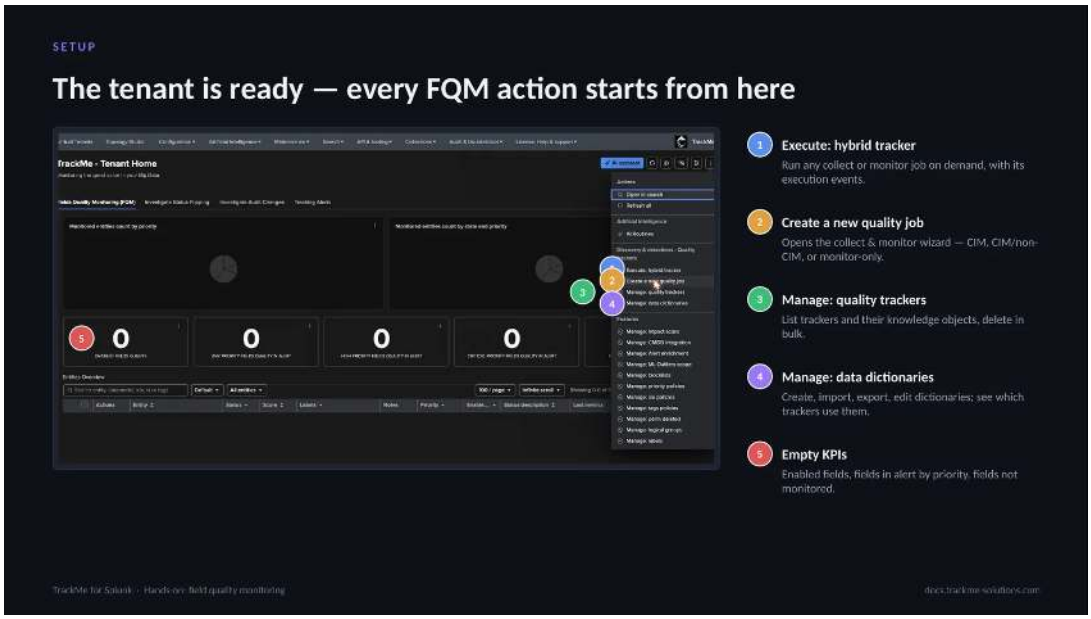
Creating the Field Quality tenant



Virtual Tenants → Actions → Create a tracking tenant opens the component chooser. Splunk Fields Quality Monitoring (callout 1) is its own card: sampling jobs for CIM and non-CIM data, quality dictionaries and alerts on quality issues. The tenant id (callout 2), field-quality, is an immutable identifier checked for availability as it is typed. Alias and description (callout 3) are what people see on the Virtual Tenants card. Next: indexes & RBAC (callout 4) covers the summary, audit, metric and notable indexes, the owner and the roles; the defaults are fine.

The wizard asks three things, basics, indexes and RBAC, and review; TrackMe then creates the KV collections, lookups and health tracker for the tenant in seconds.

FQM actions in Tenant Home



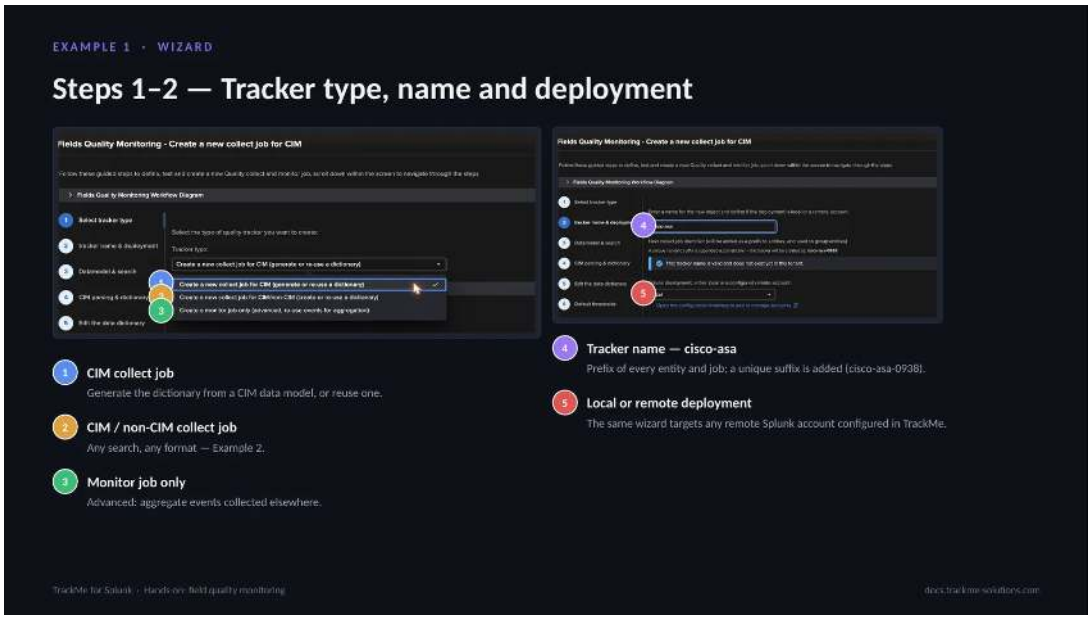
Tenant Home is where FQM lives, and the kebab menu at the top right carries every FQM action. Execute: hybrid tracker (callout 1) runs any collect or monitor job on demand and shows its execution events. Create a new quality

job (callout 2) opens the collect & monitor wizard for CIM, CIM/non-CIM or monitor-only jobs. Manage: quality trackers (callout 3) lists trackers and their knowledge objects and deletes them in bulk. Manage: data dictionaries (callout 4) creates, imports, exports and edits dictionaries and shows which trackers use them. The KPIs (callout 5), enabled fields, fields in alert by priority and fields not monitored, are still empty on a new tenant. The first step is Create a new quality job.

Example 1 — A CIM data source

The first example is a CIM source: index=siem* sourcetype="cisco:asa", four regional indexes, one sourcetype, one CIM data model. TrackMe generates the dictionary from CIM, so the interesting part is interpreting the first results: which failures are real CIM compliance problems, and which are simply fields that only exist on some message types. Expected gaps are fixed in the dictionary; real findings are kept.

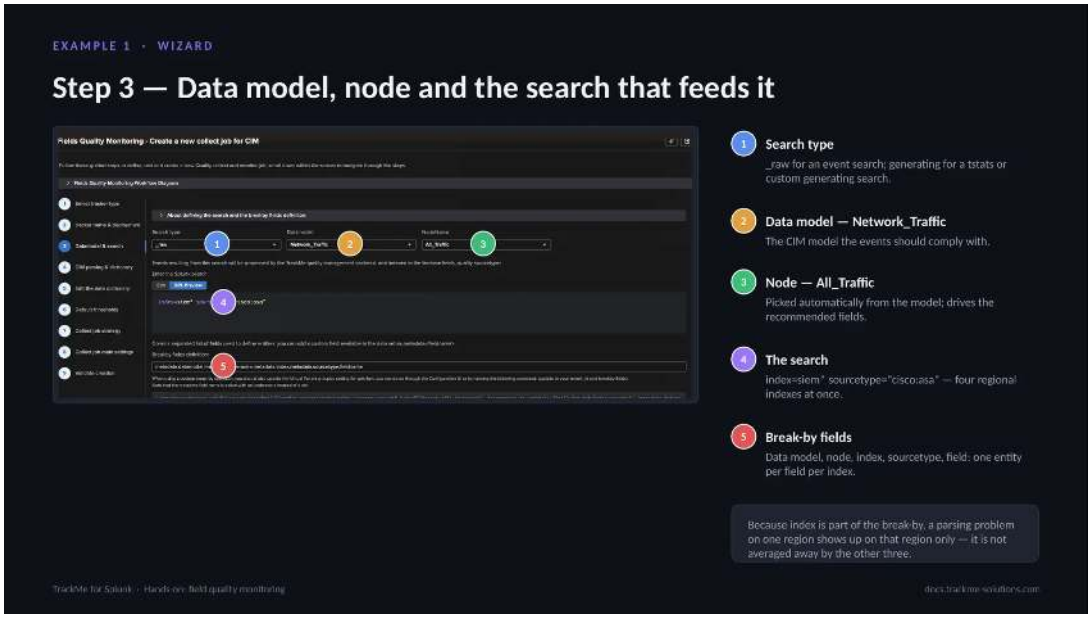
Choosing the tracker type



Steps 1 and 2 of the wizard offer three tracker types. CIM collect job (callout 1) generates the dictionary from a CIM data model or reuses one. CIM / non-CIM collect job (callout 2) takes any search and any format, used in Example 2. Monitor job only (callout 3) is advanced: it aggregates events collected elsewhere. Tracker name (callout 4), cisco-asa, is the prefix of every entity and job; TrackMe appends a short unique suffix (cisco-asa-0938). Local or remote

deployment (callout 5): the same wizard targets the local deployment or any remote Splunk account configured in TrackMe.

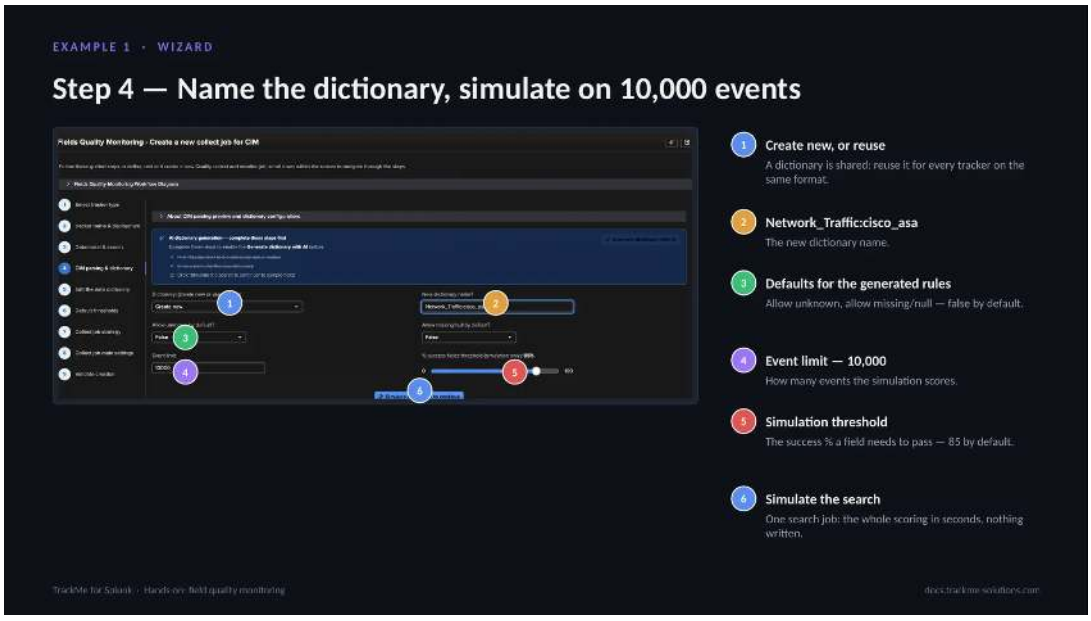
Break-by fields and the source search



Search type (callout 1) is _raw for an event search or generating for a tstats or custom generating search. Data model (callout 2) is Network_Traffic, the CIM model the events should comply with. Node (callout 3), All_Traffic, is picked automatically from the model and drives the recommended fields. The search (callout 4), index=siem* sourcetype=”cisco:asa”, covers four regional indexes at once. Break-by fields (callout 5) are data model, node, index, sourcetype and field: one entity per field per index.

The break-by is the identity of the entities. Because index is part of it, a parsing problem on one region shows up on that region only and is not averaged away by the other three.

Simulation settings



Step 4 names the dictionary and runs a simulation. Create new, or reuse (callout 1): a dictionary is shared and can be reused for every tracker on the same format. The new dictionary is named Network_Traffic:cisco_asa (callout 2). Defaults for the generated rules (callout 3), allow unknown and allow missing/null, are false by default. Event

limit (callout 4) sets how many events the simulation scores, 10,000 by default; 100,000 also works well. Simulation threshold (callout 5) is the success % a field needs to pass, 85 by default. Simulate the search (callout 6) runs the real collect logic, scoring in seconds and writing nothing.

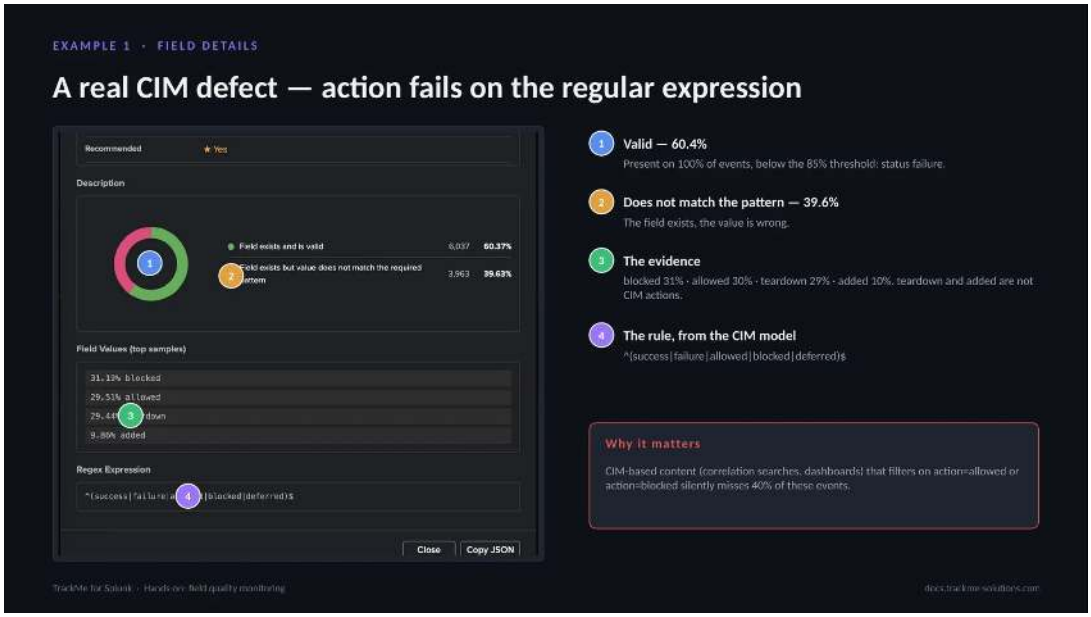
The simulation is the loop to iterate on.

Reading the first simulation

All fields (callout 1): 53 checked, 5 passed, 9.43%, across every field of the Network_Traffic model, most of which are irrelevant for a firewall. Recommended fields (callout 2): 3 of 12, the fields CIM recommends for All_Traffic, and the number that matters, 25%. Recommended only (callout 3) filters the table to those 12 fields, marked in the star column. The table (callout 4) shows, per field and per index, coverage %, success %, totals, failures and distinct values. Inspect (callout 5) opens Field Details for one field.

A low first score is normal on CIM: the model lists every possible field, and a Cisco ASA feed mixes connection builds, teardowns and translations that carry different fields.

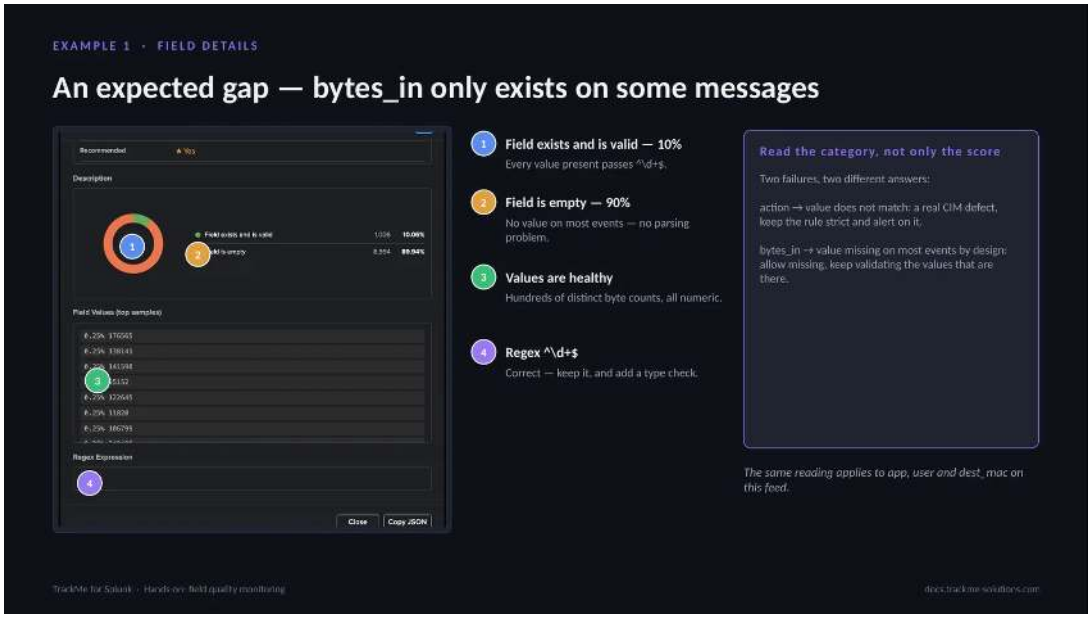
A genuine compliance defect: action



Field Details for action, opened from the simulation with Inspect. Valid (callout 1) is 60.4%: the field is present on 100% of events but below the 85% threshold, so its status is failure. Does not match the pattern (callout 2) is 39.6%: the field exists, the value is wrong. The evidence (callout 3) is the top values: blocked 31%, allowed 30%, teardown 29%, added 10%; teardown and added are not CIM actions. The rule (callout 4), from the CIM model, is ^(success|failure|allowed|blocked|deferred)$.

This is a genuine CIM compliance issue in the field extraction. CIM-based content that filters on action=allowed or action=blocked silently misses 40% of these events, so the rule is kept strict.

An expected gap: bytes_in



bytes_in reads differently. Field exists and is valid (callout 1) is 10%, and every value present passes ^d+$. Field is empty (callout 2) is 90%: no value on most events, because only connection teardown messages carry byte counts; this is not a parsing problem. Values are healthy (callout 3): hundreds of distinct byte counts, all numeric. The regex ^d+$ (callout 4) is correct; it is kept, and a type check is added.

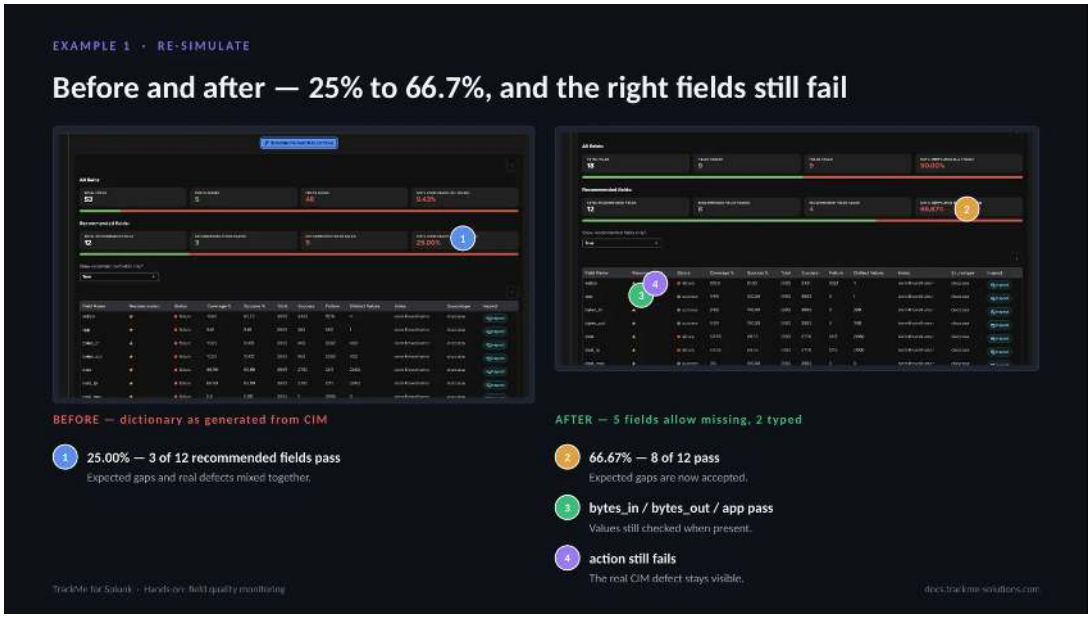
Two failures call for two answers. action fails because the value does not match: a real CIM defect, so the rule stays strict and alerts. bytes_in fails because the value is missing on most events by design: allow missing, and keep validating the values that are there.

Editing rules in the dictionary editor

Step 5 edits the dictionary in place. The unsaved changes banner (callout 1) shows that edits stay local until Save now; steps and simulation are blocked meanwhile. Allow missing/null: Yes (callout 2) is set on app, bytes_in, bytes_out, user and dest_mac. Type: integer (callout 3) is set on bytes_in and bytes_out, checking regex and type. action stays strict (callout 4): the CIM regex is kept, a real finding. Per-field AI (callout 5) asks the AI field advisor about one rule.

Every rule is editable, with allow unknown, allow missing or empty, an optional type (integer, numerical, alpha, alphanumeric, boolean) and the regex. Save writes the whole dictionary at once and checks nobody changed it in between.

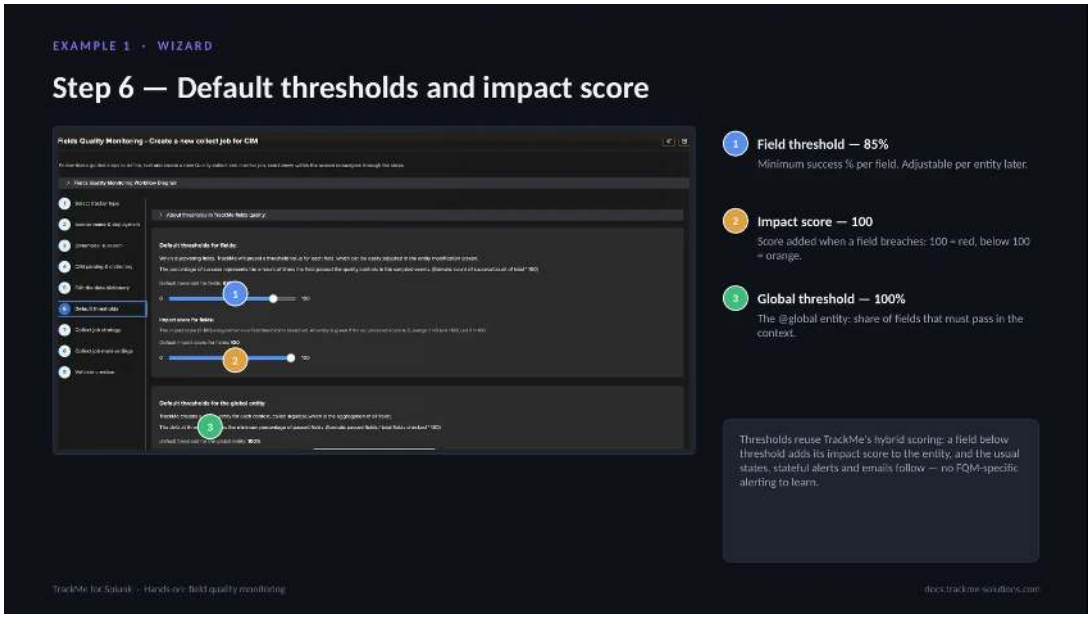
Compliance after tuning



The same data, re-simulated with the new dictionary. Before (callout 1), with the dictionary as generated from CIM, 25.00% of the recommended fields passed, 3 of 12, with expected gaps and real defects mixed together. After (callout 2), with 5 fields allowing missing and 2 typed, 66.67% pass, 8 of 12: the expected gaps are now accepted. bytes_in, bytes_out and app pass (callout 3), their values still checked when present. action still fails (callout 4): the real CIM defect stays visible.

What remains red is meaningful: action with its non-CIM values, and dest, dest_ip and protocol, missing on about 30% of events, worth raising with the TA owner.

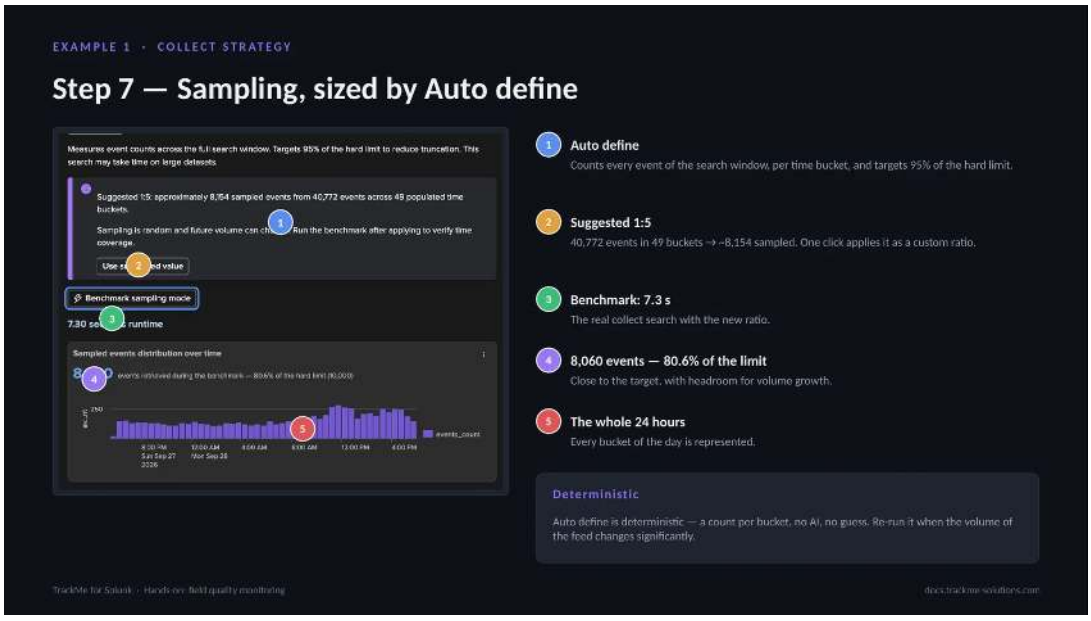
Thresholds and impact score



Step 6 sets the default thresholds. Field threshold (callout 1), 85%, is the minimum success % per field, adjustable per entity later. Impact score (callout 2), 100, is the score added when a field breaches: 100 makes the entity red, a lower value makes it orange. Global threshold (callout 3), 100%, applies to the @global entity, the share of fields that must pass in the context; at 100% any failing field turns it red.

Thresholds reuse TrackMe's hybrid scoring: a field below threshold adds its impact score to the entity, and the usual states, stateful alerts and emails follow, with no FQM-specific alerting to learn. Lowering the impact score makes quality issues show orange rather than red.

Sizing the sample with Auto define

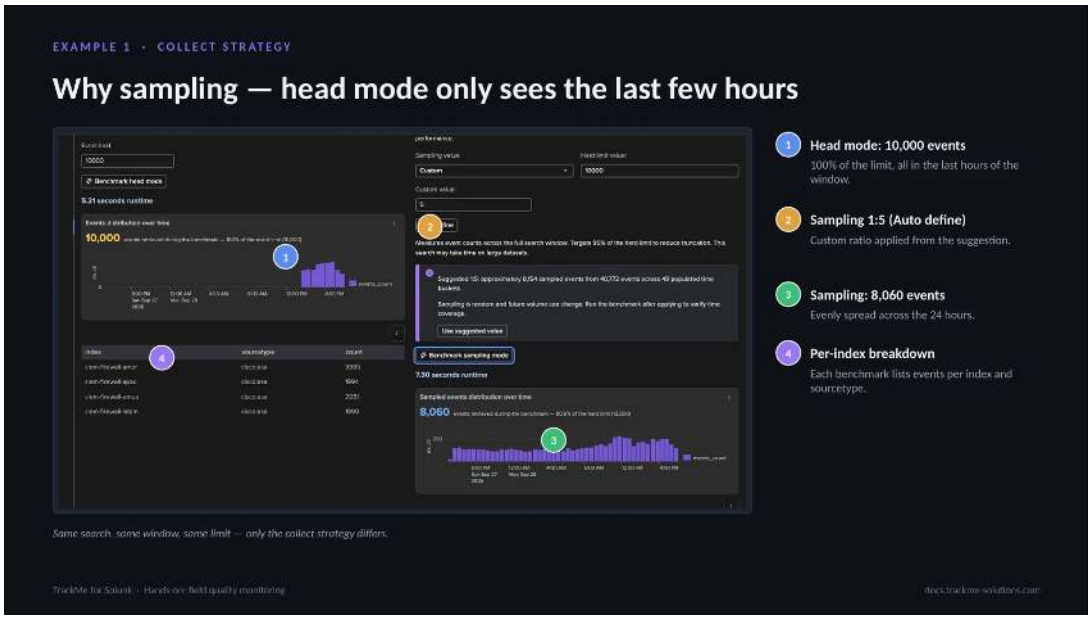


Step 7 sizes the sample. Auto define (callout 1) counts every event of the search window per time bucket and targets 95% of the hard limit. The suggestion (callout 2) is 1:5: 40,772 events in 49 buckets give about 8,154 sampled events, applied as a custom ratio in one click. Benchmark (callout 3) runs the real collect search with the new ratio in 7.3 s.

It retrieves 8,060 events (callout 4), 80.6% of the limit, with headroom for volume growth, spread over the whole 24 hours (callout 5) so every bucket of the day is represented.

Auto define is deterministic, a count per bucket, no guess; it should be re-run when the volume of the feed changes significantly.

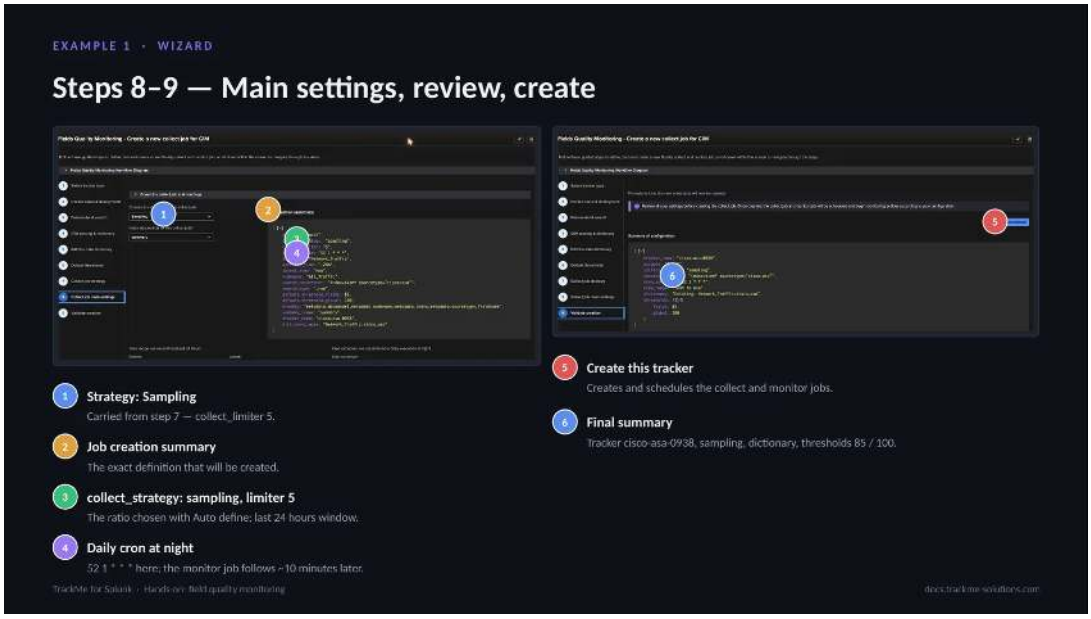
Head mode versus sampling



Same search, same window, same limit; only the collect strategy differs. Head mode (callout 1) returns the first 10,000 events the search yields, which on Splunk means the most recent: 100% of the limit, all inside the last few hours of the window. Sampling 1:5 (callout 2) is the custom ratio applied from the Auto define suggestion. It retrieves 8,060 events (callout 3), evenly spread across the 24 hours. The per-index breakdown (callout 4) lists events per index and sourcetype for each benchmark.

For quality measurement, representative beats recent: a parsing problem at 3 AM is invisible to head mode.

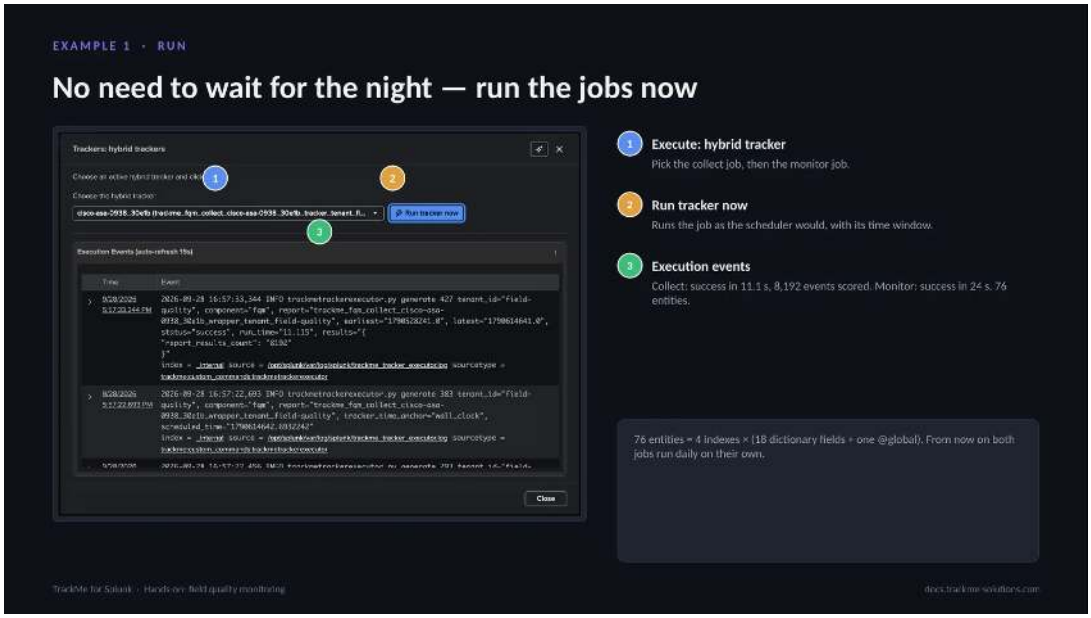
Review and job creation



Step 8 confirms the settings. Strategy: Sampling (callout 1) is carried from step 7 with collect_limiter 5. The job creation summary (callout 2) describes tracker cisco-asa-0938 with sampling, the dictionary and thresholds 85 / 100;

it is the exact payload sent to TrackMe. collect_strategy: sampling, limiter 5 (callout 3) is the ratio chosen with Auto define over a last-24-hours window. The daily cron (callout 4) runs at night as recommended, 52 1 * * * here, and the monitor job follows about 10 minutes later. Create this tracker (callout 5) creates and schedules both the collect and monitor jobs, and the final summary (callout 6) shows the configuration that will be created.

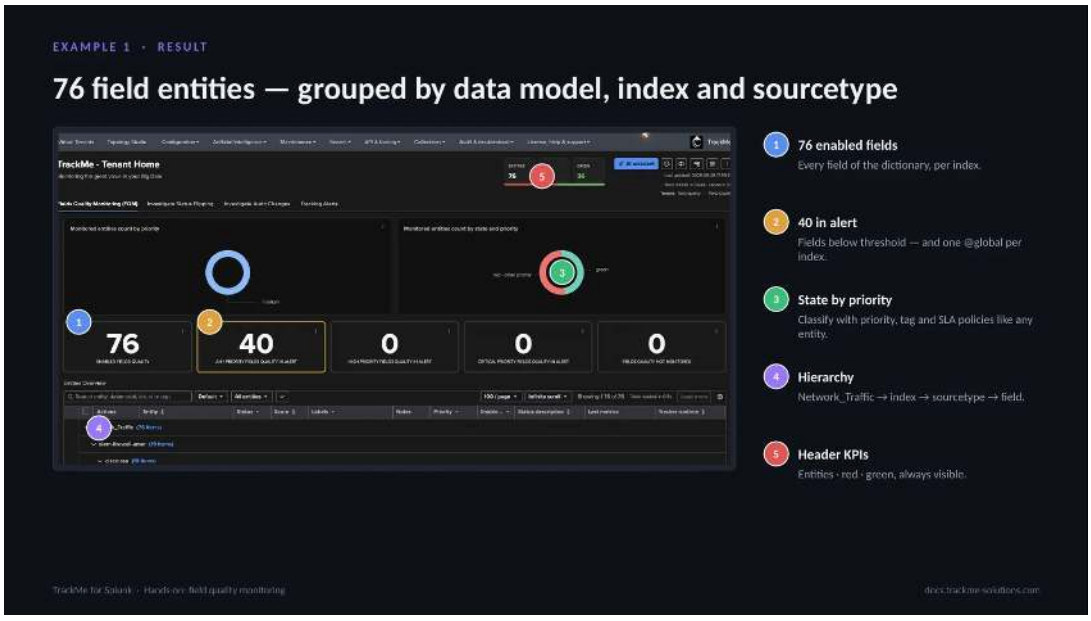
Running the jobs on demand



In production the jobs run on their cron; for a first validation they can be run on demand from the Tenant Home menu. Execute: hybrid tracker (callout 1) picks the collect job, then the monitor job. Run tracker now (callout 2) runs the job as the scheduler would, with its time window. Execution events (callout 3) stream from the executor: the collect job succeeds in 11.1 s with 8,192 events scored, and the monitor job succeeds in 24 s with 76 entities.

76 entities is 4 indexes × (18 dictionary fields + one @global). From now on both jobs run daily on their own.

The field entities in Tenant Home

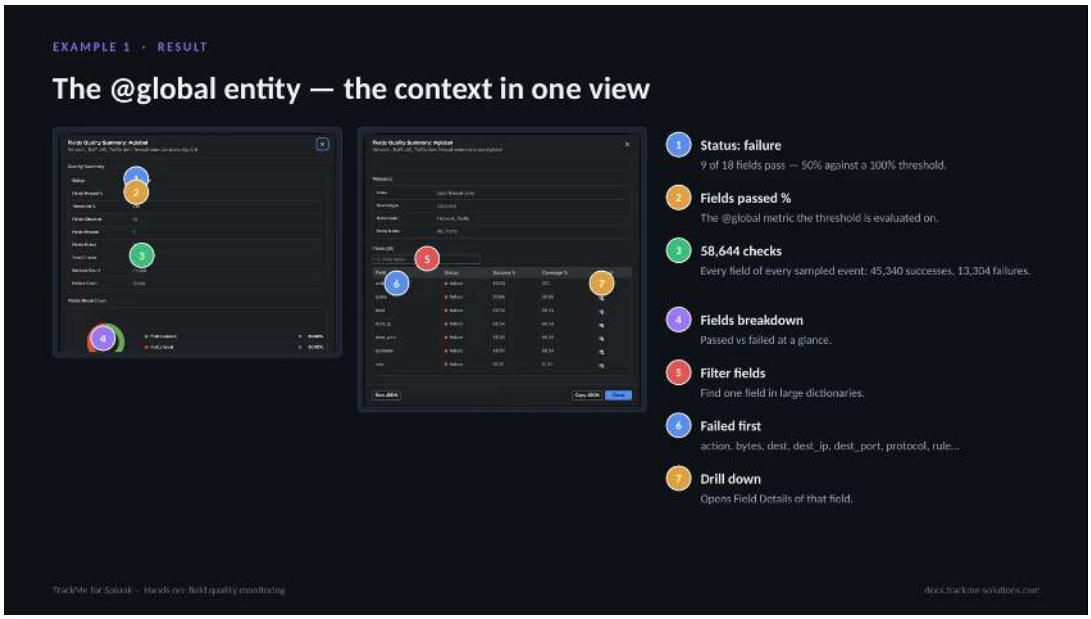


The tenant now holds 76 enabled fields (callout 1), every field of the dictionary, per index. 40 are in alert (callout 2): fields below threshold, plus one @global per index. State by priority (callout 3) classifies them with priority, tag and

SLA policies like any entity. The hierarchy (callout 4) follows the break-by: Network_Traffic → index → sourcetype → field. Header KPIs (callout 5) show entities, red and green, always visible.

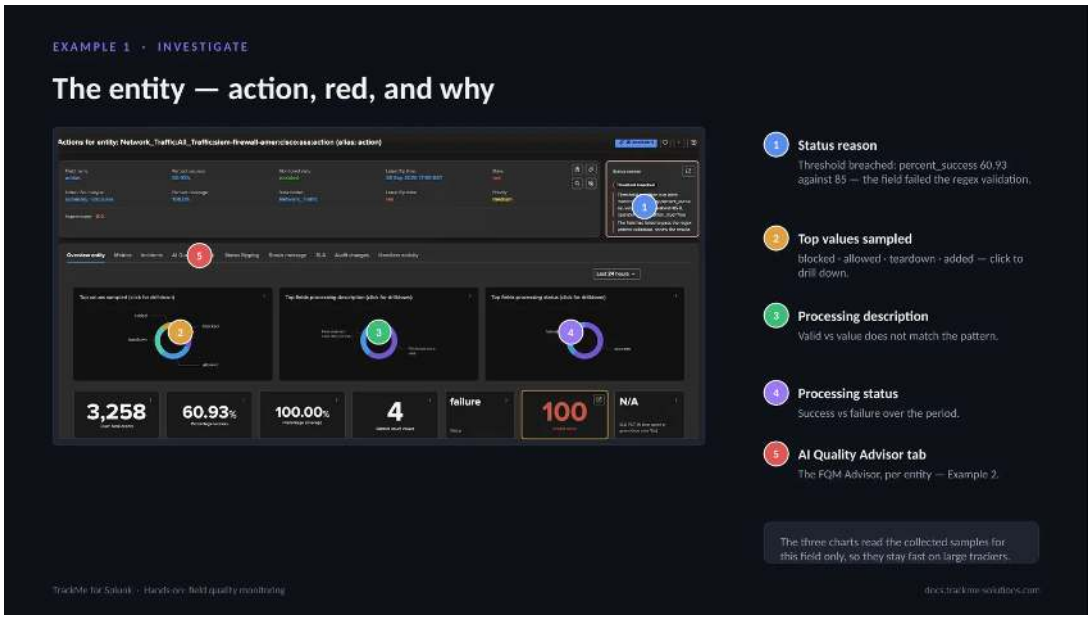
FQM entities are regular TrackMe entities: priority, tags, SLA, labels, logical groups, acknowledgments, maintenance and stateful alerting all apply.

Inspecting the @global entity



@global aggregates every field of one context, here Network_Traffic / All_Traffic / siem-firewall-amer / cisco:asa. Status: failure (callout 1): 9 of 18 fields pass, 50% against a 100% threshold. Fields passed % (callout 2) is the @global metric the threshold is evaluated on. 58,644 checks (callout 3) cover every field of every sampled event: 45,340 successes and 13,304 failures. The fields breakdown (callout 4) shows passed against failed at a glance. Filter fields (callout 5) finds one field in large dictionaries. Failed first (callout 6) lists action, bytes, dest, dest_ip, dest_port, protocol, rule and so on. Drill down (callout 7) opens the Field Details of that field, with a Back to @global link.

The action entity over time



Opening the action entity gives the same evidence as the wizard, now over time. The status reason (callout 1) is written in plain language: threshold breached, percent_success 60.93 against 85, the field failed the regex validation. Top

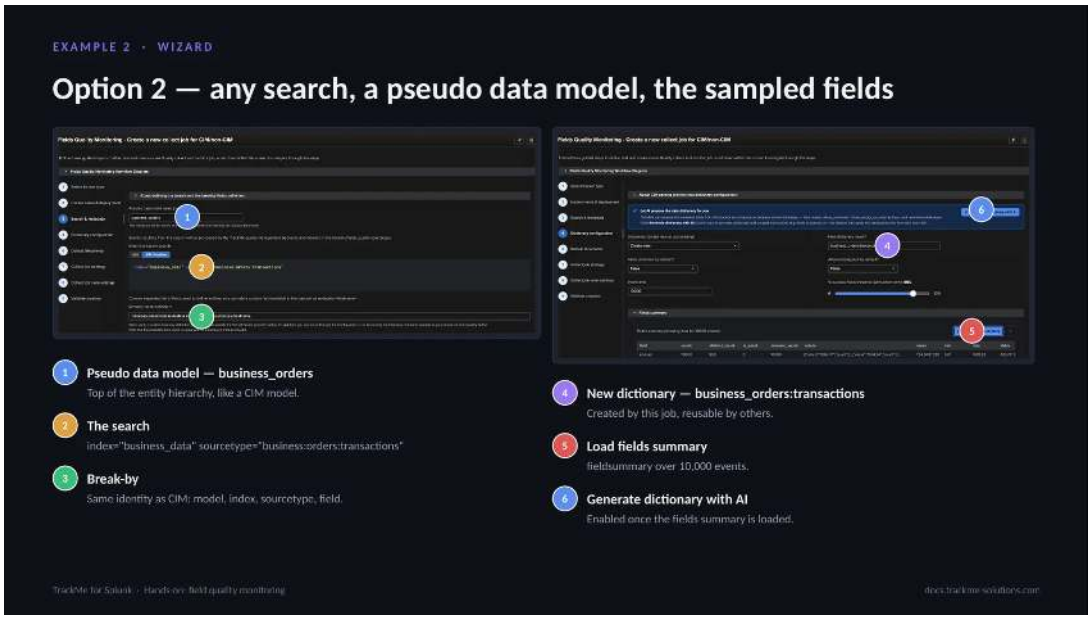
values sampled (callout 2), blocked, allowed, teardown and added, each drill down on click. Processing description (callout 3) splits valid values from values that do not match the pattern. Processing status (callout 4) shows success against failure over the period. The AI Quality Advisor tab (callout 5) hosts the FQM Advisor for this entity, used in Example 2.

The three charts read the collected samples for this field only, so they stay fast on large trackers.

Example 2 — A non-CIM data source

The second example is a business feed with no CIM model behind it: index=”business_data” sourcetype=”business:orders:transactions”, JSON order events. This is where the AI Advisors do the heavy lifting: they turn the sampled fields into a starter dictionary, tighten one rule on request and review the verdict. The analyst stays in control of every change.

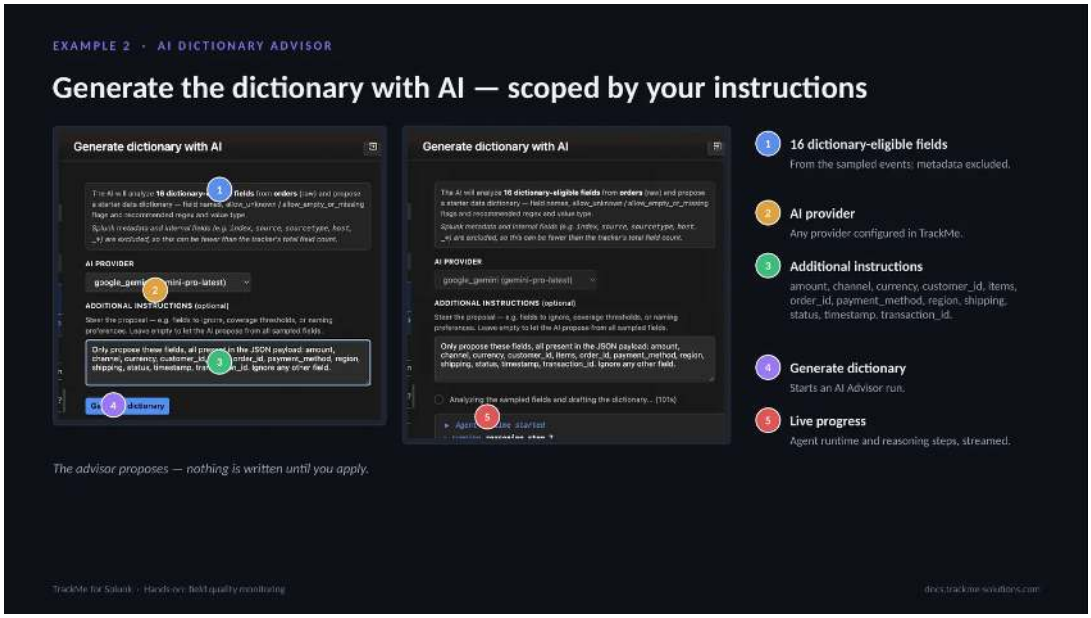
Pseudo data model and fields summary



The tracker type is CIM/non-CIM. Pseudo data model (callout 1), business_orders, is the top of the entity hierarchy, like a CIM model, and groups the entities. The search (callout 2) is index=”business_data” sourcetype=”business:orders:transactions”. Break-by (callout 3) keeps the same identity as CIM: model, index, sourcetype

and field. New dictionary (callout 4), business_orders:transactions, is created by this job and reusable by others. Load fields summary (callout 5) runs fieldsummary over 10,000 events: the fields found, with counts, distinct values and statistics. Generate dictionary with AI (callout 6) is enabled once the fields summary is loaded; that summary is what the AI dictionary advisor analyses.

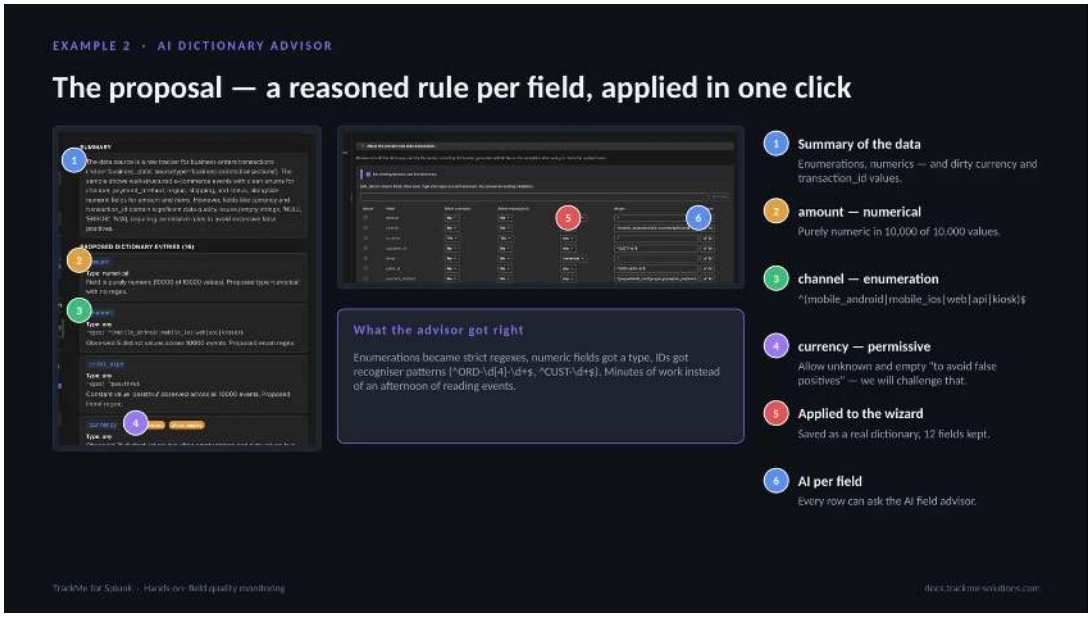
Starting the AI dictionary advisor



The AI dictionary advisor analyses the 16 dictionary-eligible fields (callout 1) of the sampled events; Splunk metadata and internal fields are excluded. AI provider (callout 2) is any provider configured in TrackMe. Additional instructions (callout 3) steer the advisor; here they list the business fields of interest: amount, channel, currency, customer_id, items, order_id, payment_method, region, shipping, status, timestamp and transaction_id. Generate dictionary (callout 4) starts an AI Advisor run, whose live progress (callout 5), agent runtime and reasoning steps, is streamed in the panel.

The advisor proposes a complete starter dictionary: field names, allow flags, a recommended regex and a value type. Nothing is written until it is applied.

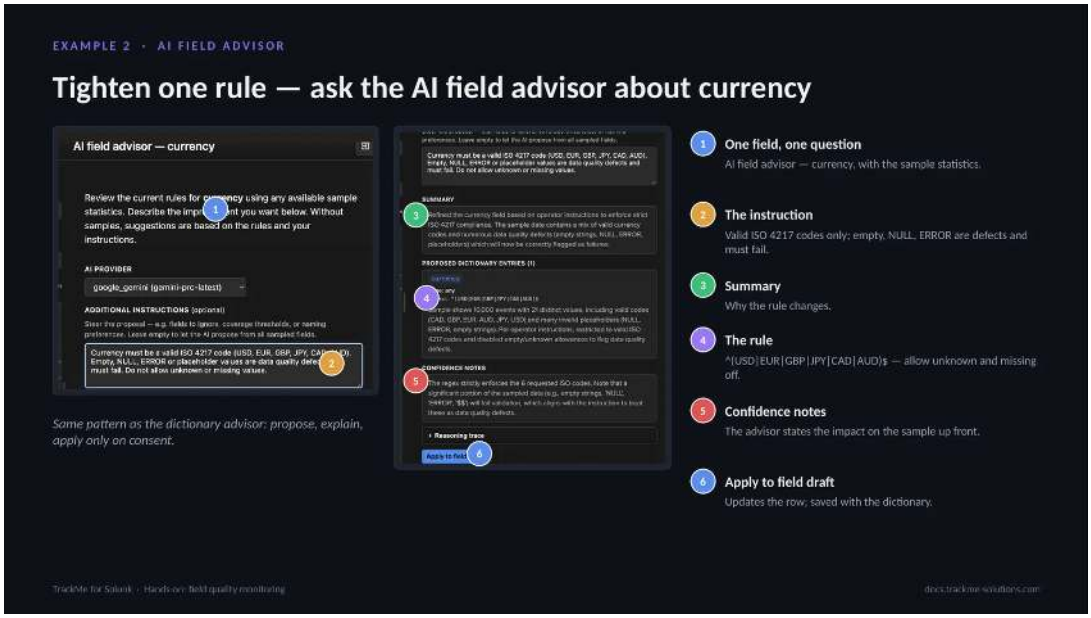
Applying the proposed dictionary



The summary of the data (callout 1) reports clean enumerations for channel, payment_method, region, shipping and status, numeric amount and items, and dirty currency and transaction_id values. amount (callout 2) is typed numerical, numeric in every sampled value. channel (callout 3) becomes the enumeration ^(mobile_android|mobile_ios|web|api|kiosk)$. currency (callout 4) is left permissive, allowing unknown and empty "to avoid false positives". Applied to the wizard (callout 5) saves it as a real dictionary with 12 fields kept; four ingestion pipeline fields are removed in the editor. AI per field (callout 6) lets every row ask the AI field advisor.

Enumerations became strict regexes, numeric fields got a type and IDs got recogniser patterns; each entry explains its rule.

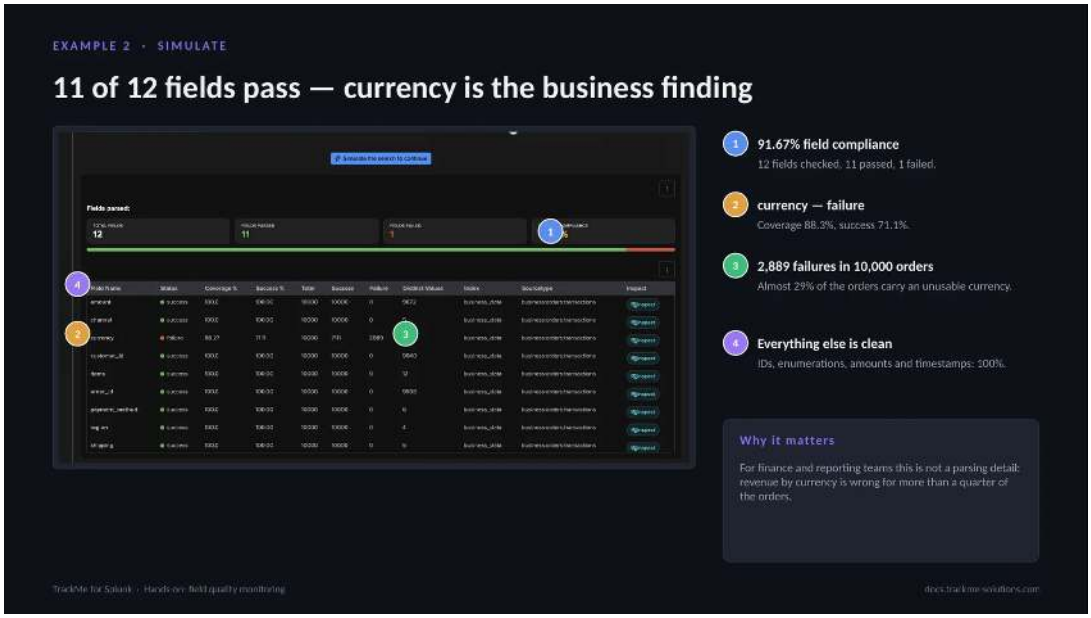
Tightening the currency rule



The permissive currency rule is the wrong call for a quality monitor: the dirty values are precisely what should be caught. The AI field advisor (callout 1) reviews one field, currency, with the sample statistics. The instruction (callout 2): valid ISO 4217 codes only; empty, NULL and ERROR are defects and must fail. The summary (callout 3) explains why the rule changes. The rule (callout 4) becomes ^(USD|EUR|GBP|JPY|CAD|AUD)$ with allow unknown and missing off. Confidence notes (callout 5) state the impact on the sample up front: a significant share will fail. Apply to field draft (callout 6) updates the row, saved with the dictionary.

Same pattern as the dictionary advisor: propose, explain, apply only on consent.

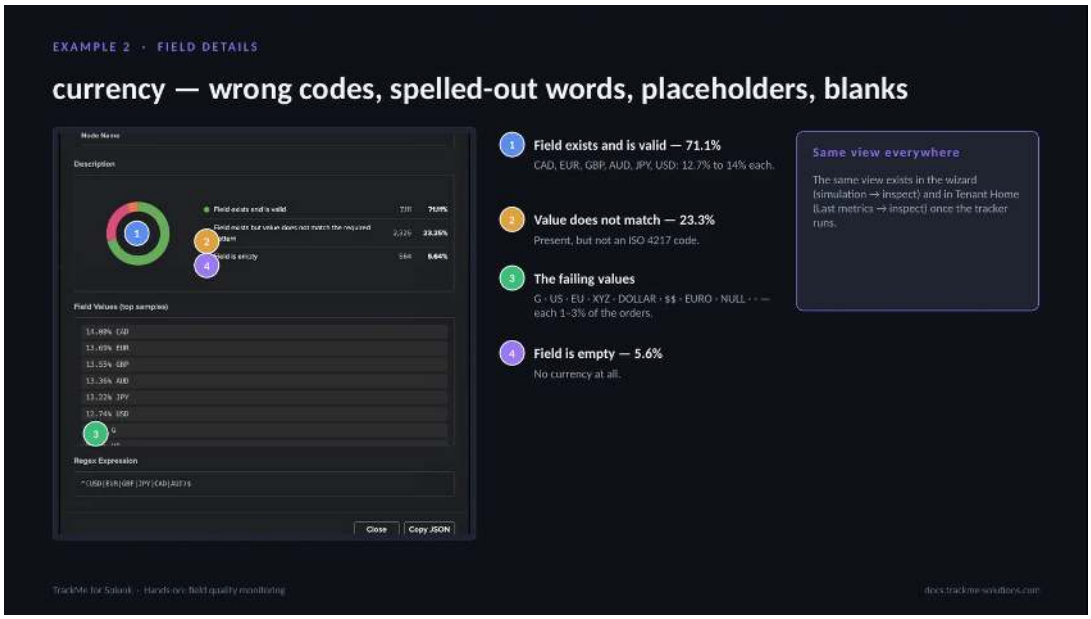
Simulation with the tightened rule



With the tightened rule, the simulation isolates exactly one problem. Field compliance (callout 1) is 91.67%: 12 fields checked, 11 passed, 1 failed. currency (callout 2) fails with coverage 88.3% and success 71.1%. 2,889 failures in 10,000 orders (callout 3): almost 29% of the orders carry an unusable currency. Everything else (callout 4) is clean: IDs, enumerations, amounts and timestamps at 100%.

For finance and reporting teams this is not a parsing detail: revenue by currency is wrong for more than a quarter of the orders. The failure is a genuine data quality issue in the source application.

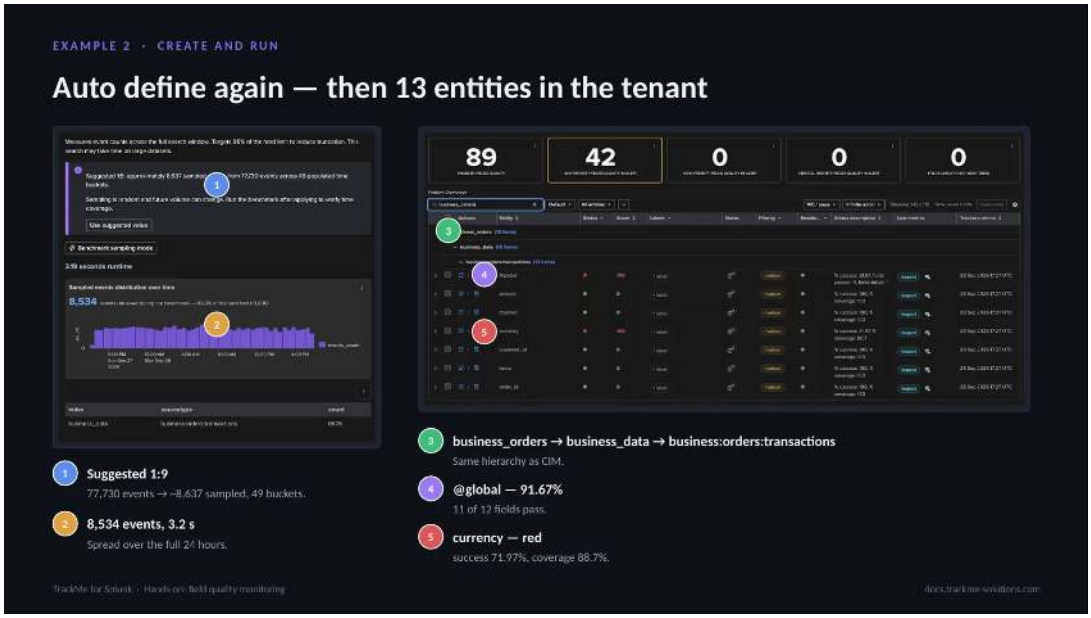
The failing currency values



Field Details for currency. Field exists and is valid (callout 1) is 71.1%: CAD, EUR, GBP, AUD, JPY and USD at 12.7% to 14% each. Value does not match (callout 2) is 23.3%: present, but not an ISO 4217 code. The failing values (callout 3) are G, US, EU, XYZ, DOLLAR, $$, EURO, NULL and -, each 1–3% of the orders: truncated codes, spelled-out words, symbols and placeholders. Field is empty (callout 4) is 5.6%, no currency at all.

The top values are the evidence to forward to the application team. The same view exists in the wizard (simulation → inspect) and in Tenant Home (Last metrics → inspect) once the tracker runs.

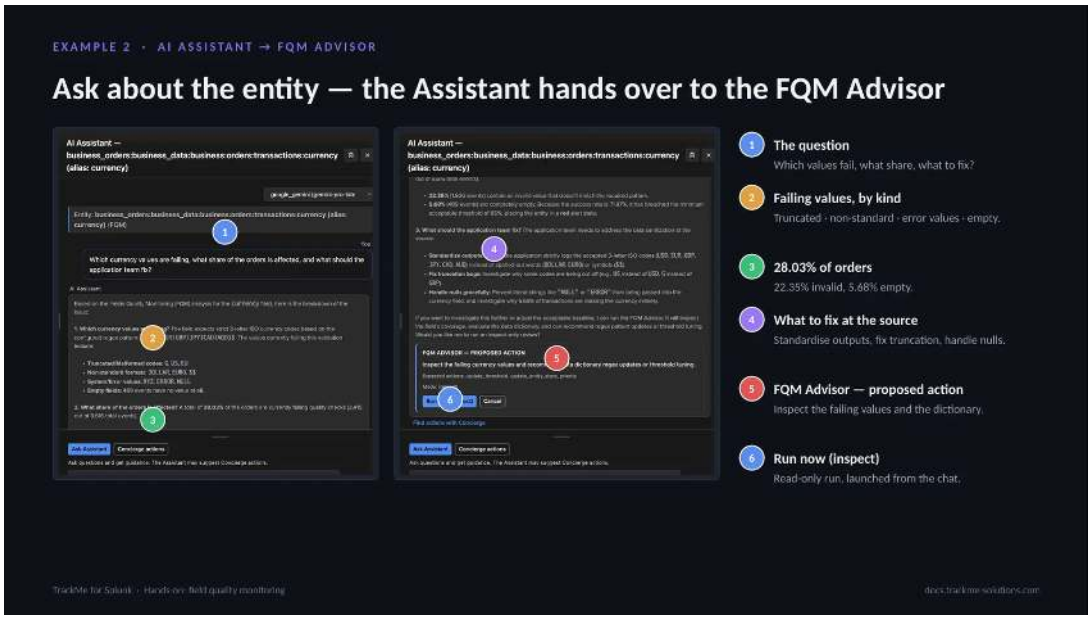
Creating and running the orders tracker



Step 7 again sizes the sample. Auto define suggests 1:9 (callout 1): 77,730 events in 49 buckets give about 8,637 sampled events. The benchmark (callout 2) retrieves 8,534 events in 3.2 s, spread over the full 24 hours. After creation and a first run, the hierarchy (callout 3) reads business_orders → business_data → business:orders:transactions, the same as CIM. @global (callout 4) is at 91.67%, 11 of 12 fields pass. currency (callout 5) is red with success 71.97% and coverage 88.7%.

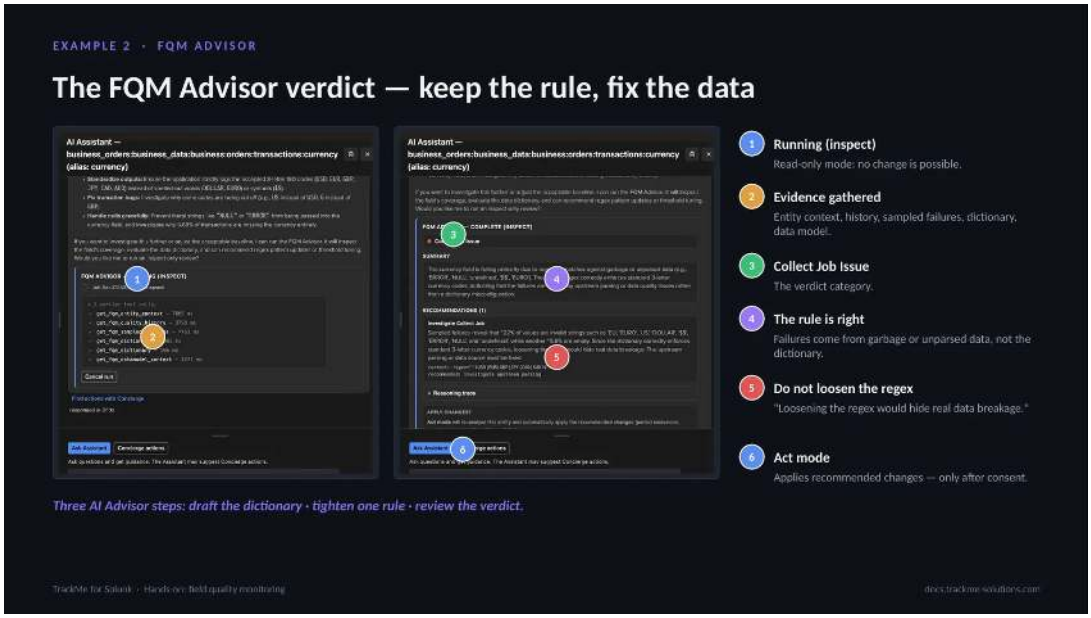
The tenant now has 13 new entities: 12 fields and the @global. currency and @global are red, everything else green.

From the AI Assistant to the FQM Advisor



On the currency entity, the AI Assistant is asked which values fail, what share of orders is affected and what to fix (callout 1). It answers from the entity data. Failing values, by kind (callout 2): truncated, non-standard, error values and empty. 28.03% of orders (callout 3) are affected: 22.35% invalid and 5.68% empty. What to fix at the source (callout 4): standardise outputs, fix truncation, handle nulls. The Assistant then proposes the right specialist, an FQM Advisor proposed action (callout 5) to inspect the failing values and the dictionary, as an action card. Run now (inspect) (callout 6) launches a read-only run from the chat in one click.

The advisor's inspect verdict



The FQM Advisor runs as an agent with read tools. Running (inspect) (callout 1) is read-only mode: no change is possible. Evidence gathered (callout 2) covers the entity context, quality history, sampled failures, the dictionary and the data model; the live feed shows each call. The verdict category (callout 3) is Collect Job Issue. The rule is right (callout 4): the failures come from garbage or unparsed data, not from the dictionary. Do not loosen the regex (callout 5), because "loosening the regex would hide real data breakage." Act mode (callout 6) applies recommended changes, only after consent.

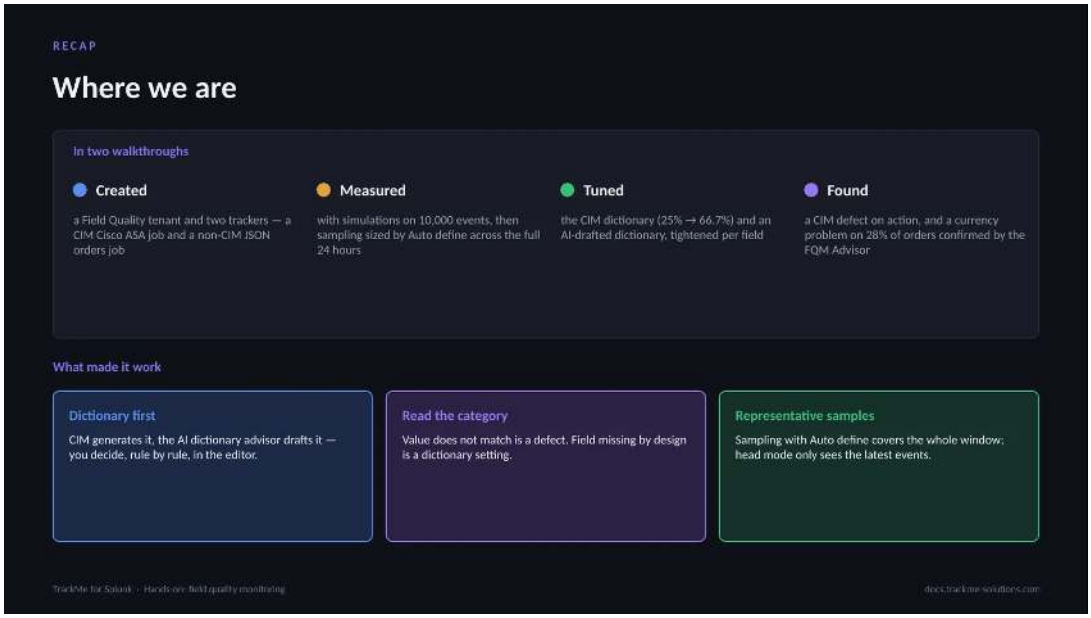
Three AI Advisor steps cover the example: draft the dictionary, tighten one rule, review the verdict.

A mature tenant and its topology

The same model on an established tenant with several business and CIM trackers. 214 enabled fields (callout 1) span business and CIM trackers, with months of history. 97 in alert (callout 2) are quality issues to route to owners. Grouped by data model (callout 3): business, Network_Traffic and Web. The Field Quality topology (callout 4) shows tenant → data model with live health. business (callout 5) is 61% healthy, aggregated from every field below it; Web is at 62%. Network_Traffic (callout 6) is at 0%. The topology can be saved as a Topology Studio view.

Every entity keeps its history, flips, incidents and SLA like any TrackMe entity, and stateful alerts notify the owners.

Where we are



Two feeds, two dictionary strategies. Created: a Field Quality tenant and two trackers, CIM Cisco ASA and non-CIM JSON orders. Measured: simulations on 10,000 events, then Auto define sampling across the full 24 hours. Tuned: the CIM dictionary from 25% to 66.7%, and an AI-drafted dictionary tightened per field. Found: a CIM defect on action, and a currency problem on 28% of orders confirmed by the FQM Advisor.

What made it work: dictionary first, CIM generates it, the AI dictionary advisor drafts it, the analyst decides. Read the category: value does not match is a defect, field missing by design is a dictionary setting. Representative samples: Auto define covers the whole window, head mode only the latest events.

2.1.7 Volume Outliers

Licensed volume per index as entities: rolling volume, daily licensed volume verified against the license usage log, daily changes and the month projection, ML outliers on drops and spikes, and the ML Advisor.

`Download the deck (PDF) · PowerPoint`

about 35 minutes · 43 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

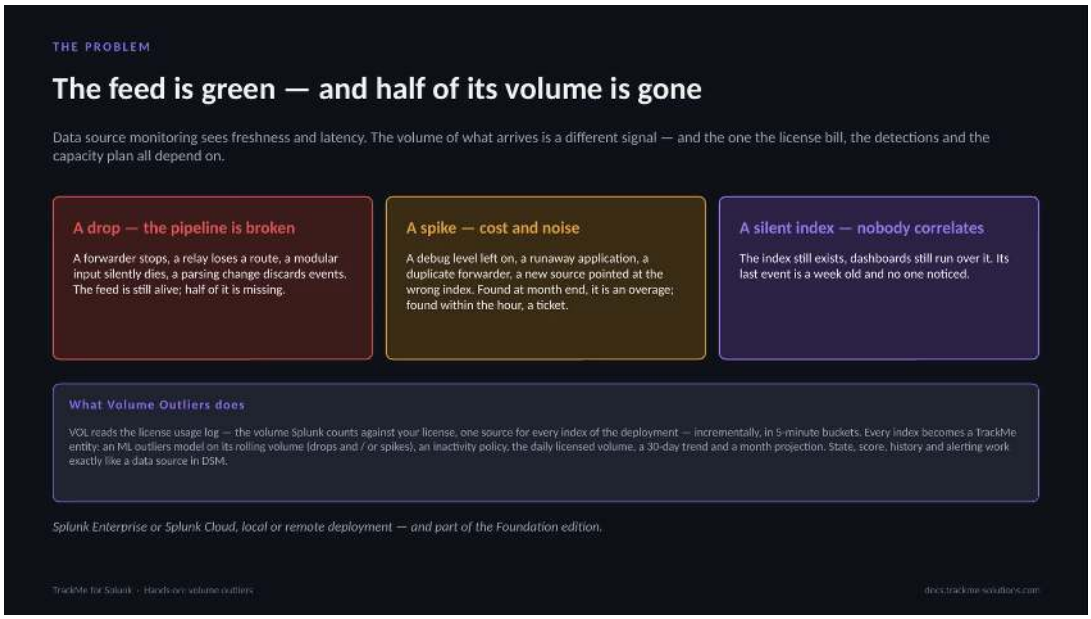
Overview

Volume Outliers (VOL) is the seventh TrackMe component, introduced in 2.4.18: the standardised, first-class form of the volume detection TrackMe has always offered. One tenant watches every index of a deployment for abnormal drops, spikes and silence, backfills its history at creation, and adds a cost trend, a month projection and the whole environment's license usage. Parts 1 to 3 were captured on TrackMe 2.4.18, from an empty tenant on a Splunk Enterprise deployment with 43 indexes in one license pool; the license usage view of Part 4 on TrackMe 2.4.19.

The path runs from the tenant creation and the backfill, through reading the results and tuning the detection, to the global license usage view from scopes to chargeback, alerting, the AI Assistant and an AI ML Advisor review of a volume model.

Parts 2 and 4 were refreshed on TrackMe 2.4.22: binary units with IEC labels, a collection that waits for a late source, the closed-day reconciliation against the license usage log, and the Daily changes and Investigate an index views.

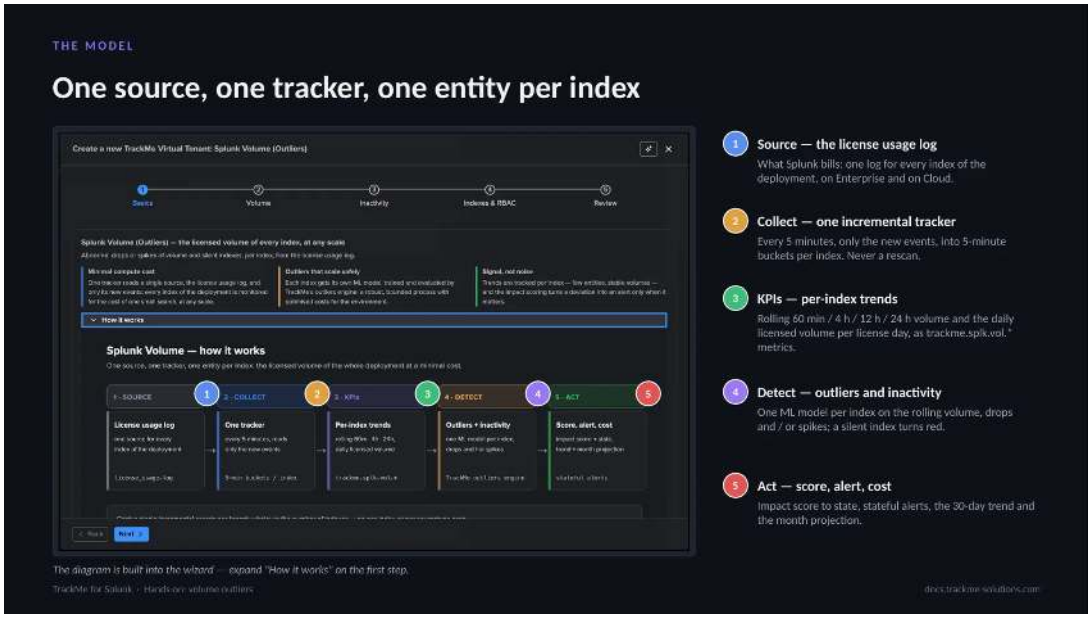
Why volume needs its own signal



Availability monitoring answers whether data arrives on time, not whether the amount is normal. A broken forwarder, a lost route or a parser change leaves the feed green while half of the data is missing; a debug level left on is an overage at month end; a silent index still exists while its last event is a week old.

VOL watches the volume itself, from the license usage log Splunk bills, read incrementally in 5-minute buckets. Every index becomes a TrackMe entity with an ML outliers model on its rolling volume, an inactivity policy, the daily licensed volume, a 30-day trend and a month projection, on Enterprise or Cloud, in the Foundation edition.

Source, tracker, KPIs, detection, action



Callouts 1 to 5 follow the pipeline. The source is the license usage log: what Splunk bills, one log for every index, on Enterprise and on Cloud. One incremental tracker collects every 5 minutes, only the new events, into 5-minute buckets per index, never rescanning. The KPIs are per-index trends: rolling 60 min, 4 h, 12 h and 24 h volume and the daily licensed volume, as trackme.splk.vol.* metrics.

Detection runs one ML model per index on the rolling volume, drops and / or spikes, and a silent index turns red. Action is the impact score to state, stateful alerts, the 30-day trend and the month projection. The same diagram sits under How it works in the wizard.

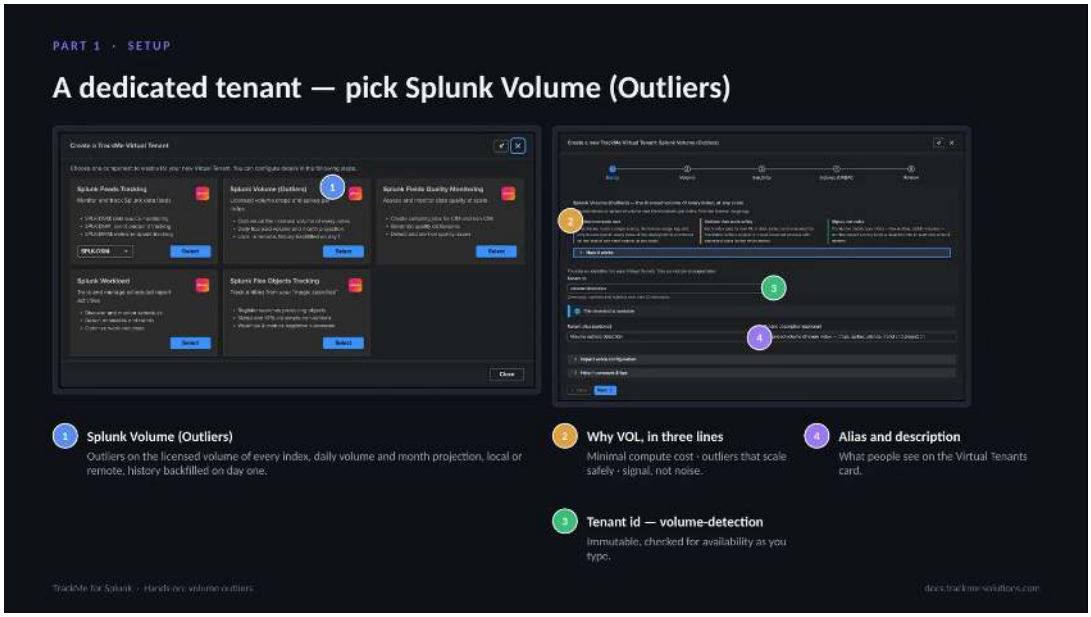
The four parts

One Virtual Tenant covers the whole deployment. Part 1, Setup, creates the tenant through the wizard (basics, volume, inactivity, RBAC), replays 30 days of history at creation, and follows day one from pending to complete. Part 2, Read,

covers the VOL table (volume, yesterday, trend, projection), an index with its Volume & cost tab, rolling volume and hourly profile, and the outliers model with its bounds.

Part 3, Tune, sets drops, spikes or both per index and in bulk, the inactivity policy for business hours versus nights, and the default KPIs and outliers scope. Part 4, Operate, covers the global license usage view (scopes, working days, days over quota, costs and chargeback), SPLK-VOL alerts with stateful emails, the AI Assistant and the AI ML Advisor review of a volume model.

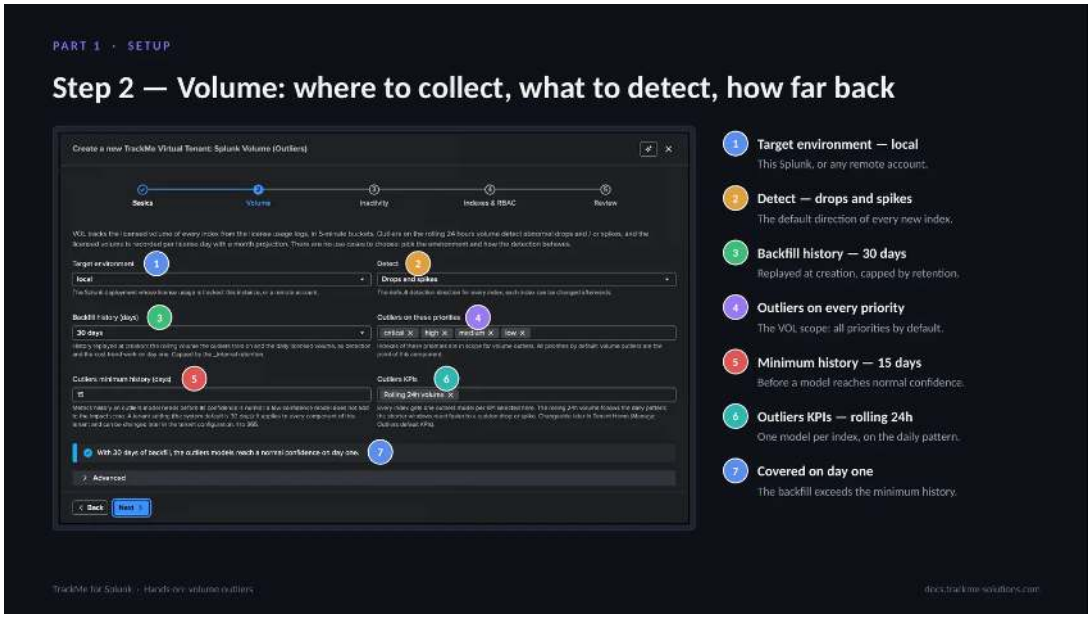
Choosing the Volume tenant type



The tenant chooser opens from Virtual Tenants, Actions, Create a tracking tenant, and the Splunk Volume (Outliers) card sits second in it (callout 1). The wizard has five steps: basics, volume, inactivity, indexes & RBAC, review. The first step recalls the three arguments of the component (callout 2), minimal compute cost, outliers that scale safely, signal rather than noise, and what VOL provides: outliers on the licensed volume of every index, daily volume and month projection, local or remote, history backfilled on day one.

The tenant id (callout 3) is immutable, checked for availability as it is typed, twenty characters at most; volume-detection is used here. The alias and description (callout 4) appear on the Virtual Tenants card.

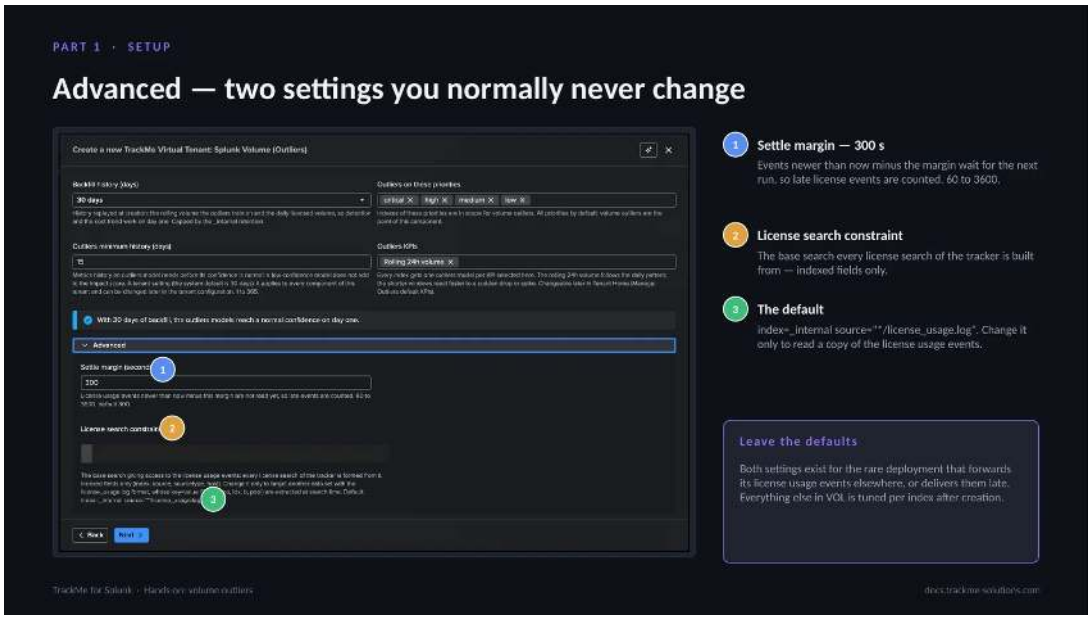
The Volume step and its defaults



The Volume step is the whole configuration and its defaults are the recommended values. Target environment (callout 1) is this Splunk or any remote account configured in TrackMe. Detect (callout 2) sets the default direction of every new index, drops and spikes, changed per index later. Backfill history (callout 3) is 30 days replayed at creation, capped by the retention of the license usage log.

The outliers scope (callout 4) covers every priority by default, because volume outliers are the point of this component. Minimum history (callout 5) is 15 days before a model reaches normal confidence; the notice (callout 7) confirms the backfill covers it. The default outliers KPI (callout 6) is the rolling 24h volume.

Settle margin and license search constraint

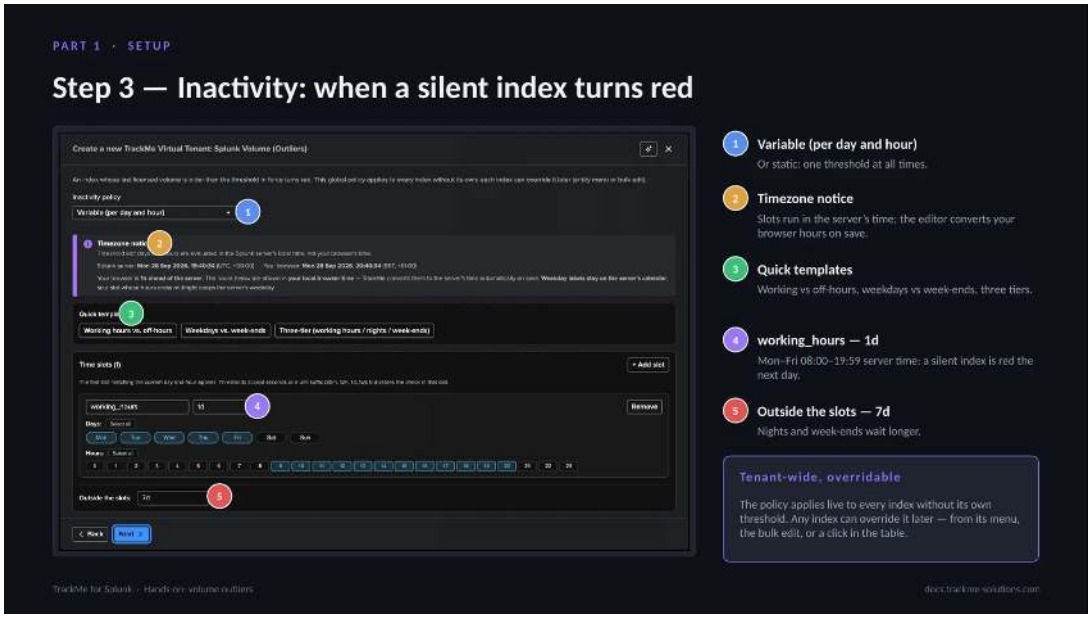


Expanding Advanced reveals two technical settings that normally stay at their defaults. The settle margin (callout 1), 300 s by default and adjustable from 60 to 3600, keeps the tracker behind the newest license events: events newer than now minus the margin wait for the next run, so late license events are still counted in their bucket.

The license search constraint (callout 2) is the base search every license search of the tracker is built from, indexed fields only. The default (callout 3) is index=_internal source="*/license_usage.log"; it changes only to read a copy

of the license usage events. Both exist for the rare deployment that forwards its license usage events elsewhere or delivers them late.

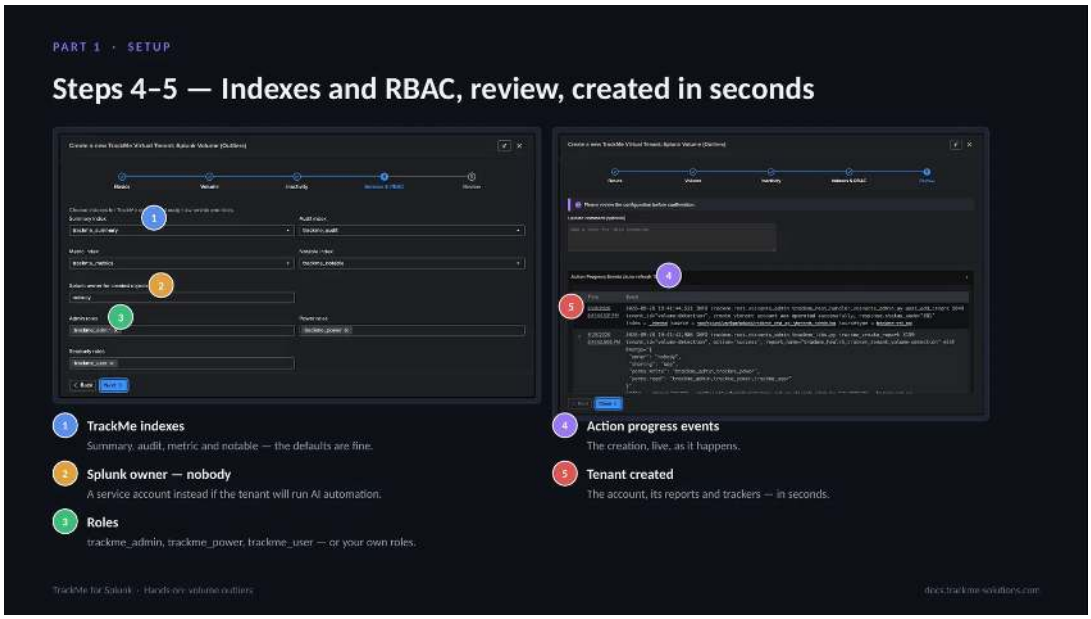
The inactivity policy by day and hour



Inactivity is the second detection: after how long without licensed volume an index turns red. The policy is variable by day and hour (callout 1), or static with one threshold. The timezone notice (callout 2) shows the server and browser clocks side by side: slots run in the server's time and the editor converts browser hours on save. Quick templates (callout 3) cover working versus off-hours, weekdays versus week-ends and three tiers.

The default working_hours slot (callout 4), Monday to Friday 08:00 to 19:59 server time, uses 1d: a silent index is red the next day. Outside the slots (callout 5) the threshold is 7d. The policy applies live to every index without its own threshold.

Indexes, RBAC and creation

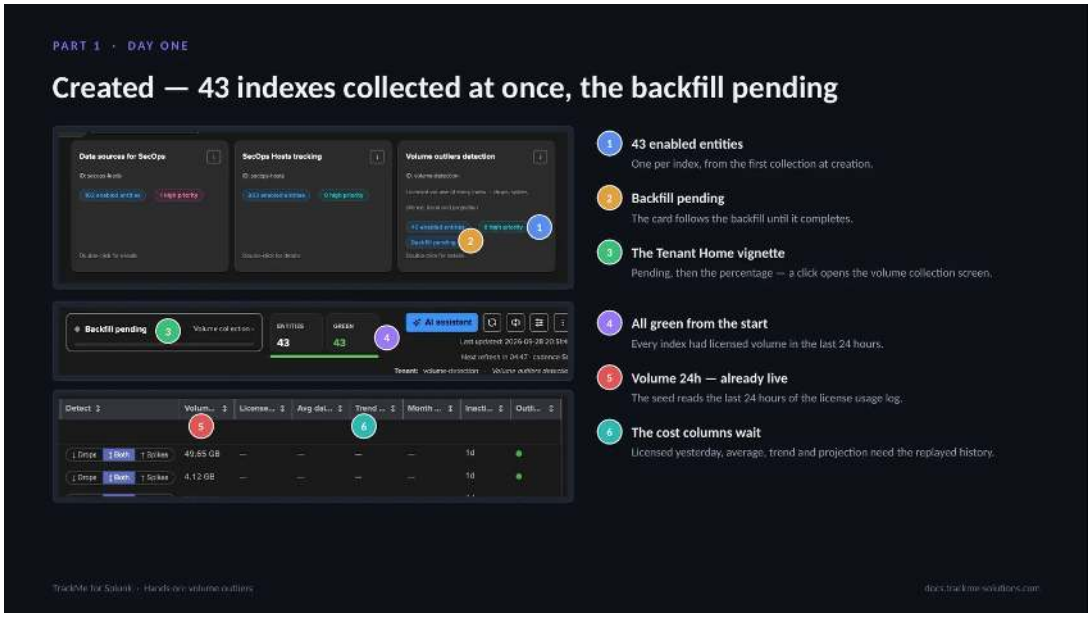


The last two steps are shared by every tenant type. Indexes & RBAC sets the TrackMe indexes (callout 1): summary, audit, metric and notable, where the defaults are fine. The Splunk owner (callout 2) is nobody by default; a

service account is the better choice if the tenant will run AI automation. Roles (callout 3) default to trackme_admin, trackme_power and trackme_user, or any custom roles.

The review step is followed by Done, and the action progress events (callout 4) show the creation live as it happens: the tenant account, its reports and its trackers are created in seconds (callout 5), and the first collection runs straight away.

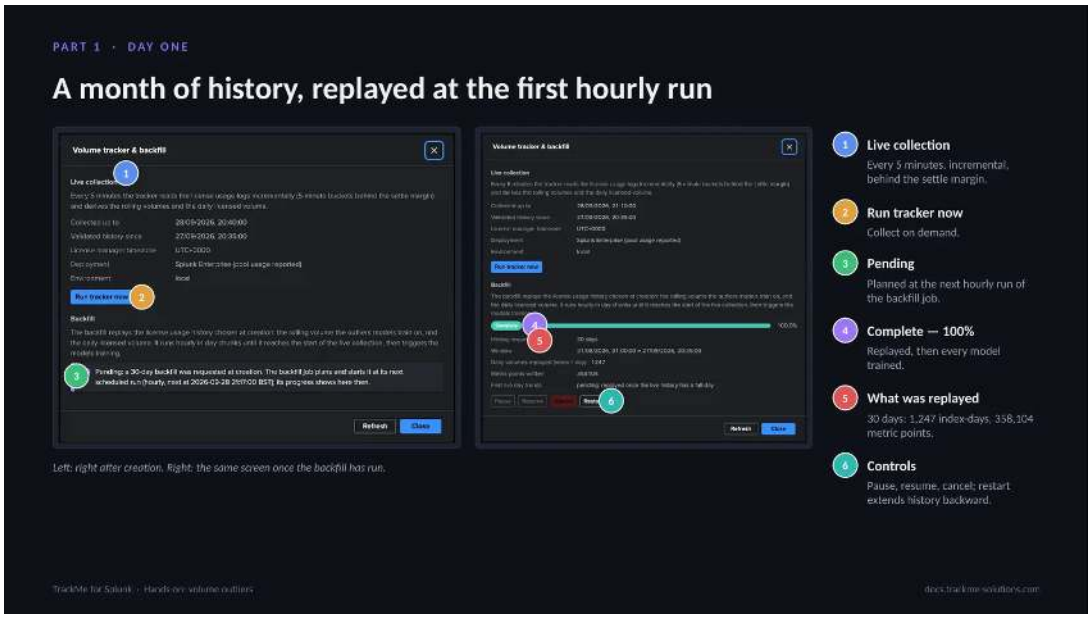
First collection and the pending backfill



The creation runs the first collection: the tracker seeds the last 24 hours of the license usage log and one entity per index appears, 43 enabled entities here (callout 1), each with its rolling volume. The backfill job plans itself at its first hourly run; until then the Virtual Tenants card reads Backfill pending (callout 2) and follows the backfill until it completes.

The Tenant Home header shows a matching vignette (callout 3): pending, then the percentage; a click opens the volume collection screen. Every index is green from the start (callout 4) because each had licensed volume in the last 24 hours. Volume 24h is already live (callout 5); the cost columns (callout 6) wait for the replayed history.

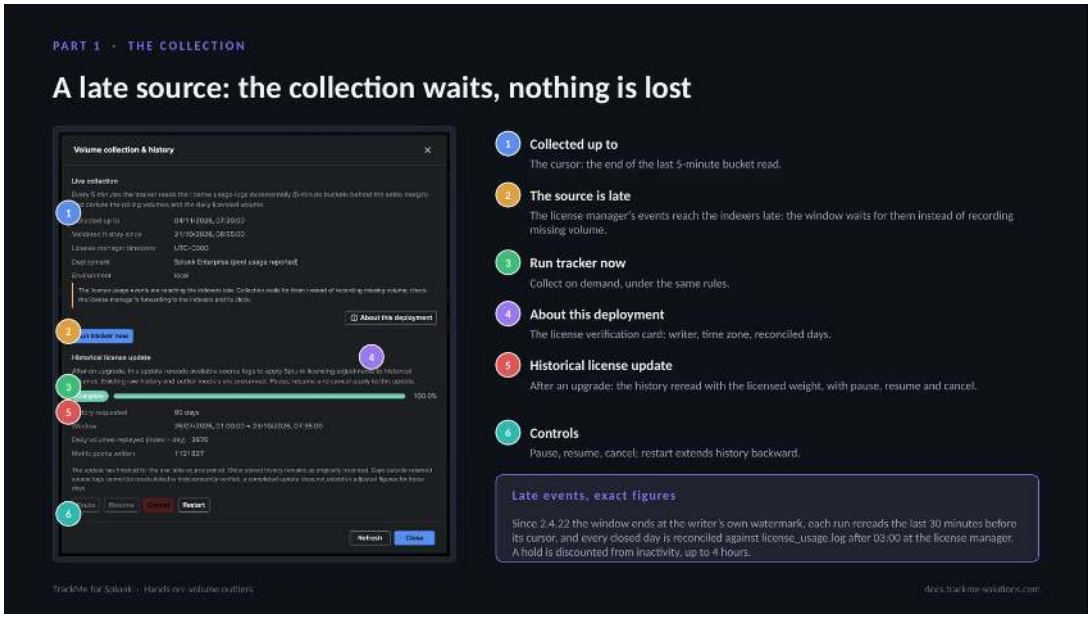
The volume collection screen



The volume collection screen explains both jobs, shown right after creation on the left and after the backfill on the right. Live collection (callout 1) runs every 5 minutes, incrementally, behind the settle margin; Run tracker now (callout 2) collects on demand. The backfill is Pending (callout 3) until the backfill job plans it at its next hourly run, then Complete at 100% (callout 4): the history is replayed day by day through the same code as the live collection, with historical timestamps.

The replay summary (callout 5) reports 30 days, 1,247 index-days and 358,104 metric points. The controls (callout 6) pause, resume and cancel; a restart extends the history backward. On completion every model is trained.

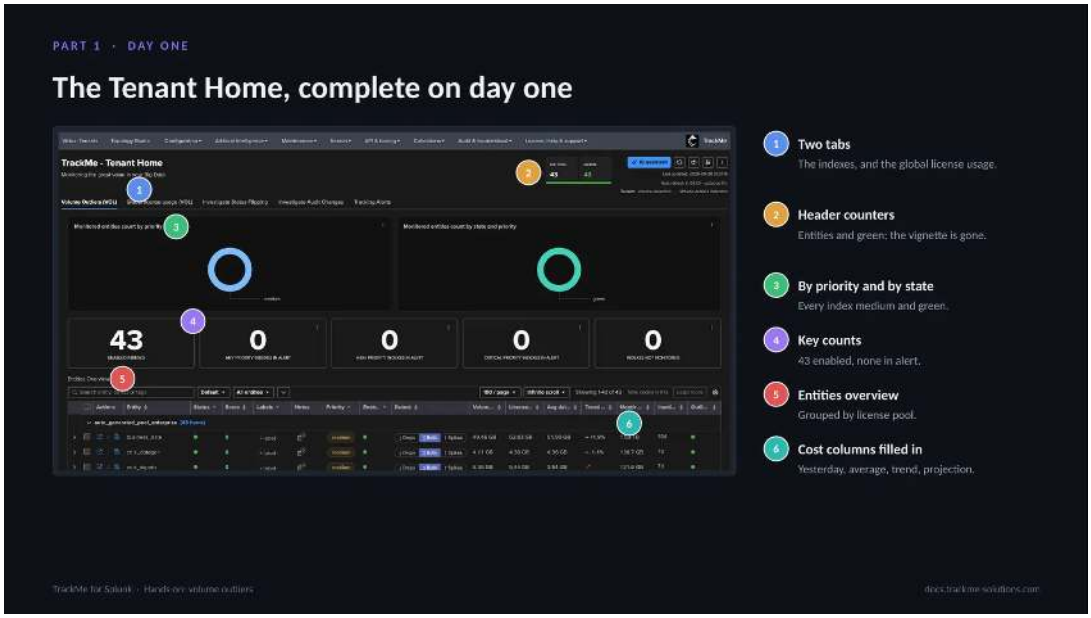
A late source and the collection



The Volume collection & history screen on a deployment whose license manager delivers its events late. Collected up to names the cursor (callout 1); the notice (callout 2) says that the license usage events are reaching the indexers late and that the collection waits for them instead of recording missing volume. Run tracker now collects on demand (callout 3) and About this deployment opens the license verification card (callout 4). The Historical license update (callout 5) is the post-upgrade replay that applied the licensed weight to the stored history, with its pause, resume, cancel and restart controls (callout 6).

Since 2.4.22 the window ends at the writer's own watermark, each run rereads the last 30 minutes before its cursor, and every closed day is reconciled against license_usage.log after 03:00 at the license manager; a hold is discounted from inactivity, up to four hours.

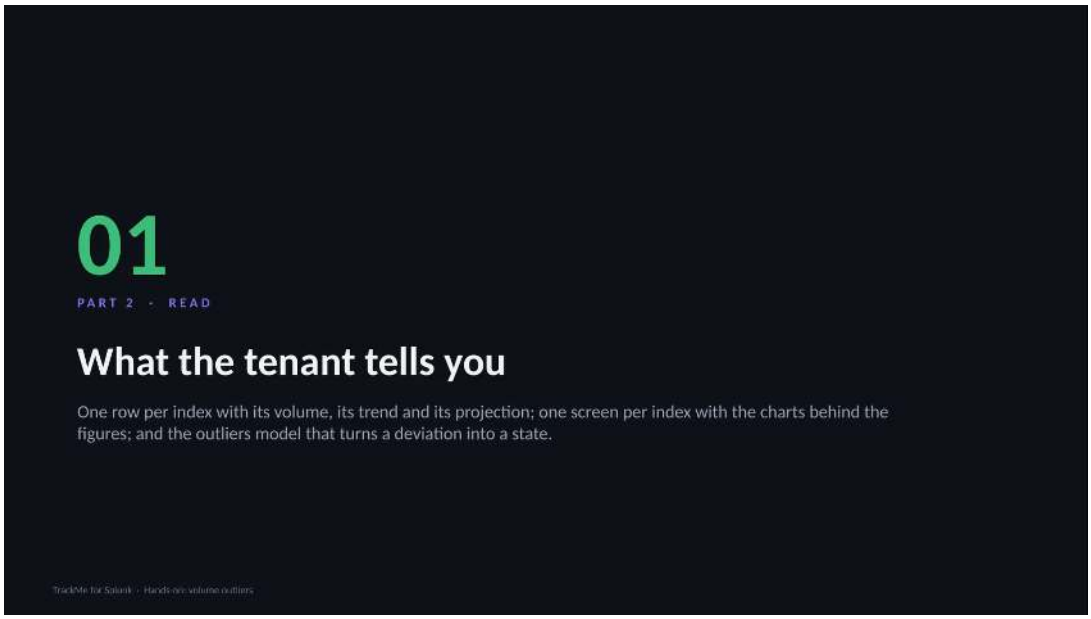
Tenant Home after the backfill



Once the backfill has completed, the Tenant Home is the finished product. Two tabs (callout 1) hold the Volume Outliers indexes and the global license usage. The header counters (callout 2) show the entities and the green count, and the backfill vignette is gone. The charts by priority and by state (callout 3) show every index medium and green, and the key counts (callout 4) read 43 enabled and none in alert.

The entities overview (callout 5) is grouped by license pool, and the cost columns (callout 6), yesterday, average, trend and projection, are now filled from the replayed month.

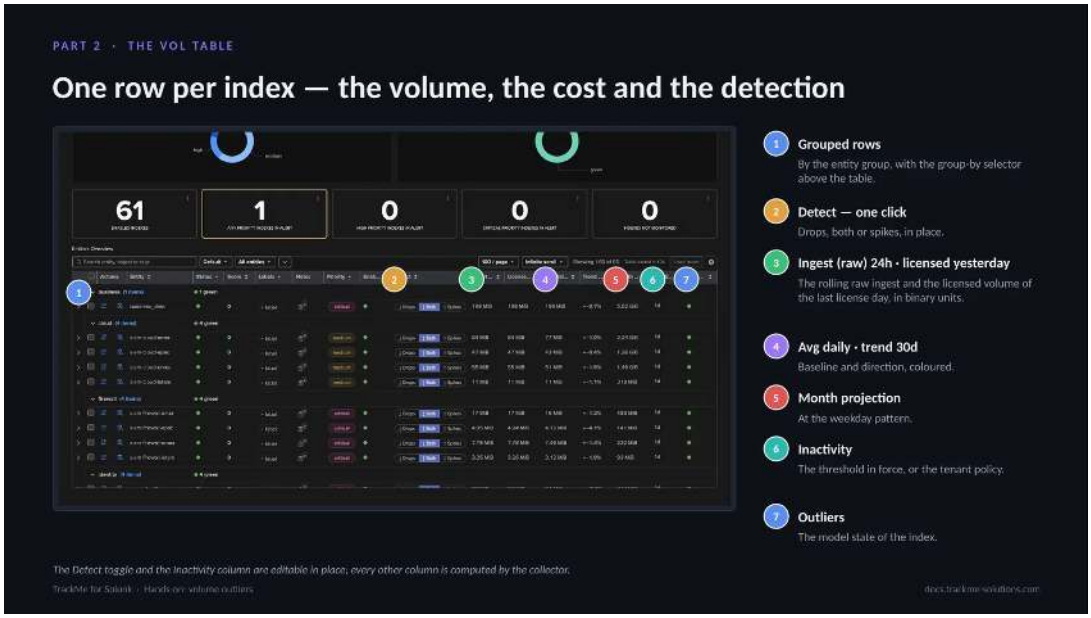
Part 2 — Read



Part 2 reads what the tenant shows. The VOL table has one row per index with its volume, its trend and its projection. The entity screen of an index has the charts behind the figures: the daily licensed volume, the rolling volume windows and the hourly profile.

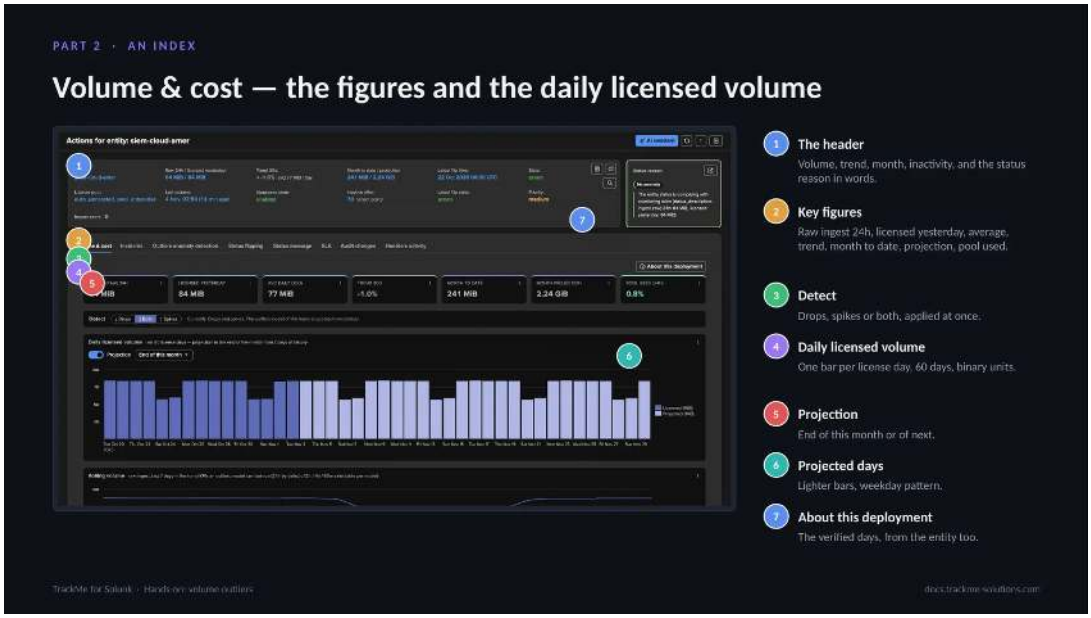
Behind each state sits the outliers model that turns a deviation into a state, with its bounds, its direction and its confidence.

Reading the VOL table columns



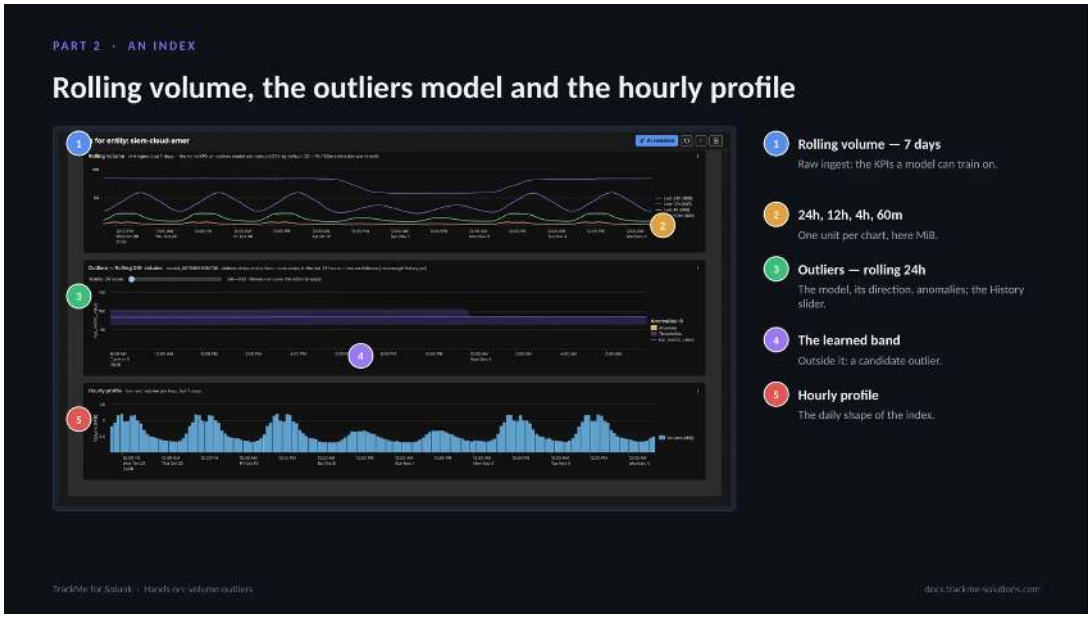
One row per index, grouped by the entity group with the group-by selector above the table (callout 1). The Detect toggle switches the direction in place (callout 2). Ingest (raw) 24h is the rolling raw ingest and Licensed yesterday the licensed volume of the last license day, both in binary units (callout 3); Avg daily and the 30-day trend give the baseline and its direction (callout 4), the month projection follows the weekday pattern (callout 5), Inactivity shows the threshold in force or the tenant policy (callout 6) and Outliers the model state (callout 7). Everything but the Detect toggle and the Inactivity column is computed by the collector every five minutes.

The Volume & cost tab



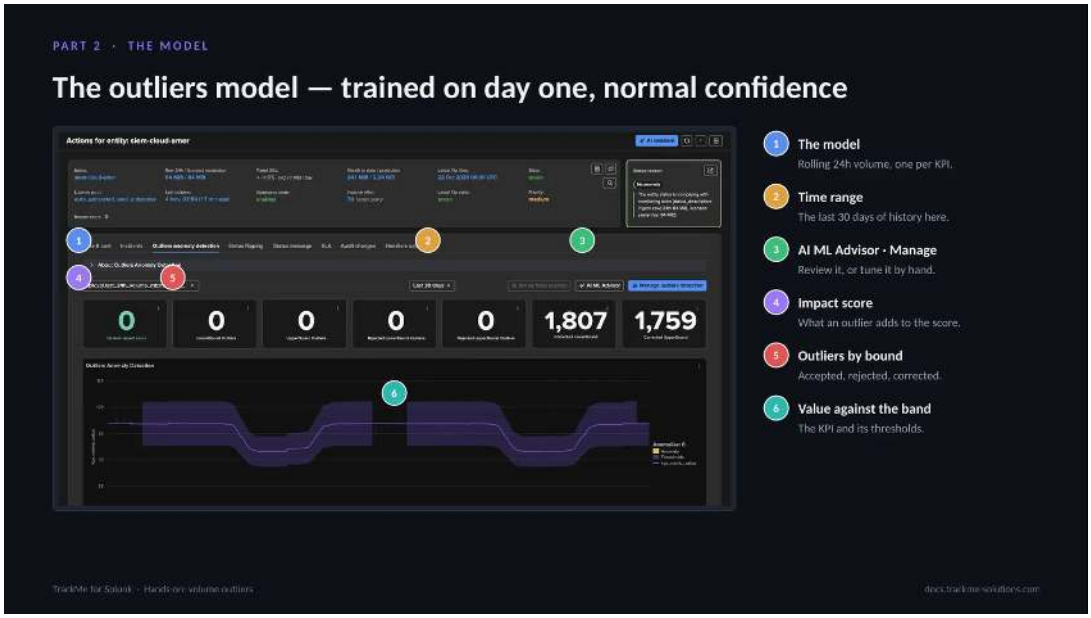
The entity opens on Volume & cost. The header gives the volume, the trend, the month, the inactivity and the status reason in words (callout 1). The key figures (callout 2) are the raw ingest of the last 24 hours, licensed yesterday, the 30-day average, the trend, month to date, the month projection and the pool used; the Detect control applies the direction at once (callout 3). The daily licensed volume chart (callout 4) draws one bar per license day over 60 days, in binary units, with the projection switch (callout 5) and the projected days as lighter bars (callout 6). About this deployment (callout 7) opens the verified days from the entity too.

Rolling volume and hourly profile charts



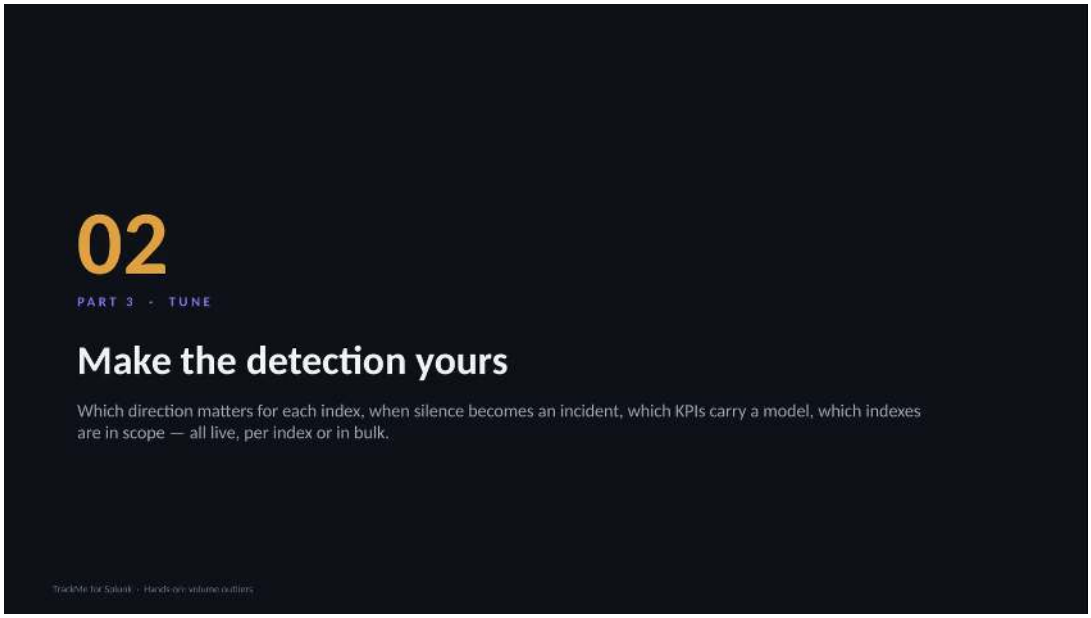
The rolling volume chart (callout 1) draws the last 7 days of the raw ingest, the KPIs a model can train on: 24 hours, 12 hours, 4 hours and 60 minutes, one unit per chart (callout 2). The outliers chart (callout 3) shows the model on the rolling 24-hour volume with its direction and anomalies, and the History slider widens the window; a value outside the learned band is a candidate outlier (callout 4). The hourly profile (callout 5) draws the daily shape of the index, which explains the band.

The outliers model of an index



The Outliers anomaly detection tab carries the model of the index on the rolling 24-hour volume (callout 1) over the time range picked, here the last 30 days (callout 2). AI ML Advisor and Manage outliers detection (callout 3) review it or tune it by hand. The counters give the impact score of an outlier (callout 4) and the outliers by bound, accepted, rejected and corrected (callout 5); the chart draws the KPI against its thresholds (callout 6). Because the history was backfilled, the model reached normal confidence on day one.

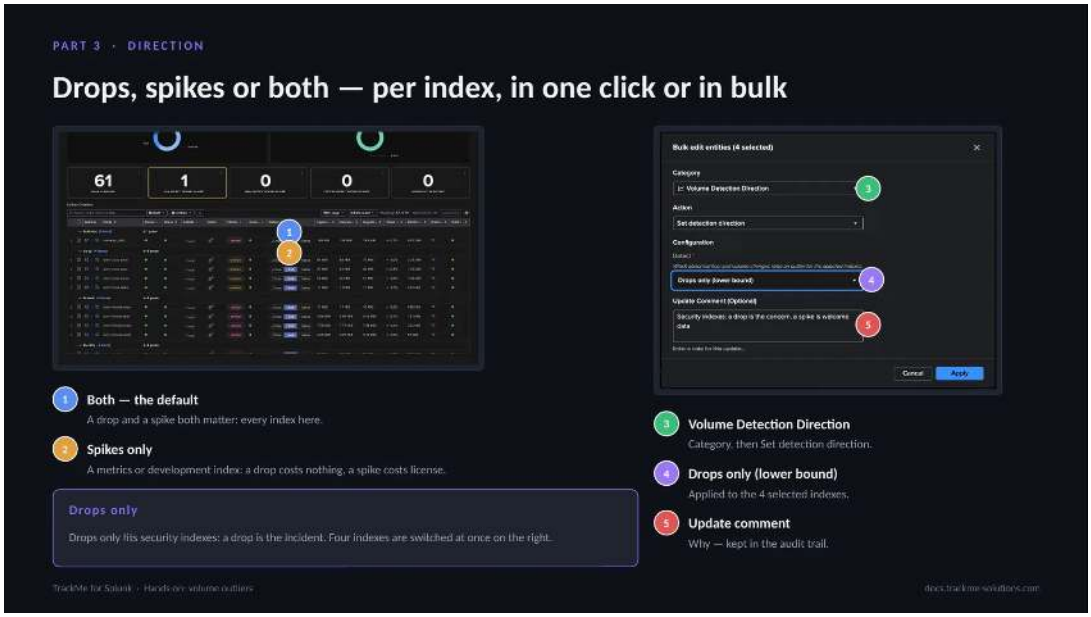
Part 3 — Tune



Part 3 tunes the detection. The defaults are sensible; these are the settings operators actually use: which direction matters for each index, when silence becomes an incident, which KPIs carry a model, and which indexes are in scope.

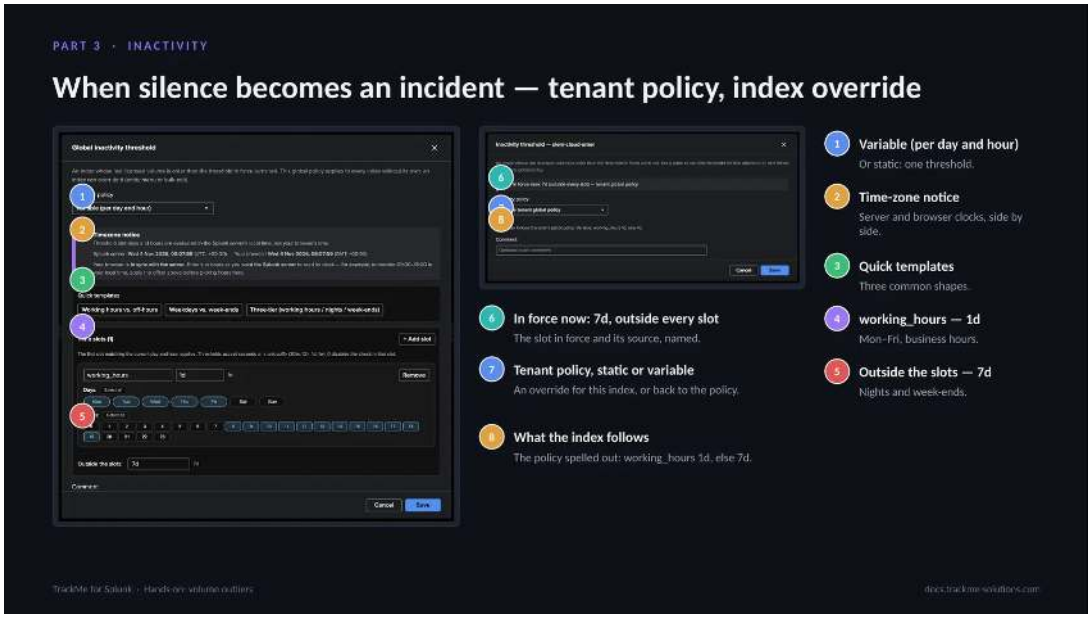
Every setting applies live, per index or in bulk.

Setting the detection direction



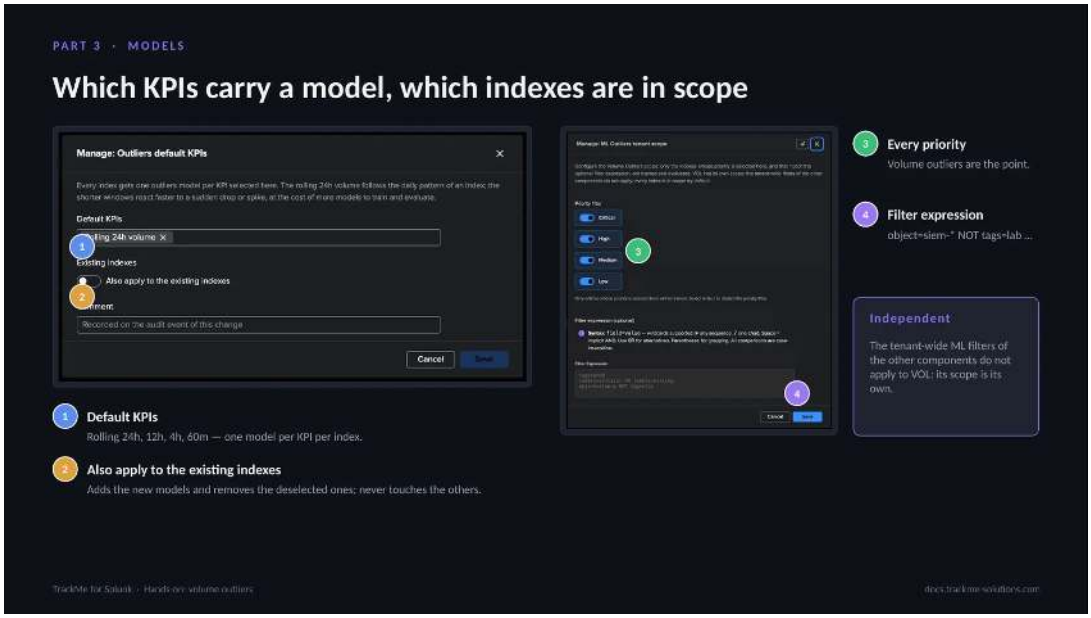
The Detect toggle in the table switches one index (callouts 1 and 2): both directions is the default, a metrics or development index is a spike concern, a security index a drop concern. The bulk edit category Volume Detection Direction (callout 3) applies Drops only, Spikes only or both to a selection (callout 4), with an update comment kept in the audit trail (callout 5). The direction is stored on the index's outliers model and takes effect immediately.

Tenant inactivity policy and index overrides



Manage: Global inactivity threshold edits the tenant policy: variable per day and hour, or static (callout 1), with a time-zone notice that shows the server and browser clocks side by side because the slots are evaluated on the server (callout 2), quick templates (callout 3), the working_hours slot at one day (callout 4) and the threshold outside every slot, seven days (callout 5). The per-index modal names the slot in force and its source before anything changes (callout 6), offers the tenant policy, a static or a variable override (callout 7) and spells out what the index follows (callout 8).

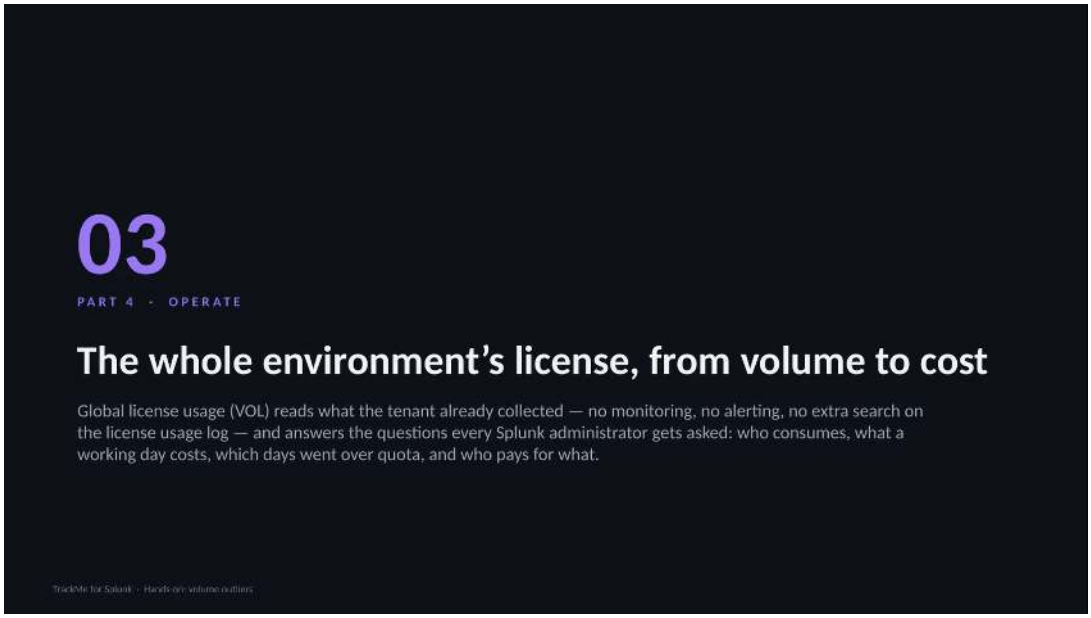
Default KPIs and the outliers scope



Manage: Outliers default KPIs (callout 1) sets the rolling KPIs every new index gets a model on: rolling 24h, 12h, 4h and 60m, one model per KPI per index, the 24-hour volume by default. The shorter windows react faster, at the cost of more models. Also apply to the existing indexes (callout 2) adds the new models and removes the deselected ones, never touching the others.

Manage: ML Outliers tenant scope sets which indexes are trained and evaluated. Every priority is in scope by default (callout 3), and an optional filter expression (callout 4), such as object=siem-* NOT tags=lab, narrows on object, priority, tags, labels and pool. The other components' ML filters do not apply to VOL.

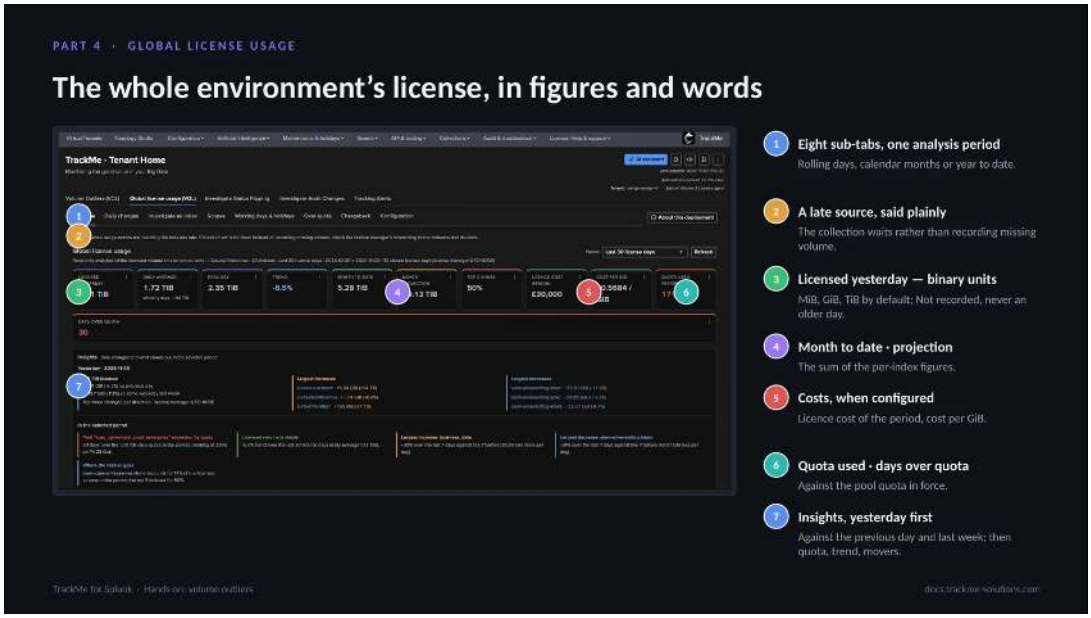
Part 4 — Operate



Part 4 covers the global license usage view, alerting, and the AI Advisors. Global license usage (VOL) takes the whole environment's licence from volume to cost.

It reads what the tenant already collected, with no monitoring, no alerting and no extra search on the license usage log, and answers the questions every Splunk administrator gets asked: who consumes, what a working day costs, which days went over quota, and who pays for what.

Global license usage overview



The Overview of the Global license usage view. Eight sub-tabs share one analysis period (callout 1): Overview, Daily changes, Investigate an index, Scopes, Working days and holidays, Over quota, Chargeback and Configuration, on rolling days, calendar months or the year to date. On this deployment the license manager delivers its events late, and the banner says that the collection waits for them rather than recording missing volume (callout 2). Licensed yesterday is the last closed license day in binary units, MiB, GiB and TiB by default, or Not recorded (callout 3); month to date and the projection sum the per-index figures (callout 4). With costs configured, the licence cost of the period and the cost per GiB appear (callout 5); with a quota in force, the quota used yesterday and the days over quota (callout 6). The insights start with yesterday against the previous day and the same weekday last week (callout 7).

The figures verified against the license log

About this deployment leads with the verification state. Daily figures successfully reconciled means that TrackMe's totals and per-index figures match the detailed Usage records of license_usage.log (callout 1); the days where Splunk's own RolloverSummary reports more or less than those records are listed with the difference in MiB and in percent (callout 2), then the range of days matched against the license manager (callout 3). The Deployment card names the platform, the Usage writer and the monitored indexes (callout 4); the Collection card the collected-through time, the license day frame and the unit labels (callout 5).

Technical details and verification dates lists the license source and one row per day (callout 6) with its status and revision (callout 7), both byte totals, the last successful reconciliation and the next attempt (callout 8).

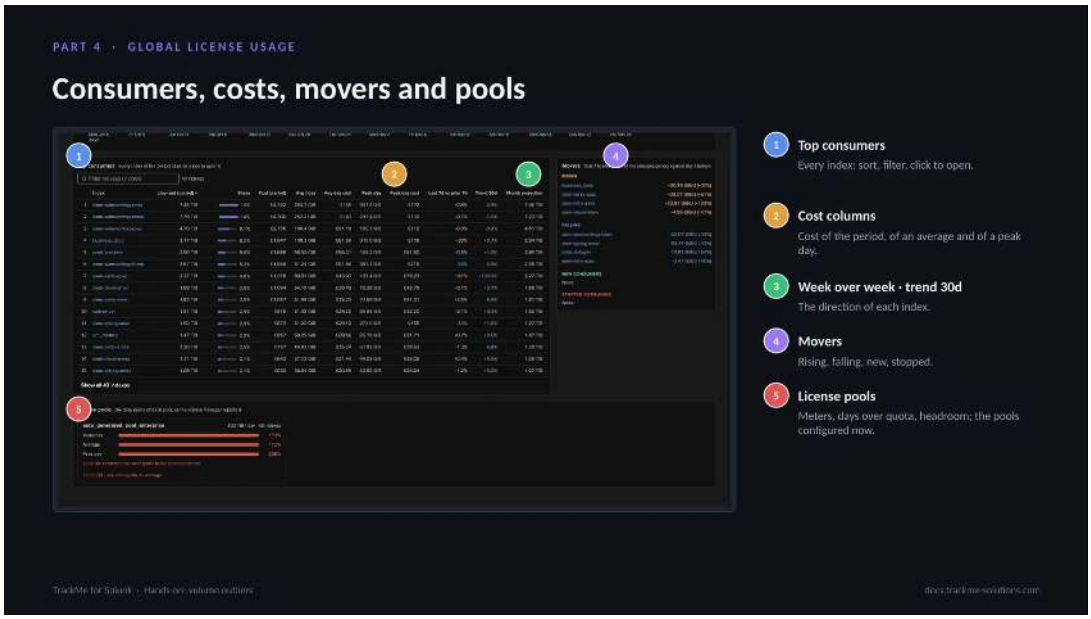
Daily consumption and month-end projection

The first chart stacks the daily consumption per index (callout 3), each closed license day by consumer. The top consumers slider (callout 1) selects 5 to 100 series, with the rest grouped together, and the daily quota line (callout 2) shows the day the pool went over its quota at a glance.

The second chart shows the whole environment with the projection switch (callout 4): to the end of this month or of next month, the same rule as the entity chart. The projected days (callout 5) appear as lighter bars following the

weekday pattern.

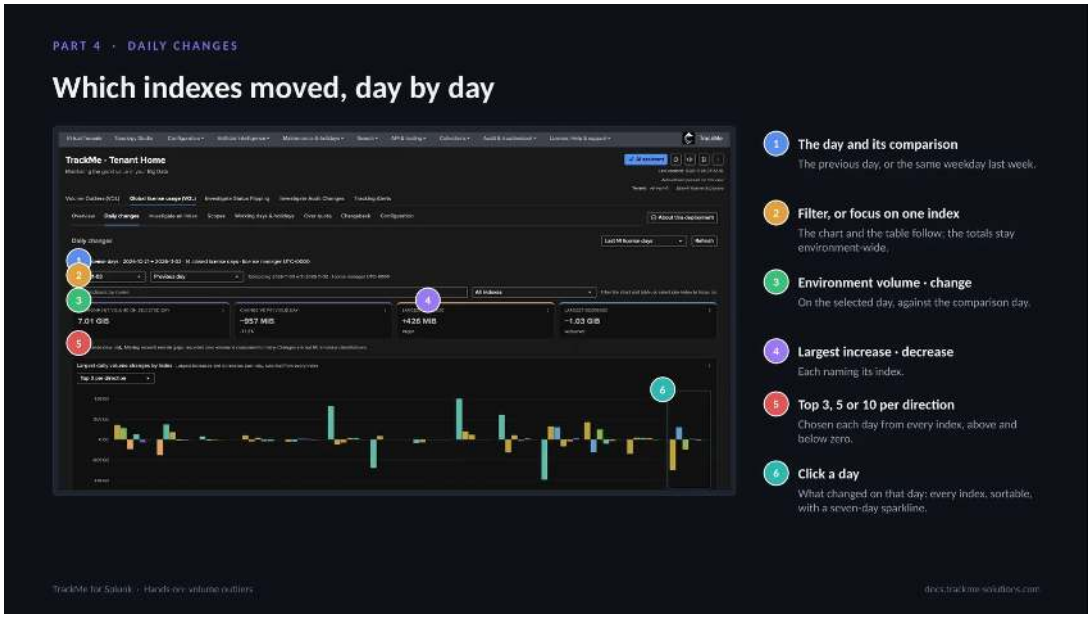
Consumers, costs, movers and pools



The top consumers table (callout 1) lists every index of the period; it sorts, filters and opens an index on click. With costs on, the cost columns (callout 2) give the cost of the period, of an average day and of a peak day, and the week-over-week and 30-day trend columns (callout 3) give each index's direction.

The movers card (callout 4) turns the week-over-week comparison into rising, falling, new and stopped indexes: here siem-osnix-apac rose by 44 %. The license pool card (callout 5) gives the capacity view: meters for yesterday, the average and the peak day, the days over quota and the headroom.

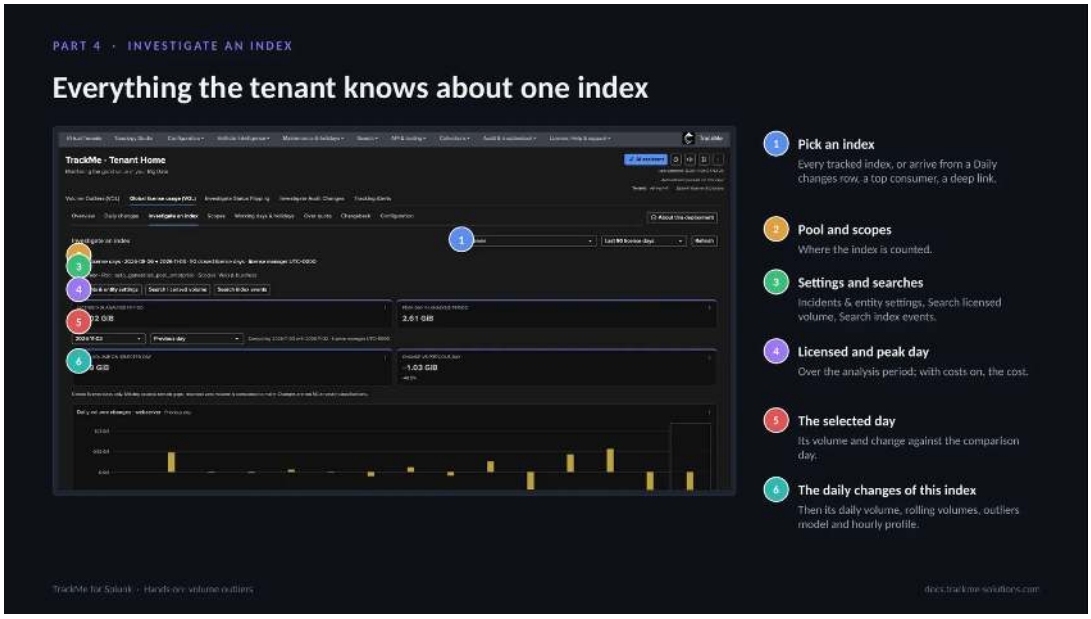
Daily changes



Daily changes compares each closed license day with the previous day or with the same weekday a week earlier (callout 1). Filter indexes narrows the chart and the table by name, and the index selector focuses them on one index (callout 2). The cards give the environment volume on the selected day and its change (callout 3), then the largest increase and the largest decrease, each naming its index (callout 4). The chart ranks the top 3, 5 or 10 increases and decreases of each day, chosen from every index (callout 5); clicking a day opens the What changed on table with

every index, sortable, with a seven-day sparkline (callout 6). Missing days stay gaps and a recorded zero is compared as zero.

Investigate an index



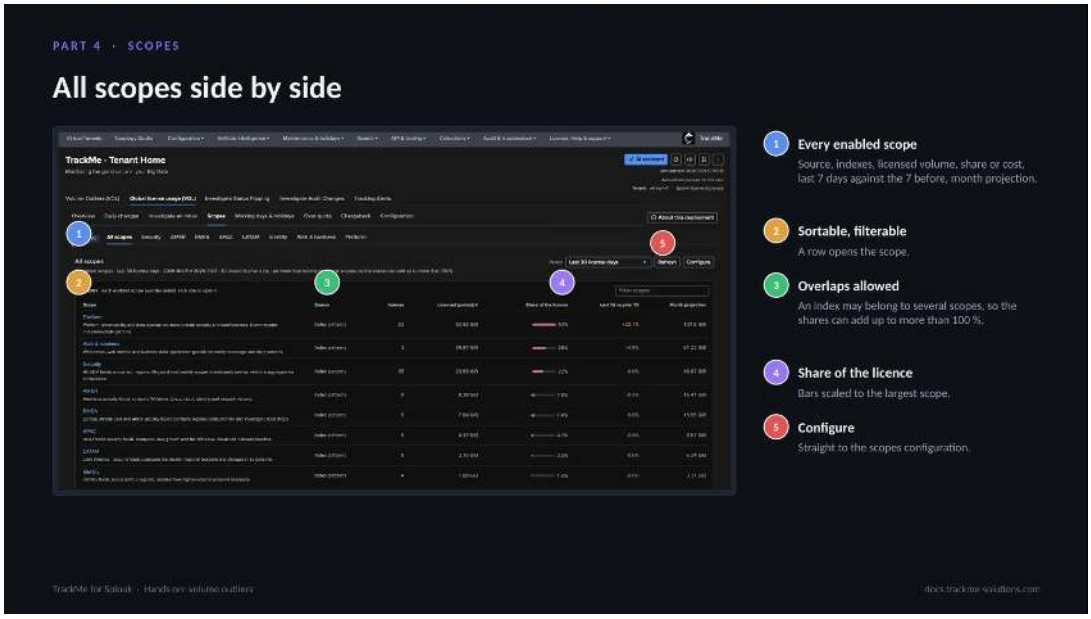
Investigate an index gathers what the tenant knows about one index, read-only. The selector lists every tracked index (callout 1); a row of Daily changes, a top consumer or a deep link arrives here too. The index's pool and scopes (callout 2) and the Incidents & entity settings, Search licensed volume and Search index events buttons (callout 3) sit above the licensed volume and peak day of the analysis period, with the cost when costs are on (callout 4). The selected day is compared with its comparison day (callout 5), followed by the daily changes of this index alone, its daily volume with the projection, the rolling volumes, the outliers model and the hourly profile (callout 6).

Named scopes

A scope is a set of indexes analysed together. The second row holds All scopes and one tab per enabled scope, a filterable selector once they no longer fit (callout 1). The scope's source is index patterns or the CIM datamodel macros, read on this search head or through a remote account on the Enterprise Security tier (callout 2). Its tab gives the licensed volume, the share of the licence or the cost of the period (callout 3), the daily average with the

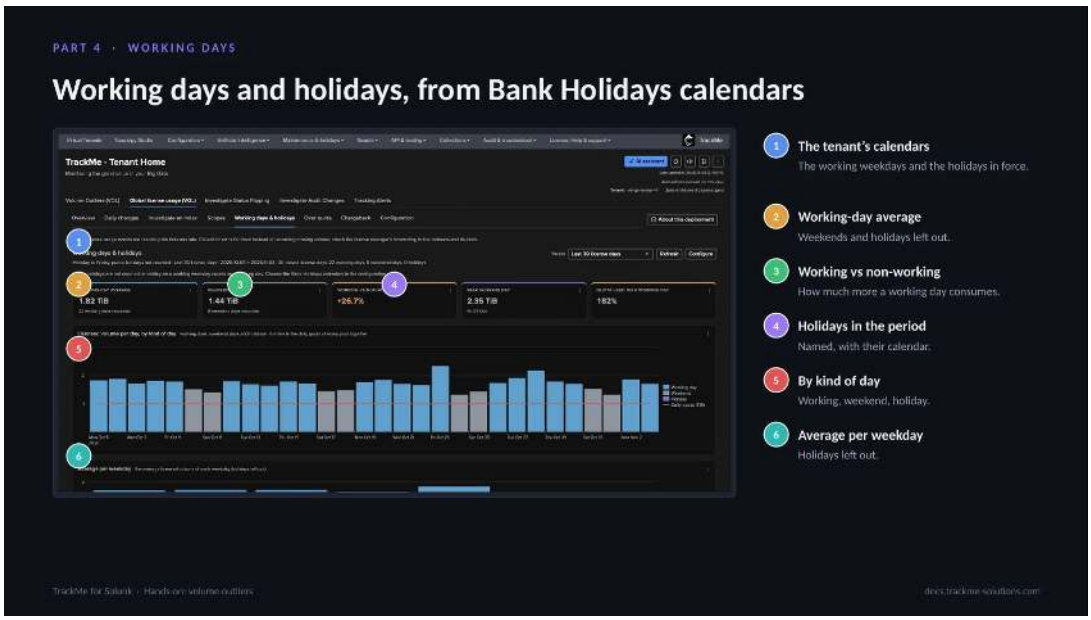
working-day average (callout 4), the peak day, the last 7 days against the 7 before, the month projection, and the daily volume stacked by index with the scope's own projection below (callout 5).

All scopes side by side



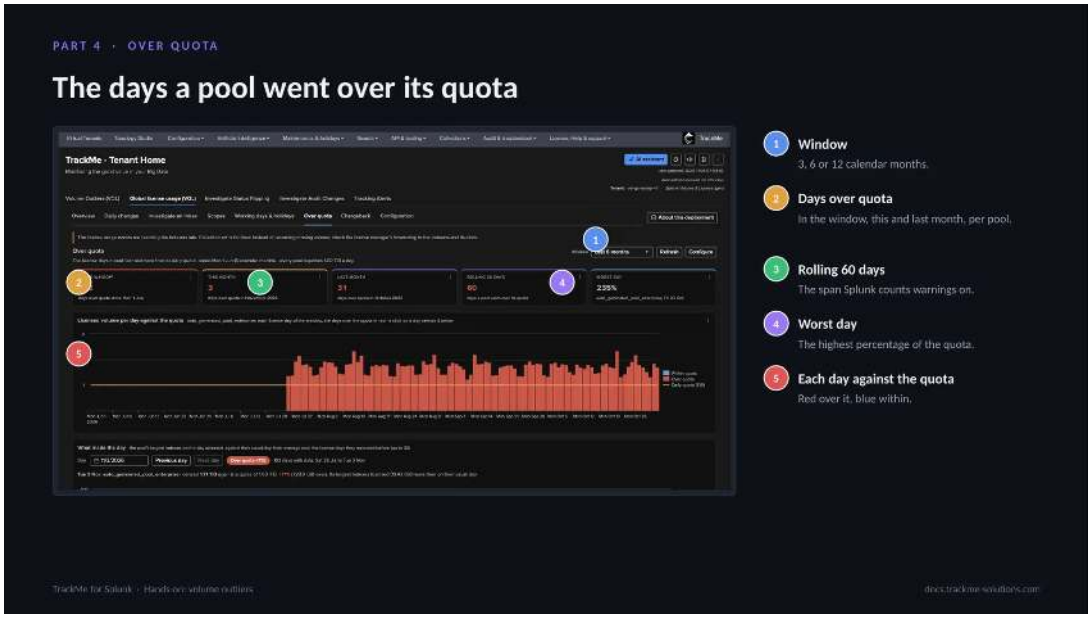
All scopes compares every enabled scope side by side (callout 1): its source, its indexes, the licensed volume of the period, the share of the licence or the cost (callout 2), the last 7 days against the 7 before and the month projection. The headers sort and the filter narrows by name; a row opens the scope. An index may belong to several scopes, so the shares can add up to more than 100 % (callout 3); the share bars are scaled to the largest scope (callout 4). Configure opens the scopes configuration (callout 5). The view is computed from the per-index search the Overview already runs, so it carries no daily average or peak.

Working days and holidays



The Working days & holidays sub-tab separates working days, weekends and holidays. The tenant's calendars and working weekdays are named (callout 1); the working-day average leaves weekends and holidays out (callout 2) and the view says how much more a working day consumes than a non-working one (callout 3); the holidays of the period are listed with their calendar (callout 4). The daily chart colours each license day by kind of day (callout 5) and the average per weekday leaves the holidays out (callout 6).

Days over quota

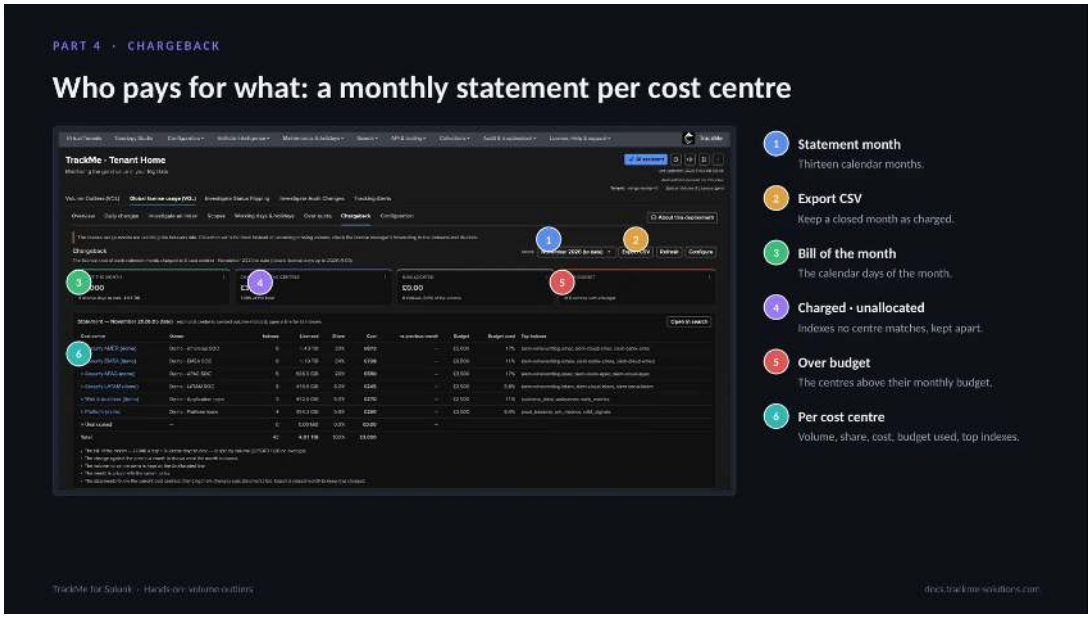


Over quota needs a quota in force: the license manager's pool size on Splunk Enterprise, or a daily quota configured per pool. The window covers 3, 6 or 12 calendar months (callout 1); the cards count the days over quota in the window, this month and last month, per pool (callout 2), the rolling 60 days Splunk counts warnings on (callout 3) and the worst day as a percentage of the quota (callout 4). The chart draws each day against the quota, red over it and blue within (callout 5). These are days over quota, not Splunk license warnings.

What made the day

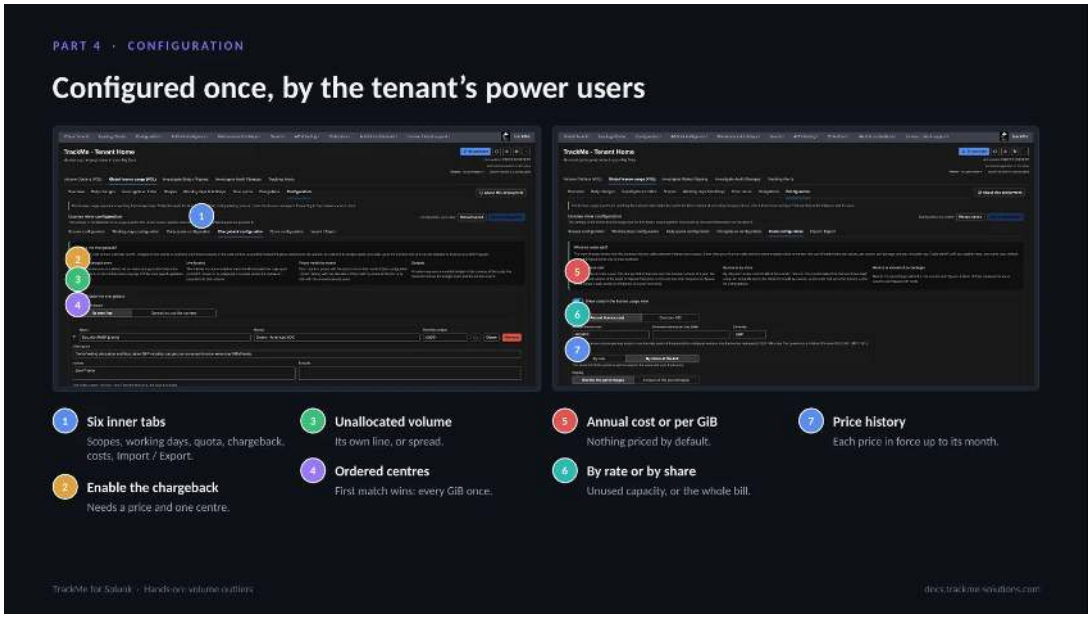
What made the day compares the pool's largest indexes on the day picked with their usual day, their average over the license days they recorded before. The day selector defaults to the latest day over quota (callout 1), Previous day and Next day step through the window (callout 2), and the badge says by how much the day was over or within its quota (callout 3). The chart draws that day against the usual day per index (callout 4), the table reads the same comparison in figures with the share of the day (callout 5), and the list of days over quota opens any of them (callout 6).

Chargeback statement



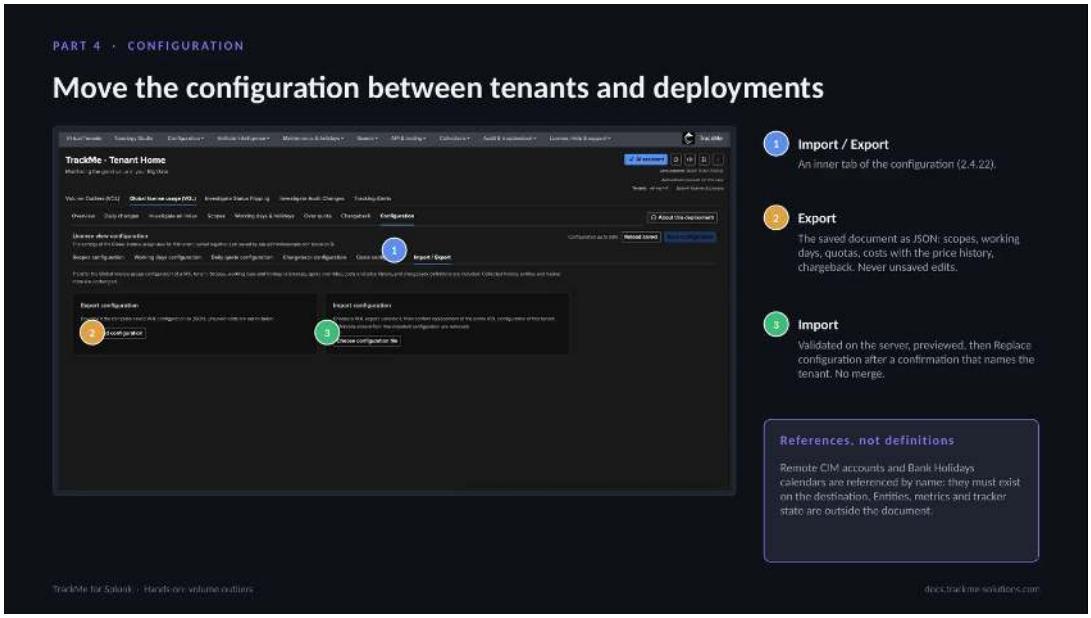
The Chargeback sub-tab turns the licence into a monthly statement per cost centre. The statement month covers thirteen calendar months (callout 1) and Export CSV keeps a closed month as charged (callout 2). The cards give the bill of the month (callout 3), the volume charged to the centres and the unallocated volume kept apart (callout 4) and the centres over their monthly budget (callout 5). The statement lists each centre's volume, share, cost, budget used and top indexes (callout 6), followed by the cost per cost centre month by month. An index belongs to the first centre that matches it, so every GiB is charged once.

Configuring the license view



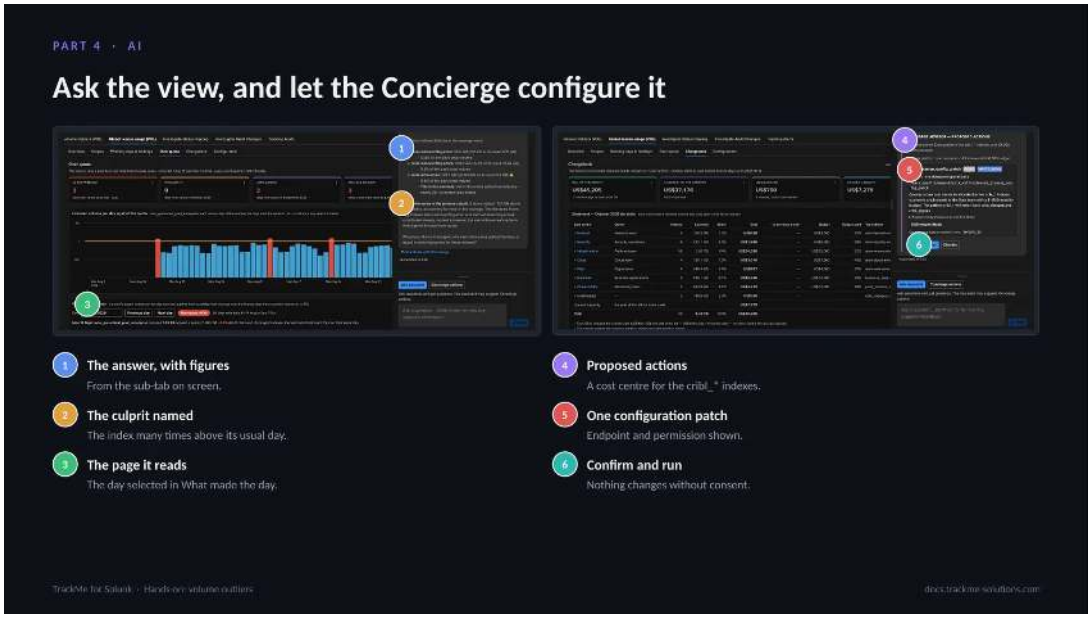
The Configuration sub-tab holds six inner tabs (callout 1): scopes, working days, daily quota, chargeback, costs and Import / Export, saved together with a revision so two people editing at once never overwrite each other. The chargeback section is enabled with a switch (callout 2), keeps the unallocated volume as its own line or spreads it (callout 3) and holds the ordered cost centres with an owner, a monthly budget and include and exclude patterns, previewing the indexes each resolves to (callout 4). The costs section holds an annual licence cost with the licensed volume per day or a cost per GiB (callout 5), the allocation by rate or by share of the bill (callout 6) and the price history, so a renewal never reprices past months (callout 7).

Moving the configuration



Import / Export, an inner tab of the configuration (callout 1), moves the whole document between tenants and deployments. Export downloads the saved configuration as a JSON file: scopes, working days, quotas, costs with the price history and chargeback, never unsaved edits (callout 2). Import reads such a file, validates it on the server, shows the summary and the JSON, and Replace configuration replaces the destination's document after a confirmation that names the tenant, with no merge (callout 3). Remote CIM accounts and Bank Holidays calendars are referenced by name and must exist on the destination.

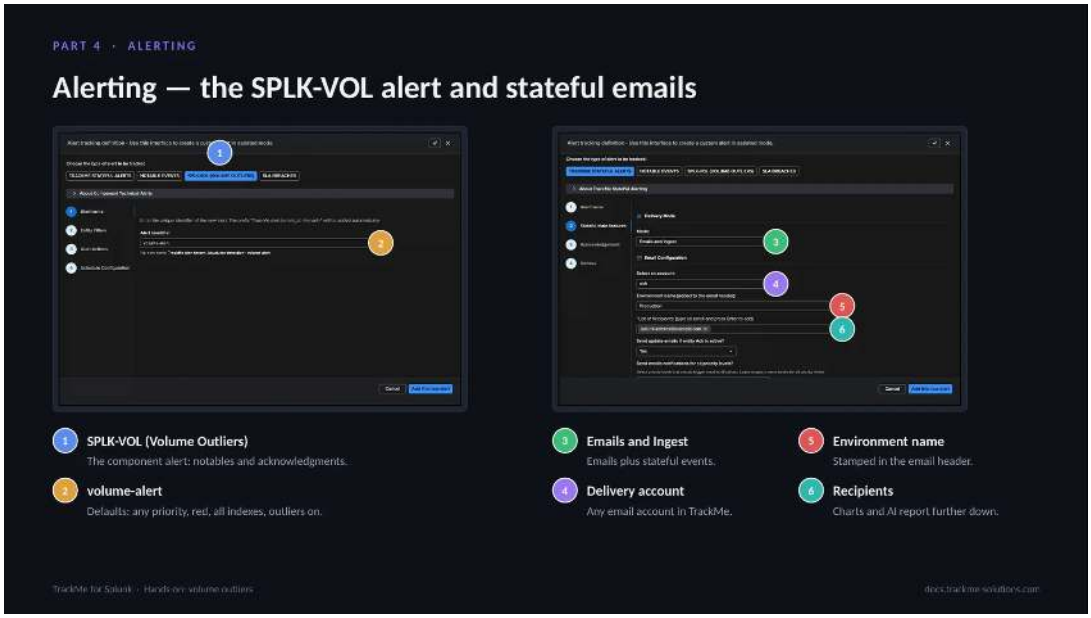
The AI Assistant on the license view



While the license view is open, the Tenant Home AI Assistant works on it. Asked what made the pool go over its quota on 14 September, it answers with the figures of the sub-tab on screen (callout 1) and names the culprit (callout 2), siem-infra-emea, from the day selected in What made the day (callout 3).

Asked to add a cost centre for the cribl_* indexes, it proposes the change through the Concierge (callout 4): one configuration patch with its endpoint and permission (callout 5), applied only on Confirm and run (callout 6), audited, and reloaded by the view.

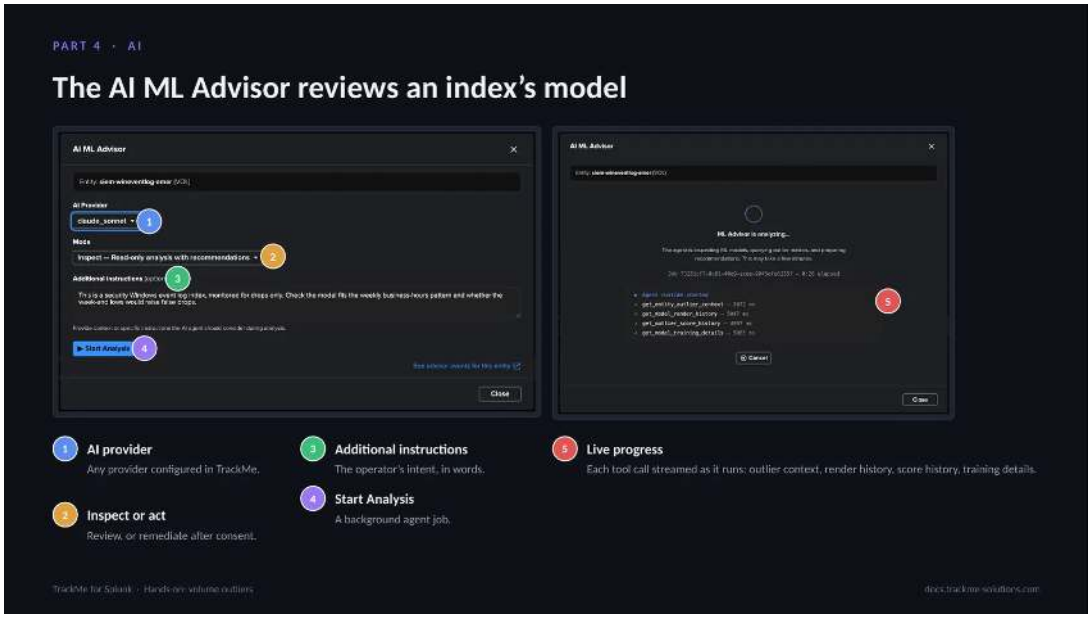
Configuring alerting for red indexes



Volume Outliers alerts like any TrackMe component. The SPLK-VOL (Volume Outliers) alert type (callout 1) generates the notable events and acknowledgments for red indexes; its defaults (callout 2) are any priority, red, all indexes, outliers on. The outliers trigger stays on because the outliers are the state of this component; the same alert covers inactivity.

A TrackMe stateful alert, volume-alert here, sends the opened, updated and closed emails. Emails and Ingest (callout 3) delivers emails plus stateful events; the delivery account (callout 4) is any email account in TrackMe; the environment name (callout 5) is stamped in the email header; the recipients (callout 6) sit further down with the charts and the optional AI status report.

Launching the AI ML Advisor

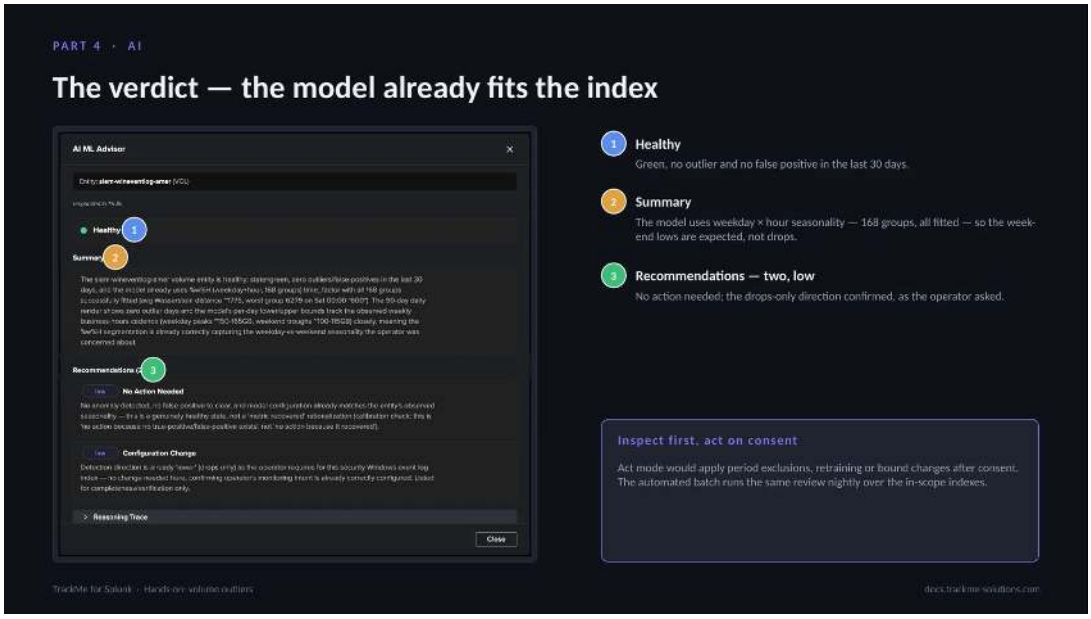


From the Outliers tab of an index, the AI ML Advisor runs as a background agent job with read tools: the entity, its model rules, the outlier and score history, the training details. The AI provider (callout 1) is any provider configured in TrackMe. Inspect or act (callout 2) chooses between a review that changes nothing and a remediation applied after consent.

Additional instructions (callout 3) carry the operator's intent in words: this security index is monitored for drops only;

does the model fit the weekly business-hours pattern, and would the week-end lows raise false drops? Start Analysis (callout 4) launches the job, and the live progress feed (callout 5) streams each tool call as it runs.

Reading the advisor verdict



The verdict is Healthy (callout 1): green, with no outlier and no false positive in the last 30 days. The summary (callout 2) answers with evidence from the model itself: it uses weekday × hour seasonality, 168 groups, all fitted, so the week-end lows are expected rather than drops, and its bounds track the weekday peaks and the week-end troughs. The two recommendations (callout 3) are low: no action needed, the drops-only direction confirmed.

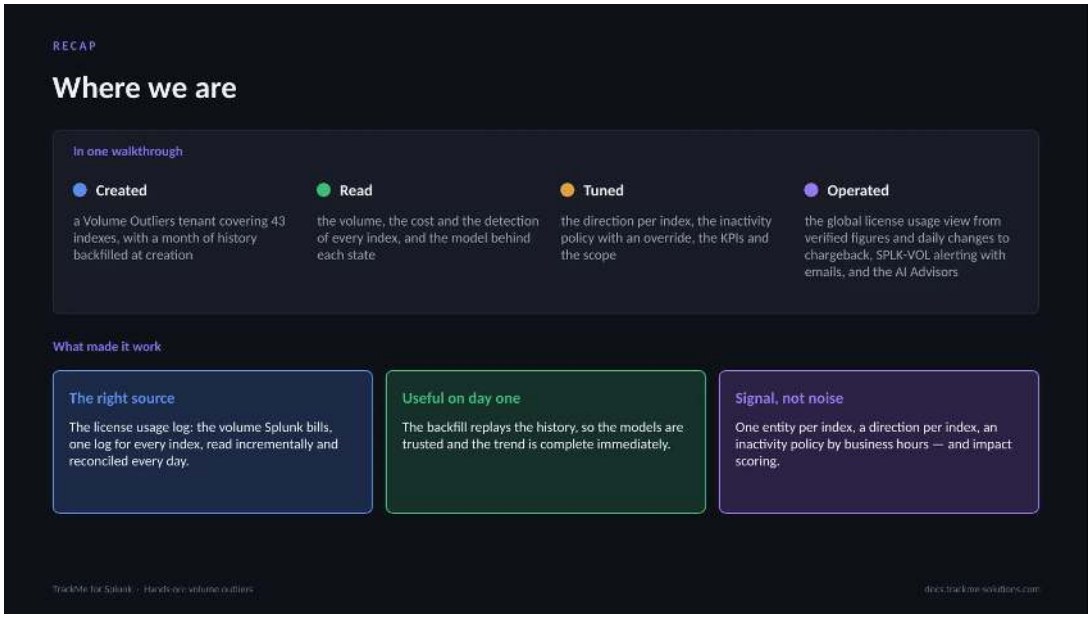
The advisor explains why nothing changes rather than rationalising a recovered metric; the reasoning trace shows every step. Act mode would apply period exclusions, retraining or bound changes after consent. The automated batch runs the same review nightly over the in-scope indexes.

Running cost of the component

Collection is one bounded search per tenant every 5 minutes, reading only the new license usage events, whatever the number of indexes: no per-index and no per-sourcetype scan. Metrics cost about 216 KB per index per day of metric-index licensing; the backfill writes the same series over the chosen depth, and the wizard shows the estimate.

Models are one per index on the rolling 24 hours; the VOL scope and the default KPIs control how many. Live and backfill never overlap, the window waits for a late source and every closed day is reconciled against the license usage log, and a failed search never advances the cursor, so missing volume is never recorded as a drop. The rolling values come from the buckets TrackMe holds, not from its own metrics.

Where we are



One tenant watches the licensed volume of every index. The backfill makes it useful on day one; the table, the entity screen and the model explain every figure, in binary units and verified against the license usage log every day; the direction per index, the inactivity policy with its overrides, the default KPIs and the scope make the detection the operator's own. The Global license usage view, from the verified figures and the daily changes to the scopes, the working days, the days over quota, the costs and the chargeback, SPLK-VOL alerting with stateful emails and the AI Advisors take the component into operations.

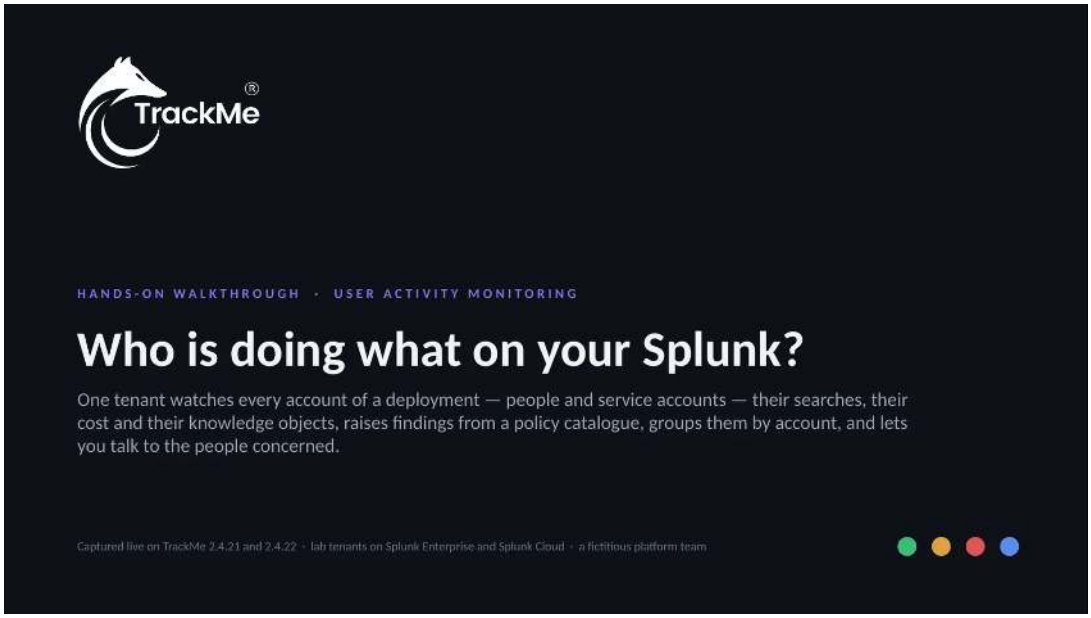
2.1.8 User Activity Monitoring

Who is doing what on your Splunk: one tenant watches every account through the audit trail, the introspection and the REST API catalogs, raises findings from sixteen built-in policies and your custom policies, groups them by account, lets you investigate, assign and email the people concerned, and maps which indexes are read, by whom, and what the unread data costs.

`Download the deck (PDF) · PowerPoint`

about 48 minutes · 48 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

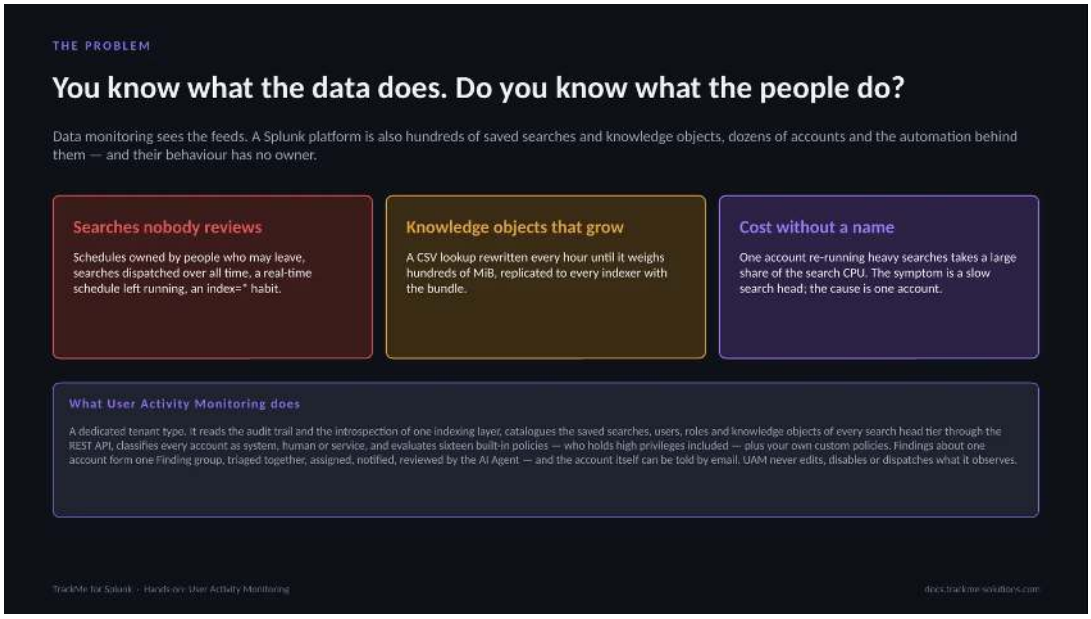
Overview



User Activity Monitoring (UAM) is a dedicated tenant type of TrackMe, generally available since 2.4.19. One tenant watches every account of a deployment: their searches, their cost and the knowledge objects they own. It raises findings from a policy catalogue, groups them by account, and lets operators talk to the people concerned.

Everything shown here was captured live on TrackMe 2.4.21 and 2.4.22: on a tenant watching two search head tiers of one indexing layer, on a second lab tenant for the screens that need a longer history, and on a Splunk Cloud tenant with seven thousand accounts. The accounts that appear, alice.moreau, jane.doe, ben.okafor, svc-siem and others, are fictitious names of a small platform team. Five parts follow: setup, reading and grouping, communicating, tuning and operating, and Data usage.

The other half of the platform



Data monitoring sees the feeds. A Splunk platform is also hundreds of saved searches and knowledge objects, dozens of accounts and the automation behind them, and their behaviour has no owner. Three cards name the symptoms: searches nobody reviews, knowledge objects that grow (a CSV lookup rewritten every hour until it weighs hundreds of MiB) and cost without a name (one account taking a large share of the search CPU).

UAM reads the audit trail and the introspection of one indexing layer, catalogues every search head tier through the

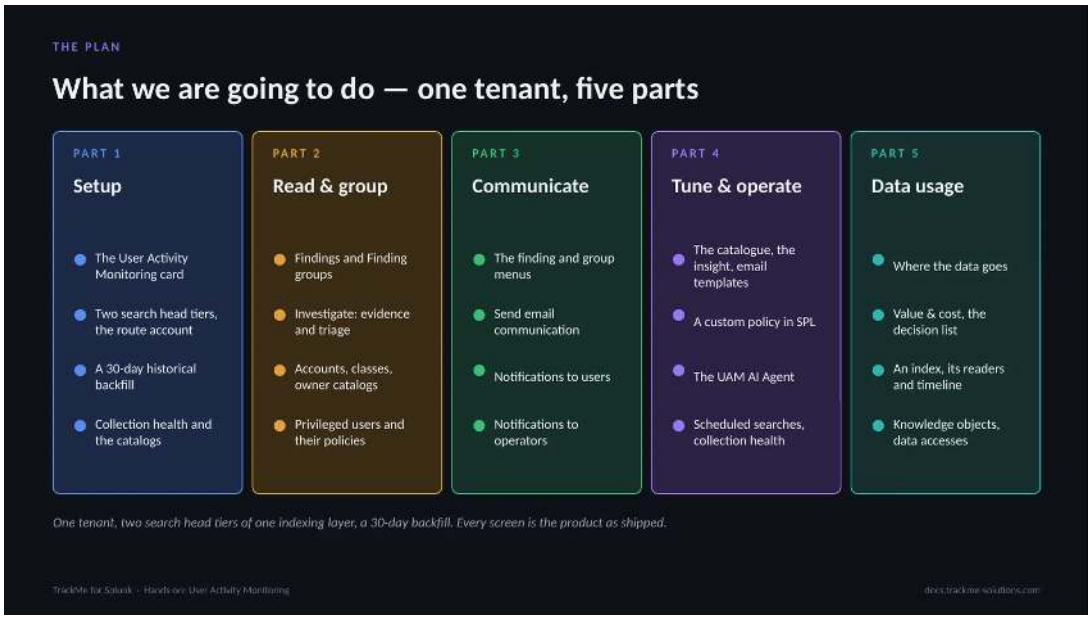
REST API, classifies every account as system, human or service, and evaluates sixteen built-in policies, who holds high privileges included, plus custom policies. It never edits, disables or dispatches what it observes.

From sources to Finding groups

Five stages make the model. Sources: the audit trail, the introspection, and the REST API of every search head tier. Reports: catalogs per tier, three indexing-layer trackers (Audit activity, Resource usage, Account signals), policies every fifteen minutes and a bounded backfill. Evidence: compact trackme:uam:* records in the tenant indexes. Classes: system, human or service. Finding groups: the sixteen built-in and the custom policies raise findings, and an account with its saved searches forms one Finding group.

On top of the findings sit the triage, assignment, notifications, emails to the account concerned, findings actions and the UAM AI Agent. An account is the one Splunk reports in its audit trail, not a verified person, and collection never drops data: what a run cannot do carries over.

Five parts, one tenant



The walkthrough has five parts. Setup creates the tenant from the User Activity Monitoring card, with two search head tiers, the route account and a 30-day backfill, then checks the collection health. Read and group covers the

findings and Finding groups, the investigation, the accounts with their classes and owner catalogs, and the privileged users.

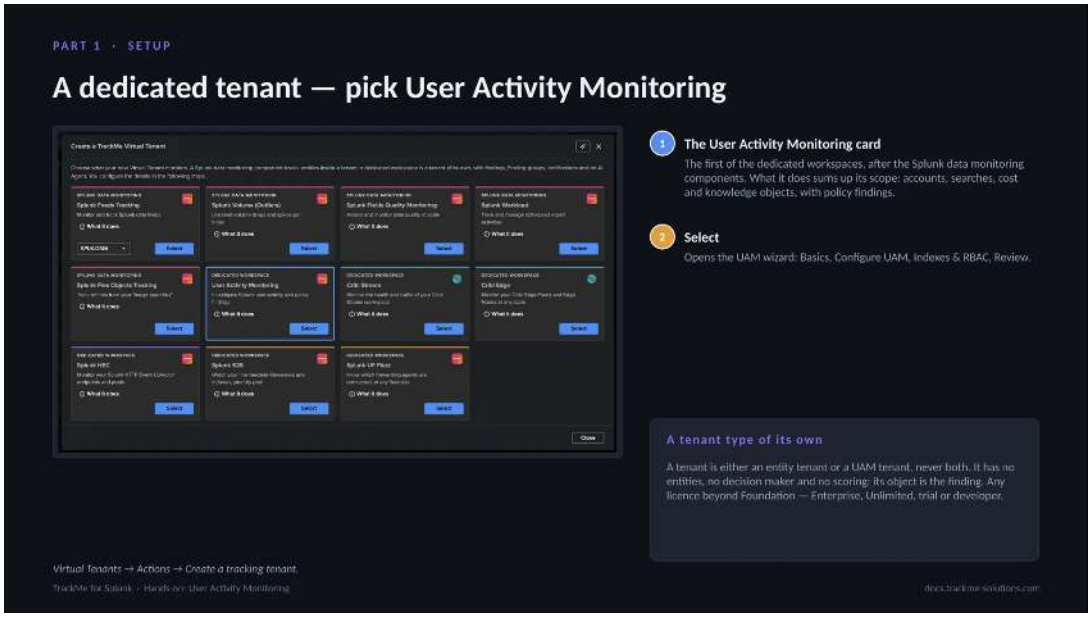
Communicate covers the menus, the email communication and the notifications. Tune and operate covers the policy catalogue, a custom policy in SPL, the UAM AI Agent and the scheduled searches. Data usage shows where the data goes, value and cost, an index in depth, the knowledge objects and an account's data accesses. Every screen is the product as shipped.

Part 1 — Setup

The first part creates the tenant and follows its first collection: the User Activity Monitoring card, the search head tiers and the route account, the historical backfill, then the tenant card, the status strip and the collection health on day one.

The wizard has four steps. Within minutes of the creation the catalogs of every tier are published and the first activity records arrive, and Collection health shows every report at work.

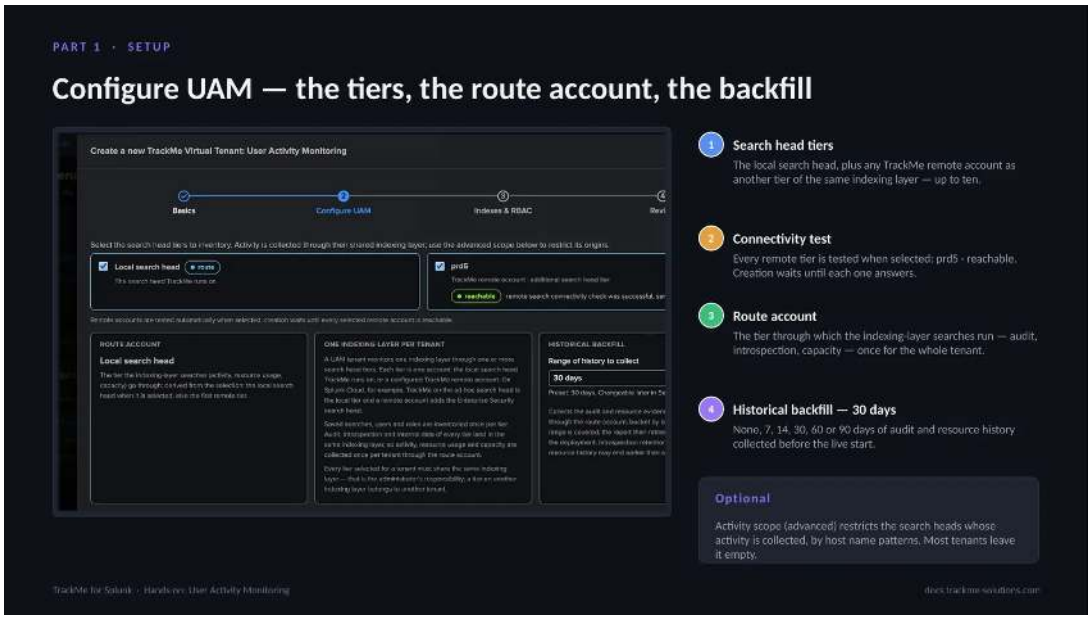
Choosing the tenant type



Virtual Tenants, Actions, Create a tracking tenant opens the chooser. The User Activity Monitoring card is the first of the dedicated workspaces, after the Splunk data monitoring components; What it does sums up its scope: the accounts, searches, cost and knowledge objects of one indexing layer, with policy findings grouped by account. Select opens the UAM wizard: Basics, Configure UAM, Indexes & RBAC, Review.

A tenant is either an entity tenant or a UAM tenant, never both. A UAM tenant has no entities, no decision maker and no scoring: its object is the finding. It requires any licence beyond Foundation: Enterprise, Unlimited, trial or developer.

Tiers, route account and backfill



Configure UAM shapes the tenant. Search head tiers lists the local search head plus any TrackMe remote account as another tier of the same indexing layer, up to ten. Every remote tier is tested when selected (here prd5, reachable), and creation waits until each one answers. The route account is the tier through which the indexing-layer searches run (audit, introspection, capacity), once for the whole tenant.

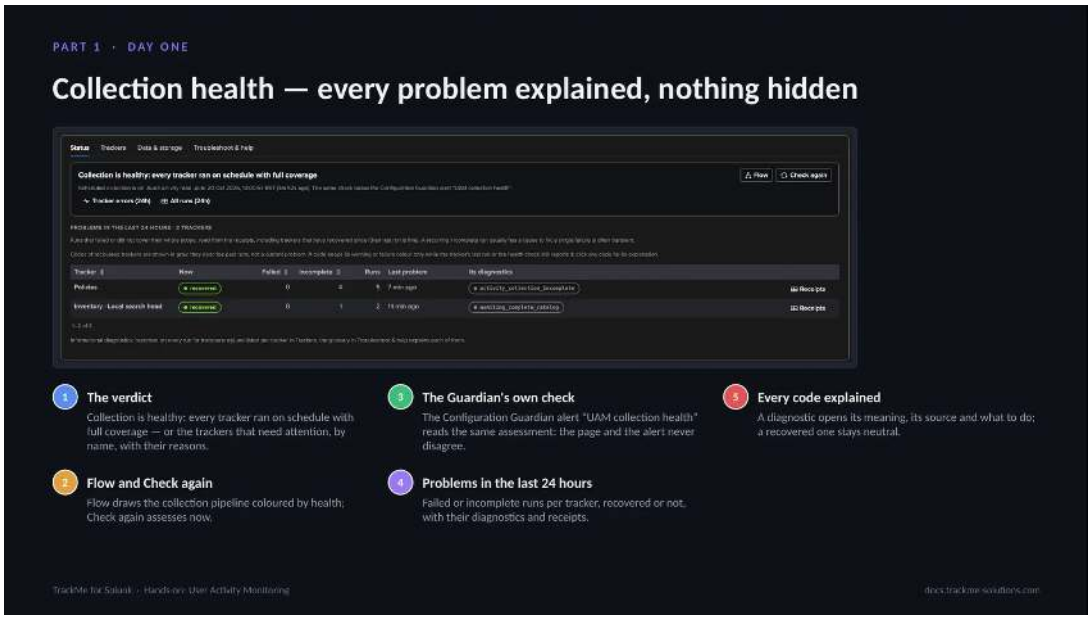
The historical backfill collects none, 7, 14, 30, 60 or 90 days of audit and resource history before the live start; 30 days are chosen here, so that classification and the first findings are meaningful on day one. The optional activity scope restricts the collected search heads by host name patterns.

Status at a glance

On the Virtual Tenants page, the tenant card shows the open Finding groups and findings (10 groups, 36 findings), the high or critical ones, and the collection status, here the backfill at 16 %. Selecting the card opens the workspace; a double-click opens a read-only overview.

Inside the workspace, the status strip summarises the collection: the tiers with the route marked, the age of the inventory, Audit activity, Resource usage, Account signals and policies runs, the checkpoint lag and the coverage. Refresh and Collect now sit on the right; Collect now runs every report on demand.

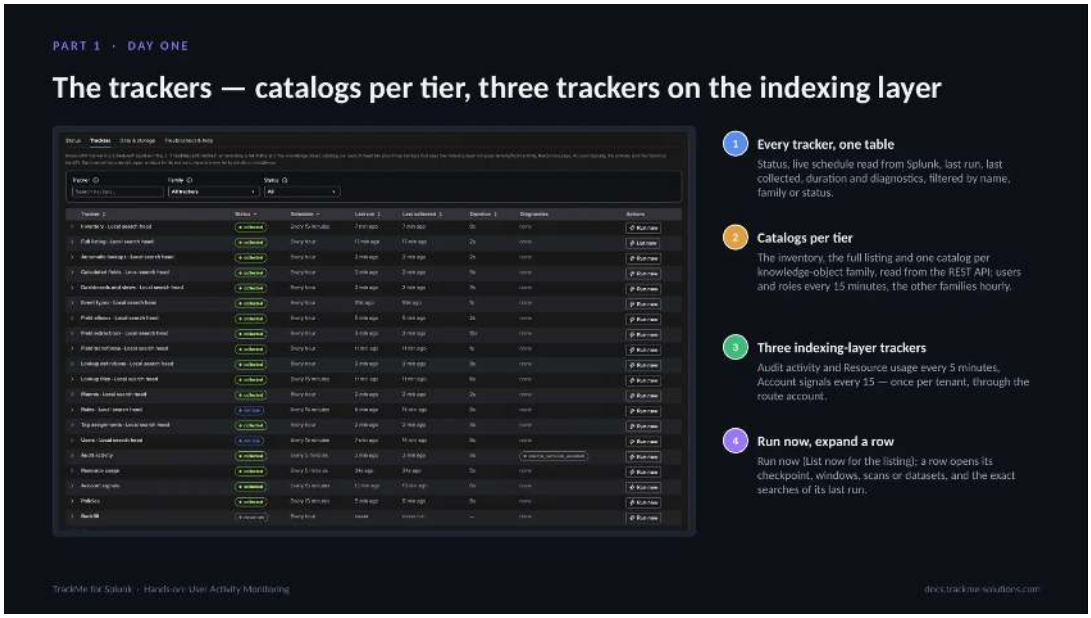
Day one in Collection health



Collection health answers one question: is UAM collecting what it should, and if not, why and what to do. The Status view gives the verdict, here Collection is healthy: every tracker ran on schedule with full coverage, or names the trackers that need attention with their reasons. Flow and Check again sit beside it. The Configuration Guardian alert UAM collection health reads the same assessment, so the page and the alert never disagree.

Problems in the last 24 hours lists the failed or incomplete runs of each tracker, recovered or not, with their diagnostics and receipts. Every diagnostic opens its meaning, its source and what to do; a code that only describes a recovered run stays neutral. The other views are Trackers, Data & storage and Troubleshoot & help.

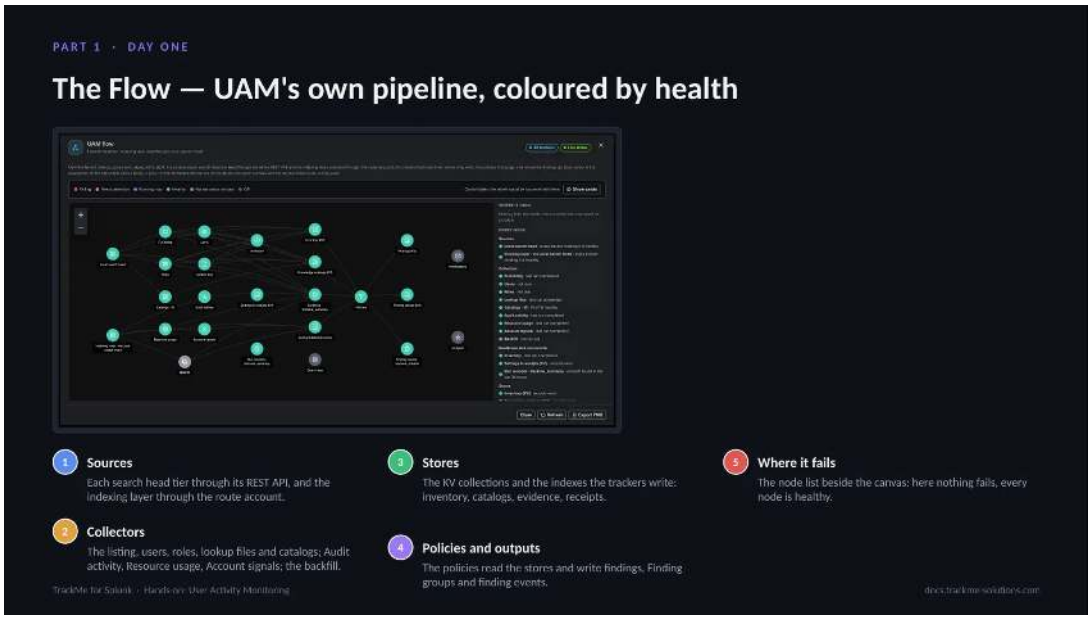
Every tracker in one table



The Trackers view lists every UAM report with its status, its live schedule read from Splunk, last run, last collected, duration and diagnostics, filtered by name, family or status. Per search head tier come the inventory, the full listing and one catalog per knowledge-object family, read from the REST API: users and roles every 15 minutes, the other families hourly, each published on its own so one slow family never blocks the others.

Once per tenant, through the route account, three trackers read the indexing layer: Audit activity and Resource usage every 5 minutes, Account signals every 15. Run now dispatches a tracker (List now for the full listing), and a row expands to its checkpoint, windows, scans or datasets and the exact searches of its last run.

The collection pipeline

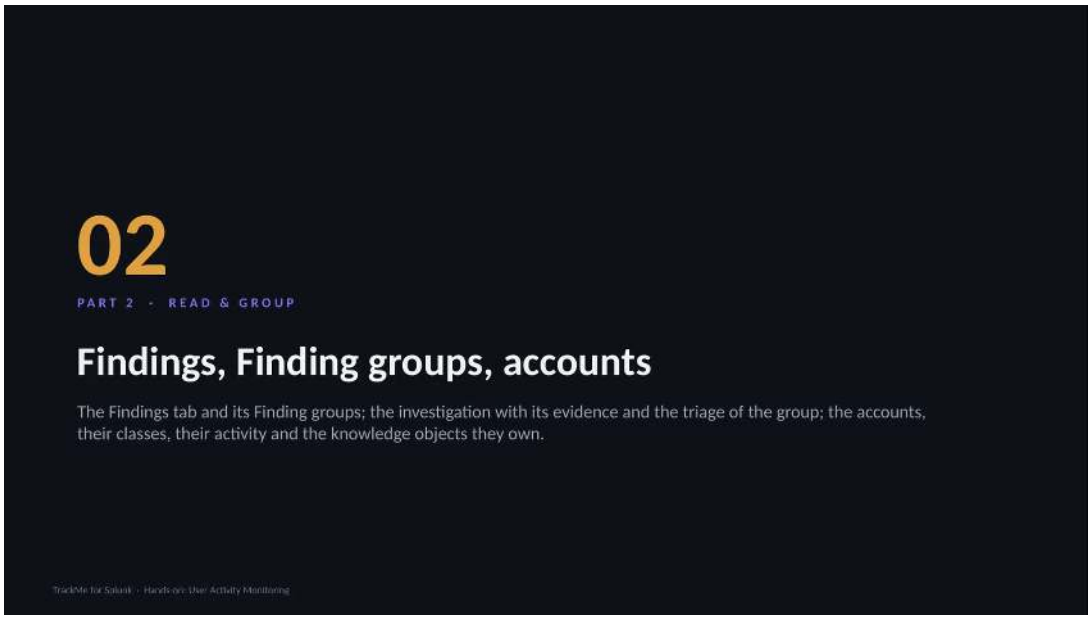


Flow, opened from the Status view, draws how the tenant collects, stores and judges, left to right: the sources (each search head tier through its REST API, and the indexing layer through the route account), the collectors, the stores they write (the KV collections and the indexes) and the policies with the findings, Finding groups and finding events they produce.

Each node is coloured by the same assessment as the Status view: failing, needs attention, running now, healthy, not run yet or off. The list beside the canvas names where it fails; here nothing fails and every node is healthy. The view

exports as a PNG.

Part 2 — Read and group



The second part is about reading what the tenant found: the Findings tab and its Finding groups, the investigation with its evidence and the triage of the group, then the accounts, their classes, their activity and the knowledge objects they own.

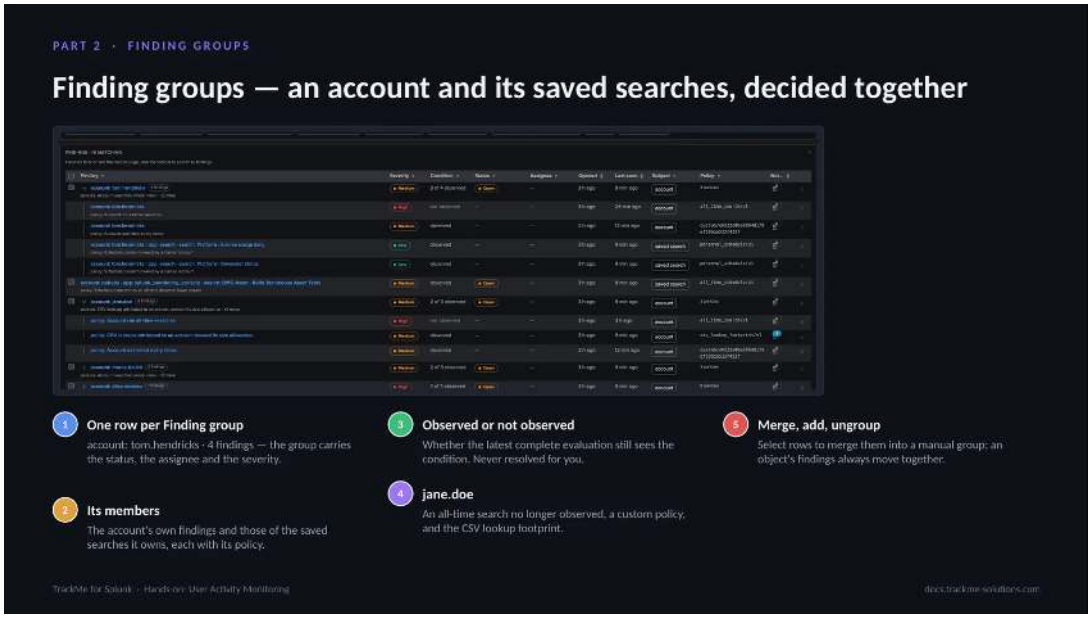
Findings about the same account and the saved searches it owns form one Finding group, decided on together.

The findings backlog

The Findings tab is the backlog. The tiles count Finding groups: here 9 open groups holding 12 findings, 7 of them high or critical, with the groups new in the range, assigned to the current user, resolved and dismissed. Finding transitions charts the reobserved, unobserved and updated findings over the last 24 hours.

By severity shows where the weight is across low, medium and high. By policy shows which policies raised what: accounts that ran all-time searches, scheduled searches owned by a human account and repeated resource-intensive searches. Below the charts come the filters and one row per Finding group.

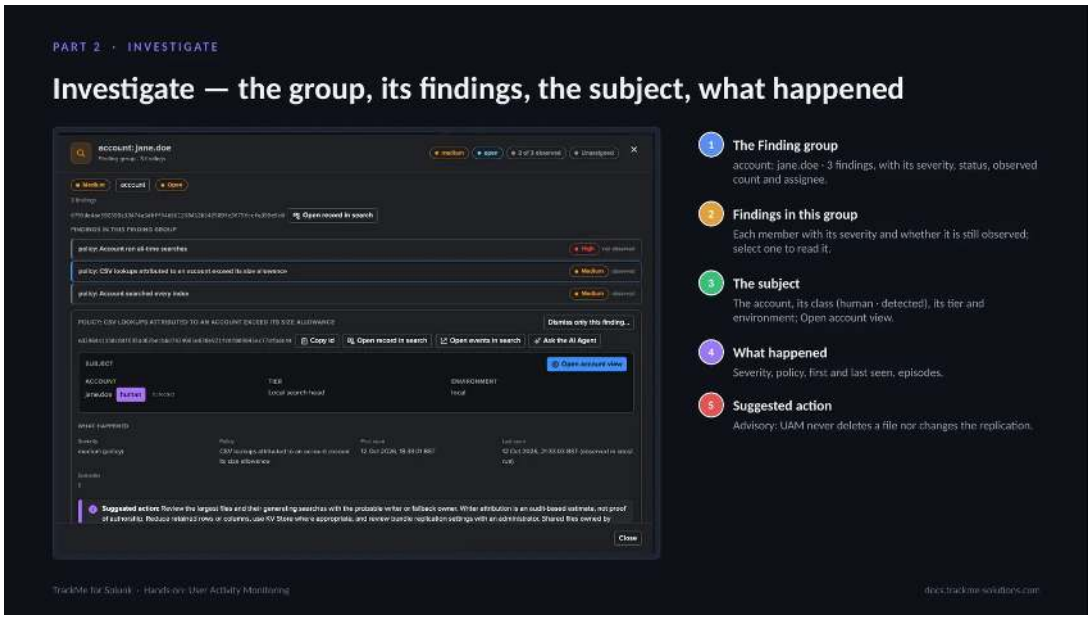
One decision per account



All findings about the same account and the saved searches it owns automatically form one Finding group. Each row is a group, for example account: tom.hendricks with 4 findings; the group carries the status, the assignee and the severity, and expands to its members, each with its policy and its own evidence.

The condition column says whether the latest complete evaluation still observes the condition; a finding that is no longer observed stays listed until a person resolves it. The jane.doe group combines an all-time search no longer observed, a custom policy and the CSV lookup footprint. Selecting rows merges them into a manual group; an object's findings always move together.

The investigation view

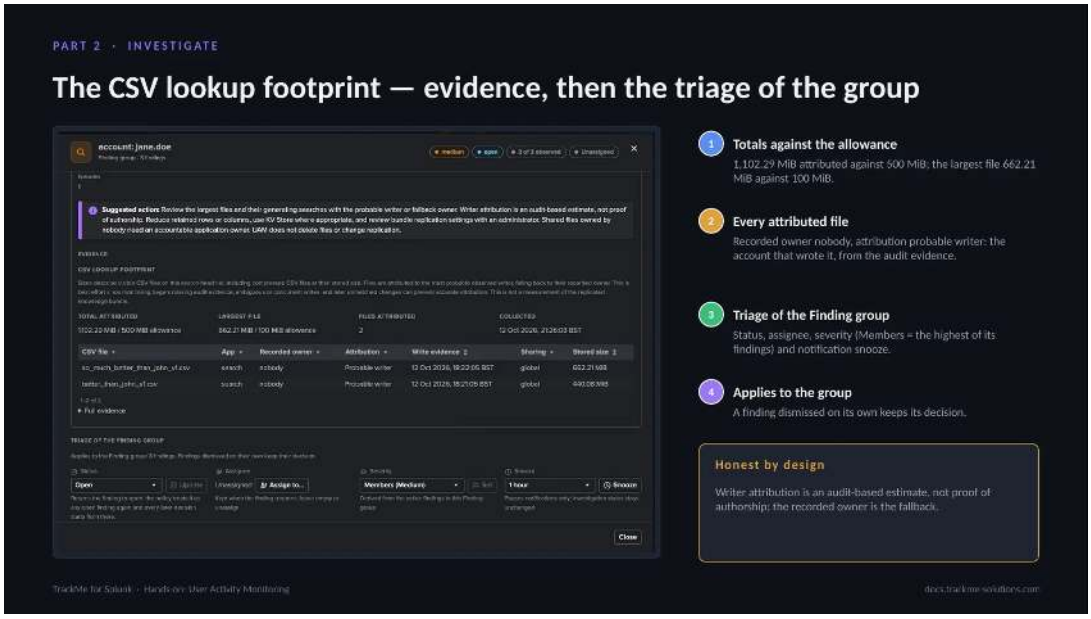


Investigate opens the whole case. The header names the Finding group, account: jane.doe with 3 findings, with its severity, status, observed count and assignee. Findings in this group lists each member with its severity and whether it is still observed; selecting one shows it below.

For the CSV lookup footprint finding, the subject section shows the account, its class (human, detected), its tier and environment, with Open account view. What happened gives the severity, the policy, the first and last seen times and

the episodes. The suggested action is advisory: UAM never deletes a file nor changes the replication. Copy id, Open record in search, Open events in search and Ask the AI Agent complete the view.

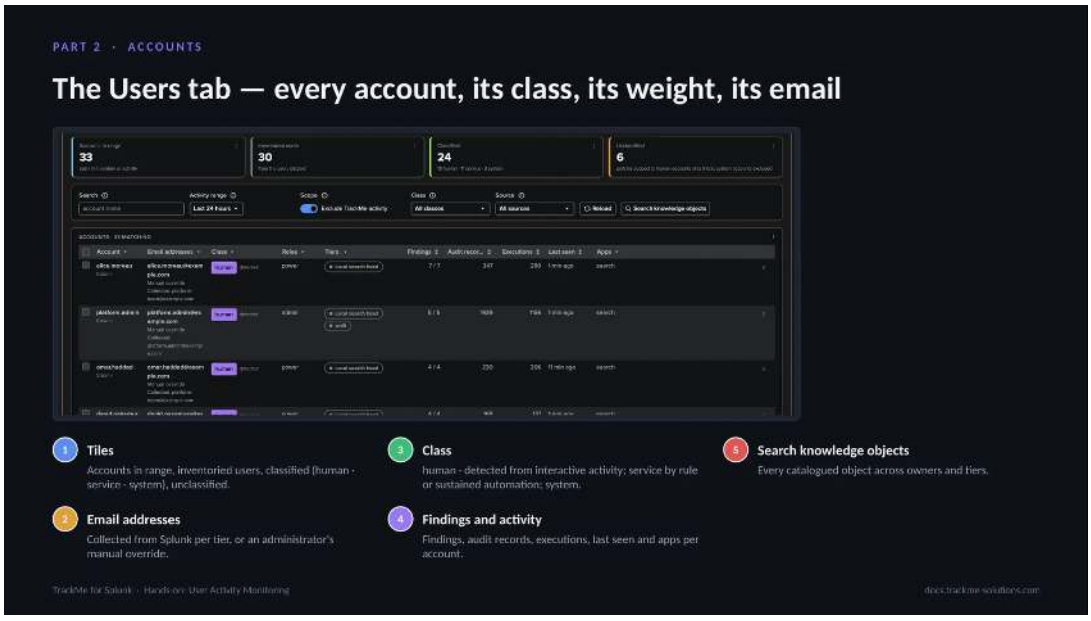
Evidence and triage of the group



The CSV lookup footprint policy came with 2.4.19. The evidence totals 1,102.29 MiB of CSV lookups attributed to jane.doe against a 500 MiB allowance, with a largest file of 662.21 MiB against 100 MiB. Every attributed file is listed: the recorded owner is nobody, and the attribution is probable writer, the account that wrote the file according to the audit evidence. Writer attribution is an audit-based estimate, not proof of authorship; the recorded owner is the fallback.

Below the evidence, the triage applies to the whole Finding group: status, assignee, severity (Members means the highest of its findings) and notification snooze. A finding dismissed on its own keeps its decision.

Every account in one table

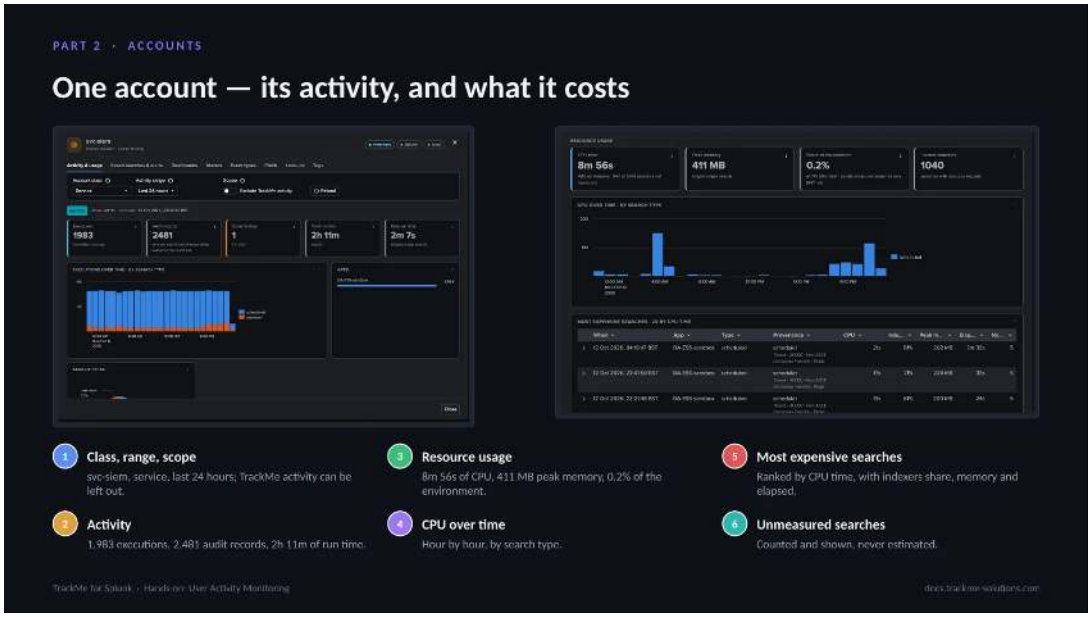


The Users tab is the account-centric view. The tiles count the accounts in range, the inventoried users, the classified accounts (human, service, system) and the unclassified ones. Each row shows the email address, collected from

Splunk per tier or set by an administrator as a manual override; that address is where notifications to users and email communications are sent.

The class column shows human (detected from interactive activity), service (by rule or sustained automation) or system. Findings, audit records, executions, last seen and apps complete the row. Search knowledge objects opens a search over every catalogued object across owners and tiers.

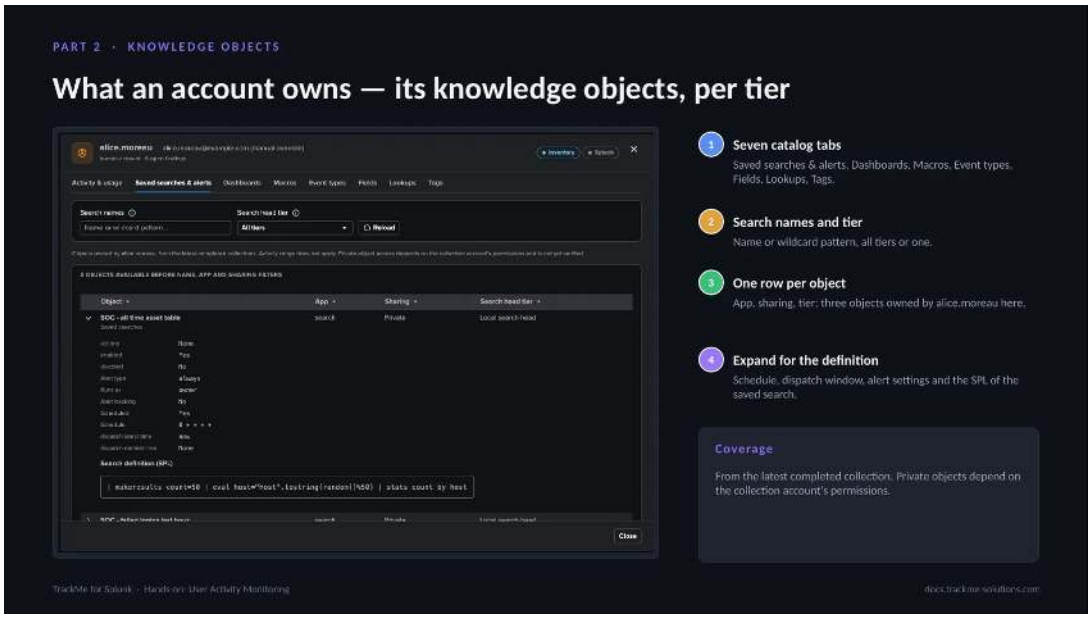
Activity and cost of one account



The account view gathers everything about one account, here svc-siem, a service account, over the last 24 hours. The top shows its class, the activity range and the scope, then the tiles: 1,983 executions, 2,481 audit records, one open finding and 2h 11m of run time, with the executions over time by search type and the app it works in.

Further down, the resource usage tells what the account costs: 8m 56s of CPU time, 411 MB peak memory and 0.2% of the environment, with CPU over time and the most expensive searches ranked by CPU time. Searches the resource records could not measure are counted and shown, never estimated. Seven catalog tabs list what the account owns.

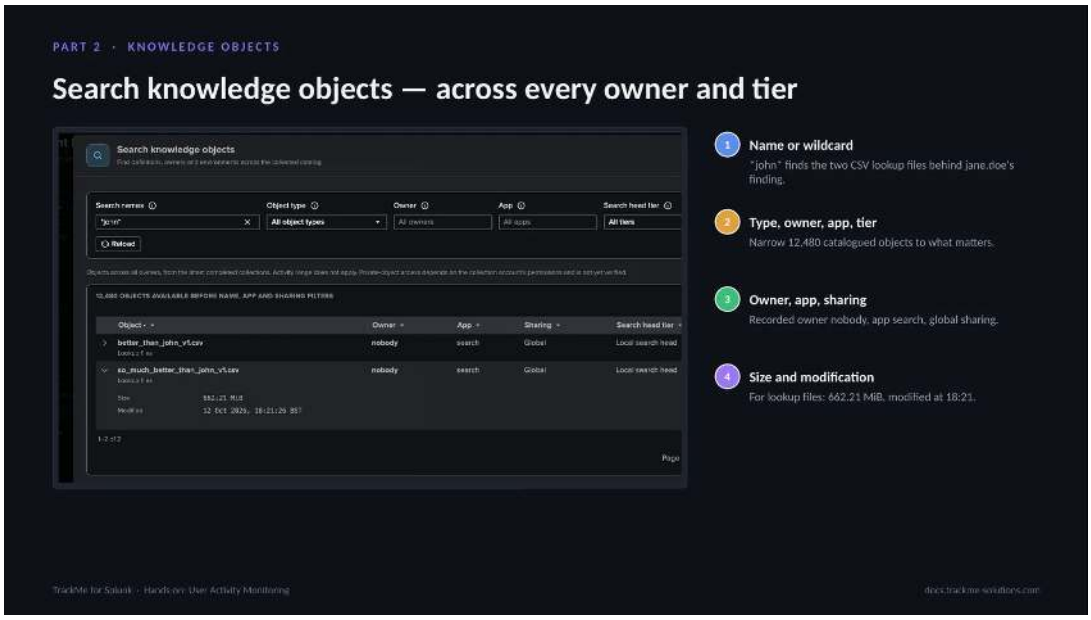
What an account owns



The seven catalog tabs of the account view (Saved searches & alerts, Dashboards, Macros, Event types, Fields, Lookups, Tags) answer the question every offboarding asks: what does this account own? A name or wildcard pattern and a search head tier narrow the list; here three objects are owned by alice.moreau, each with its app, sharing and tier.

Expanding a saved search shows its definition: schedule, dispatch window, alert settings and SPL. The data comes from the latest completed catalog collection, not from a live call, and private objects depend on the permissions of the collection account.

Finding objects across owners



Search knowledge objects runs one search across the catalogued objects of every tier and owner. The name *john* finds the two CSV lookup files behind jane.doe's footprint finding; the object type, owner, app and search head tier narrow the 12,480 catalogued objects.

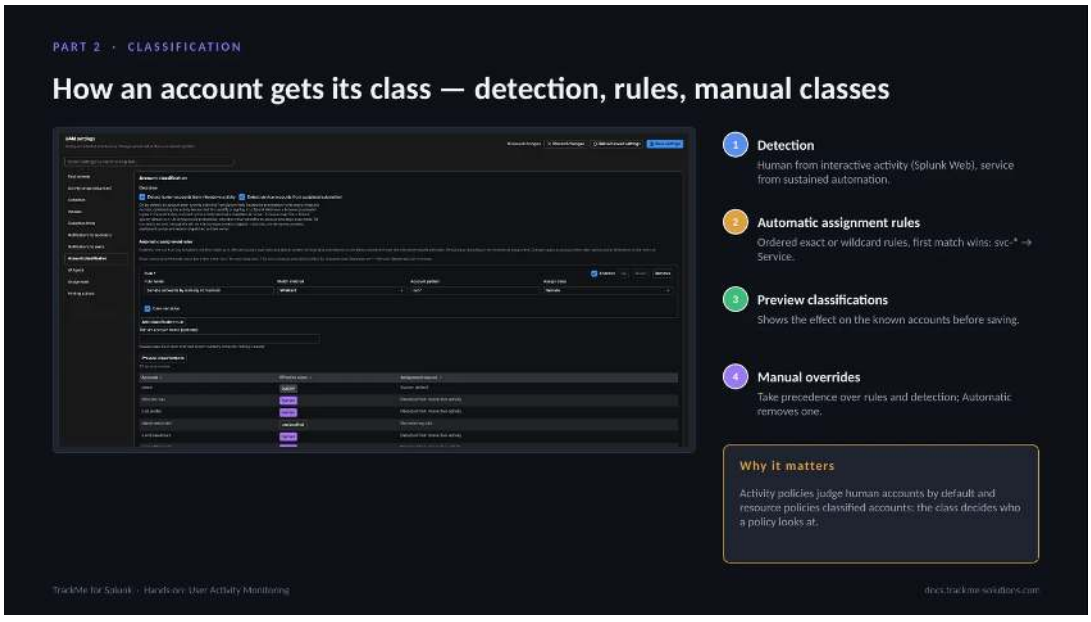
Each row shows the owner, app and sharing, here recorded owner nobody, app search, global sharing. For lookup files, the expanded row adds the size and the last modification: 662.21 MiB, modified at 18:21. The files are owned by nobody and were written by jane.doe, which is exactly the case the writer attribution resolves.

The raw audit evidence

The Activity tab is the raw evidence: one record per search and window rather than one line per audit event. The time range and scope sit on top; Exclude TrackMe activity leaves out the searches run in the trackme app. Evidence switches between the audit records and the executions correlated per search id, and the account and app filters narrow the view, here to alice.moreau.

The chart shows the records over time by account source, with history from the backfill. The table lists the 500 most recent records with search id, outcome, run time and evidence state; Inspect opens a record. This is the material every activity policy is evaluated on.

Account classification

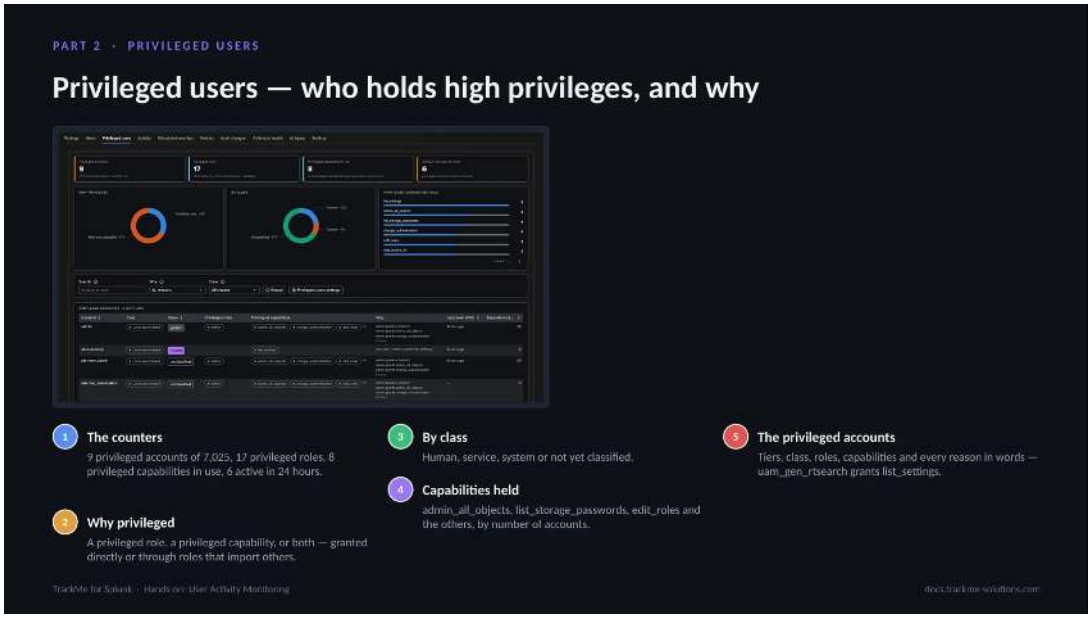


Settings, Account classification decides who each policy looks at: activity policies judge human accounts by default, resource policies classified accounts. Detection classifies an account as human from interactive activity in Splunk Web and as service from sustained automation.

Automatic assignment rules are ordered exact or wildcard rules where the first match wins; the rule svc-* to Service classifies every service account that will ever be created. Preview classifications shows the effect on the known

accounts before saving. Manual overrides take precedence over rules and detection, and Automatic removes one. Precedence is always manual class, Splunk system defaults, the first matching rule, then detection.

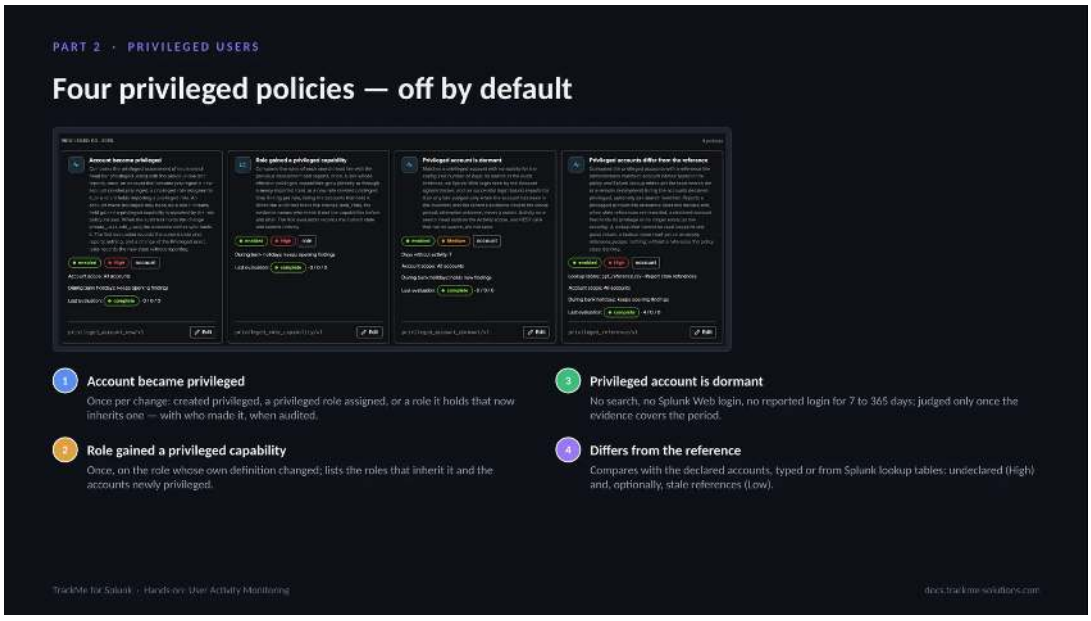
Who holds high privileges



The Privileged users tab reads the users and roles catalogs UAM already collects and makes no call to Splunk. The counters show 9 privileged accounts of 7,025, 17 privileged roles, 8 privileged capabilities in use and 6 privileged accounts active in the last 24 hours. Charts show why accounts are privileged (a role, a capability or both), their classes and the accounts holding each privileged capability.

An account is privileged when one of its roles, or a role that role imports however indirectly, is a privileged role or grants a privileged capability. The table lists every privileged account with its tiers, class, roles, capabilities and each reason in words, for example uam_gen_rtsearch grants list_settings.

Four policies on privileges

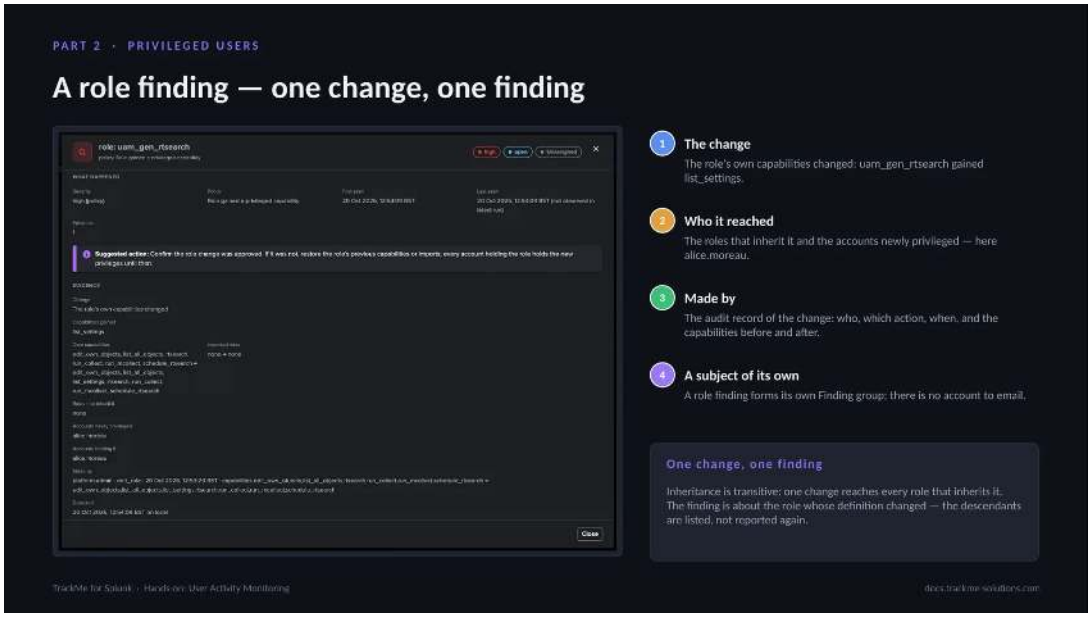


Four privileged policies build on that assessment, all off by default. Account became privileged reports once per change an account created privileged, given a privileged role, or holding a role that now inherits one, with who made

the change when Splunk audited it. Role gained a privileged capability reports once, on the role whose own definition changed, the roles that inherit it and the accounts newly privileged.

Privileged account is dormant reports a privileged account with no search, no Splunk Web login and no reported login for 7 to 365 days, once the evidence covers the period. Privileged accounts differ from the reference compares the accounts with the declared privileged accounts, typed names and Splunk lookup tables: undeclared at high severity and, optionally, stale references at low severity.

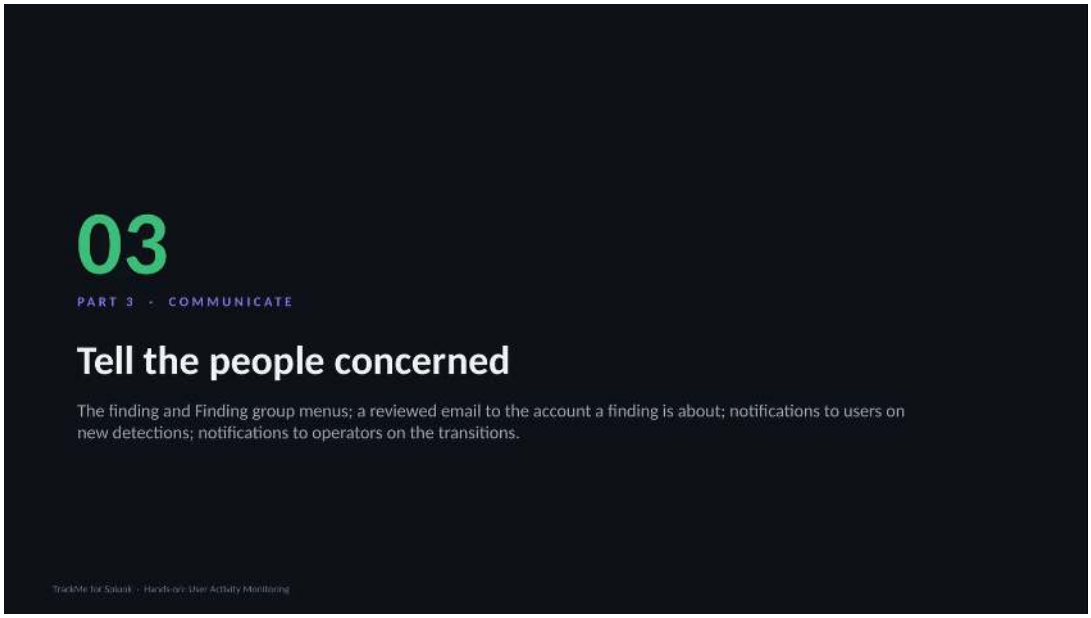
One change, one finding



A role finding opened in Investigate. The role's own capabilities changed: uam_gen_rtsearch gained list_settings, a privileged capability. The finding lists the roles that inherit the change and the accounts newly privileged through it, here alice.moreau, and the audit record of who made the change, the action, when, and the capabilities before and after.

Inheritance is transitive: one change reaches every role that inherits it, and the finding is about the role whose definition changed, its descendants listed rather than reported again. A role finding forms its own Finding group, and there is no account to email.

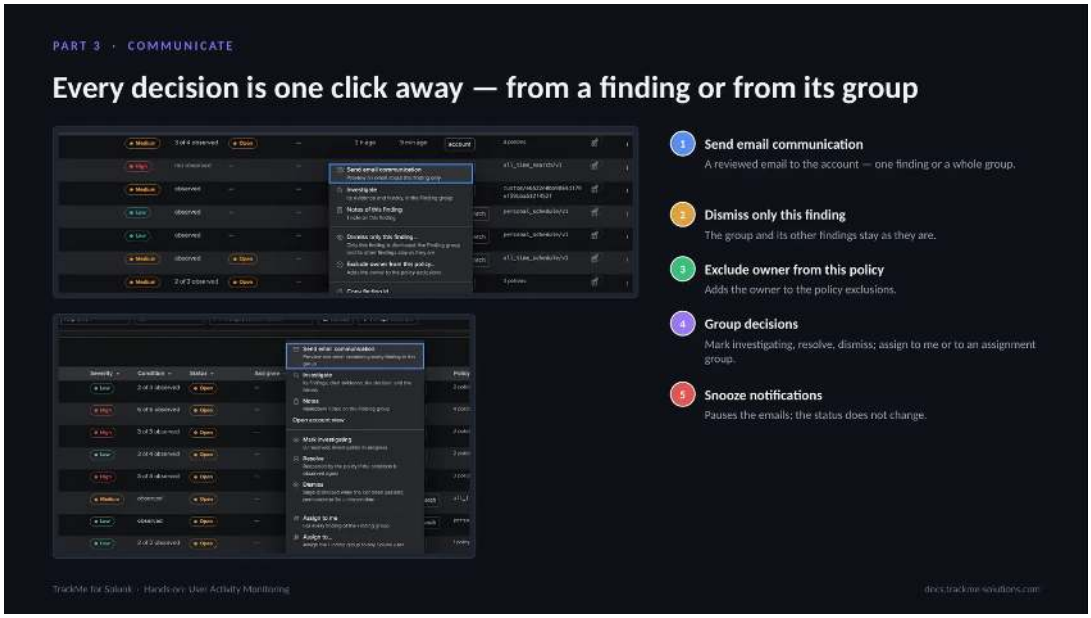
Part 3 — Communicate



The third part is about talking to the people behind the accounts. It covers the finding and Finding group menus, a reviewed email to the account a finding is about, notifications to users on new detections, and notifications to operators on the transitions of the findings.

A one-off communication is reviewed before it leaves; automatic notifications to users work independently of the operators' notifications.

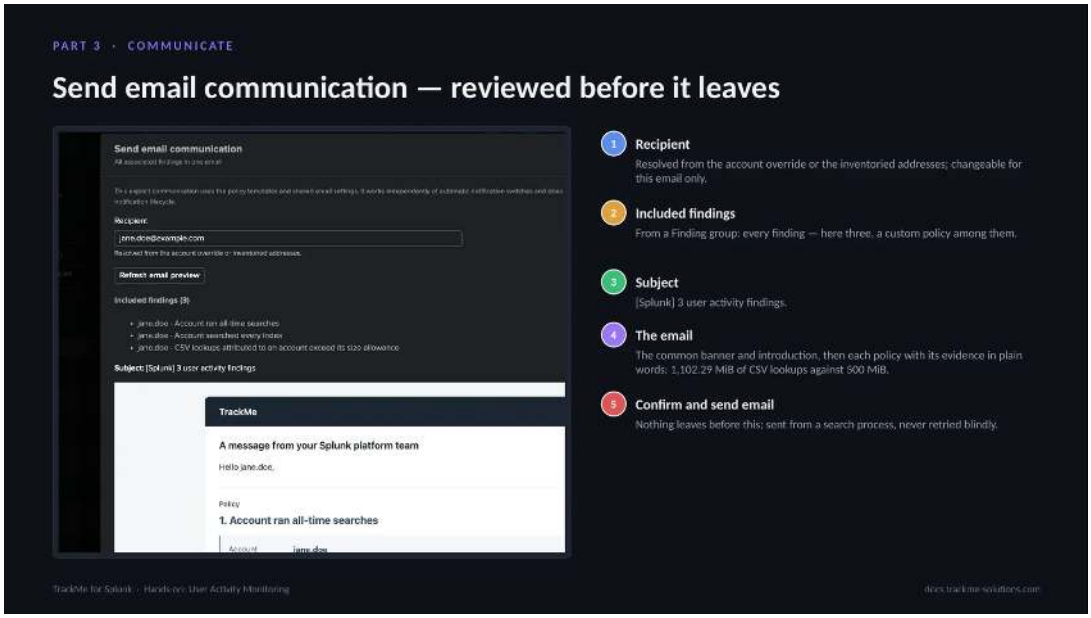
The finding and group menus



Two menus carry the decisions. The menu of a single finding offers Send email communication, Investigate, Notes, Dismiss only this finding (the group and its other findings stay as they are), Exclude owner from this policy (which adds the owner to the policy exclusions), Copy finding id, and Open record and events in search.

The Finding group menu offers Send email communication for every finding of the group, Investigate, Notes and Open account view, then the group decisions: mark investigating, resolve, dismiss, assign to me or to an assignment group. Snooze notifications pauses the emails without changing the status.

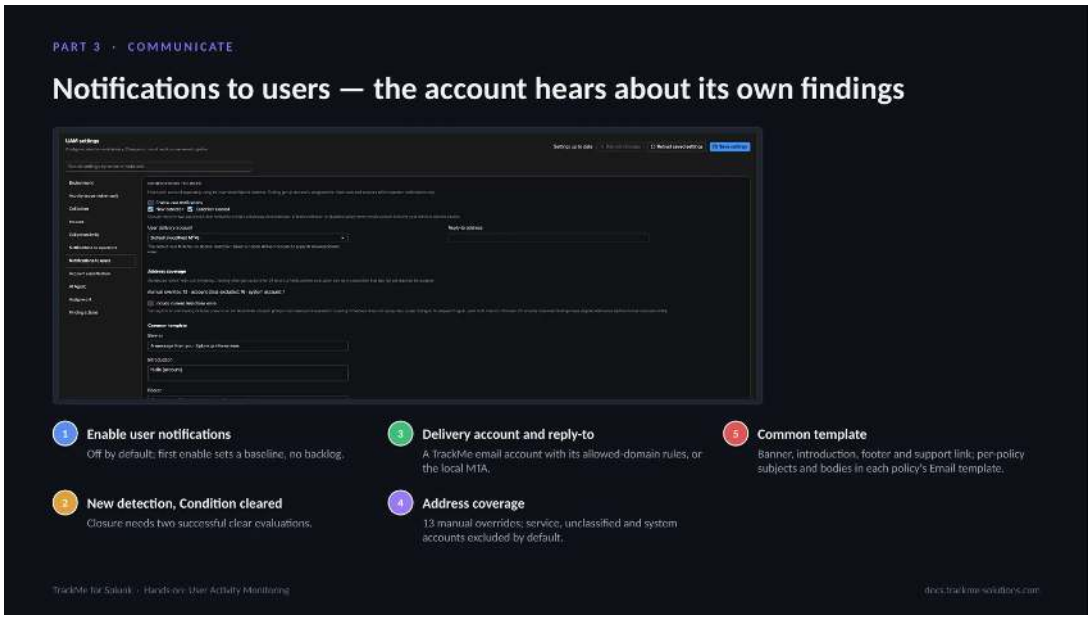
A reviewed email to the account



Send email communication prepares a private preview of one email for the account concerned. The recipient is resolved from the account override or the inventoried addresses and can be changed for this email only. From a Finding group, every finding is included, here three, a custom policy among them, under the subject [Splunk] 3 user activity findings.

The email carries the common banner and introduction, then each policy with its evidence in plain words, such as 1,102.29 MiB of CSV lookups against 500 MiB. Nothing leaves before Confirm and send email; the email is sent from a search process and never retried blindly. It changes neither the findings nor their notification lifecycle.

Automatic emails to account owners

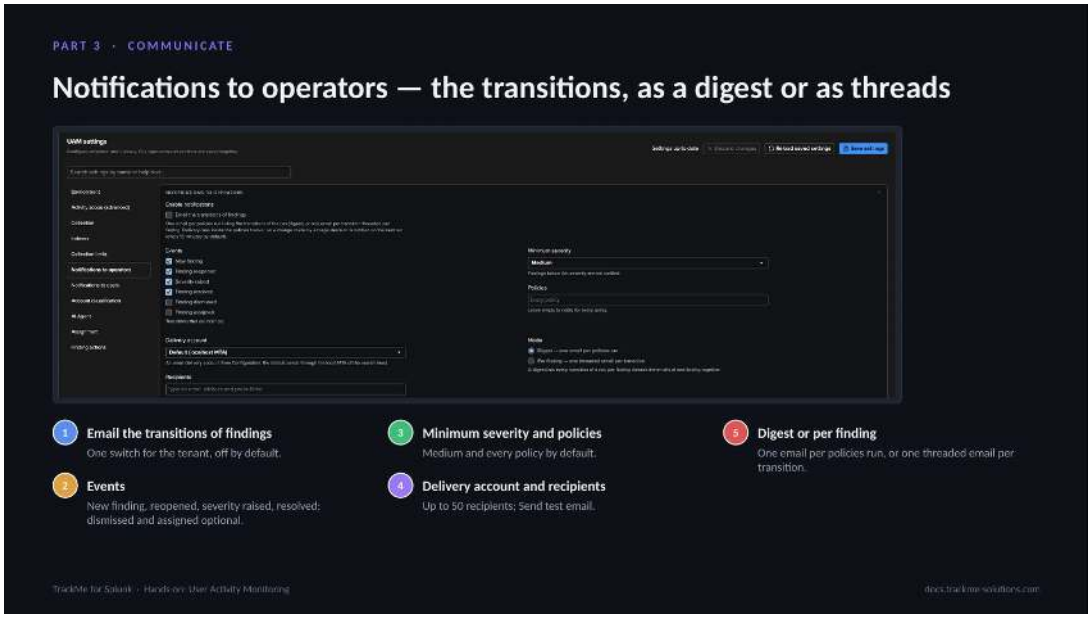


Notifications to users email each account about its own findings at its inventoried address. Enable user notifications is off by default, and the first enable sets a baseline so that no backlog is sent. Events are New detection and Condition cleared; a closure needs two successful clear evaluations.

A delivery account (a TrackMe email account with its allowed-domain rules, or the local MTA) and a reply-to address send them. Address coverage shows 13 manual overrides; service, unclassified and system accounts are excluded by

default. The common template holds the banner, introduction, footer and support link, while each policy has its own subject and body. Limits protect the mailboxes: at most 50 per run and 3 per user per hour.

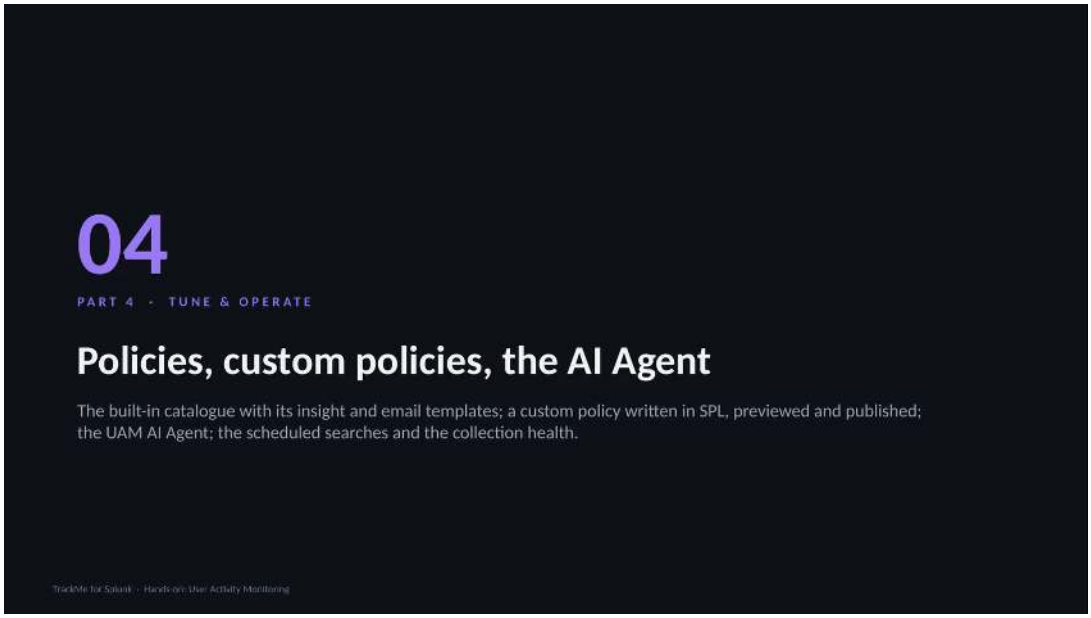
Emails to the operators



Notifications to operators email the transitions of the findings, behind one switch for the tenant that is off by default. The events are new finding, reopened, severity raised and resolved, with dismissed and assigned optional. A minimum severity (medium by default) and a policy list (every policy by default) narrow them.

A delivery account sends them to up to 50 recipients, and Send test email checks the delivery. The mode is either a digest, one email per policies run, or one threaded email per finding transition. Emails link straight to the finding in its investigation.

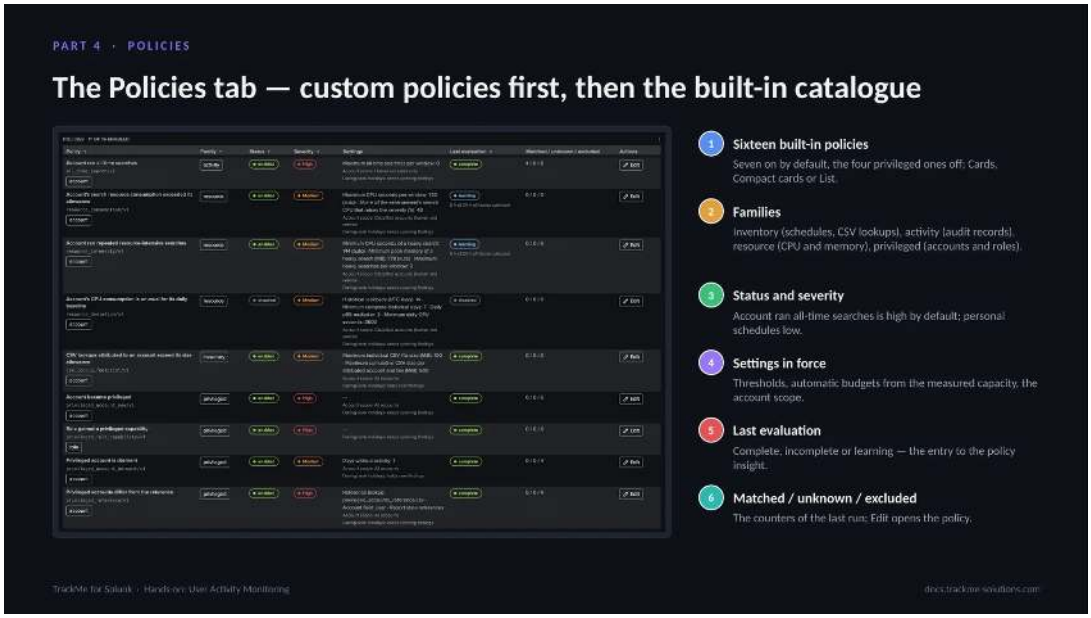
Part 4 — Tune and operate



The fourth part covers tuning and operating: the built-in policy catalogue with its insight and email templates, a custom policy written in SPL, previewed and published, the UAM AI Agent, the scheduled searches and the collection health.

The catalogue ships with defaults that fit a busy platform; a rule that is not in it can be written as a custom policy.

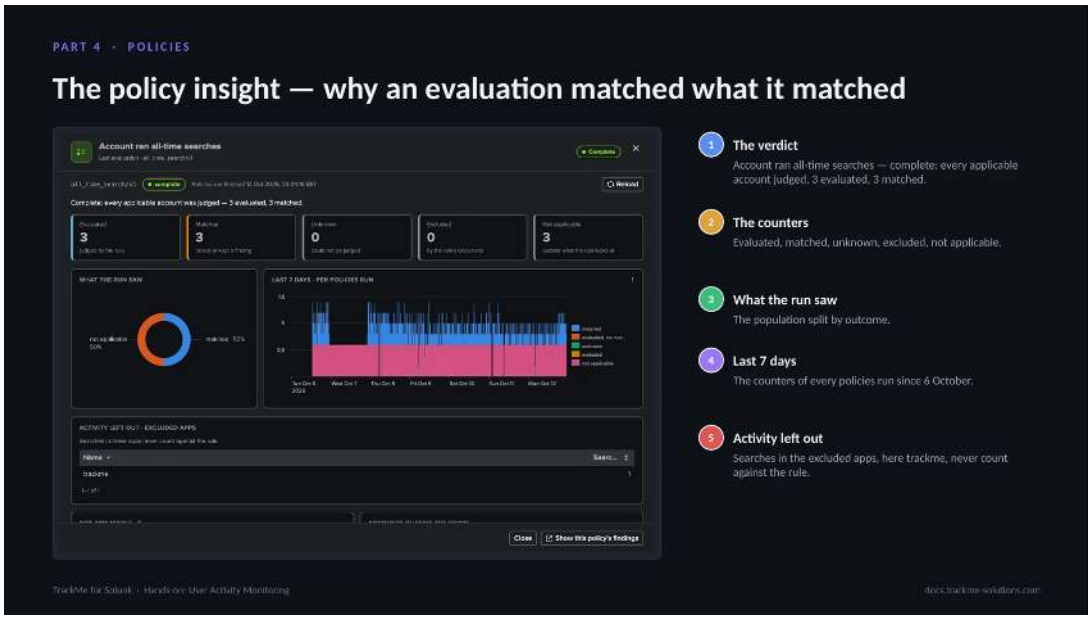
The policy catalogue



The Policies tab lists the custom policies of the tenant first, then the sixteen built-in policies, seven of them on by default and the four privileged ones off, as cards, compact cards or a list. The families are inventory (schedules and CSV lookups), activity (audit records), resource (CPU and memory) and privileged (accounts and roles).

Each row shows the status and severity (Account ran all-time searches is high by default, personal schedules low), the settings in force (thresholds, automatic budgets from the measured capacity, the account scope), the last evaluation (complete, incomplete or learning) and the matched, unknown and excluded counters; Edit opens the policy. Resource policies learn for 24 hours before they judge anyone, and a policy never resolves a finding.

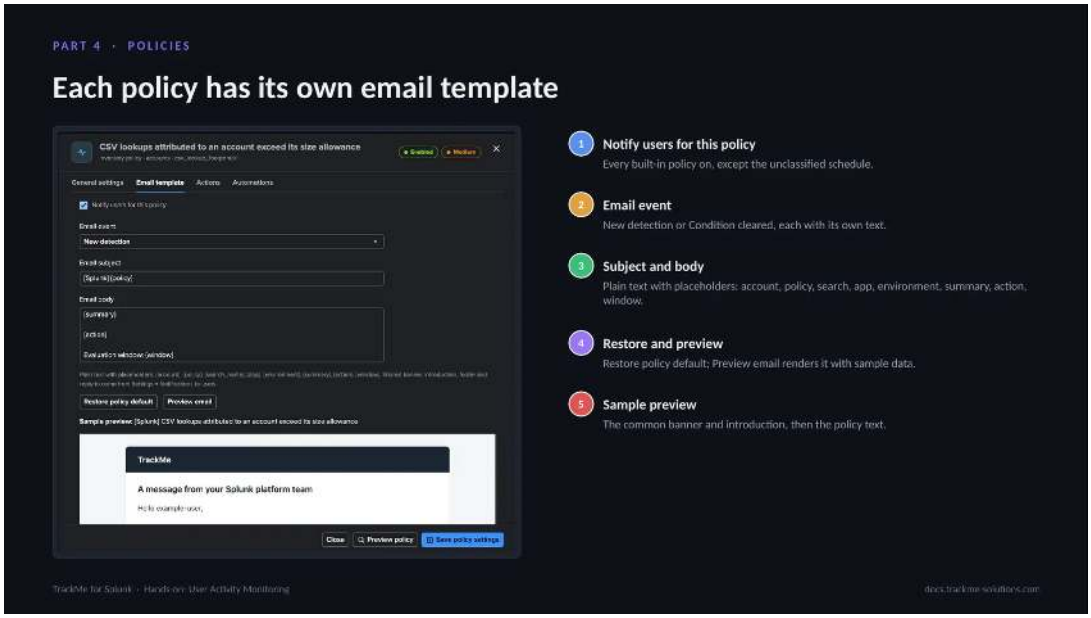
Explaining one evaluation



The policy insight opens from the Last evaluation pill. For Account ran all-time searches the verdict reads Complete: every applicable account was judged, 3 evaluated and 3 matched. The counters show evaluated, matched, unknown, excluded and not applicable.

What the run saw splits the population by outcome, and the last 7 days chart repeats the counters for every policies run since 6 October. Activity left out lists the excluded apps, here trackme, whose searches never count against the rule. Show this policy's findings jumps to the findings the policy raised.

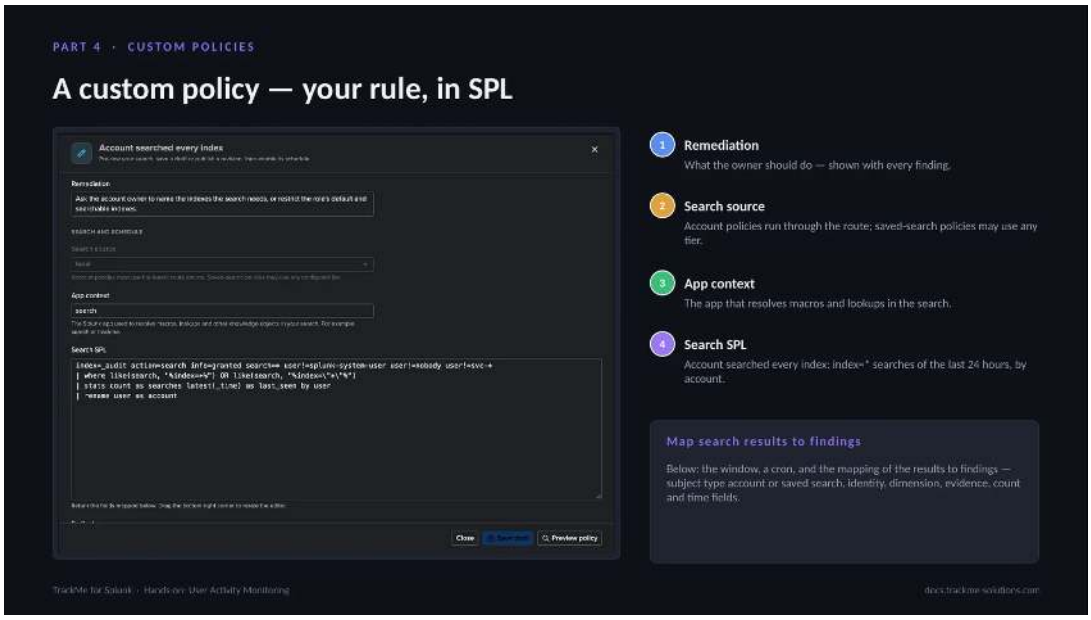
Policy email templates



The edit modal of a policy has four tabs: General settings, Email template, Actions and Automations. Email template holds the words sent to the account. Notify users for this policy is on for every built-in policy except the unclassified schedule.

Each email event (New detection or Condition cleared) has its own subject and body, in plain text with placeholders such as account, policy, search, app, environment, summary, action and window. Restore policy default reverts the text, and Preview email renders it with sample data under the common banner and introduction; a test recipient receives a synthetic test email.

Writing a custom policy

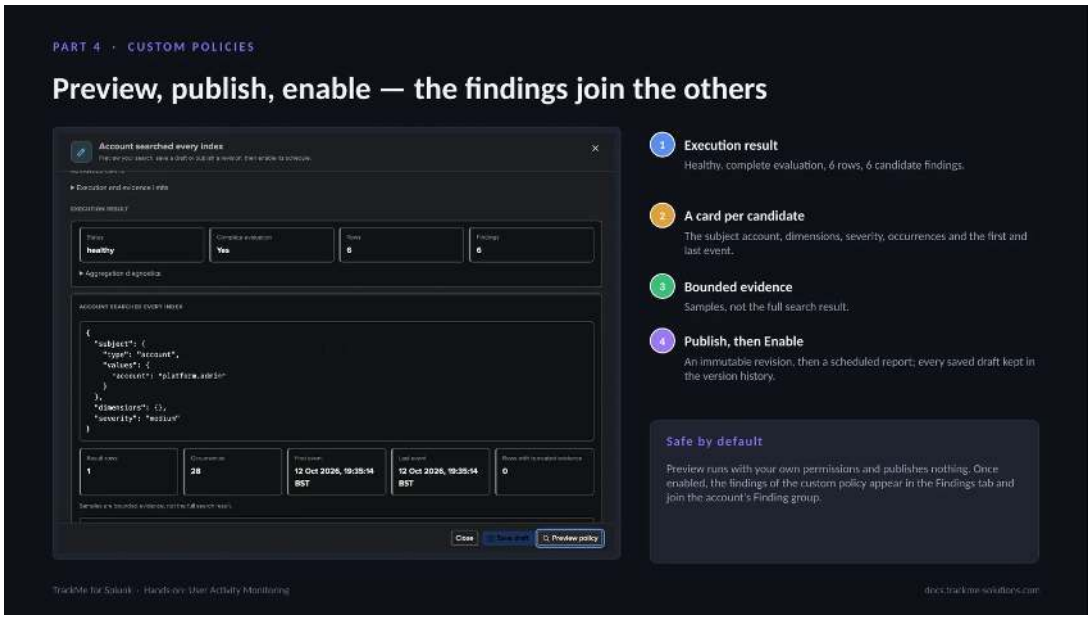


When the catalogue lacks a rule, a custom policy adds it: an SPL search plus a mapping of its results to findings. This one, Account searched every index, flags accounts that searched index=* in the last 24 hours. The remediation text is shown with every finding. The search source is the route for account policies, while saved-search policies may use any tier, and the app context resolves the macros and lookups of the search.

Below the SPL, the policy defines its window, a cron, and the mapping of the results to findings: subject type (account or saved search), identity, dimensions, evidence, count and time fields. A tenant holds up to 100 definitions and 25

enabled policies.

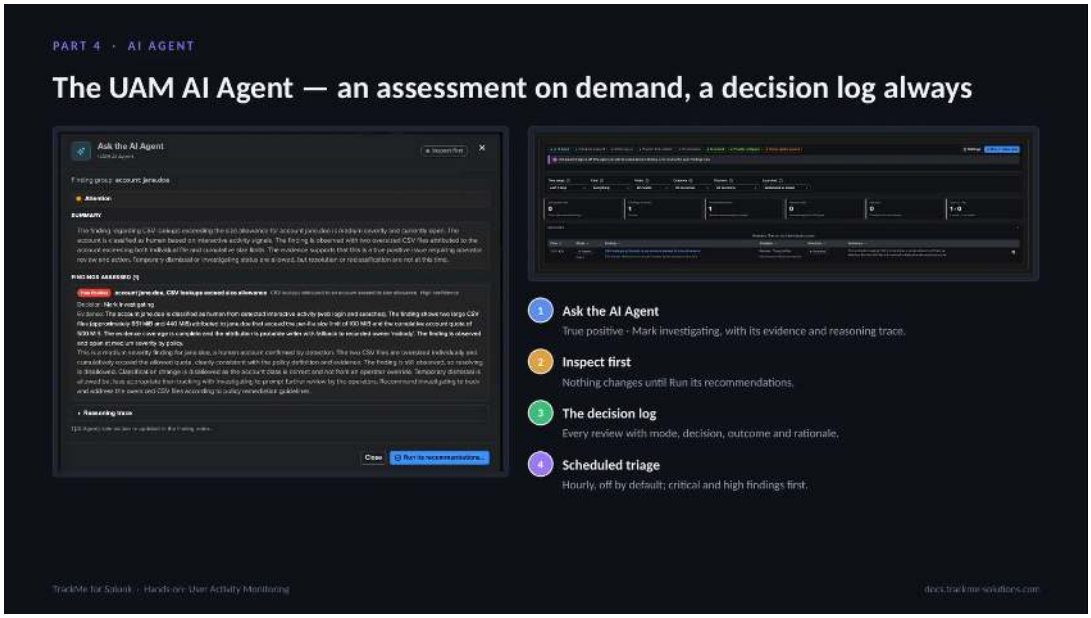
Preview, publish and enable



Preview runs the search as the author, asynchronously, and publishes nothing. The execution result reads healthy, complete evaluation, 6 rows and 6 candidate findings. Each candidate is a card with its subject, dimensions, severity, occurrences and first and last event; the evidence is a bounded sample, not the full search result.

Publish freezes an immutable revision, and Enable installs its scheduled report; every saved draft stays in the version history. Once enabled, the findings of the custom policy appear in the Findings tab and join the Finding groups of the accounts concerned, next to the built-in policies.

Assessments and the decision log

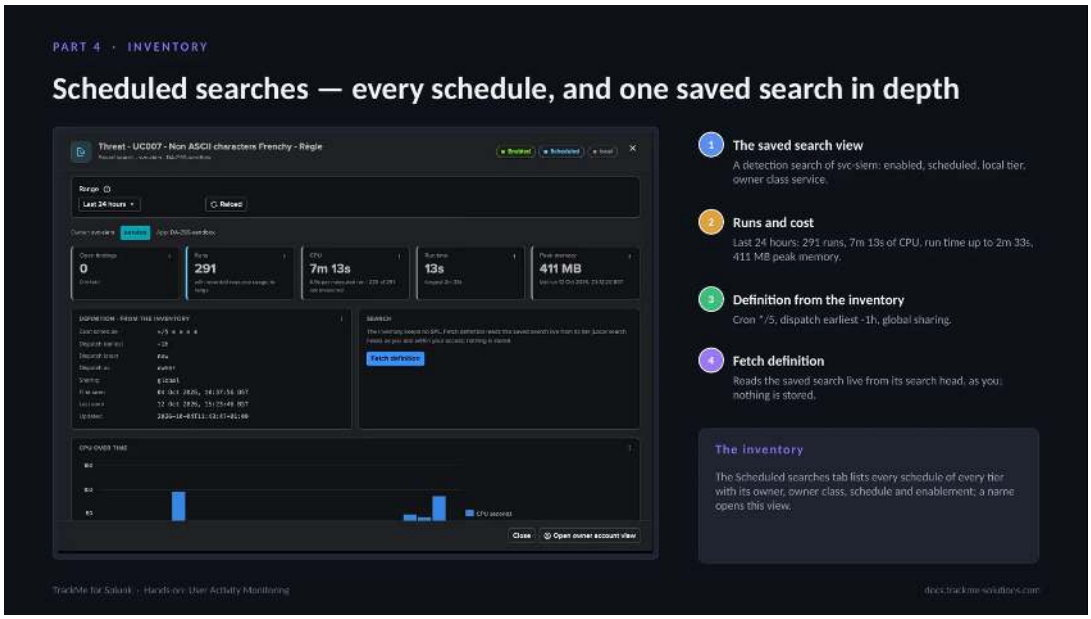


Ask the AI Agent on a finding reads the evidence of the Finding group and returns an assessment, here a true positive of medium severity with its evidence and reasoning trace, and recommends a decision, Mark investigating. In inspect mode nothing changes until Run its recommendations is selected.

The AI Agent tab logs every review, asked or scheduled, with its mode, decision, outcome and rationale. Scheduled triage runs hourly and is off by default, critical and high findings first; in act mode it applies only the decisions the

tenant allows and never overrides an operator decision.

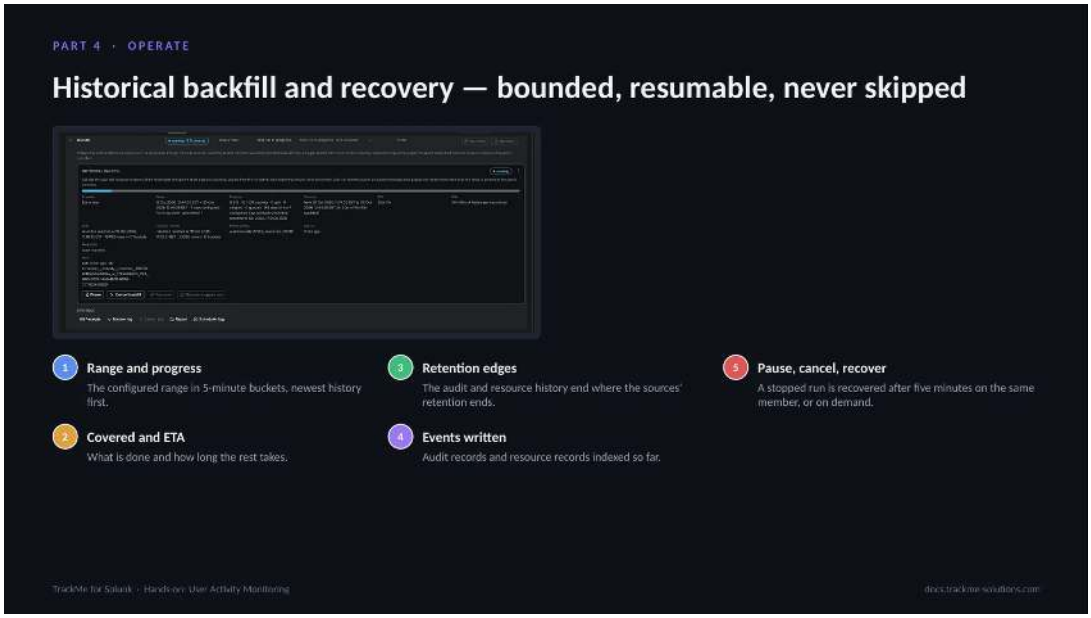
The scheduled-search inventory



The Scheduled searches tab lists every schedule of every tier with its owner, owner class, schedule and enablement; a name opens the saved search view. Here, a detection search of the svc-siem service account is enabled, scheduled on the local tier and shared globally.

Over the last 24 hours it ran 291 times for 7m 13s of CPU, with a longest run of 2m 33s and a peak memory of 411 MB. The definition from the inventory shows a cron of */5 and a dispatch earliest of -1h. Fetch definition reads the saved search live from its search head with the caller's permissions; nothing is stored.

Backfill and recovery

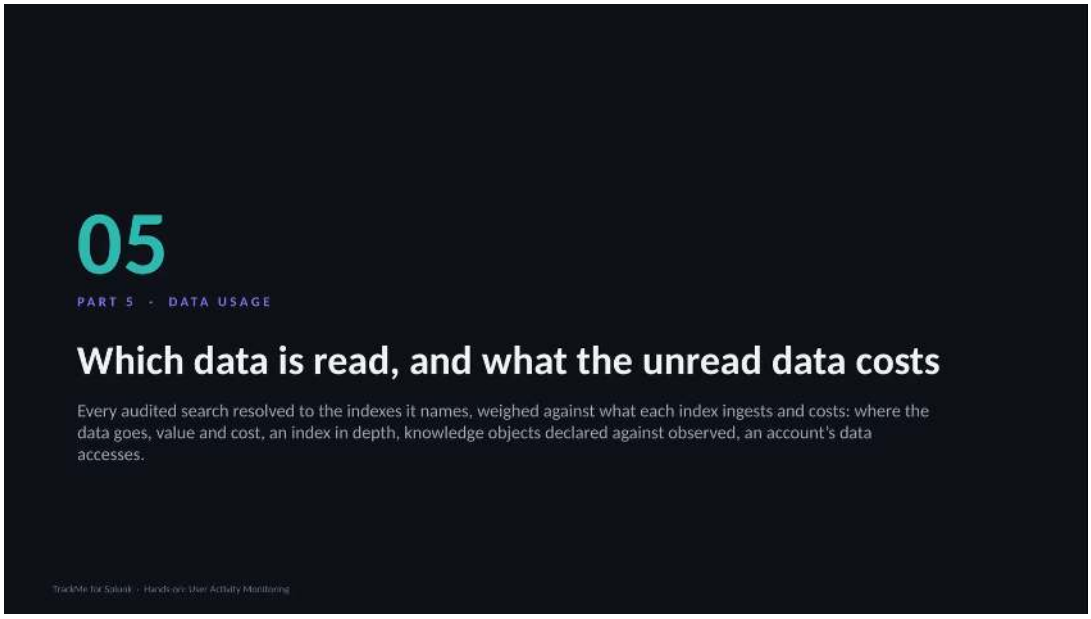


The backfill shows the configured range in 5-minute buckets collected newest first, with what is covered and the estimated time for the rest. The retention edges show where the audit and resource history end because the sources' retention ends there, and the counters show the audit records and resource records written so far.

Pause and Cancel backfill control the run; a stopped run is recovered after five minutes on the same member, or on demand. The backfill never collects a span twice, and a bucket that fails is held, split and resumed, never skipped; it

retires itself once the range is covered. The Configuration Guardian check uam_collection_health surfaces whatever stays wrong and clears itself.

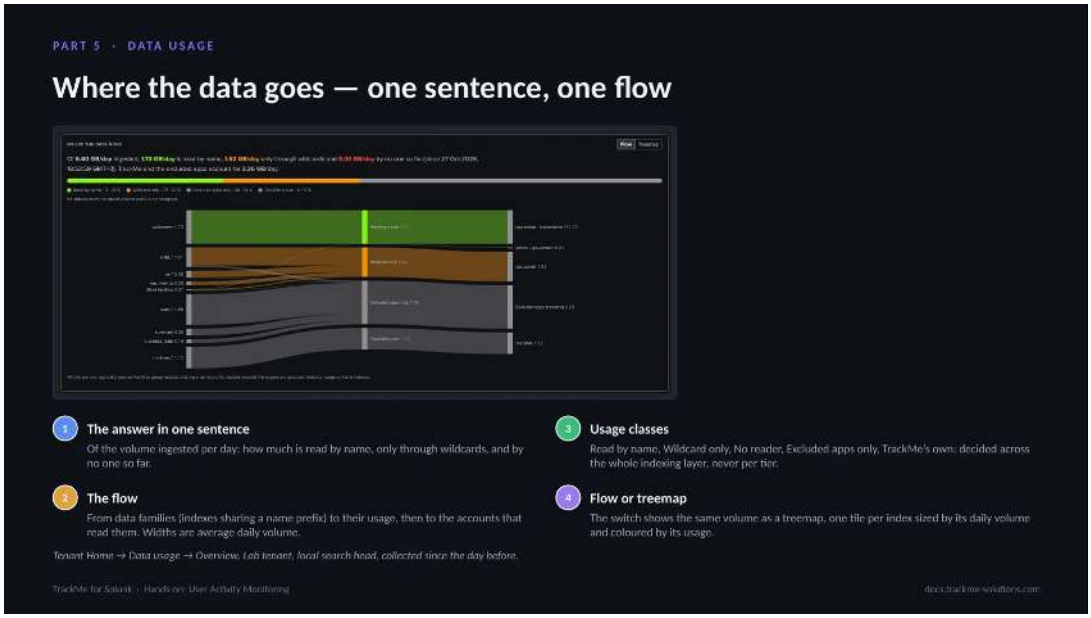
Part 5 — Data usage



Data usage, new in TrackMe 2.4.22, resolves every audited search to the indexes it names, through its macros, event types, saved searches and data models, and weighs that against what each index ingests and costs, read from linked VOL and DSM tenants.

One rule runs through every view: an absence of reads is a claim, made only when the evidence supports it. The part covers where the data goes, value and cost, an index in depth, knowledge objects declared against observed, and an account's data accesses.

From ingestion to readers



The Overview opens on one sentence: of 6.60 GB per day ingested, 1.73 GB is read by name, 1.52 GB only through wildcards and none by no one so far, since the collection is a day old. The flow runs from data families, indexes sharing a name prefix, to their usage and then to the accounts that read them; widths are average daily volume.

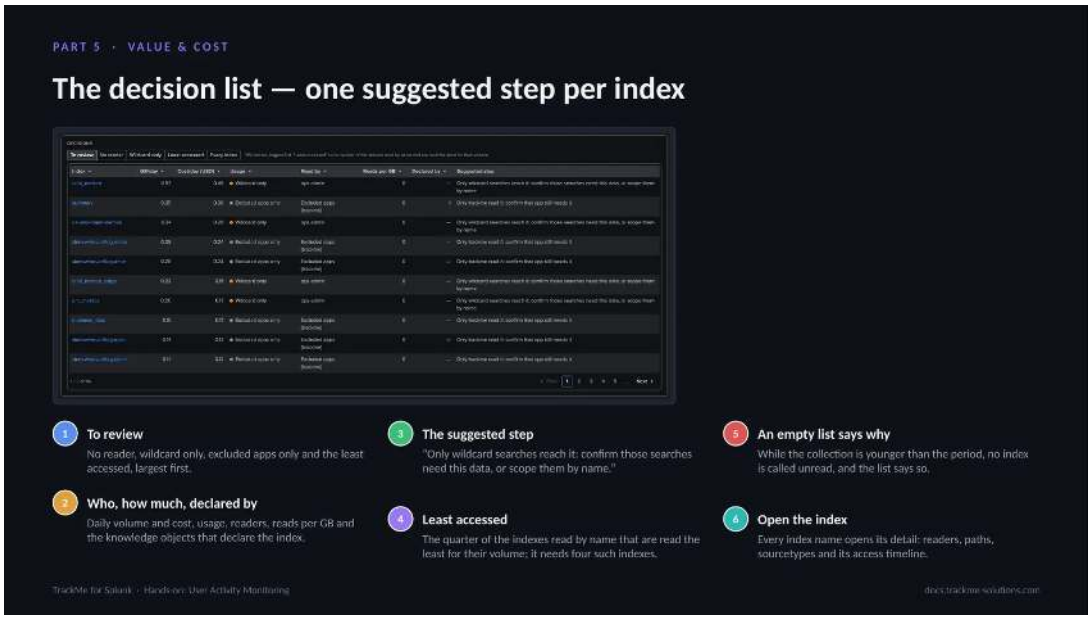
The usage classes (Read by name, Wildcard only, No reader, Excluded apps only, TrackMe's own) are decided across the whole indexing layer, never per tier. A wildcard such as index=cribl_* is a reference, not a read. The Flow and Treemap switch shows the same volume as tiles sized by daily volume.

Weighing volume against reads

Value & cost opens with the coverage card: the collection start and the date from which an index can be called unread. Ingestion by usage shows the daily volume as a treemap coloured by usage class. Volume against reads places one dot per index on log scales, with a shaded corner for the indexes larger than the median and read fewer than ten times.

Cost of disuse prices what is not read by name: here 1.52 GB per day, 1.29 USD per day, reached only by wildcards. The cost comes from the linked VOL tenant's costs when they are enabled; otherwise no cost is shown rather than a guessed one.

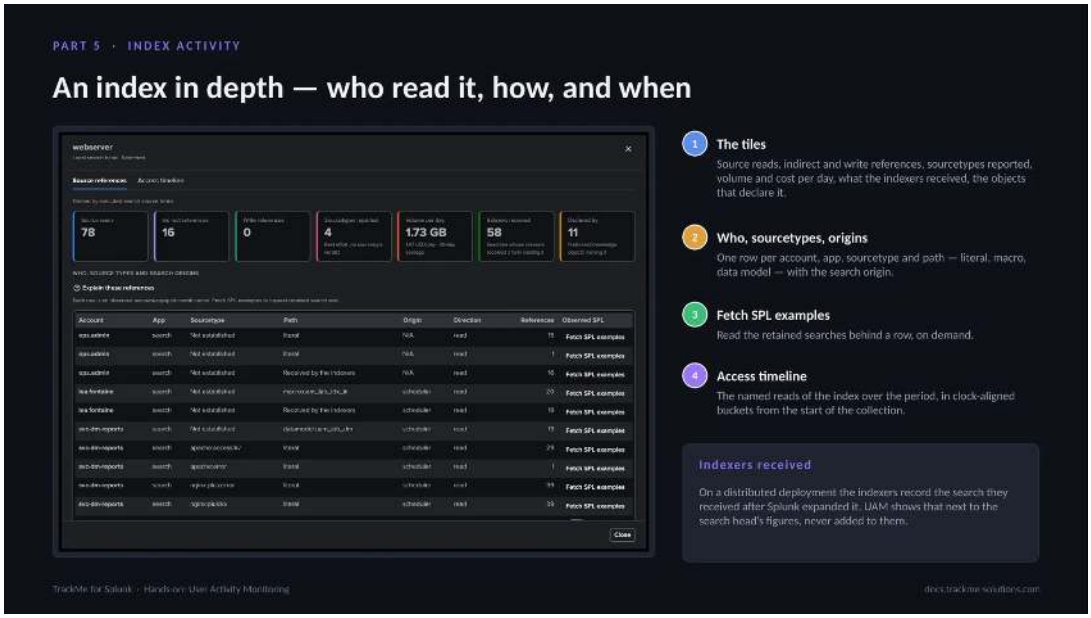
From the map to decisions



The Decisions list gives one row per index, largest first, with its daily volume and cost, usage, readers, reads per GB, the knowledge objects that declare it and a suggested step, such as confirming that wildcard searches need the data or scoping them by name.

To review gathers the indexes with no reader, those only wildcards or excluded apps reach, and the least accessed: the quarter of the indexes read by name that are read the least for their volume, ranked only when at least four such indexes exist. An empty list says why, and every index name opens its detail.

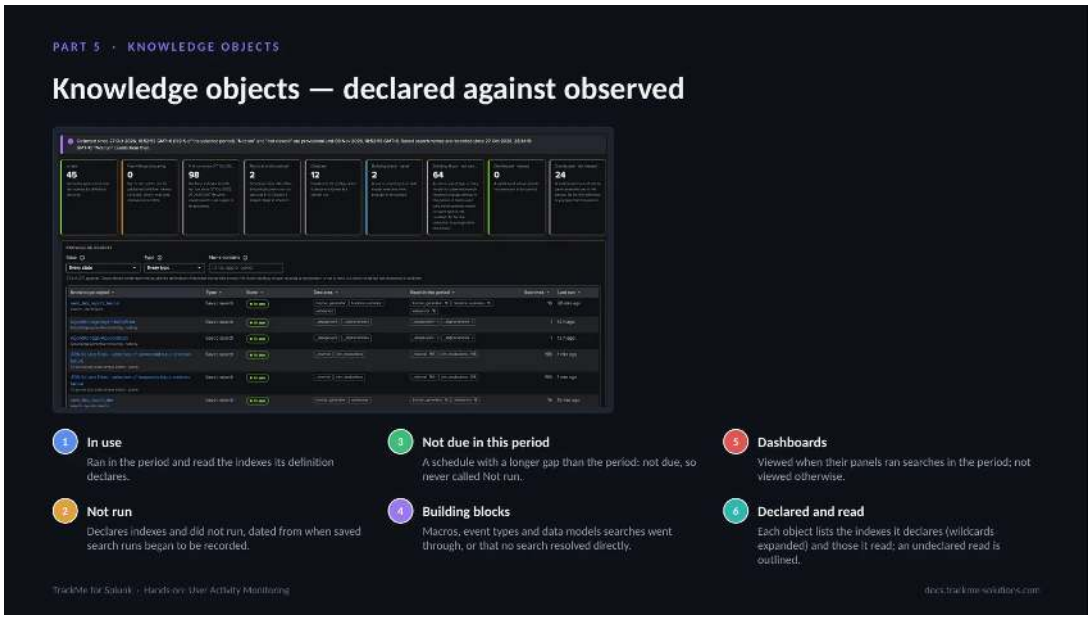
One index, its readers and paths



The webserver detail opens on Source references: 78 source reads, 16 indirect references, 4 sourcetypes reported, 1.73 GB per day at 1.47 USD, 58 searches the indexers received and 11 knowledge objects that declare it. One row per account, app, sourcetype and path shows who read it and how: by literal term, through a macro or through a data model, with Fetch SPL examples on demand.

Sourcetypes are reported on a best-effort basis and never receive a verdict. On a distributed deployment, the indexers' record of the expanded search sits beside the search head's figures, never added to them. The Access timeline tab charts the named reads in clock-aligned buckets.

Declarations checked against runs

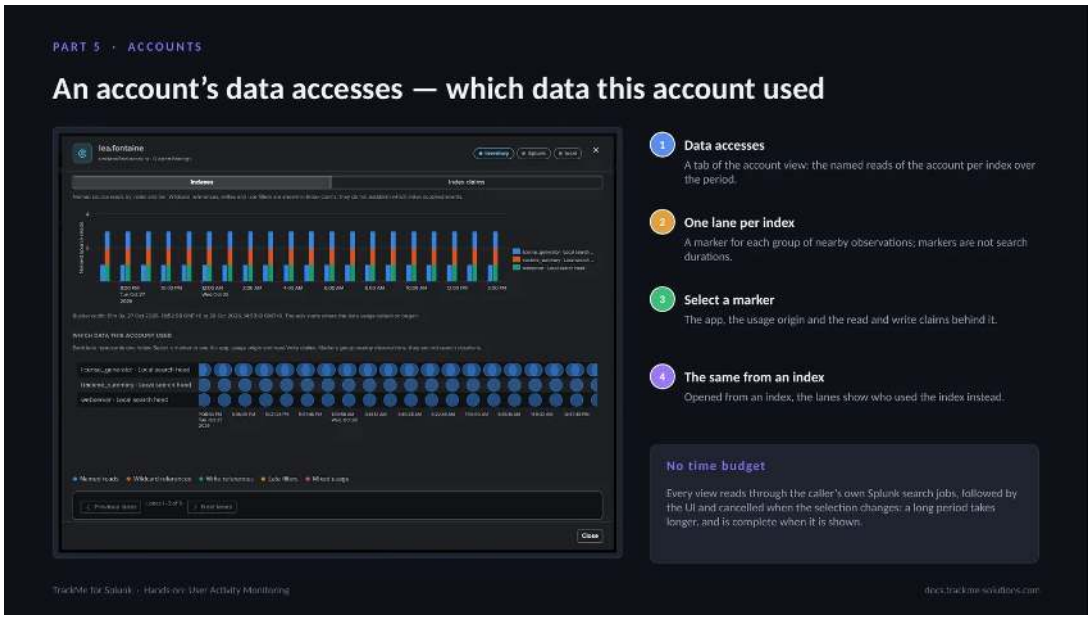


The Knowledge objects view sets each published saved search, macro, event type, dashboard and data model against what ran. Tiles count the states: 45 in use, 98 not run, 2 not due in this period, 12 disabled, building blocks used or

not seen, and dashboards viewed or not.

Each object lists the indexes its definition declares, wildcards expanded across the index catalog, next to the indexes its searches read; an undeclared read is outlined. Not run is dated from when saved search runs began to be recorded, and a schedule with a longer gap than the period is not due, never not run.

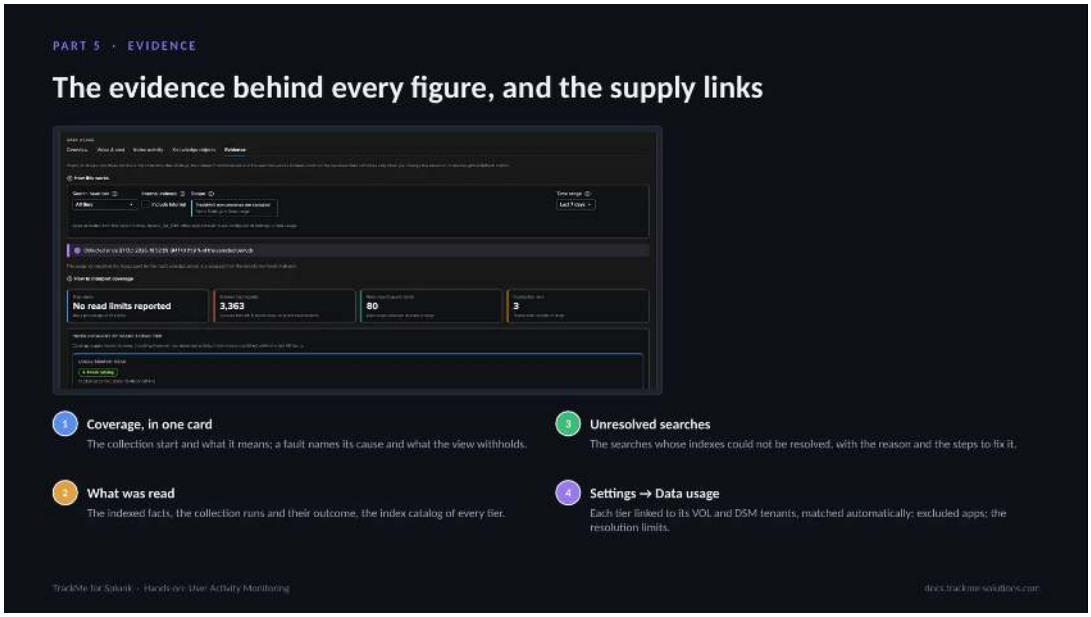
An account's indexes over time



The account view of lea.fontaine has a Data accesses tab: the named reads of the account per index over the period, then one lane per index with a marker for each group of nearby observations. Markers are not search durations. Selecting one shows the app, the usage origin and the read and write claims; opened from an index, the same lanes show who used it.

Every Data usage view reads through the caller's own Splunk search jobs, followed by the UI and cancelled when the selection changes or the view closes. There is no time budget: a long period takes longer and is complete when it is shown.

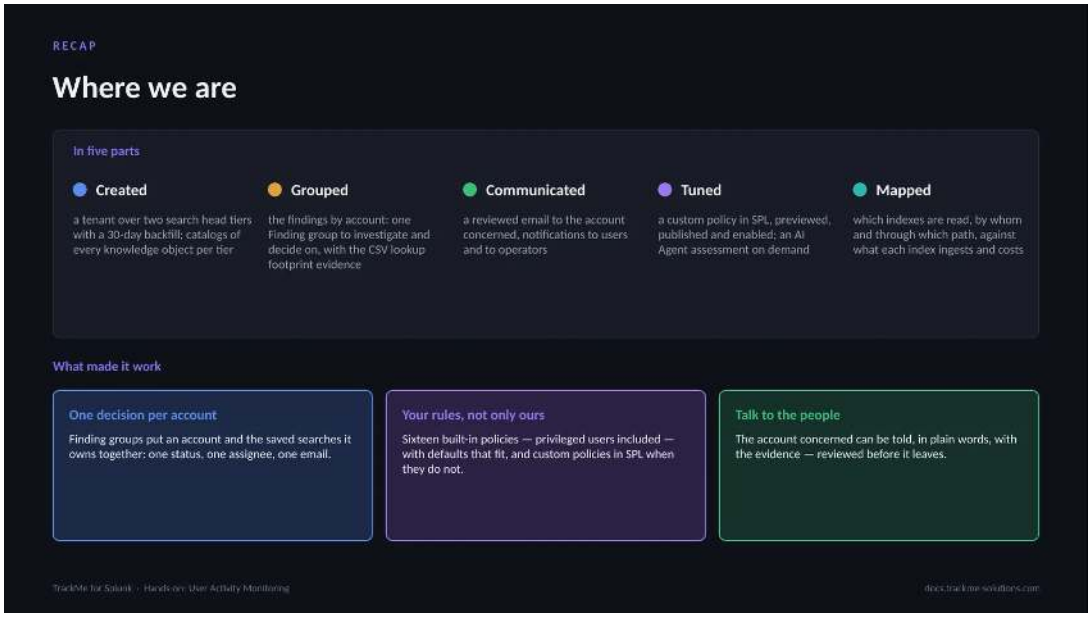
Evidence and supply links



Evidence shows what supports the figures: one coverage card with the collection start and any fault with its cause, the indexed fact records, the collection runs and their outcome, the index catalog of every tier, and the searches whose indexes could not be resolved, each with its reason and the steps to fix it.

In Settings, Data usage links each search head tier to the VOL tenant that gives its volumes and to the DSM tenants that give its incoming data, matched automatically on the same route. It also sets the excluded apps and the resolution limits. A link grants no access: every read repeats the caller's visibility.

Where we are



In five parts, a tenant was created over two search head tiers with a 30-day backfill and catalogs of every knowledge object per tier. Its findings were grouped by account into Finding groups and investigated, with the CSV lookup footprint evidence, and the accounts holding high privileges were reviewed with their policies. A reviewed email went to the account concerned, next to the notifications to users and to operators. A custom policy was written in SPL, previewed, published and enabled, and the AI Agent gave an assessment on demand. Data usage mapped which indexes are read, by whom and through which path, against what each index ingests and costs.

Three things make it work: one decision per account through Finding groups, rules beyond the built-in catalogue through custom policies, and plain-language communication with the people behind the accounts.

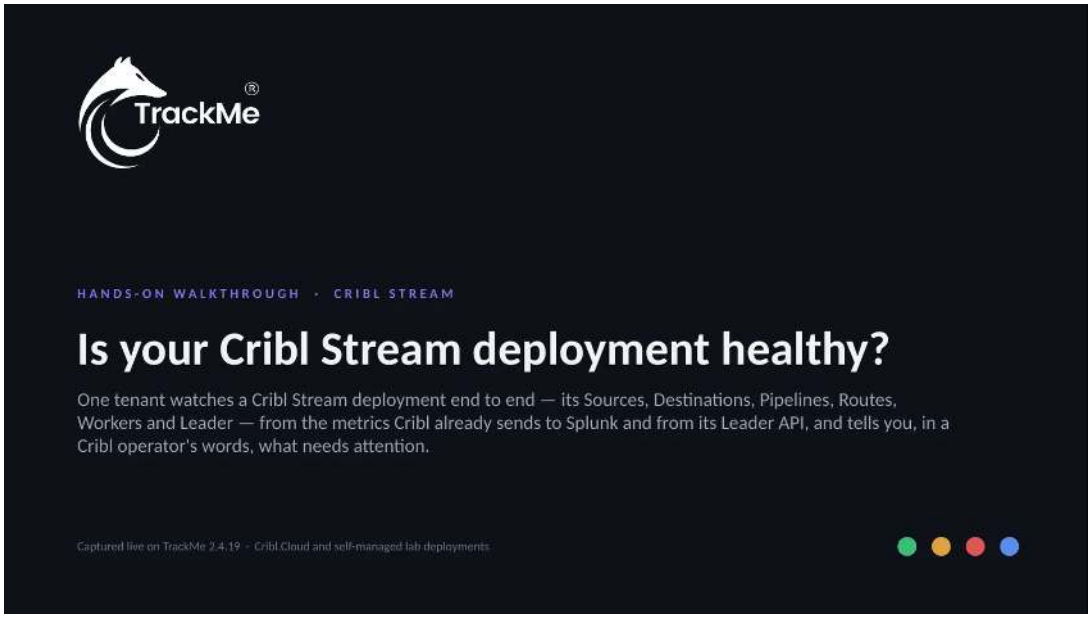
2.1.9 Cribl Stream

Monitor a Cribl Stream deployment from the metrics it already sends to Splunk and its Leader API: create the tenant, triage Finding groups, investigate traffic outliers against what each object learned, observe Workers, the Leader and the data paths, and operate the tenant with policies, notifications, the AI Agent, Topology Studio and the Configuration Guardian.

`Download the deck (PDF) · PowerPoint`

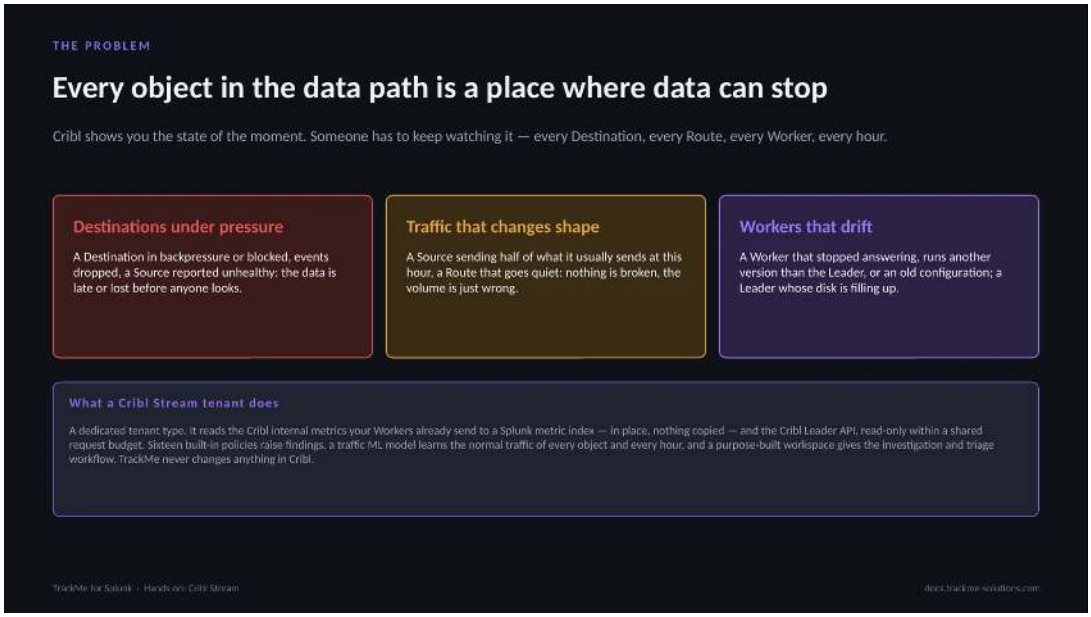
about 35 minutes · 33 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

Overview



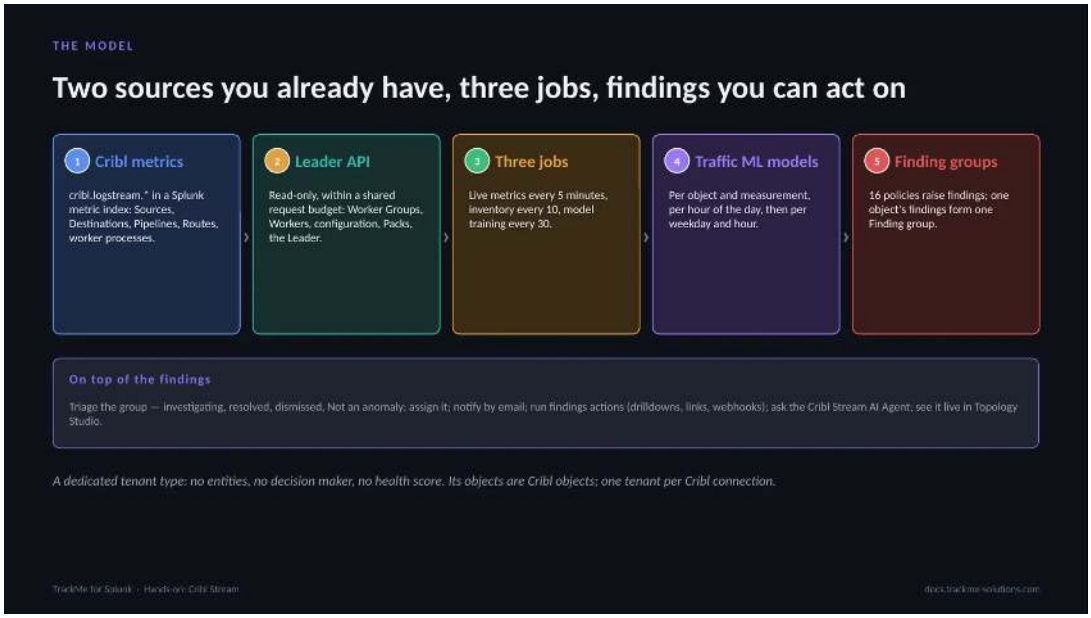
This walkthrough covers the Cribl Stream tenant, generally available in TrackMe 2.4.19. Everything was captured live on lab deployments: a Cribl.Cloud workspace and a self-managed Leader with five Workers. In four parts: create the tenant, read and triage the findings, observe the deployment and its traffic models, and operate the tenant with policies, notifications, the AI Agent and Topology Studio.

Why a dedicated Cribl Stream tenant



Cribl Stream sits in the middle of the data path. Every Source, Route, Pipeline and Destination is a place where data can slow down, back up, be dropped or stop, and every Worker can disconnect or drift from its Worker Group. The Cribl UI shows the state of one moment; a Cribl Stream tenant keeps watching, raises findings and gives you the triage workflow.

How a Cribl Stream tenant works

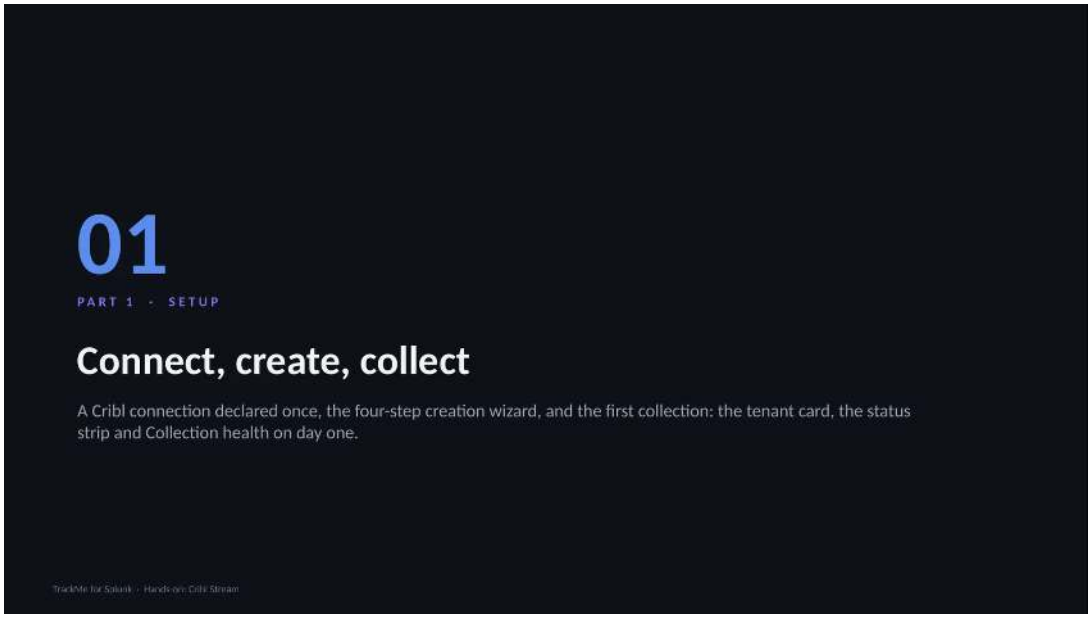


The live metrics job reads the newest five-minute interval of the Cribl metrics in Splunk every five minutes and evaluates the policies; the inventory job reads the configuration and the Workers from the Leader within its request budget; the model training job keeps a traffic ML model per object and measurement. Policies turn what is measured into findings, grouped per object into Finding groups.

The parts of the walkthrough

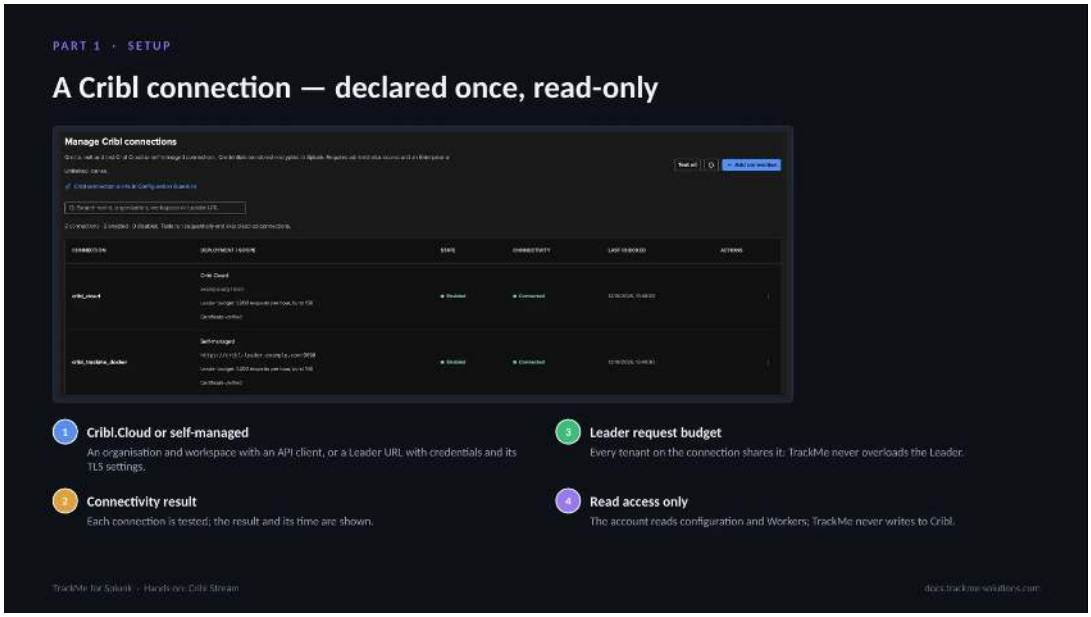
Four parts. Setup: the Cribl connection, the creation wizard, the first collection. Findings: the backlog, Finding groups, the investigation and the triage, assignment and webhooks. Observe: traffic, the traffic ML models, the machines and the data paths. Operate: inventory and exclusions, policies, notifications, the AI Agent, Topology Studio and the collection health.

Part 1 — Setup



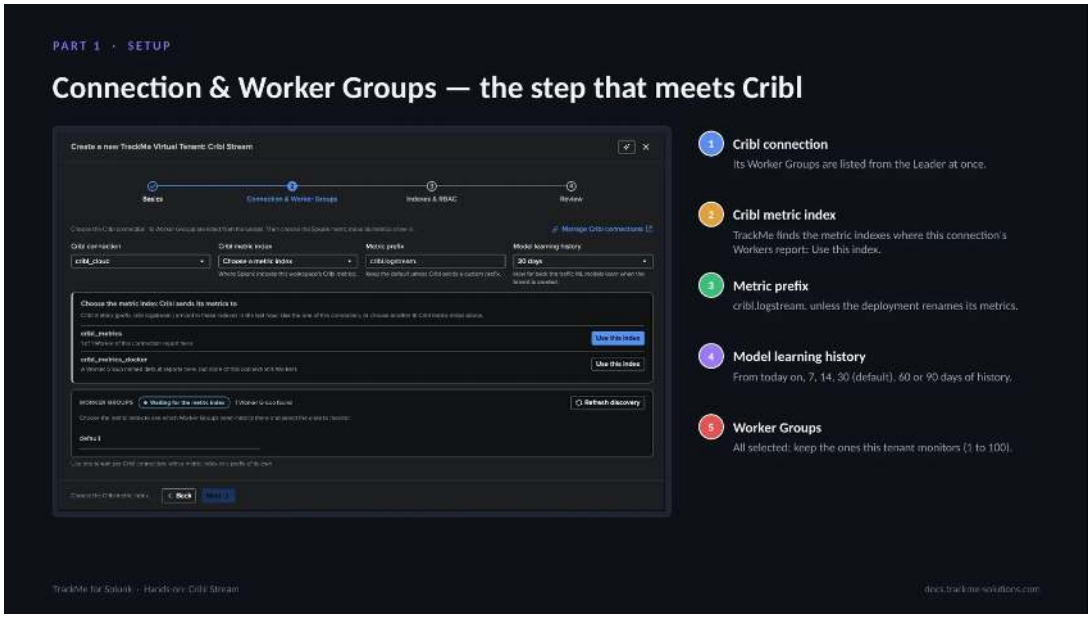
A Cribl connection is declared once and serves Cribl Stream and Cribl Edge tenants. The wizard does the rest, and the first collection starts within minutes. Configuration, Cribl connections holds one connection per Cribl.Cloud workspace or self-managed Leader, read-only. The creation wizard has four steps: Basics, Connection & Worker Groups, Indexes & RBAC and Review.

Declaring the Cribl connection



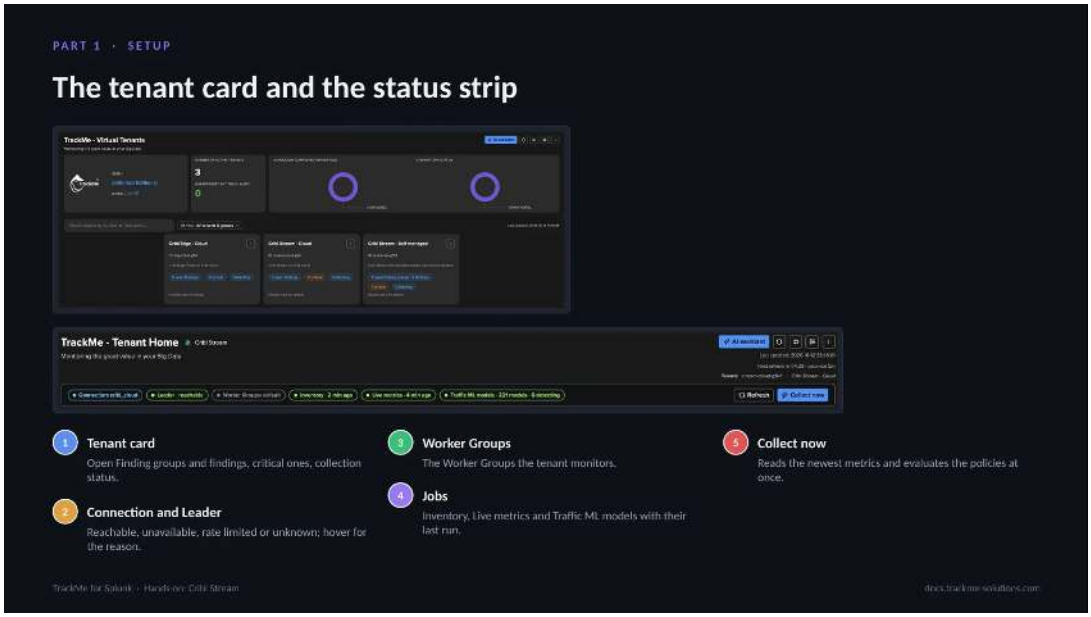
Configuration, Cribl connections. A connection is a Cribl.Cloud workspace with an API client ID and secret, or a self-managed Leader with a user name and password and its TLS settings. The Leader request budget is shared by every tenant that uses the connection. The account only needs read access: TrackMe never writes to Cribl.

Choosing the connection and Worker Groups



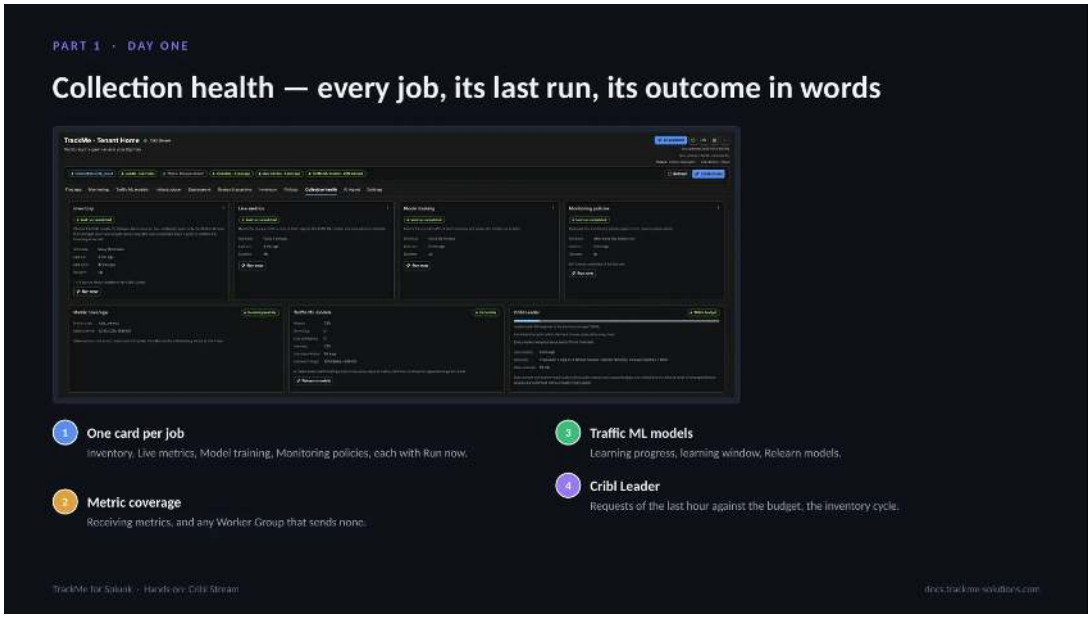
Actions, Create a tracking tenant, Cribl Stream card. Step 1 is the identifier and alias. Step 2 is where TrackMe meets the deployment: the connection, the metric index that TrackMe proposes from where this connection's Workers report, the metric prefix, how much history the traffic ML models learn from at creation, and the Worker Groups. With history in the metric index the models can detect on the first day. Steps 3 and 4 are the indexes, roles and review.

Status at a glance



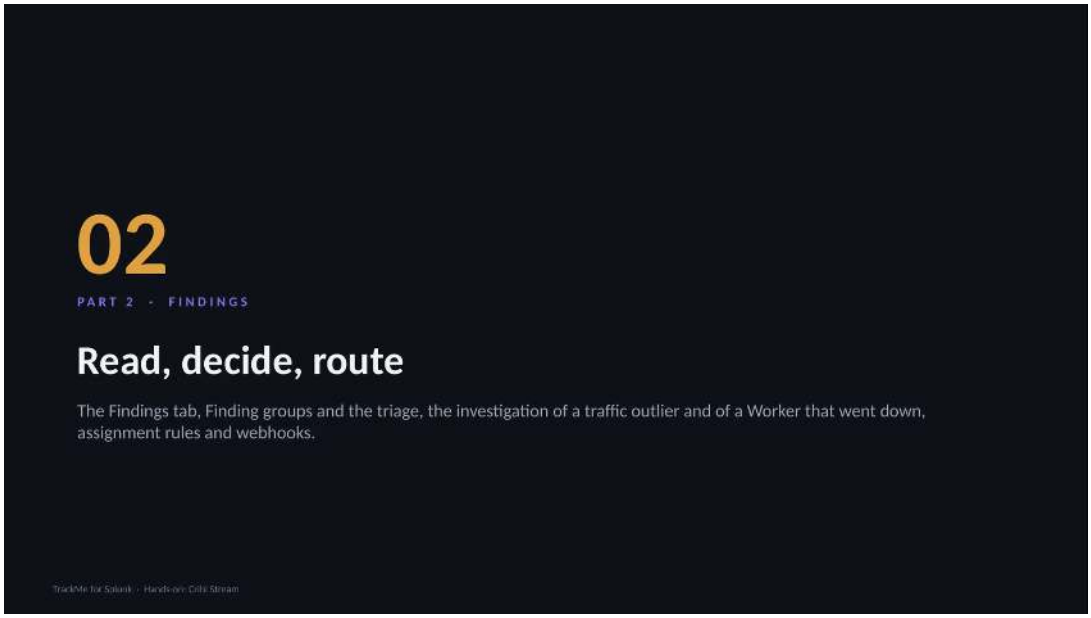
On Virtual Tenants the tenant card shows the open Finding groups and findings, the critical ones and the collection status. Inside the workspace, the status strip says at a glance that the tenant is working: the connection, the Leader, the Worker Groups, the last run of each job and how many traffic ML models are detecting; Refresh, and for a TrackMe administrator of the tenant Collect now.

Collection health on day one



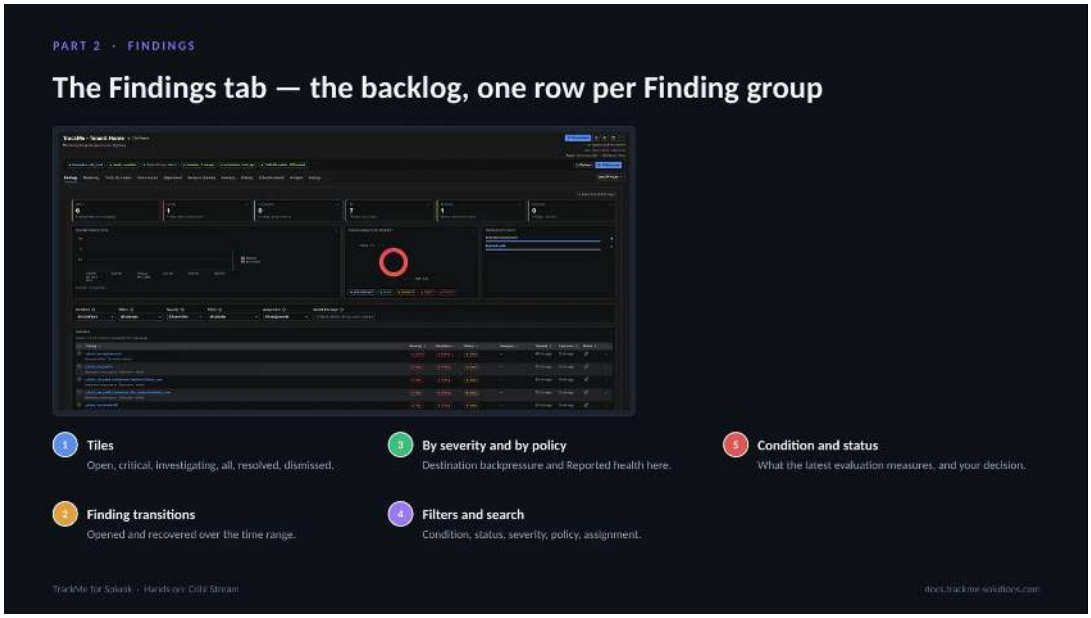
Collection health answers: is TrackMe collecting what it should? One card per job with its last run, its outcome in words, View last run and Run now; the metric coverage; the traffic ML models with their learning progress; and the Cribl Leader card with the requests against the budget and the inventory cycle.

Part 2 — Findings



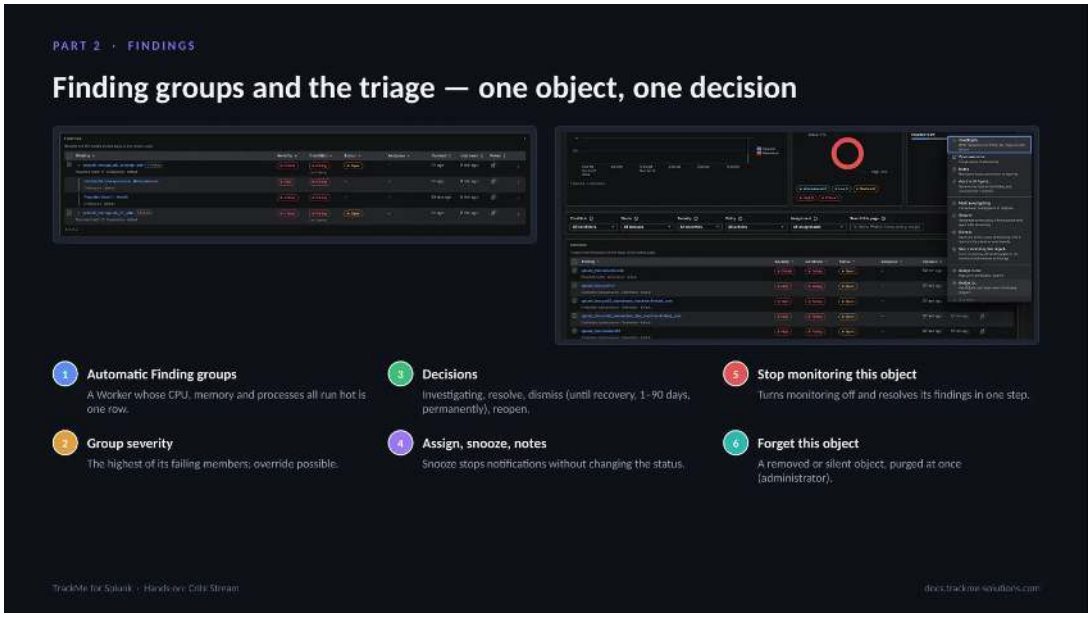
A finding is one policy applied to one measurement of one object. One object's findings form one Finding group: one row, one decision. Each finding shows its condition, what the newest evaluation measures, and its status, the decision taken. Triage, assignment rules and findings actions are shared with the other findings tenants.

The findings backlog



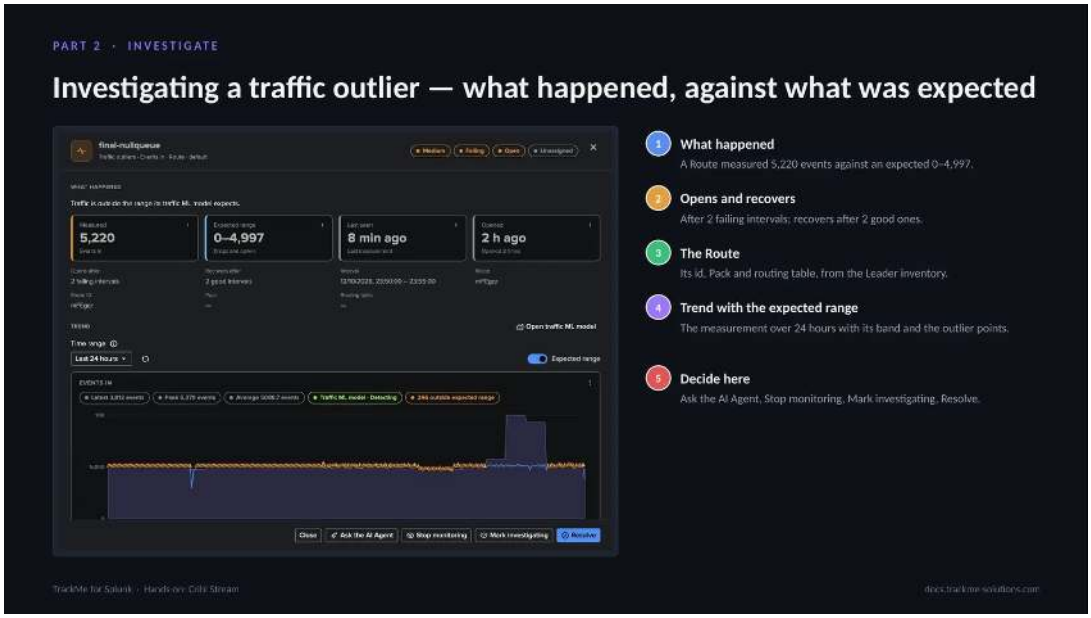
The Findings tab is the backlog and the tab the workspace opens on. Each finding shows its condition — Failing, Recovered, Awaiting data — and its status, the decision: Open, Investigating, Resolved, Dismissed. Severity uses the TrackMe scale from Informational to Critical. A measured recovery resolves an open finding by itself; a new failure reopens it.

One decision per object



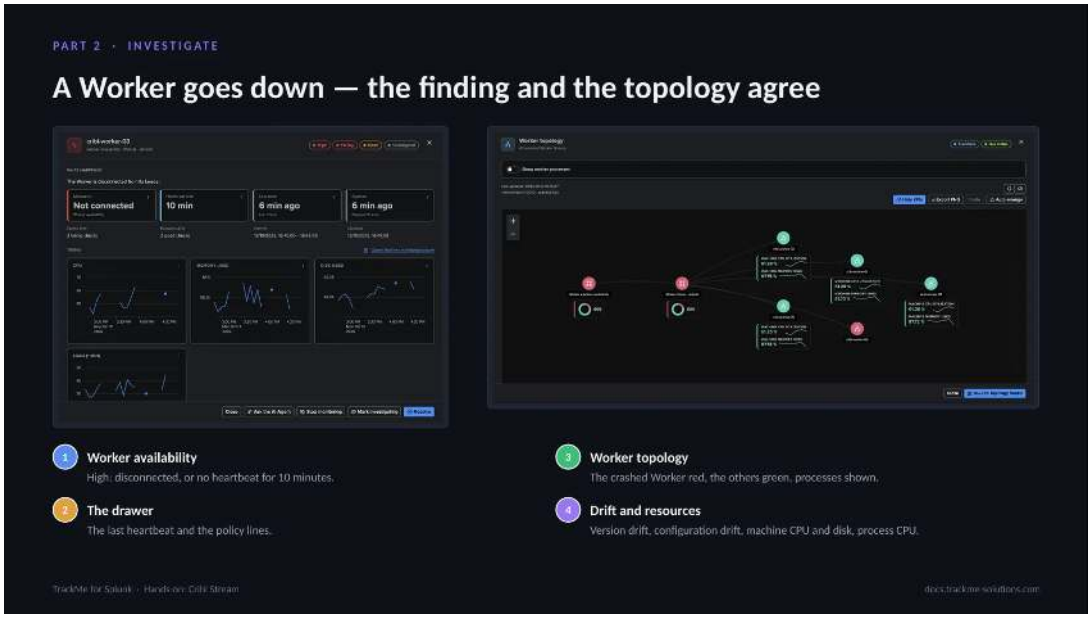
One object can fail several policies at once. TrackMe groups its findings automatically into a Finding group, so you make one decision: status, assignee, snooze, dismissal and severity override live on the group. Groups can also be merged, edited or ungrouped by hand. The row menu carries Ask the AI Agent, the decisions, and two Cribl-specific actions: Stop monitoring this object and Forget this object.

Investigating a traffic outlier



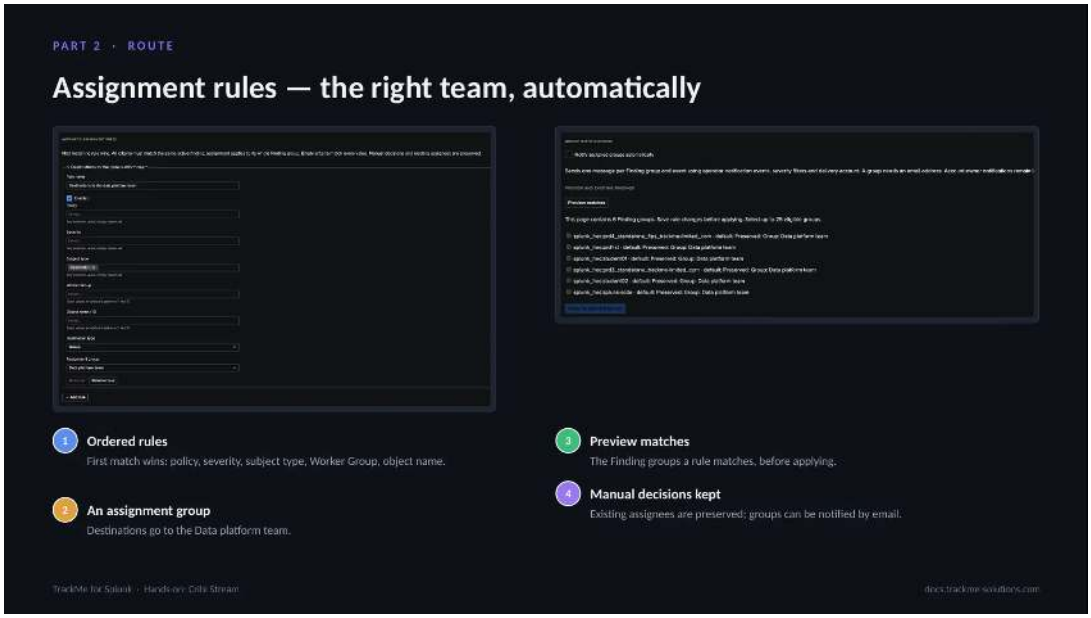
Selecting a row opens the investigation drawer: what happened in plain words, the measurement against its expected range, the open and recovery rules, the object in the inventory, the trend chart with the band, notes and history. For a Worker or the Leader the chart shows the policy threshold and recovery lines instead of a band.

When a Worker goes down



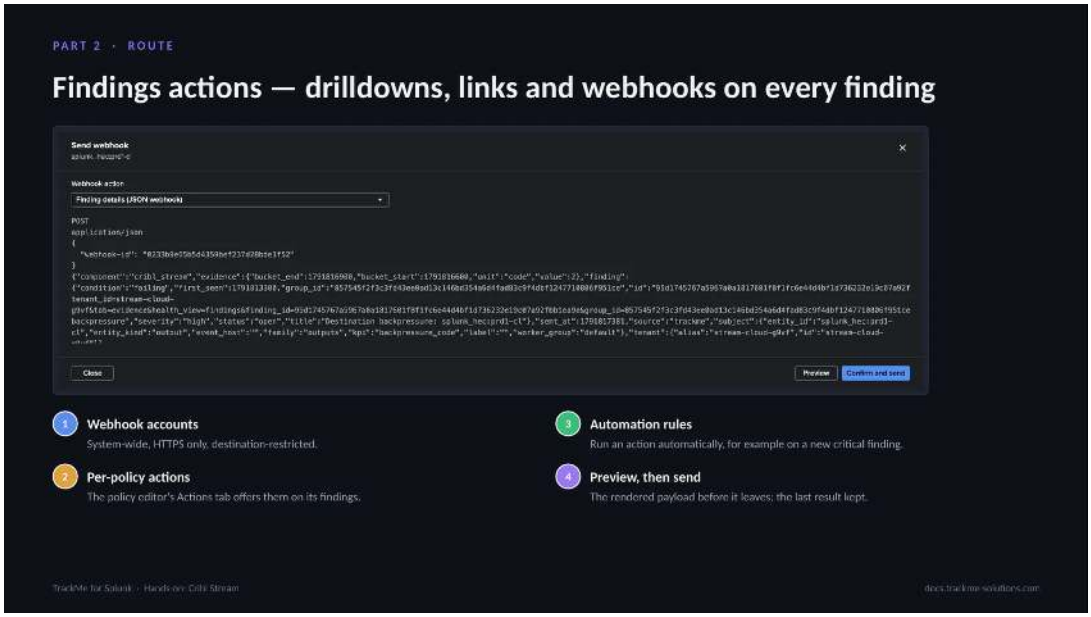
From the Leader, TrackMe knows every Worker and how it should look. A Worker that stopped answering opens a High Worker availability finding. The Worker topology of the Infrastructure tab shows the same story: the crashed Worker in red with its processes. Version and configuration drift, machine CPU and disk and process CPU follow the same pattern.

Routing findings to a team



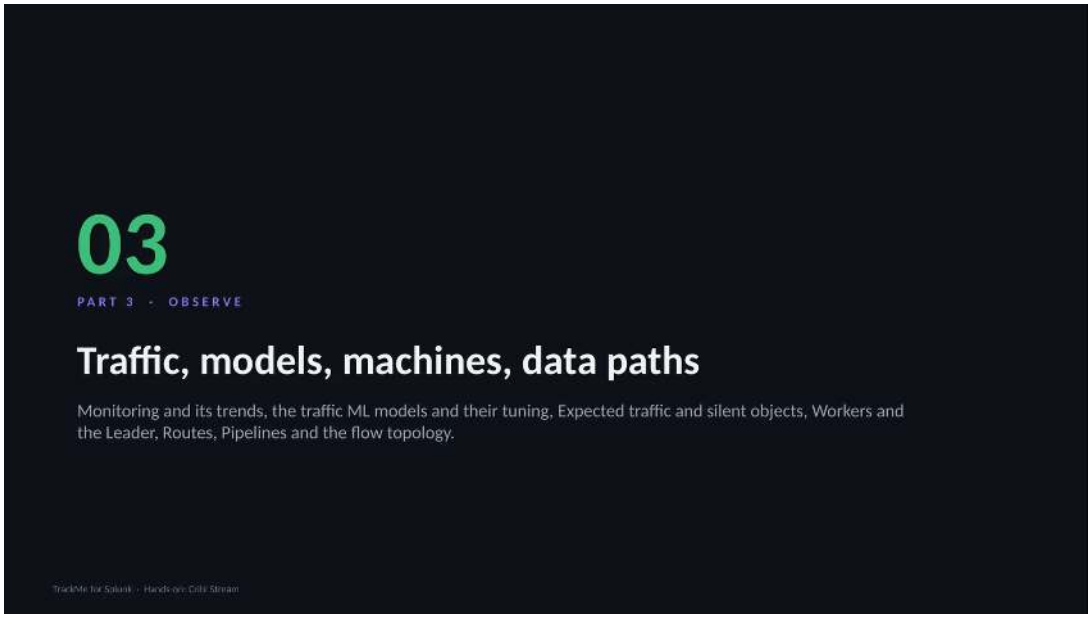
Settings, Assignment. Assignment groups and ordered rules route new findings to the right team. Preview matches lists the Finding groups a rule matches, here already assigned to the Data platform team and preserved, with Apply to selected groups for the existing ones. Assignment groups carry a team email, so an assigned group can be notified automatically.

Drilldowns, links and webhooks



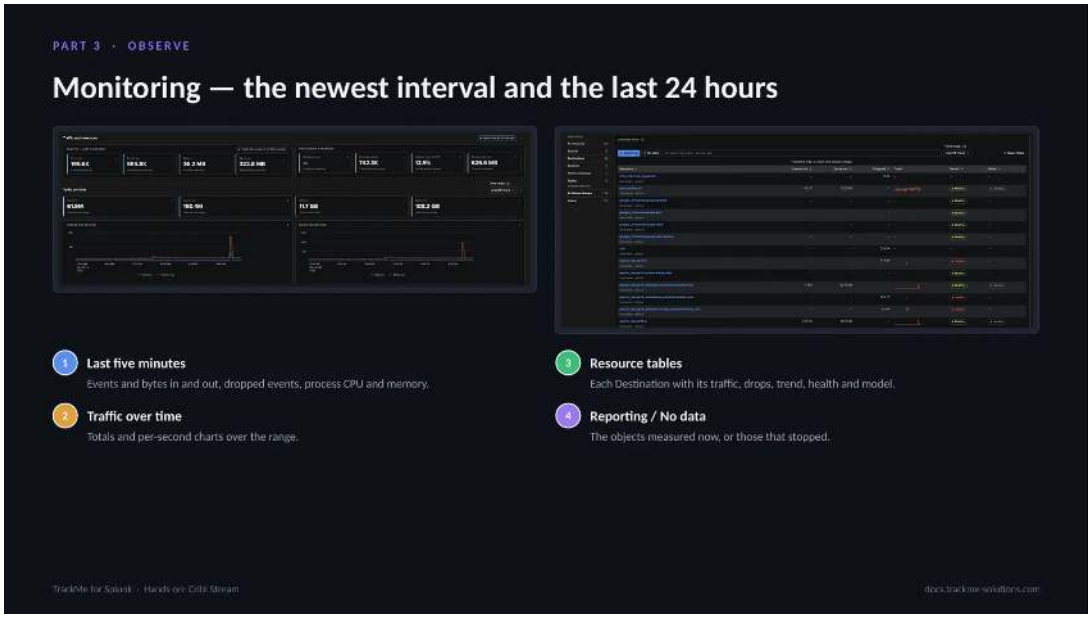
Findings actions add drilldown searches, links and webhooks to the findings, run by hand or by automation rules, through system-wide Webhook accounts. The preview shows the payload before it is sent. The concepts are shared with the other findings tenants. An automation rule can run an action without anyone opening the finding, for example posting every new critical finding to a chat channel.

Part 3 — Observe



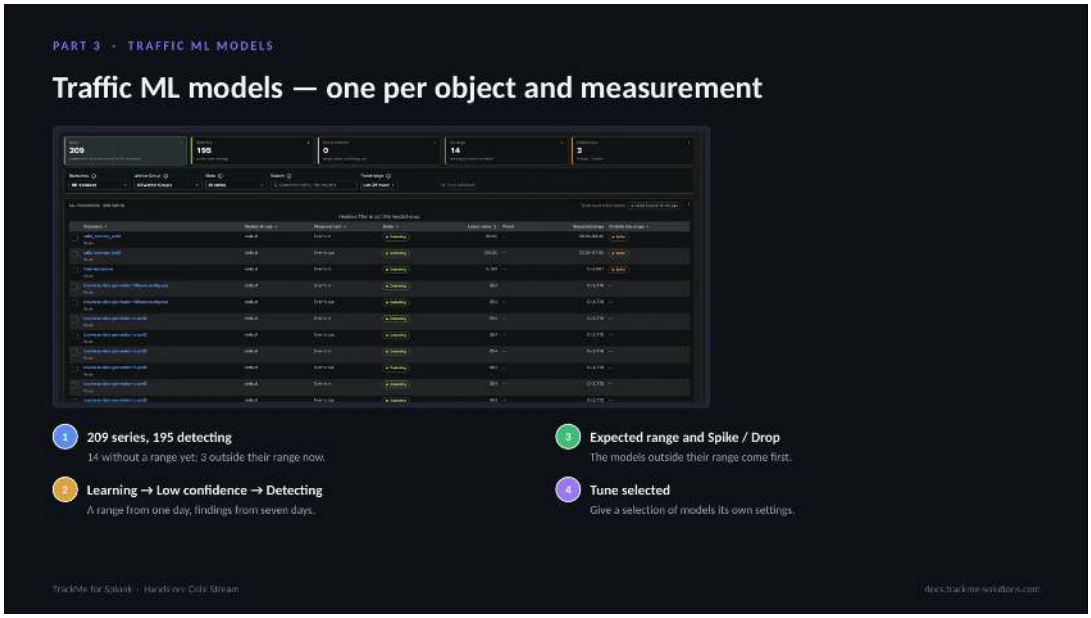
Every figure has a menu with View chart data and Open in Search, a plain editable search that reproduces it. Monitoring, the traffic ML models, Expected traffic and silent objects, the Infrastructure tab with Workers and the Leader, and Routes & pipelines with the flow topology are covered in turn.

Traffic and resources



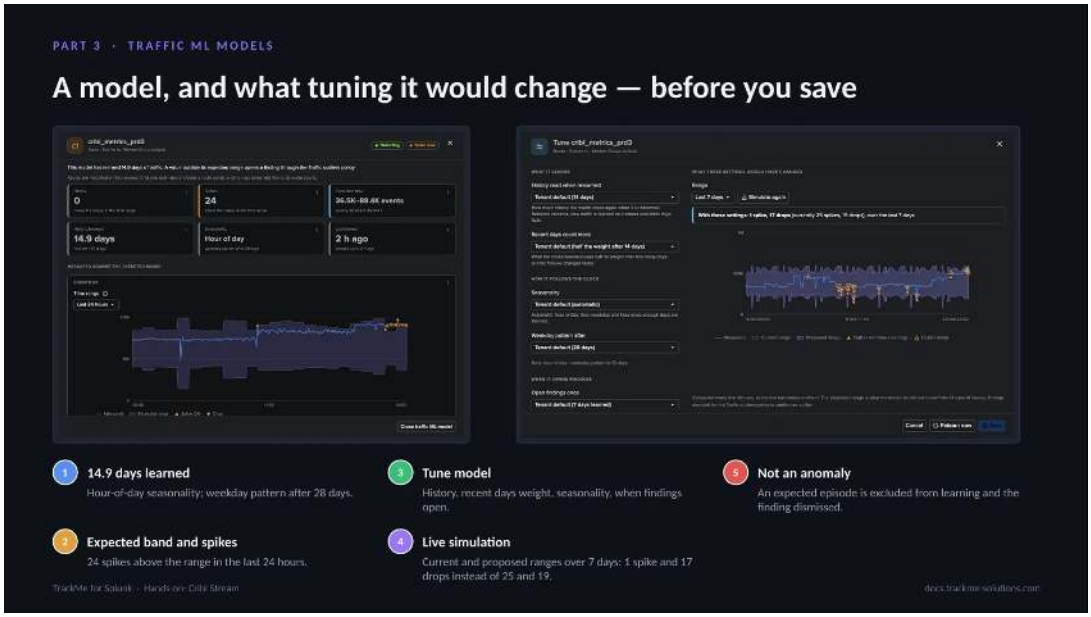
Monitoring shows the newest five-minute interval of every object and the traffic over the selected range. The resource tables list each Source, Destination, Pipeline, Route and worker process with its latest values, its health, its traffic ML model and a trend; a row opens its charts with the expected range and, for a Source or Destination, its live status from the Leader.

One model per object and measurement



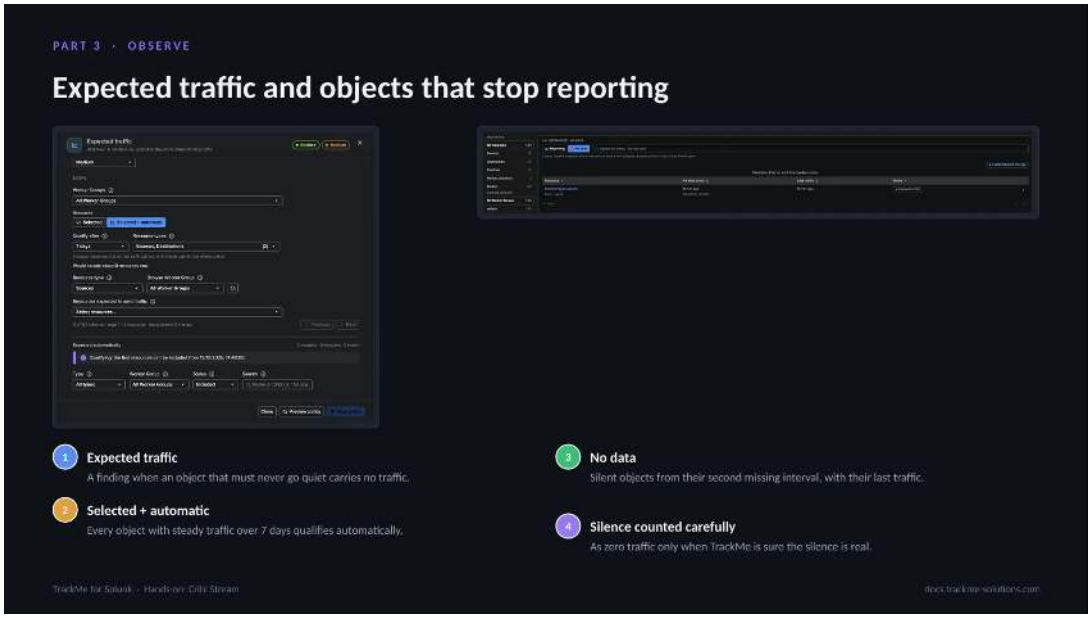
Every Source, Destination, Pipeline and Route gets its own traffic ML model. A model learns per hour of the day, then per weekday and hour after four weeks, with recent days counting more, and keeps learning from the newest intervals: there is no periodic full retrain. Learning means no range yet; Low confidence draws the range without findings; Detecting opens findings through the Traffic outliers policy.

A model and its tuning



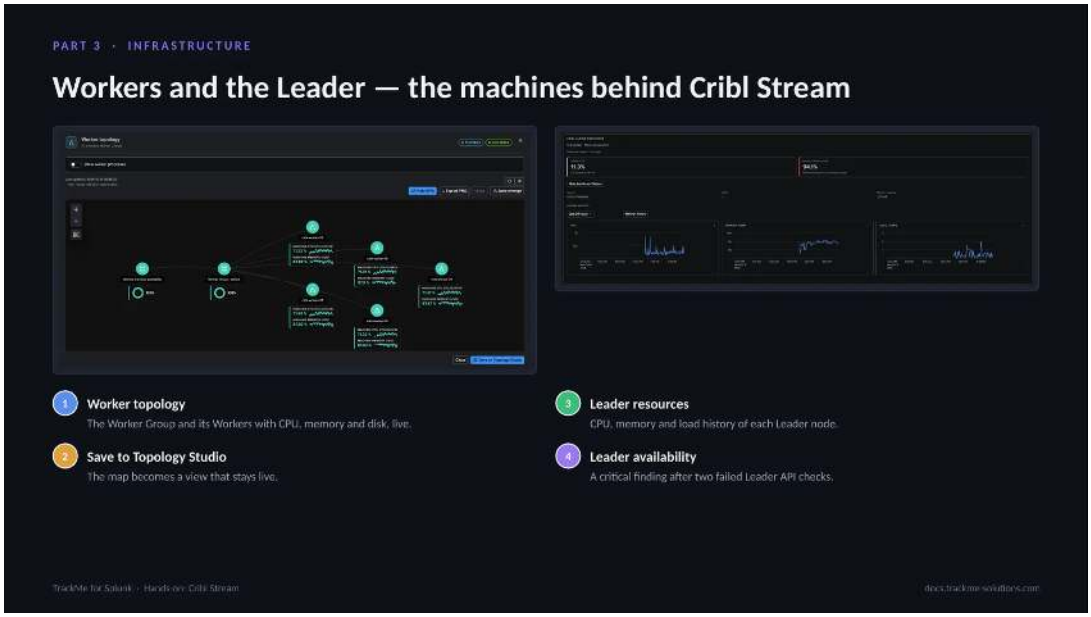
A model shows what it learned, its drops and spikes, its expected range, the history learned and its seasonality. Tune model gives a model or a selection its own settings, and the tuning screen simulates the current and proposed bands over 24 hours, 7 or 30 days, with the drops and spikes each would have raised, before anything is saved. Not an anomaly excludes an expected episode from what the model learns.

Expected traffic and silent objects



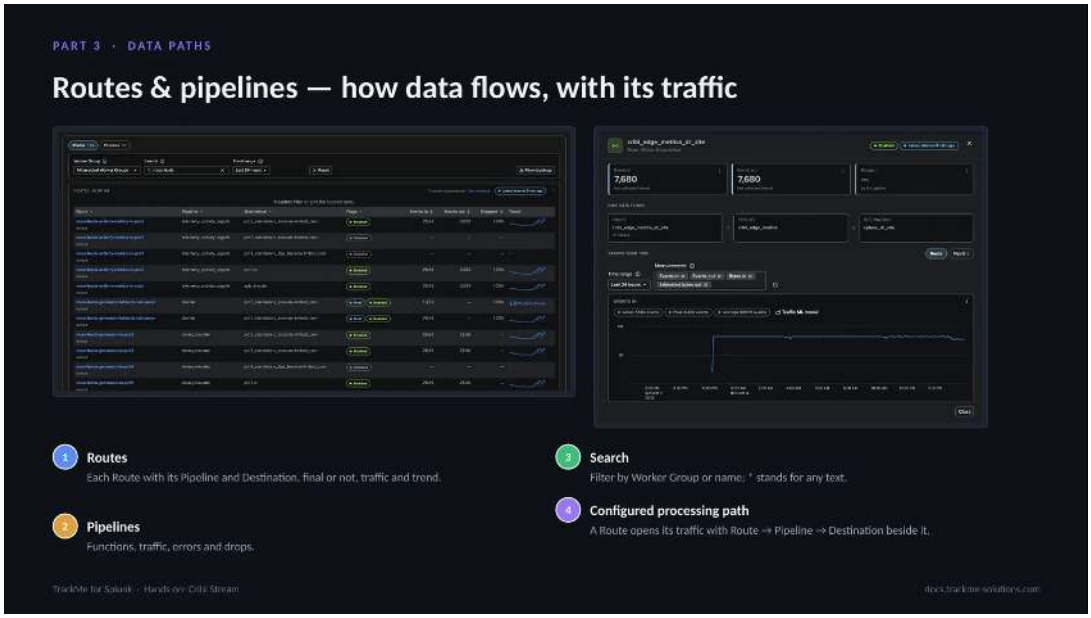
Some objects must never go quiet. Expected traffic opens a finding when an expected object carries no traffic; in Selected plus automatic mode TrackMe also expects every object that carried traffic steadily over the qualifying window. TrackMe remembers every object it measured: a silent object appears under No data, and Traffic outliers counts its silence as zero traffic only when the inventory, the Worker Group and the model confirm it is real.

Workers and the Leader



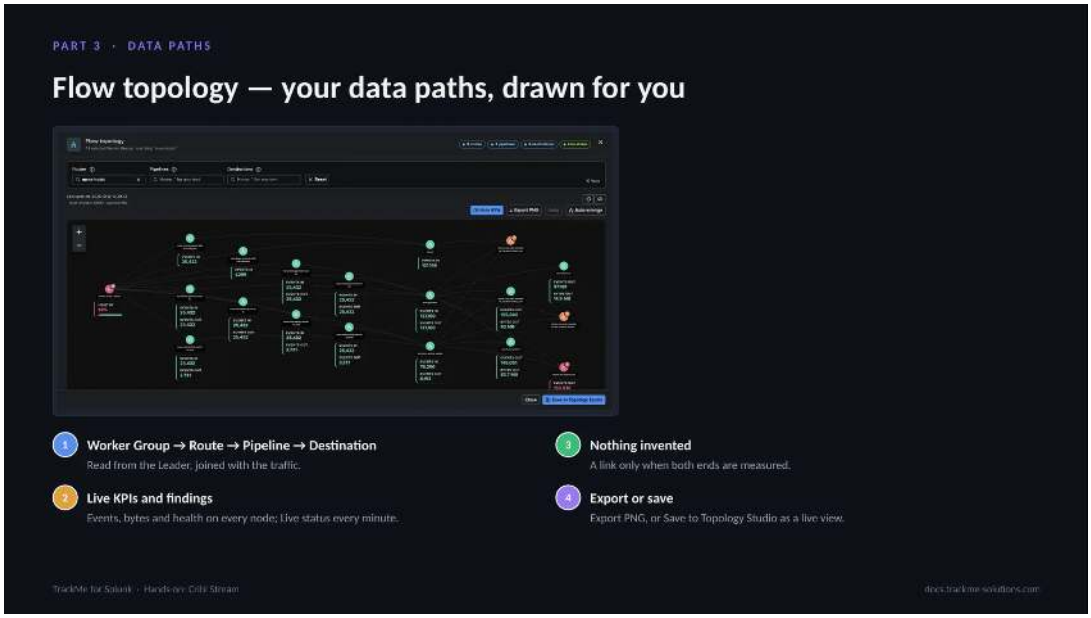
Infrastructure shows the machines: the Leader nodes with their resources and history, every Worker with its heartbeat, CPU, memory, load and disk, and every worker process. Worker topology draws them as a live map, ready to save to Topology Studio. TrackMe checks the Leader API at every live run: two failed checks open a critical Leader availability finding.

Routes and pipelines



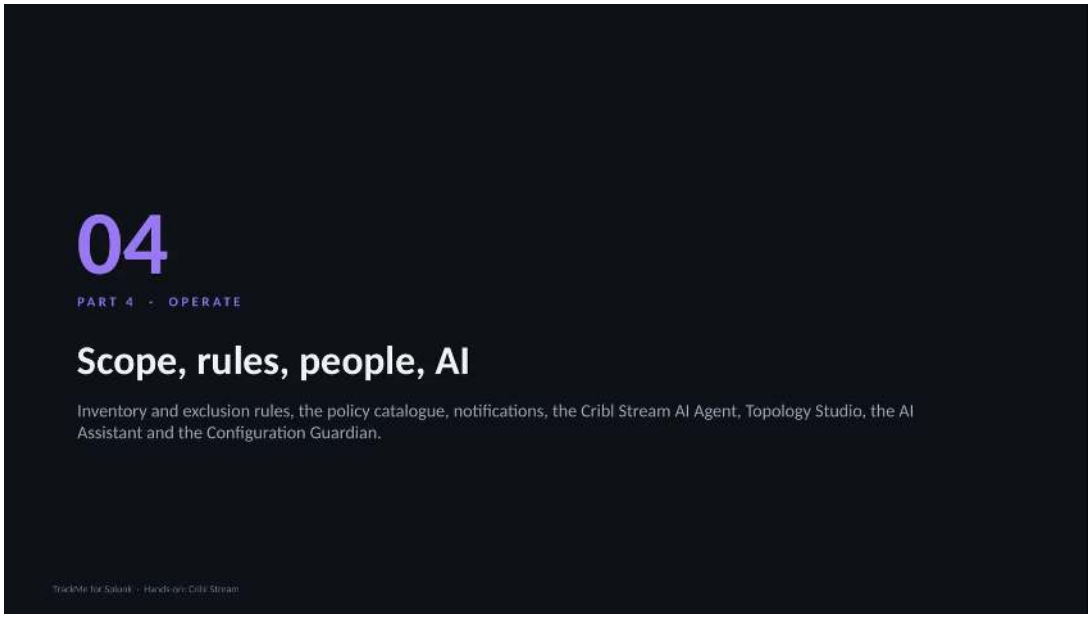
Routes & pipelines shows how data flows: every Route with its Pipeline and Destination and its measured traffic, and every Pipeline with its functions, errors and drops. A Route or Pipeline opens its traffic over time with its configured processing path beside it. Filters select a Worker Group or a name, with * standing for any text.

Data paths drawn as flows



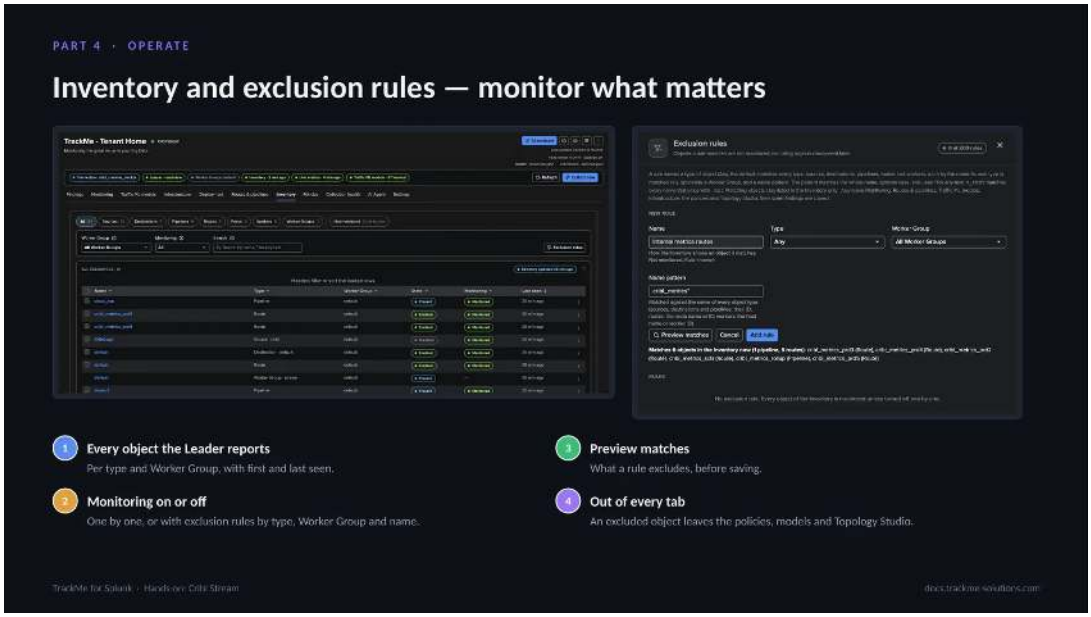
Flow topology draws the Routes the table selects as flows, left to right. You configure nothing: TrackMe reads each Route's Pipeline and Destination from the Leader and joins them with the traffic it measures. A Destination fed by several Routes shows once, so you see which Routes depend on a Destination under backpressure. It covers up to 200 Routes at a time.

Part 4 — Operate



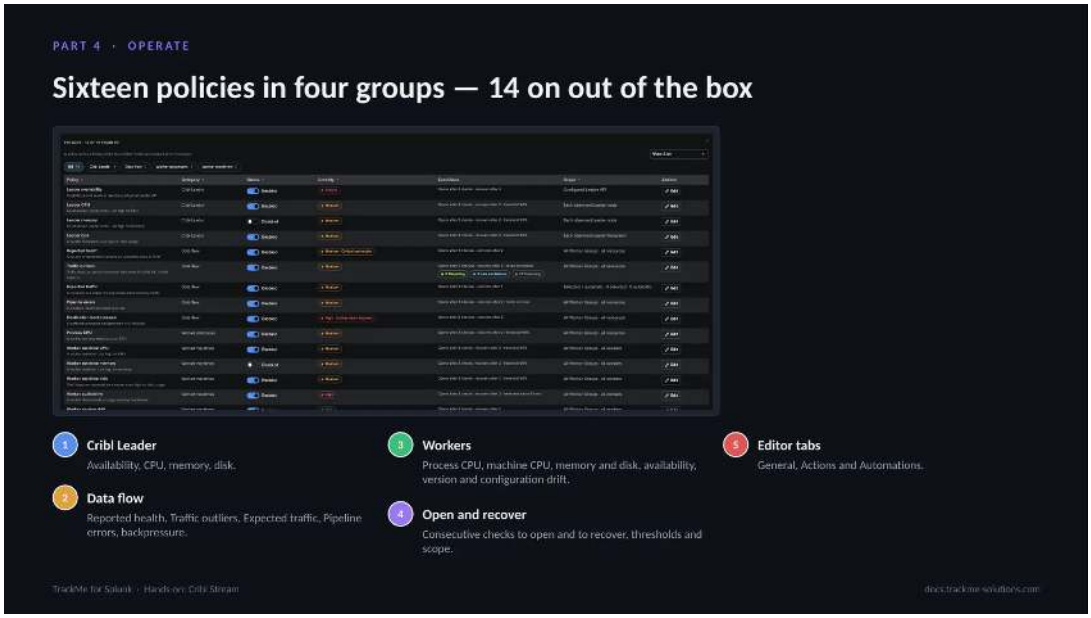
The Inventory and exclusion rules decide what is monitored; the sixteen policies, notifications, the Cribl Stream AI Agent, Topology Studio, the AI Assistant with the Concierge, and the Configuration Guardian complete the operation of the tenant. Policies, exclusion rules and settings are changed by a TrackMe administrator of the tenant; every role of the tenant reads them.

Choosing what to monitor



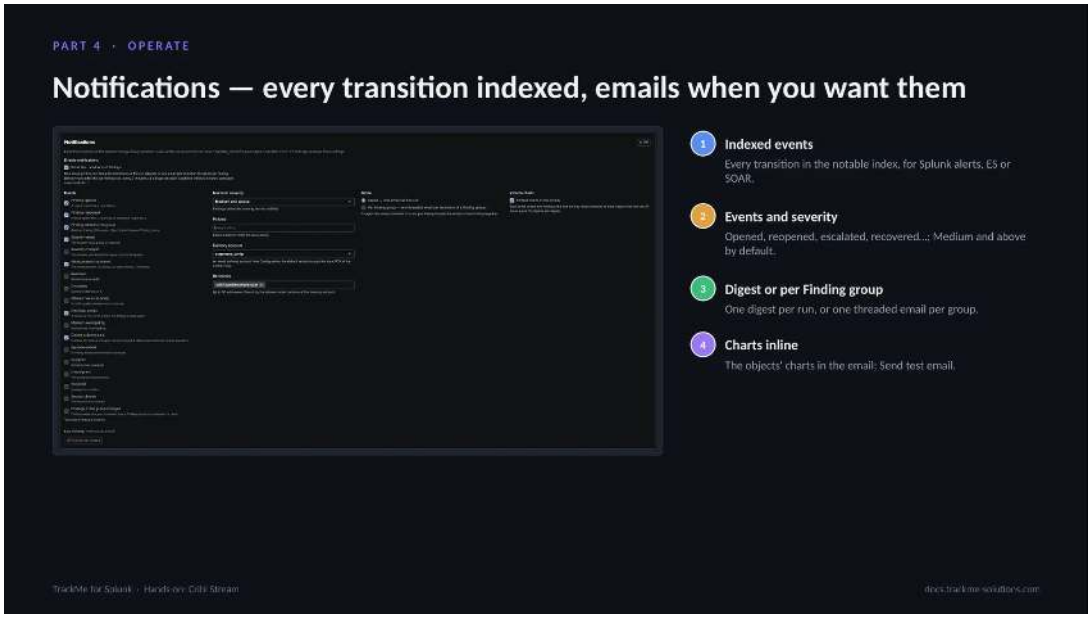
The Inventory lists every object the Leader reports, with its monitoring state. Turn monitoring off for objects you do not care about — a test Route, a retired Destination, a lab Worker — one by one or with exclusion rules. An object turned off appears only in the Inventory: it leaves the other tabs, the policies, the model training and Topology Studio, and its open findings close.

The policy catalogue



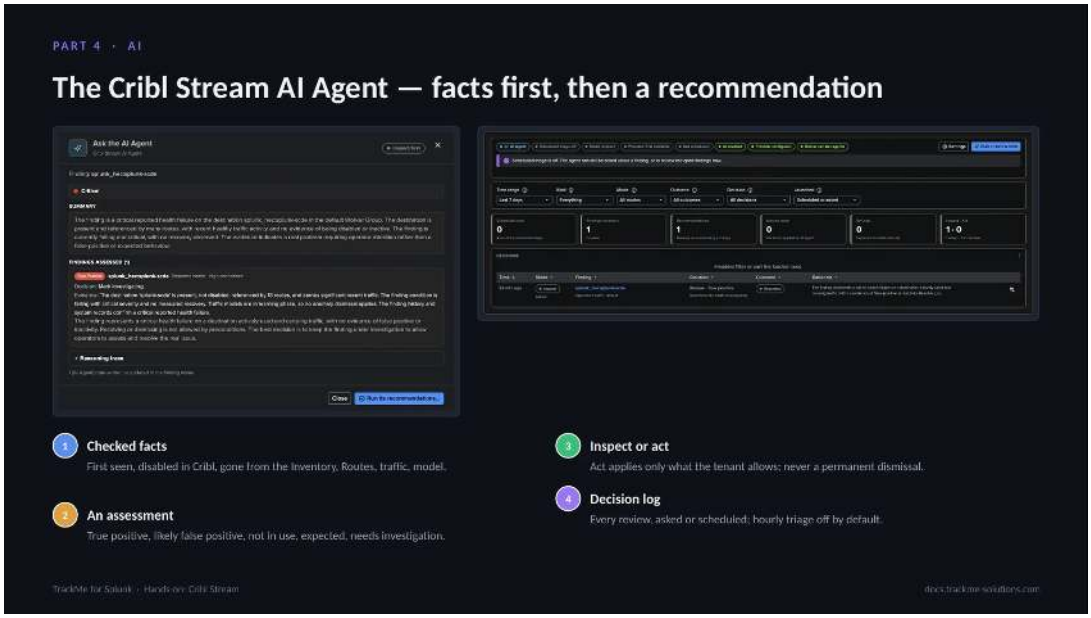
The 16 built-in policies in four groups. Each has its enablement, its severity, how many consecutive checks open and recover a finding, its thresholds and its scope, with a preview of what it would select. Leader memory and Worker machine memory are off by default because the memory the operating system reports as used includes its file cache.

Notifications and indexed events



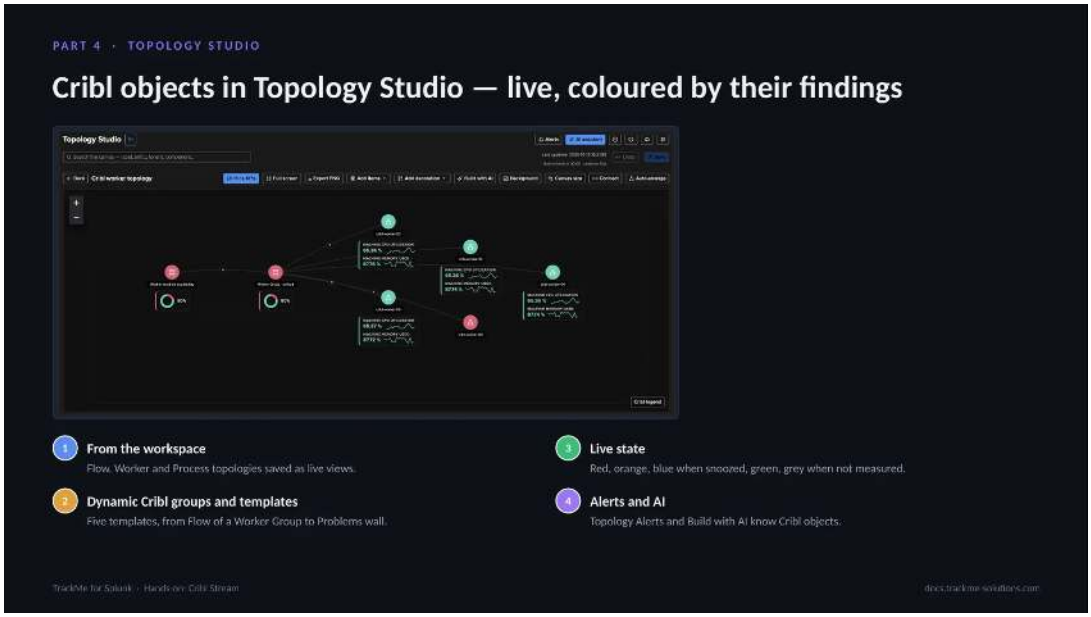
Every transition of a finding or Finding group is written to the notable index, whatever the notification settings. Email notifications are off by default; a TrackMe administrator of the tenant chooses the events, the minimum severity, the policies, the delivery account and up to 50 recipients, and the digest or per-group mode.

The Cribl Stream AI Agent



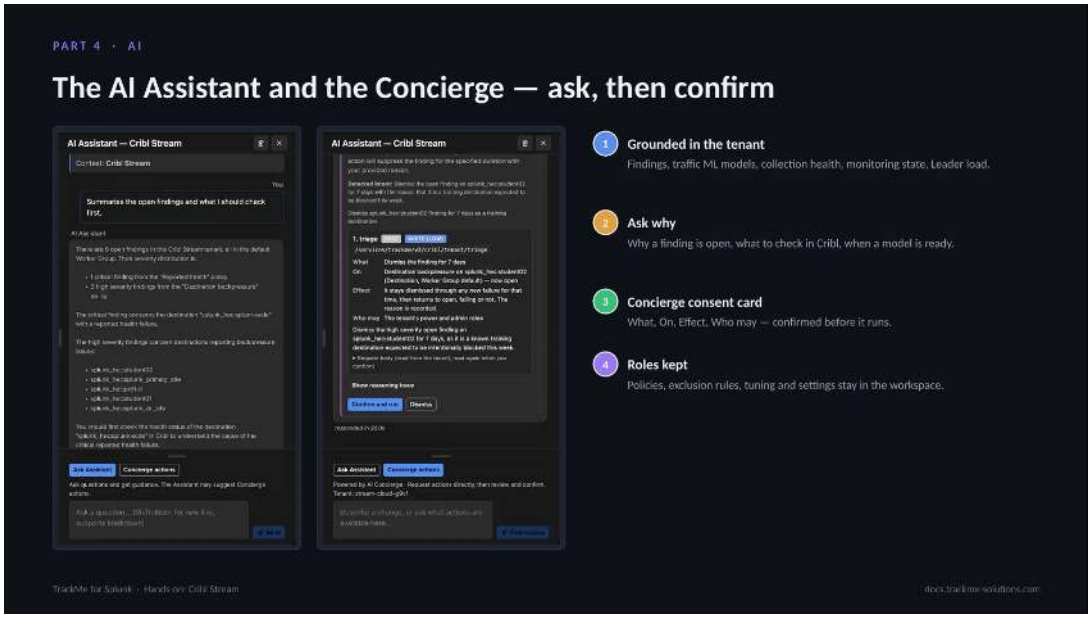
The Cribl Stream AI Agent reviews findings from facts TrackMe checks: when the object was first seen, whether it is disabled in Cribl or gone from the Inventory, which Routes reference it, its traffic and its model. It recommends a decision and keeps one current AI Agent note. Act applies by default only Mark investigating, Dismiss for a time and Not an anomaly; Resolve and Stop monitoring need a proof.

Cribl objects in Topology Studio



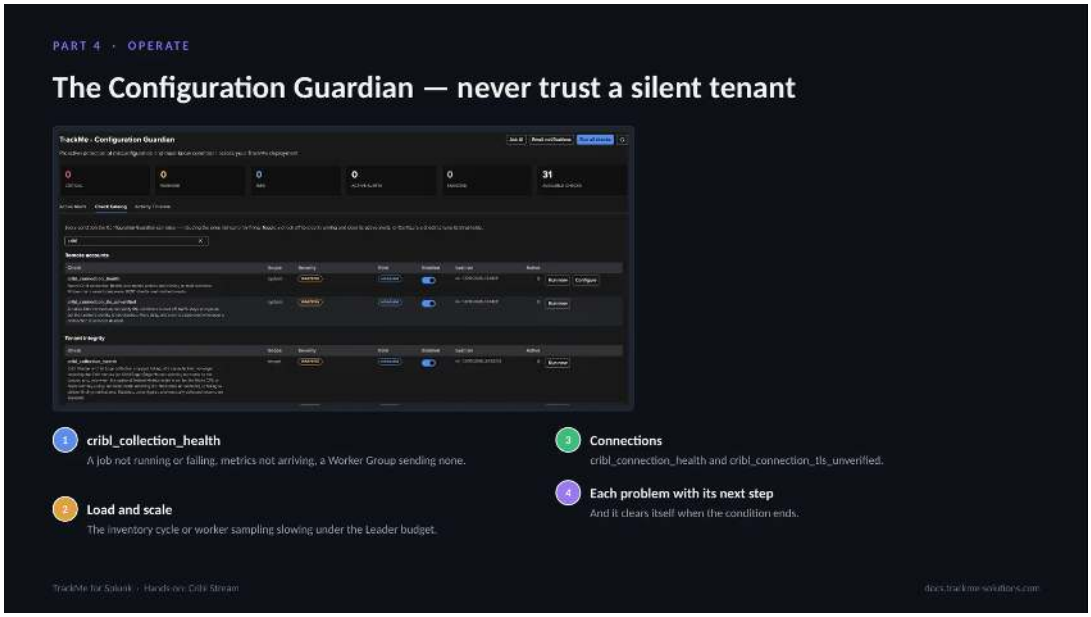
Cribl objects are first-class citizens of Topology Studio: Sources, Destinations, Pipelines, Routes, Workers and worker processes, dynamic Cribl groups that follow a selection, and five templates. Nodes carry their KPIs and 24-hour sparklines, and their colour follows their findings. From the workspace, the Flow, Worker and Process topologies are saved as live views. In the Studio, Add entities and dynamic Cribl groups pick objects, and Topology Alerts and Build with AI know Cribl objects.

AI Assistant and Concierge



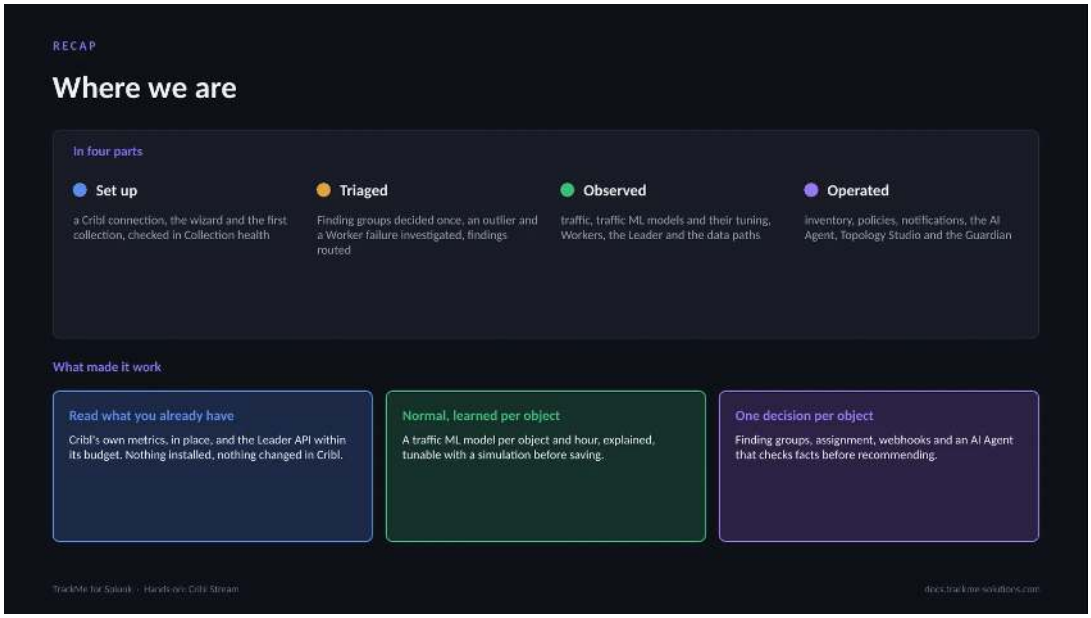
The AI Assistant of a Cribl Stream tenant is grounded in its findings, models, collection health, monitoring state and Leader load. When you ask for a change it can make, it proposes an AI Concierge consent card that you confirm before anything runs: a decision on a finding, Not an anomaly, monitoring on or off for named objects, a collection job, or relearning a model. Each action keeps the role it requires.

Collection health and the Guardian



Collection health keeps you from trusting a silent tenant. The Configuration Guardian check cribl_collection_health raises a warning when a job is not running or keeps failing, when metrics stop arriving, when the collection slows down under the Leader budget, when many objects stop together, or when notification emails fail. The Guardian also checks the Cribl connections themselves.

Where we are



A tenant created on a Cribl connection, its findings grouped per object and triaged, a traffic outlier investigated against its learned range, a Worker failure seen in the finding and the topology, findings routed to a team and to a webhook, the deployment observed from its traffic to its machines and data paths, and the tenant operated with policies, notifications, the AI Agent, Topology Studio and the Guardian.

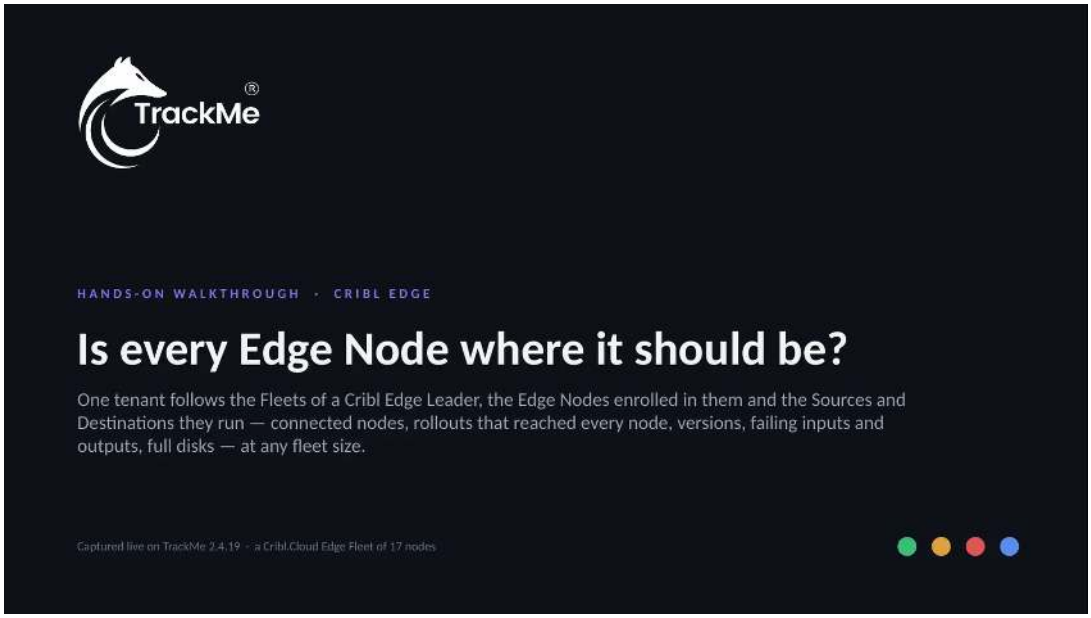
2.1.10 Cribl Edge

Follow the Fleets of a Cribl Edge Leader, the Edge Nodes enrolled in them and the Sources and Destinations they run, from one bulk read of the Leader at any fleet size: connected nodes, rollouts and version drift, failing inputs and outputs, any node opened up close with its System activity read live, the nodes that must stay connected selected from Splunk lookups, bank holidays per policy, and the Cribl Edge AI Agent with its custom instructions.

`Download the deck (PDF) · PowerPoint`

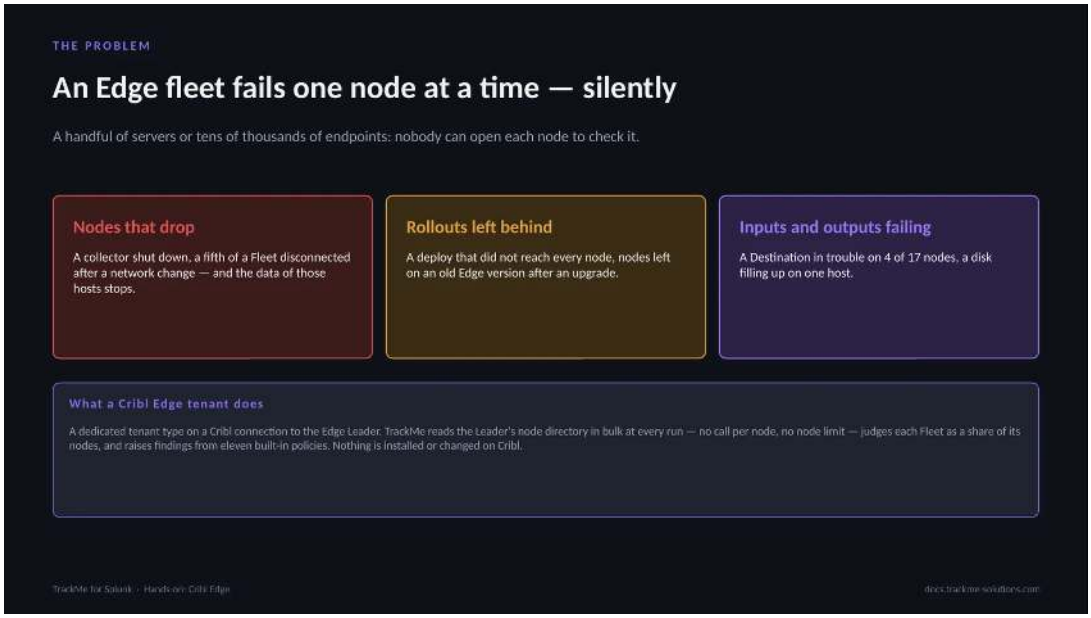
about 30 minutes · 30 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

Overview



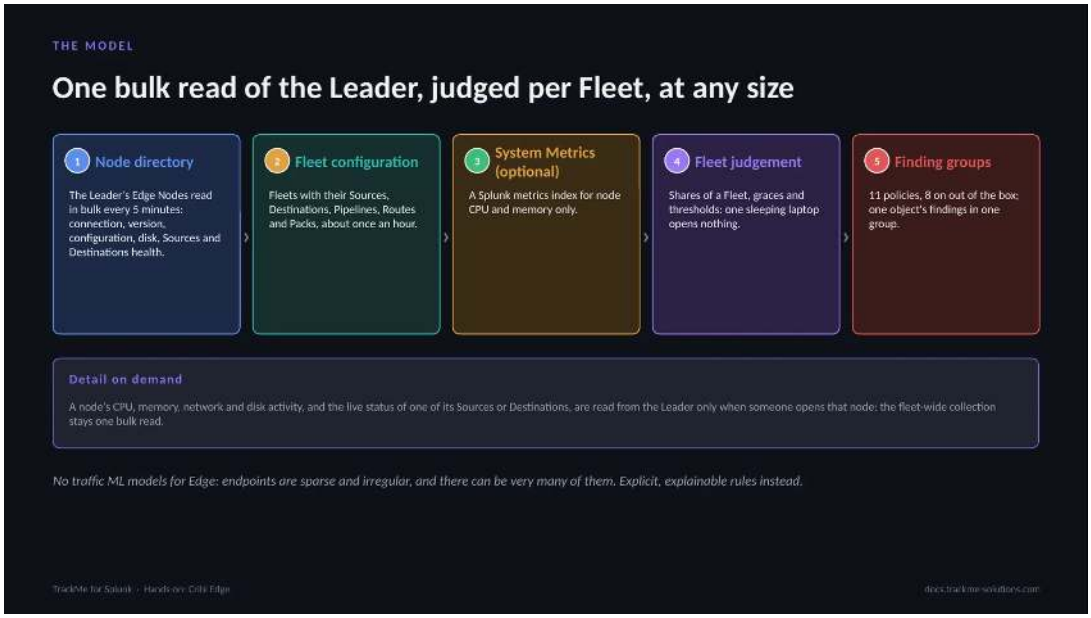
This walkthrough covers the Cribl Edge tenant, generally available in TrackMe 2.4.19. Everything was captured live on a Cribl.Cloud Edge Fleet of 17 nodes. In four parts: create the tenant, follow the Fleets and the Edge Nodes, read the findings, and operate the tenant.

Why a dedicated Cribl Edge tenant



An Edge operator asks the same questions every day: are my nodes connected, did my last deploy reach every node, is every node on the same Edge version, which Source or Destination is failing and on how many nodes, which host is running out of disk. The Cribl Edge tenant answers them with findings raised by built-in policies, with the same triage as the Cribl Stream tenant.

How a Cribl Edge tenant works



Every five minutes TrackMe reads the Leader's list of Edge Nodes page by page and keeps it as one published node directory: no call per node, no rotation, every node current within one interval. The Fleet configuration is read about once an hour. Policies judge each Fleet as a share of its nodes, select nodes that must never drop, and watch disk, and CPU and memory when a System Metrics index is set. There is no machine learning for Edge.

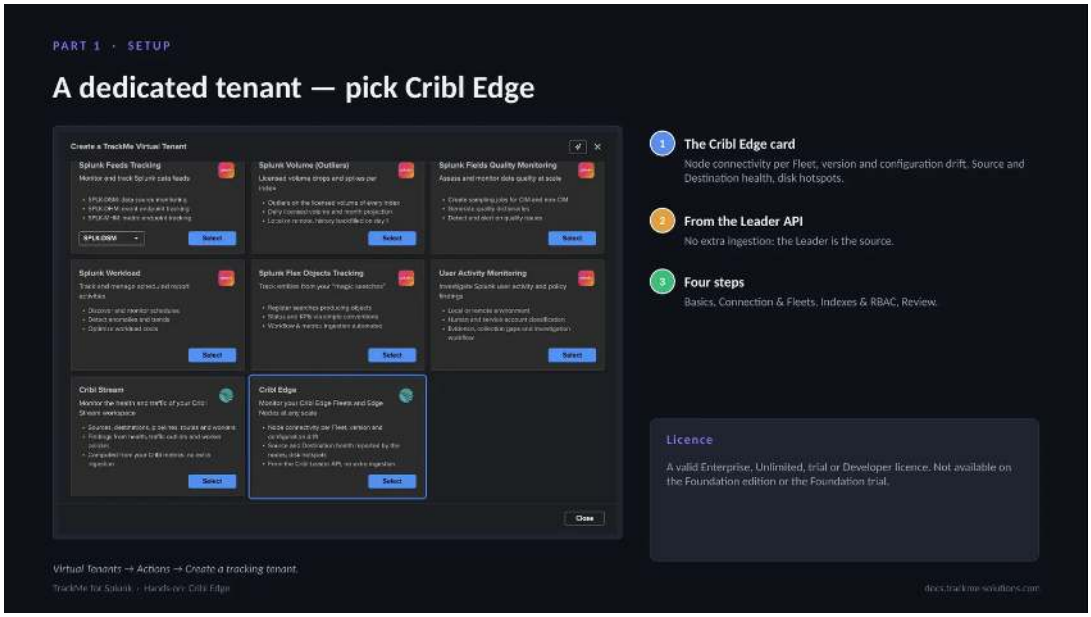
The parts of the walkthrough

Four parts. Setup: the wizard and the workspace. Fleets and nodes: the Fleets tab, a Fleet, the Edge Nodes and one node up close. Findings: the backlog, a disconnected node, the nodes that must stay connected and version drift. Operate: policies and bank holidays, collection health, settings, Topology Studio, the AI Assistant and the Cribl Edge AI Agent.

Part 1 — Setup

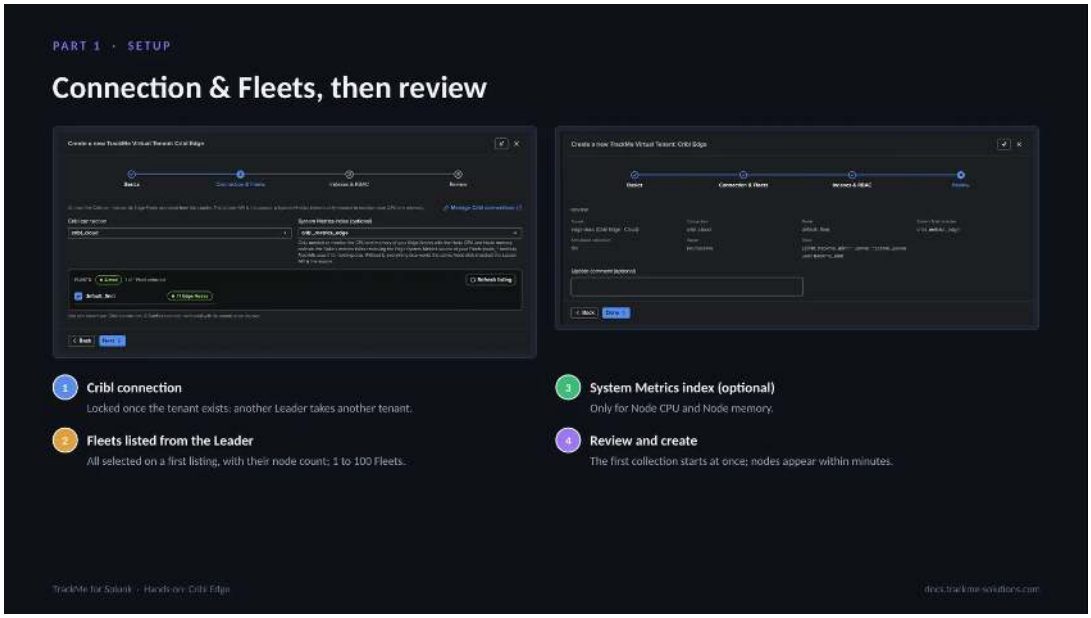
A Cribl Edge tenant uses the same Cribl connections as Cribl Stream; a Cribl.Cloud workspace running both products takes one tenant of each on the same connection. The wizard has four steps: Basics, Connection & Fleets, Indexes & RBAC and Review. The first collection starts at once, and the Fleets and Edge Nodes appear in the workspace within a few minutes.

Choosing the Cribl Edge card



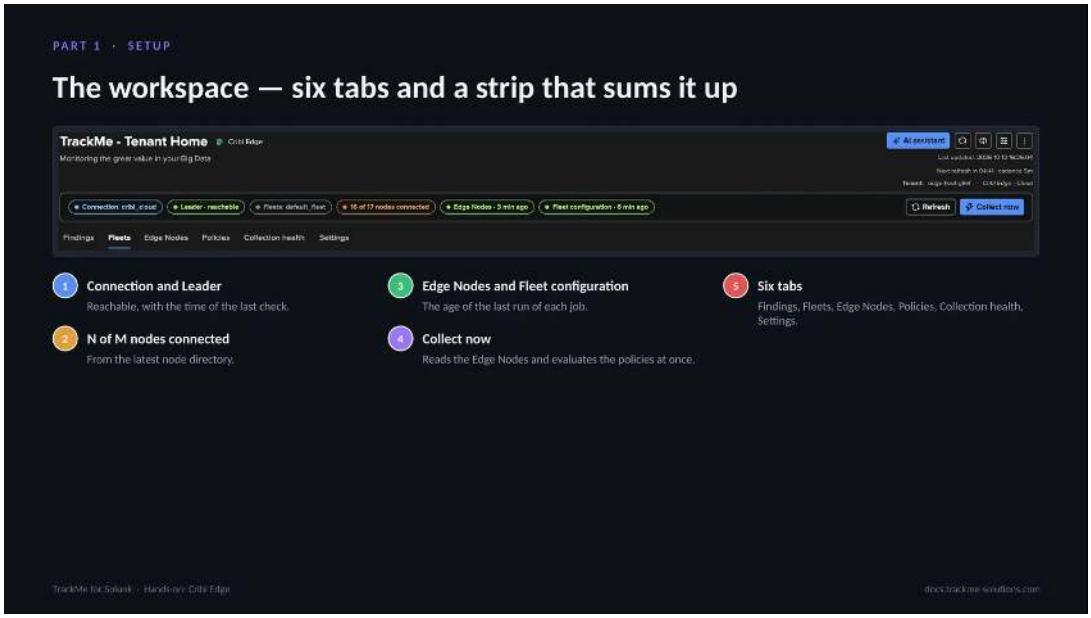
Virtual Tenants, Actions, Create a tracking tenant, Cribl Edge card. A tenant is a Cribl Edge tenant or a Cribl Stream tenant, never both. Basics is the identifier, alias and description. The card summarises what the tenant follows: node connectivity per Fleet, version and configuration drift, Source and Destination health reported by the nodes, and disk hotspots, all from the Cribl Leader API without extra ingestion.

Connection, Fleets and review



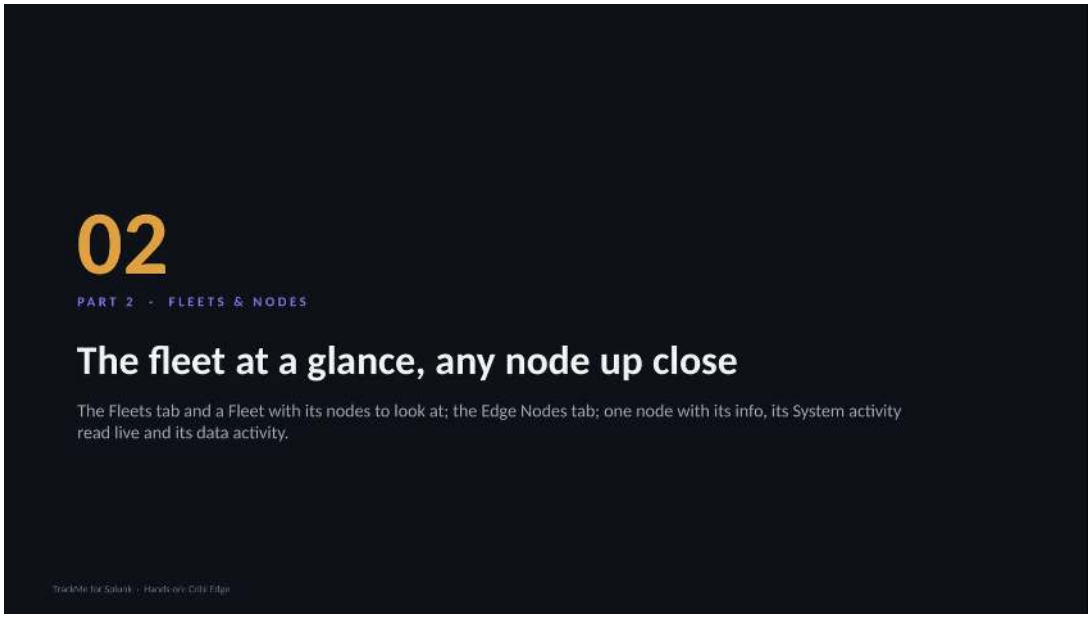
Choose the connection; TrackMe lists the Fleets from the Leader, each with its number of nodes, and a Subfleet can be monitored with its parent or on its own. The System Metrics index is optional: without it everything else works the same, node disk included. When the Leader cannot list the Fleets, the step says why and what to do.

The workspace and its status strip



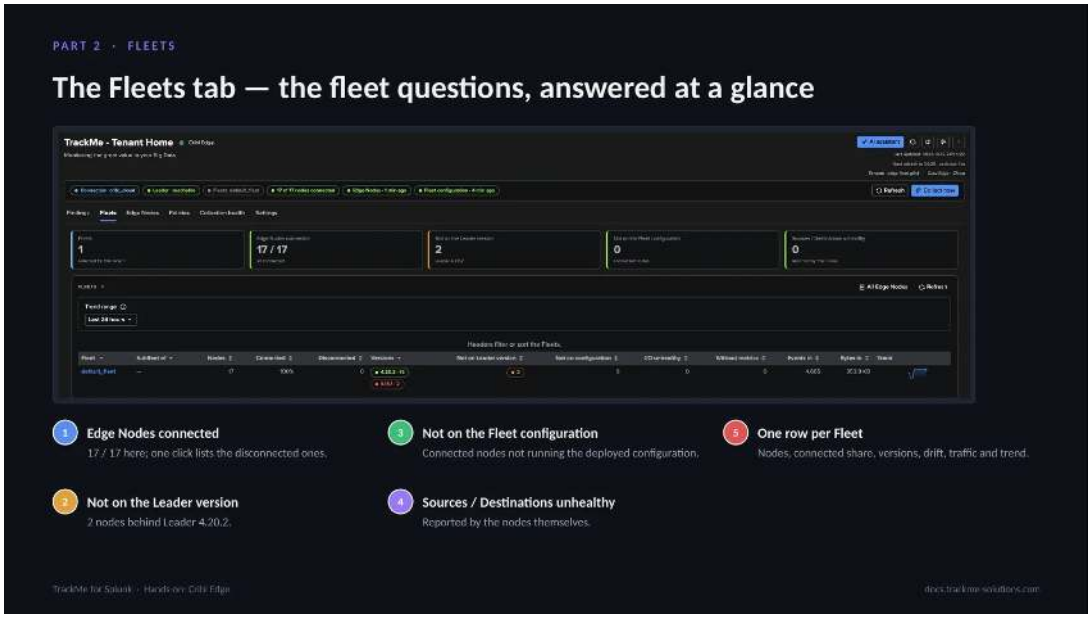
The Cribl Edge workspace is built with the same components as the Cribl Stream workspace, so the two look and behave the same. The status strip sums the tenant up; Collect now is for TrackMe administrators of the tenant. The six tabs are Findings, Fleets, Edge Nodes, Policies, Collection health and Settings. Every table is sorted, filtered and paged by the server.

Part 2 — Fleets and nodes



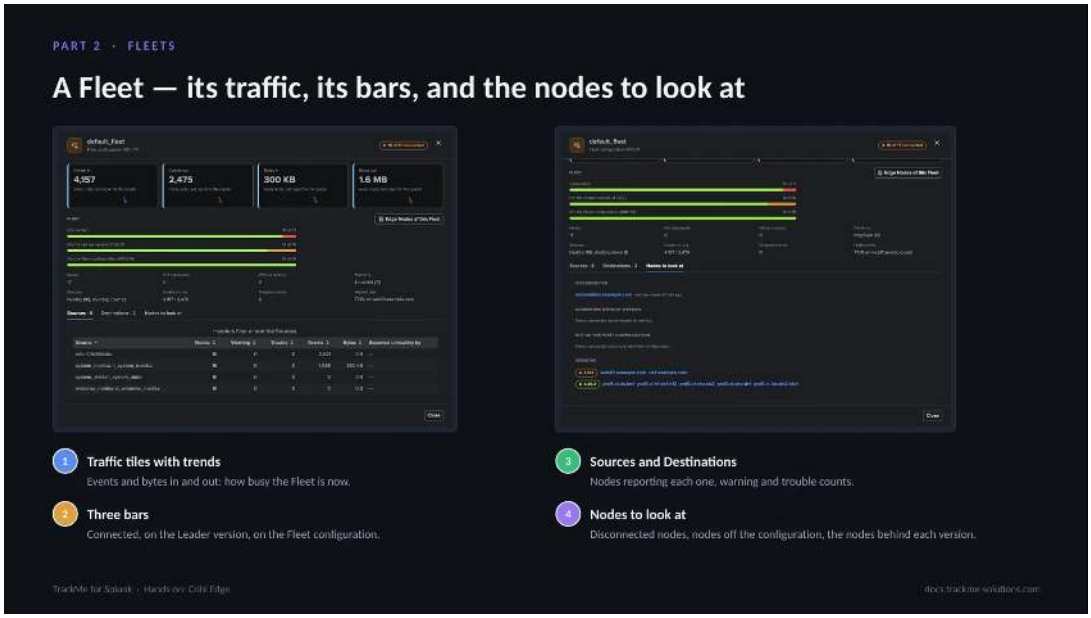
The Fleets tab answers the fleet questions at a glance; a Fleet opens with its traffic, its bars and the nodes to look at; the Edge Nodes tab lists every node; and a node opens with its Node info, its System activity read live and its Data activity.

The fleet at a glance



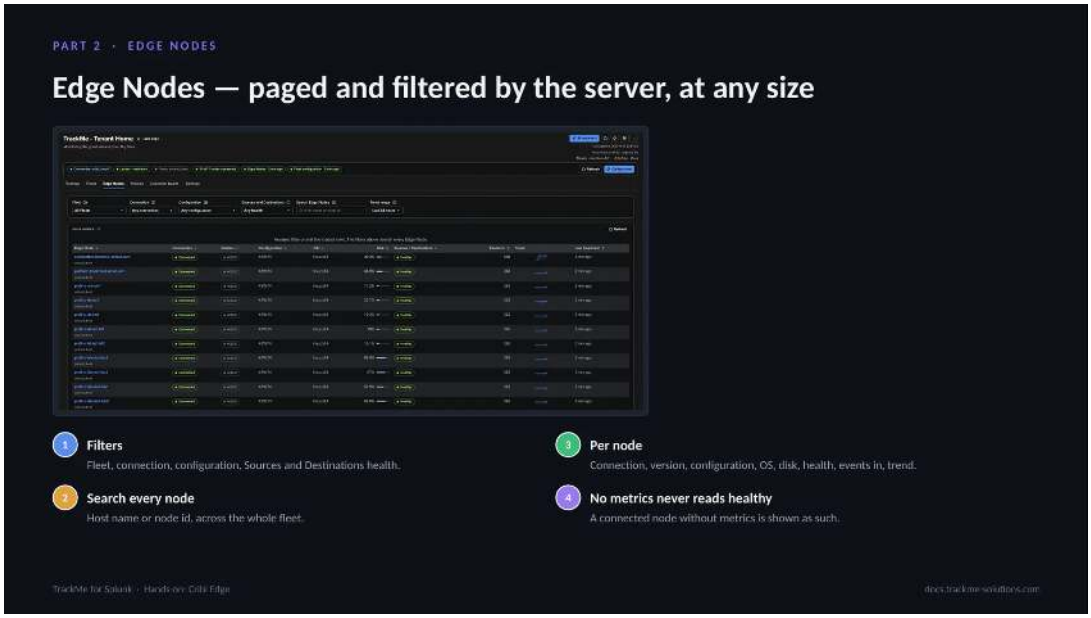
The tiles answer the fleet questions; the table has one row per Fleet with its Subfleet parent, connected share, versions running — green on the Leader version, amber otherwise, red when newer than the Leader or two minor versions behind — drift counts, unhealthy Sources and Destinations, traffic and trend. Versions are coloured green on the Leader version, amber otherwise, and red when newer than the Leader or two minor versions behind.

Inside a Fleet



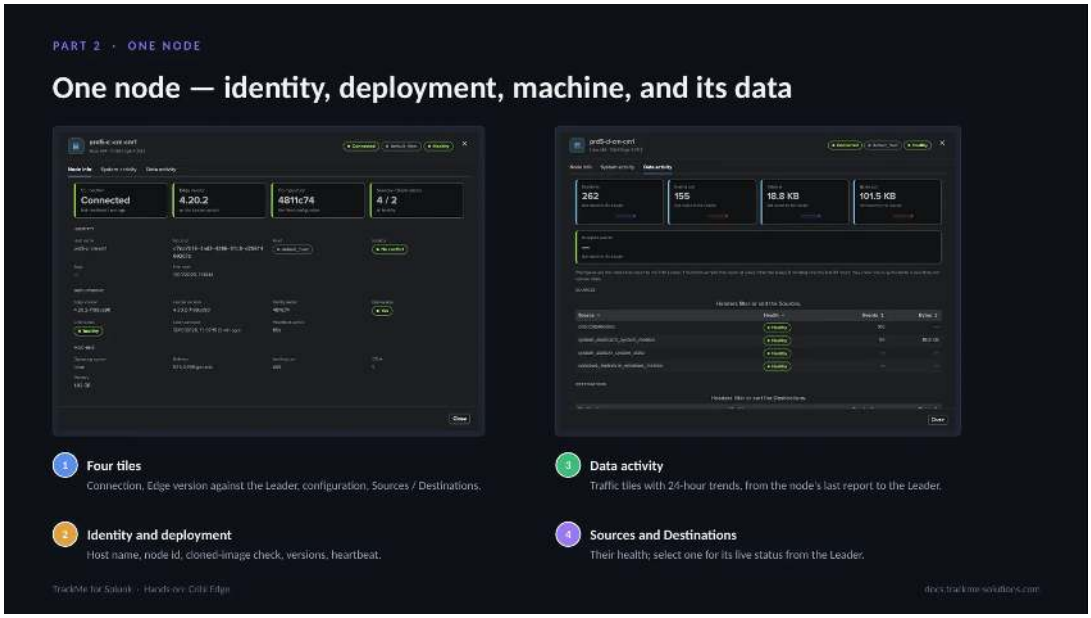
Selecting a Fleet opens it: traffic tiles, the connected, Leader-version and configuration bars, its facts, and three tabs. Sources and Destinations per object with the nodes reporting it unhealthy; Nodes to look at lists the disconnected nodes with their last heartbeat and the nodes behind each version. Every node name opens the node.

Every Edge Node, paged by the server



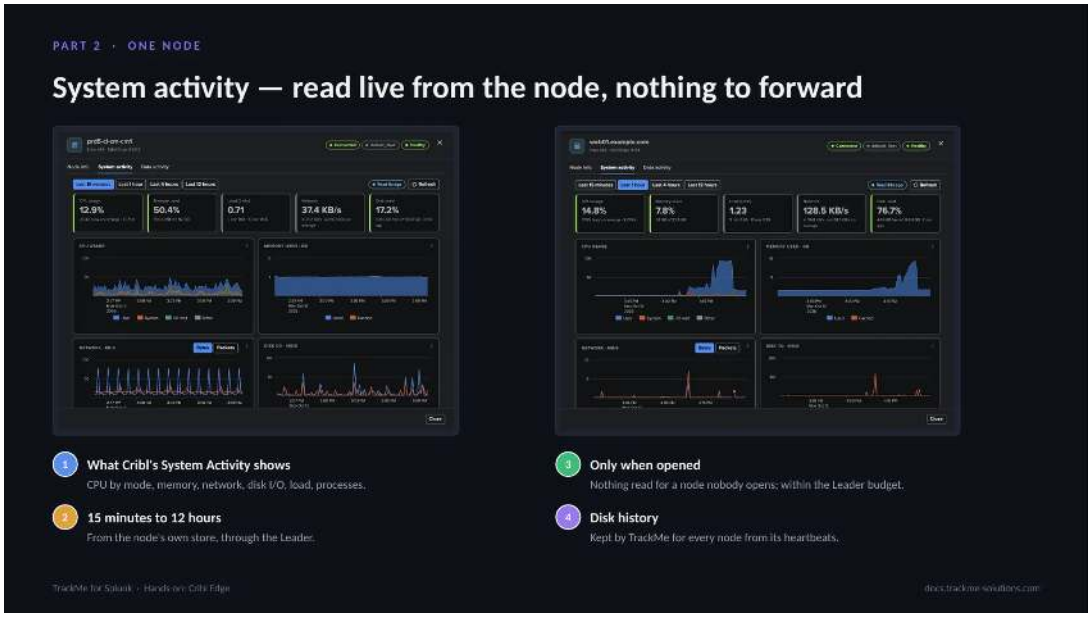
Every Edge Node of the selected Fleets, paged and filtered by the server so the tab stays fast with any number of nodes. A node is disconnected when the Leader says so or when it has sent no heartbeat for five periods, at least 10 minutes. Filters for Fleet, connection, configuration and Sources and Destinations health apply to every node, and the search finds a host name or node id across the whole fleet.

One node: info and data activity



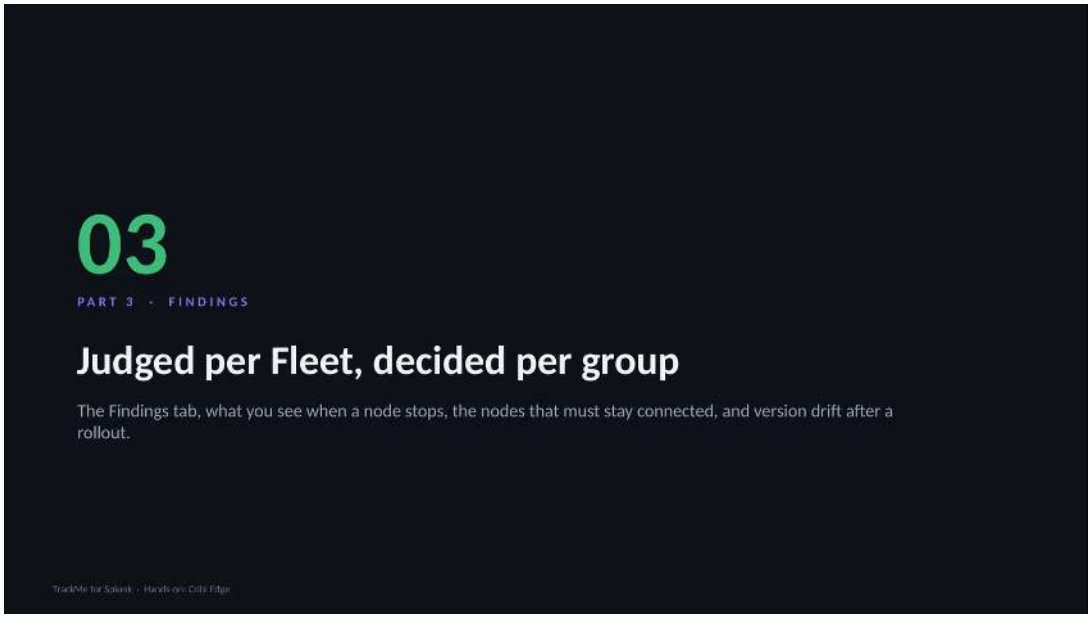
A node opens on three tabs. Node info: connection, Edge version compared with the Leader's, configuration compared with the Fleet's target, and Identity, Deployment and Machine facts. Data activity: the node's traffic with trends and its Sources and Destinations; selecting a health reads that object's live status on that node, as Cribl's Status tab shows it.

System activity read live from the node



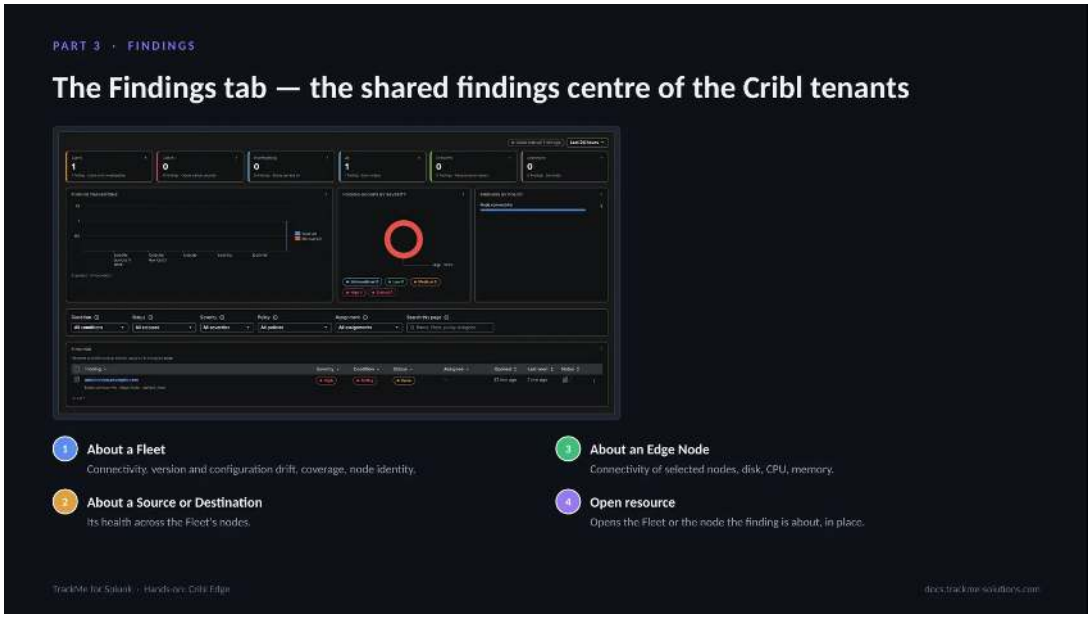
System activity shows what Cribl's own System Activity page shows for the node, read live through the Leader from the node's own store of its system metrics. It does not use the System Metrics index and needs nothing forwarded to Splunk. Nothing is read for a node nobody opens, so the fleet-wide collection stays one bulk read.

Part 3 — Findings



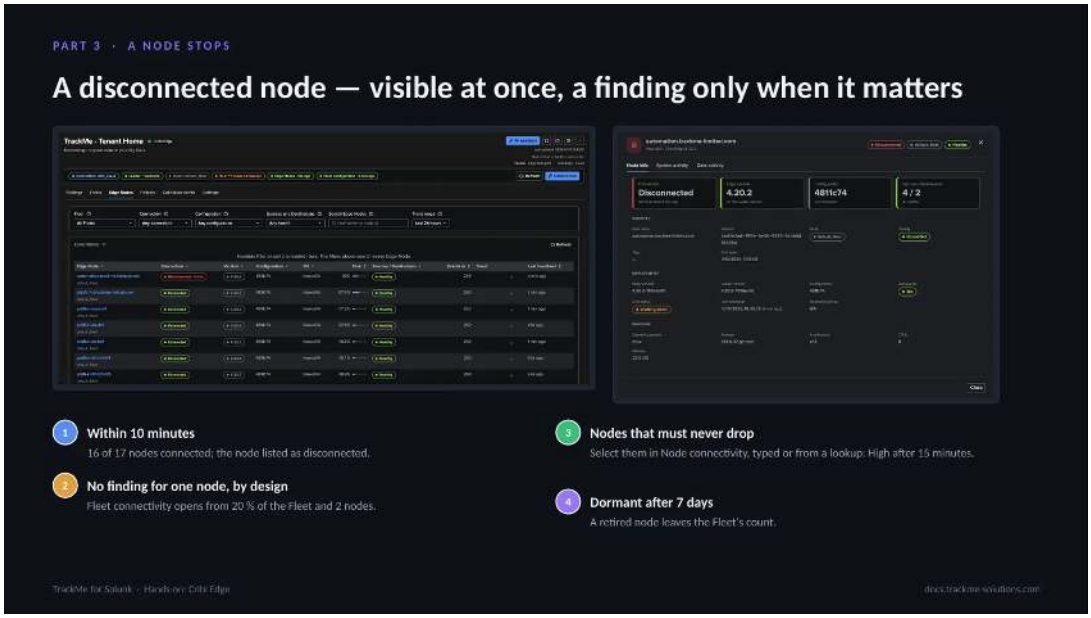
Findings work exactly as on Cribl Stream: Finding groups, triage, notifications, assignment and findings actions. A finding is about a Fleet, a Source or Destination of a Fleet, an Edge Node or the Leader. Each object gathers its findings in one automatic Finding group, the unit that is triaged and notified.

The findings backlog



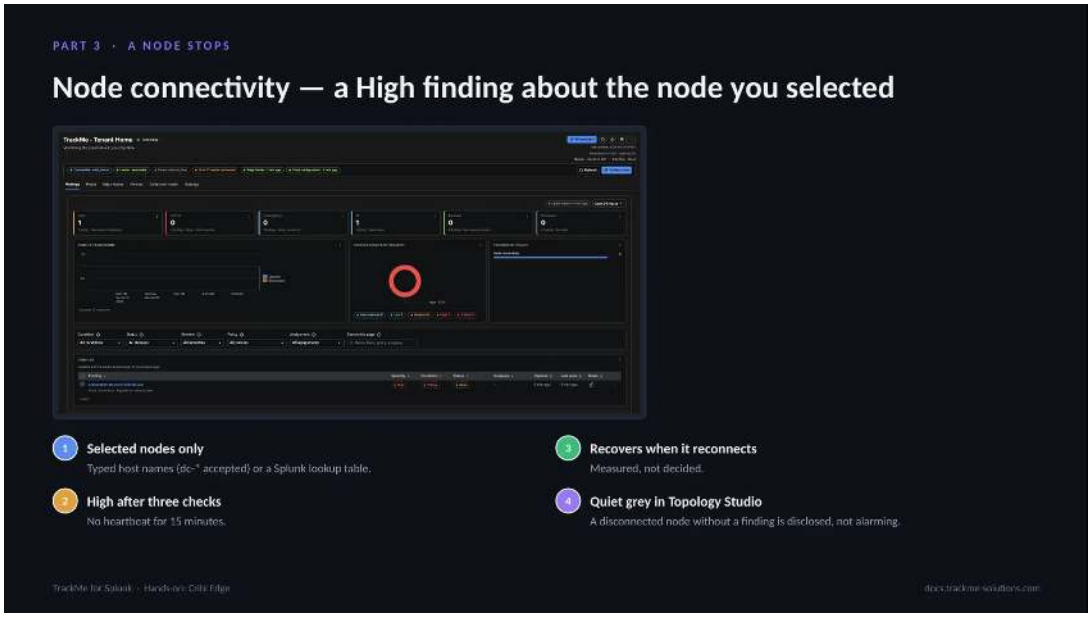
A Cribl Edge finding is about one object, one policy and one measurement: a Fleet, a Source or Destination of a Fleet, an Edge Node, or the Leader. Each object gathers its findings in one automatic Finding group. A finding recovers by itself when the condition clears. Edge has no Stop monitoring and no Not an anomaly: narrow the policy's scope instead.

When a node disconnects



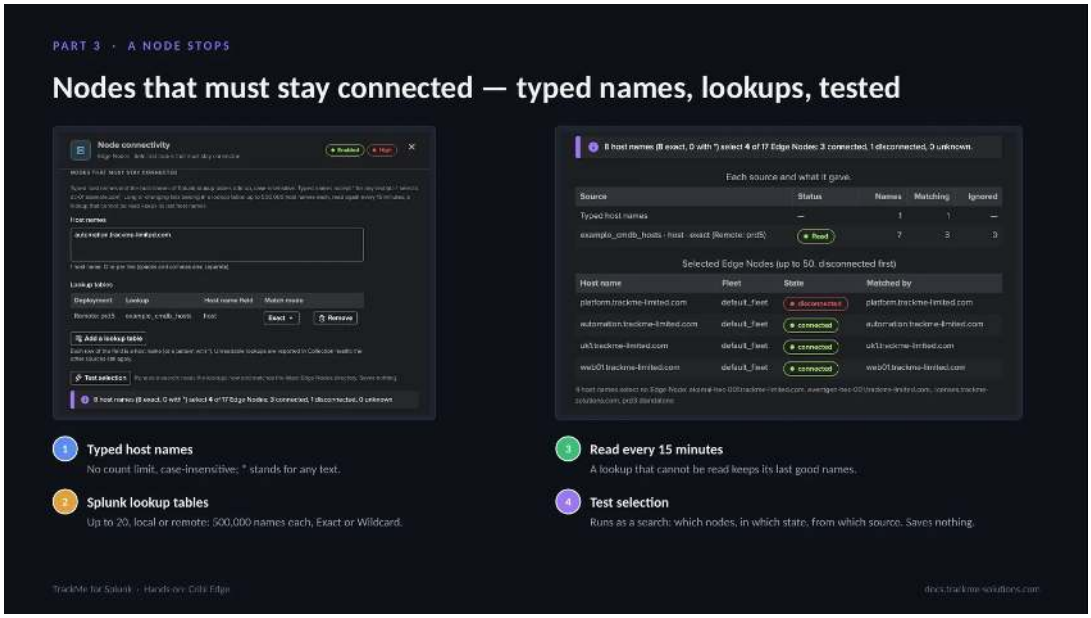
Take a Fleet of 17 nodes, one of which stops. Within 10 minutes it is disconnected in the next directory. No finding opens for that one node by default: Fleet connectivity opens when at least 20 percent of the active nodes and at least two are disconnected. For servers and collectors that must never drop, select them in Node connectivity, by host name or from a Splunk lookup table.

Nodes that must never drop



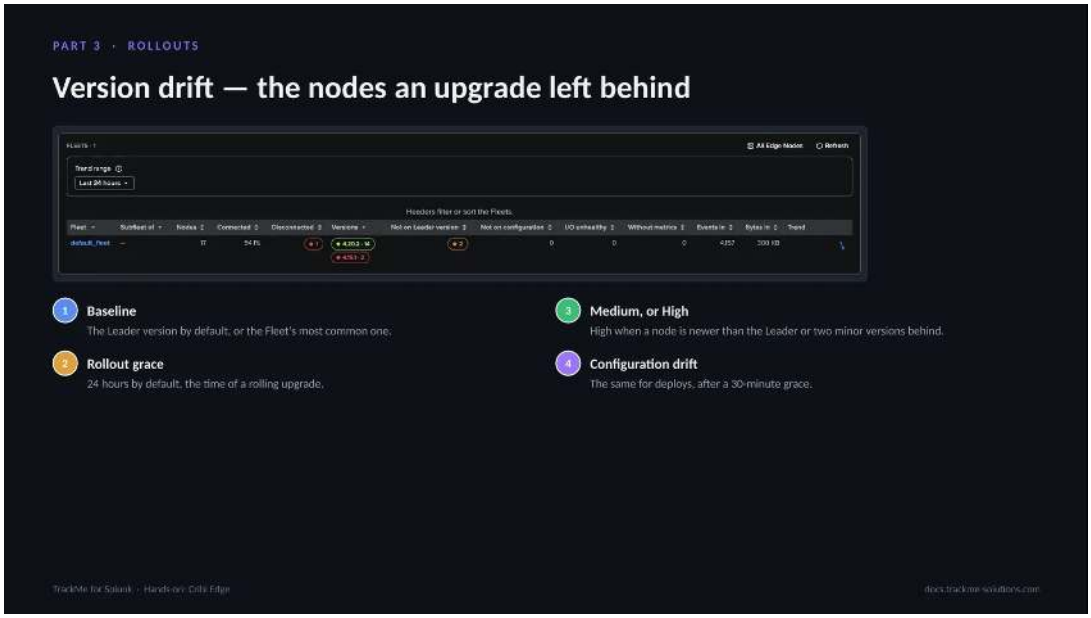
A node selected in Node connectivity opens a High finding about that node after three checks without a heartbeat, and recovers when it reconnects. In Topology Studio a disconnected node without a finding is drawn quiet grey and does not count in a group's healthy share. The Findings tab lists it with the host name it was selected by; its Finding group is triaged, notified and assigned like every other.

Nodes that must stay connected



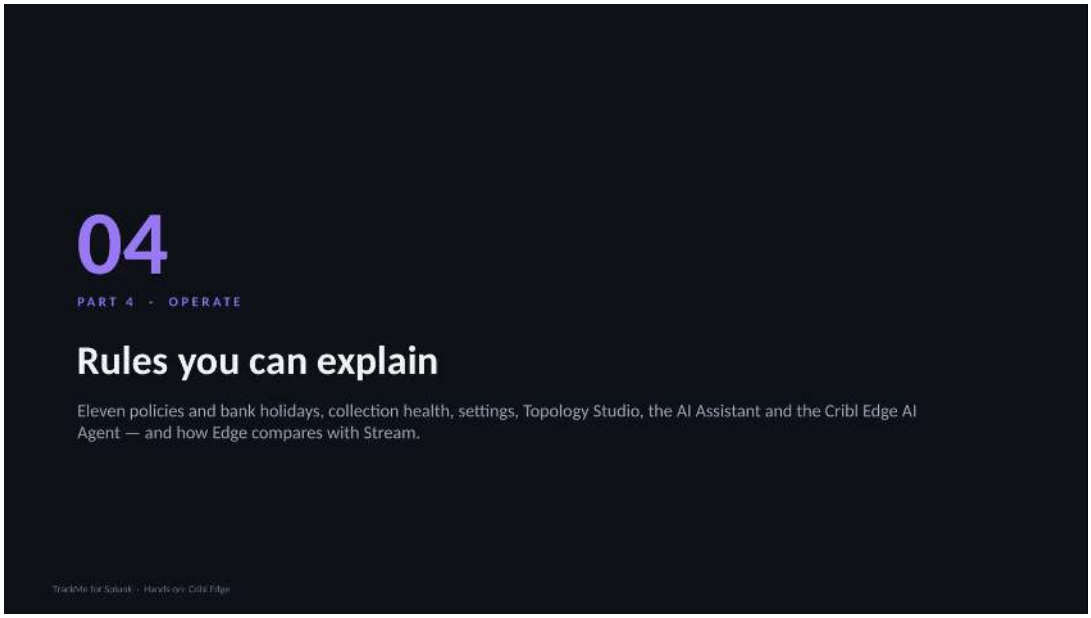
Node connectivity selects the nodes that must stay connected from two sources that add up. Typed host names have no count limit and accept a star for any text. Long or changing lists belong in Splunk lookup tables, such as a CMDB extract, on the local search tier or a remote deployment: up to twenty per policy and 500,000 host names each, matched exactly or with wildcards, read again every 15 minutes. A lookup that cannot be read keeps its last good names, and Collection health says so. Test selection runs as a search and shows which nodes the names select, in which state and from which source, before anything is saved.

Version drift after a rollout



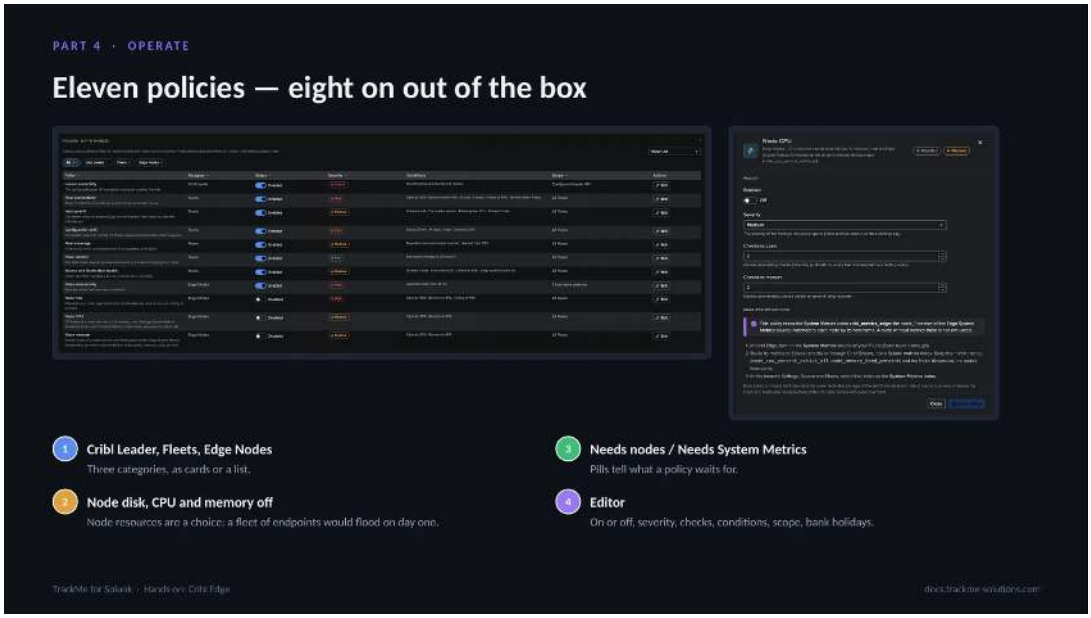
Version drift compares every connected node with a baseline. Once nodes stay off it for the rollout grace, a finding opens on the Fleet: Medium, raised to High for the cases Cribl does not support. Configuration drift works the same way for deployments. The Fleet's Nodes to look at names the nodes behind each version.

Part 4 — Operate



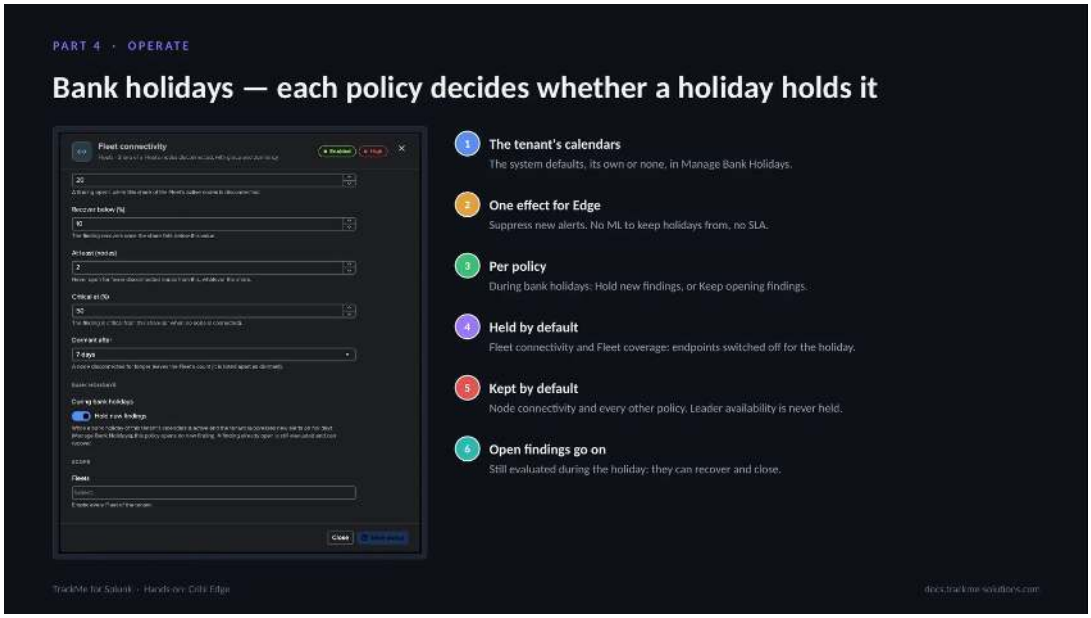
Eleven built-in policies, eight on out of the box, two collection jobs with the Leader request budget, one Save for every setting, Edge objects and groups in Topology Studio, the AI Assistant, and the Cribl Edge AI Agent with its custom instructions. The comparison with Cribl Stream closes the part.

The policy catalogue



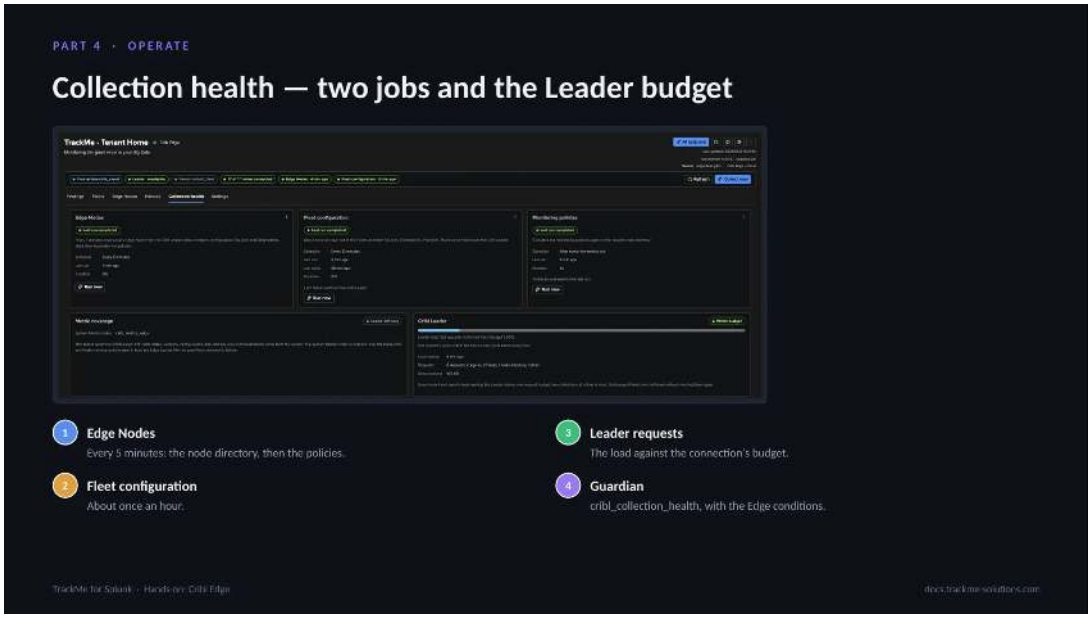
The catalogue of eleven policies in three categories. Two pills tell what a policy is waiting for: Needs nodes on Node connectivity until you select the nodes, and Needs System Metrics on Node CPU and Node memory until the tenant has a System Metrics index. Node disk, CPU and memory are off by default.

Bank holidays, per policy



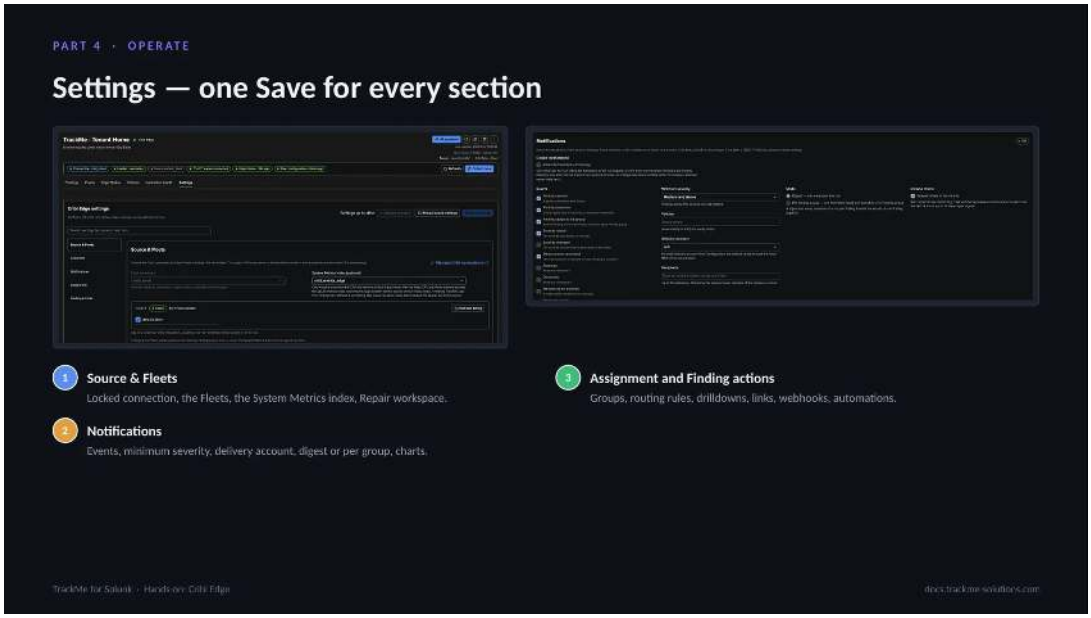
A Cribl Edge tenant uses the bank holiday calendars like every tenant: the system defaults, its own selection, or none. One effect applies to Edge, Suppress new alerts: while a holiday is active, the policies set to hold open no new finding. Each policy decides in its editor. By default Fleet connectivity and Fleet coverage hold, because laptops and desktops switched off for the holiday would otherwise open findings; Node connectivity and every other policy keep opening findings, and Leader availability is always judged. A finding already open is still evaluated and can recover.

Collection health and the Leader budget



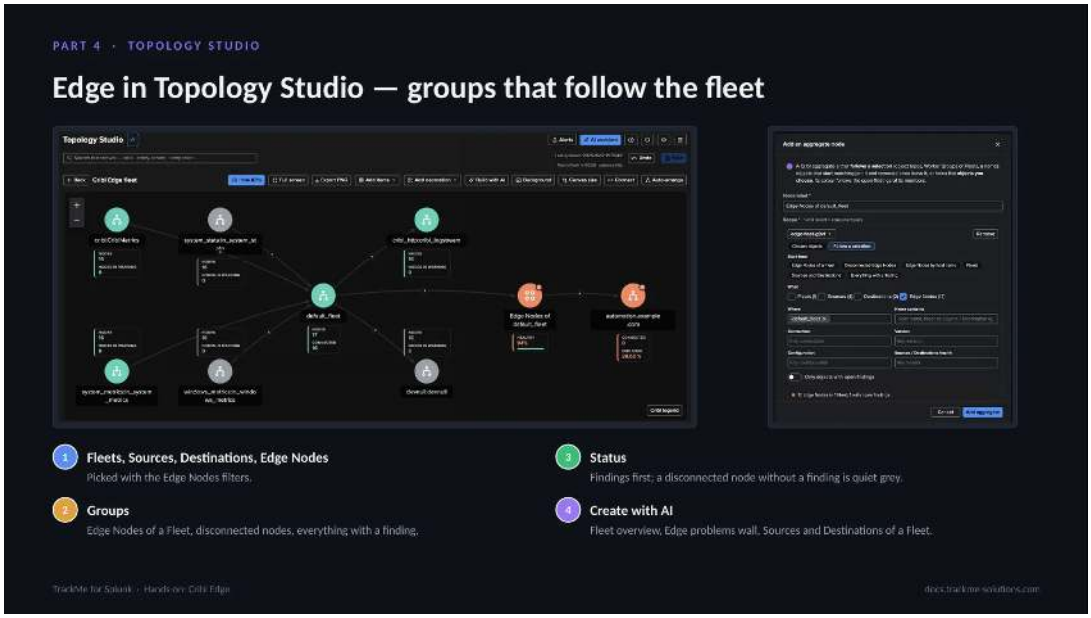
One card per job with its last run, duration, next run and Run now, the Leader requests against the budget and the System Metrics index. When collection does not run as configured, the tab lists the problems and the Configuration Guardian raises Cribl Edge collection needs attention, including the Edge conditions: many nodes without metrics, or no System Metrics arriving.

Settings and notifications



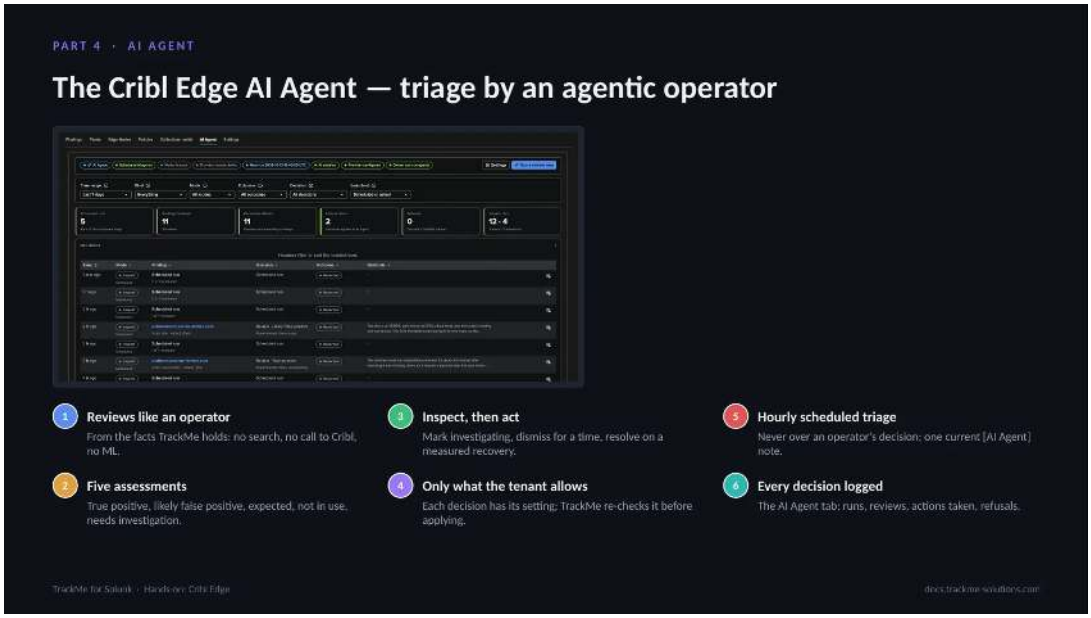
Settings gathers every section with one Save. Changing the Fleets starts a new source and closes the findings of the previous one; the System Metrics index can change at any time. Notifications work as for Cribl Stream, and every transition is also an indexed event.

Edge in Topology Studio



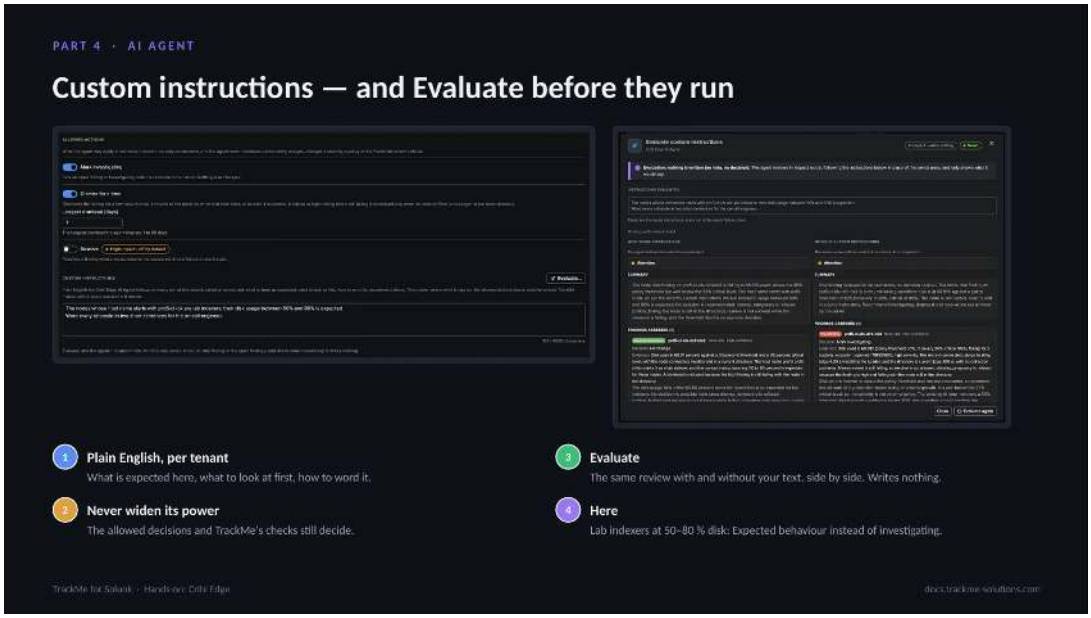
Cribl Edge objects are Topology Studio objects. Groups are the recommended way to show nodes: they follow their nodes as they come and go, at any fleet size, and show their health and healthy share. Topology Alerts work on Edge objects and groups. A view built from an Edge tenant shows the Fleet, its Sources and Destinations and a group of Edge Nodes with its healthy share; a stopped node is drawn quiet grey. Topology Alerts work on Edge objects and groups.

The Cribl Edge AI Agent



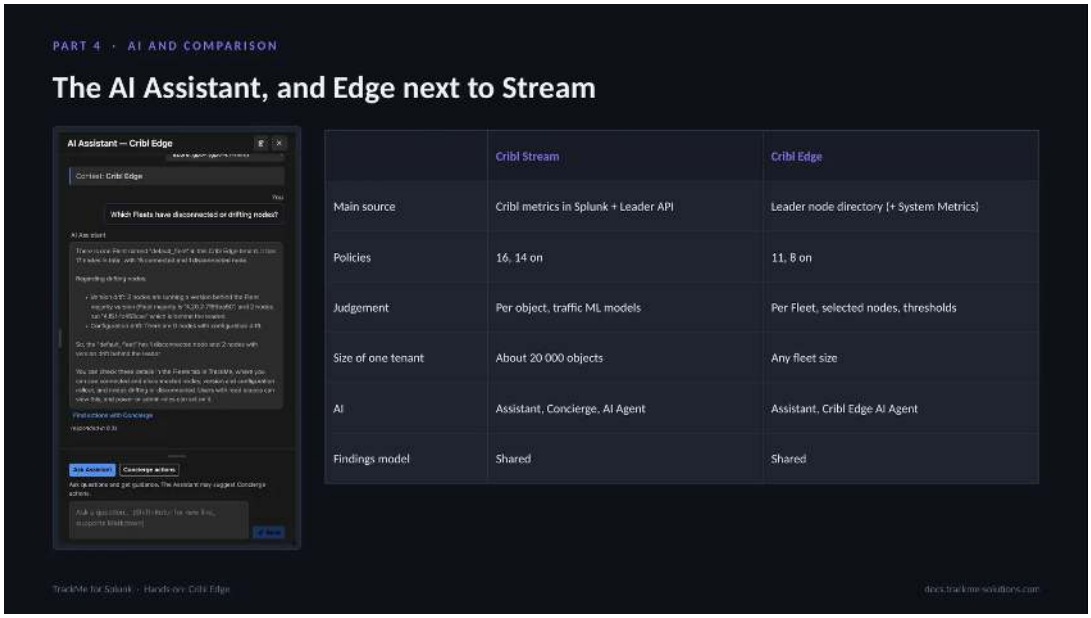
The Cribl Edge AI Agent reviews Edge findings the way an operator would, from facts TrackMe already holds: the finding and its group, the Fleet and the node in the published directory, whether they are still there, and Collection health. It never runs a search, never calls Cribl and uses no machine learning. It assesses each finding and recommends a decision; in act mode it applies only the decisions the tenant allows, and TrackMe checks their conditions again before applying them. Scheduled triage runs hourly and never overrides an operator; the AI Agent tab logs every run and decision.

Custom instructions and Evaluate



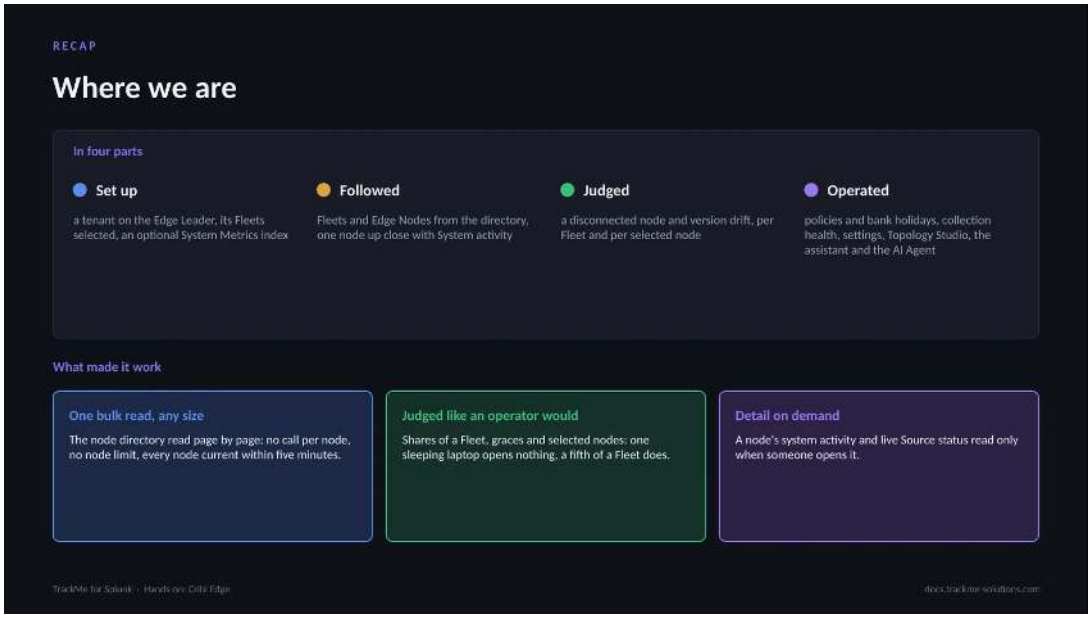
In Settings, AI Agent, a TrackMe administrator of the tenant chooses the decisions the agent may apply and writes custom instructions in plain English: what to treat as expected, what to look at first, how to word the recommendations. Every run follows them, and they never widen what the agent may do. Evaluate runs the agent in inspect mode with the text and shows the same review with and without it, side by side, writing nothing. Here, lab indexers between 50 and 80 percent disk are declared expected: the same Node disk finding reads Expected behaviour instead of a true positive.

The AI Assistant and Edge compared with Stream



On an Edge tenant, the AI Assistant knows the workspace, the policies and their settings, the Fleets, the node summary, the Leader version and the age of the node directory, and reads the open findings. Edge and Stream share the findings model and each has its own AI Agent; they differ in sources, judgement and machine learning.

Where we are



A Cribl Edge tenant on a Cribl connection, its Fleets and nodes followed from one bulk read of the Leader, any node opened up close with its System activity read live, a disconnected node and version drift seen the way the policies judge them, the nodes that must stay connected selected by name or from a lookup, and the tenant operated with its policies and bank holidays, collection health, settings, Topology Studio, the AI Assistant and the Cribl Edge AI Agent.

2.1.11 Splunk HEC

Follow the HTTP Event Collector of a Splunk deployment from the telemetry Splunk already writes: endpoints found from their heartbeats, pools of heavy forwarders judged as a whole, tokens known only by name, one endpoint's ingestion pipeline and a pool's traffic distribution; a heavy forwarder stopped on purpose and the two findings it opens, how each is evaluated, the data centres in Topology Studio and the Splunk HEC AI Agent; then the eighteen policies, token silence, the traffic models and their tuning, collection health and the optional splunkd API.

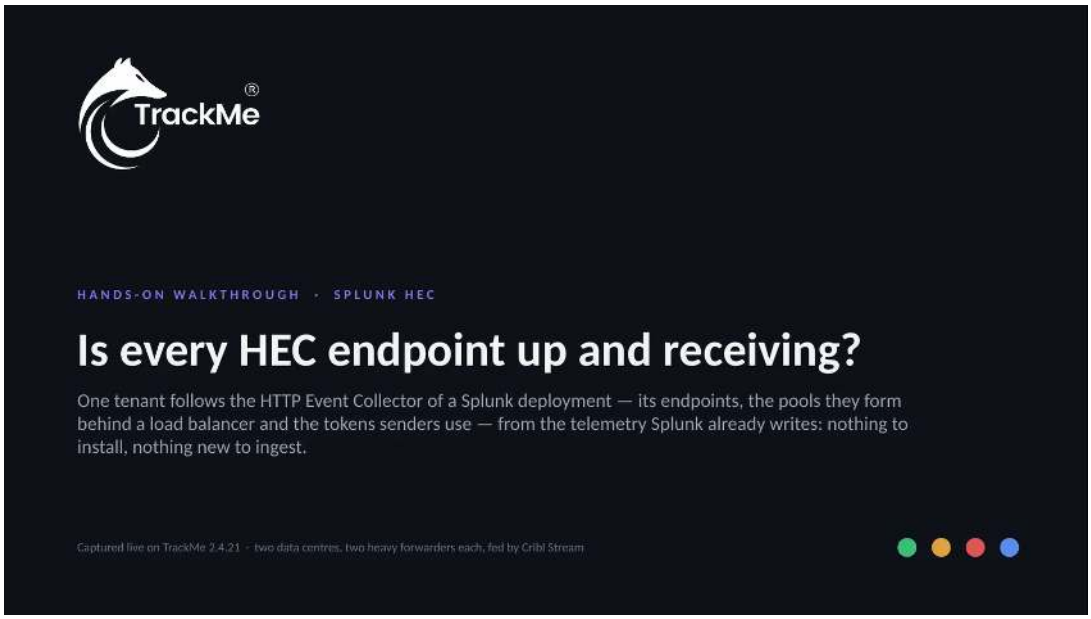
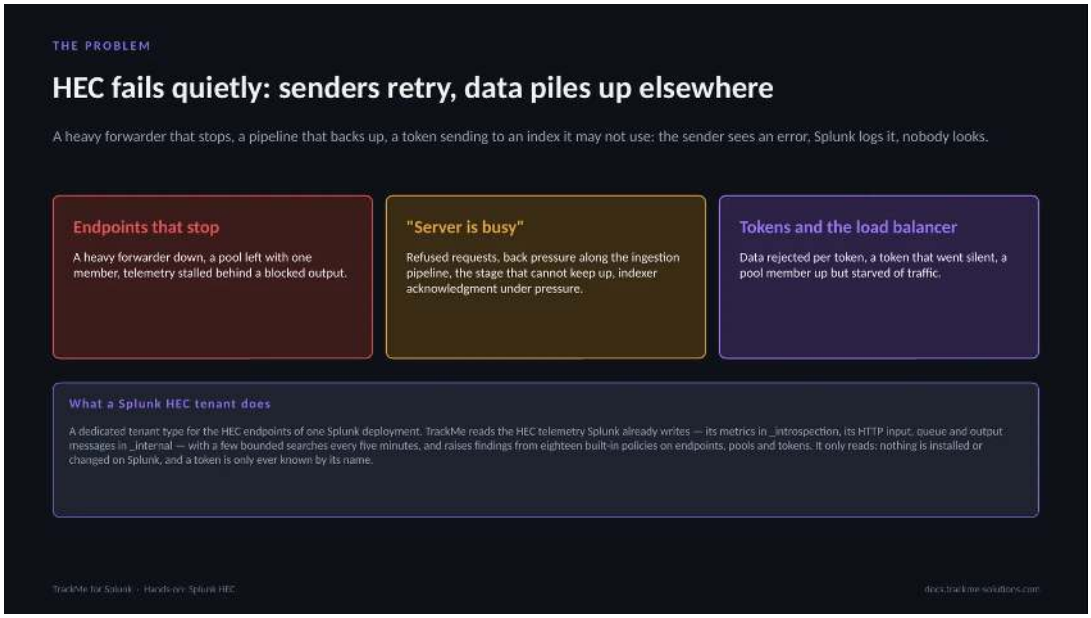
Overview



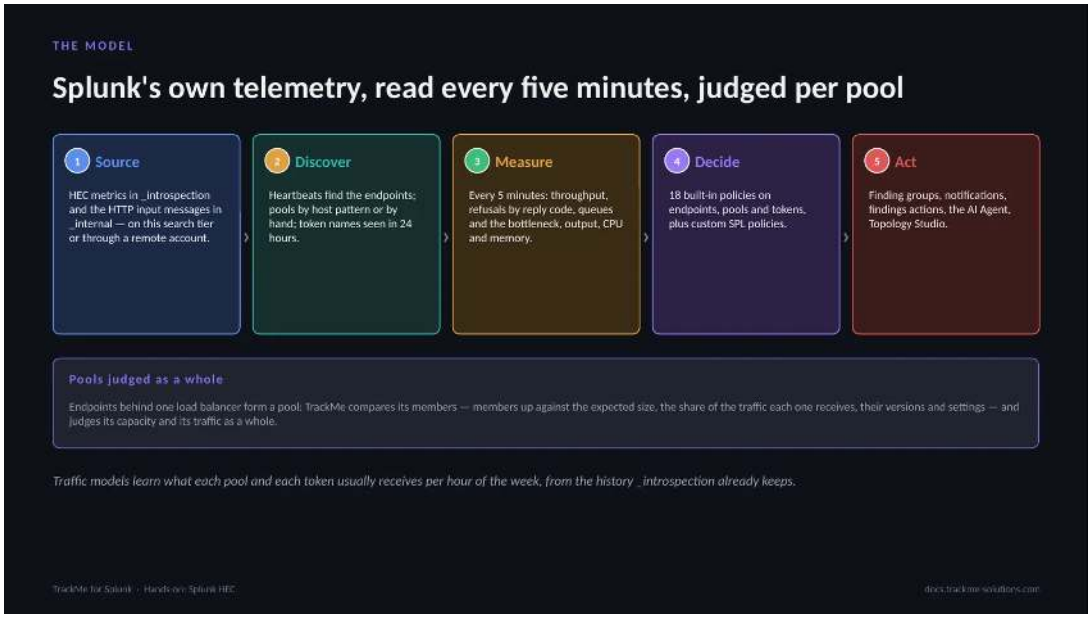
This walkthrough covers the Splunk HEC tenant, generally available in TrackMe 2.4.21. Everything was captured live on a deployment with two data centres: two pools of two heavy forwarders each, every pool receiving its own HEC token from Cribl Stream senders. In four parts: create the tenant, follow the endpoints, pools and tokens, read the findings of a heavy forwarder stopped on purpose, and operate the tenant.

Why a dedicated Splunk HEC tenant



A Splunk administrator asks the same HEC questions every day: are all the HEC endpoints up and receiving, are senders being refused and why, where is the bottleneck when HEC answers Server is busy, which tokens send data Splunk rejects, did a business-critical token stop sending, and does the load balancer spread the traffic over every member of the pool. The Splunk HEC tenant answers them with findings raised by eighteen built-in policies on endpoints, pools and tokens. It only reads: nothing is installed or changed on Splunk, and a token is only ever known by its name.

How a Splunk HEC tenant works

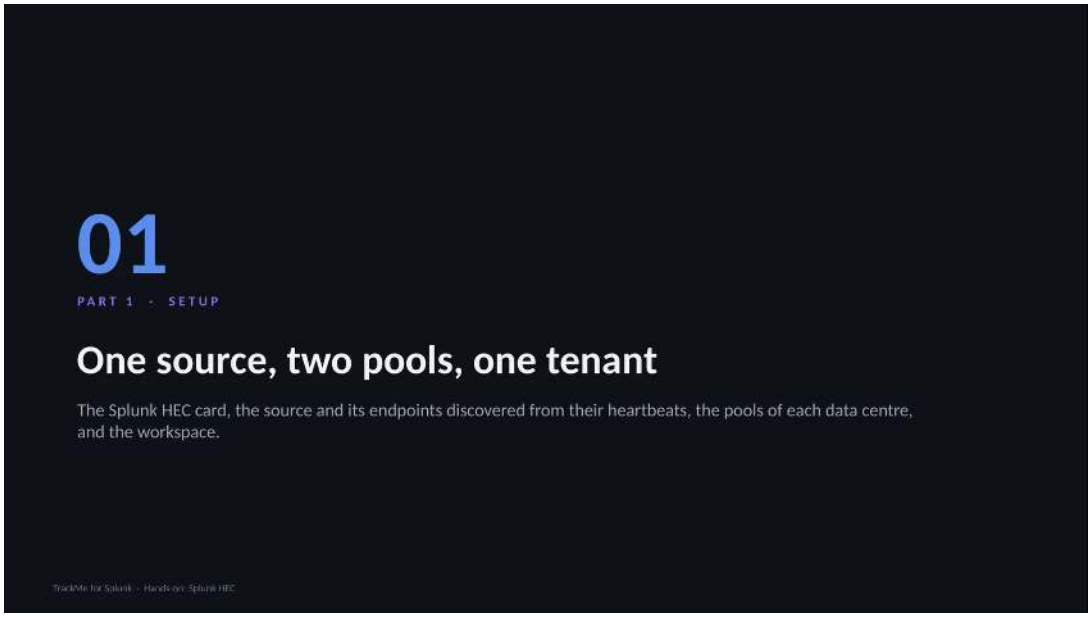


Every HEC instance writes its HEC metrics every minute, traffic or not: that heartbeat finds the endpoints and says whether they are up. Every five minutes TrackMe reads the last settled window of what Splunk indexed — throughput, refusals by reply code, queues and the bottleneck, output and load per endpoint and token — with a few bounded searches whatever the number of endpoints. Endpoints behind one load balancer form a pool, judged as a whole, and traffic models learn what each pool and token usually receives from the history _introspection already keeps.

The four parts of the walkthrough

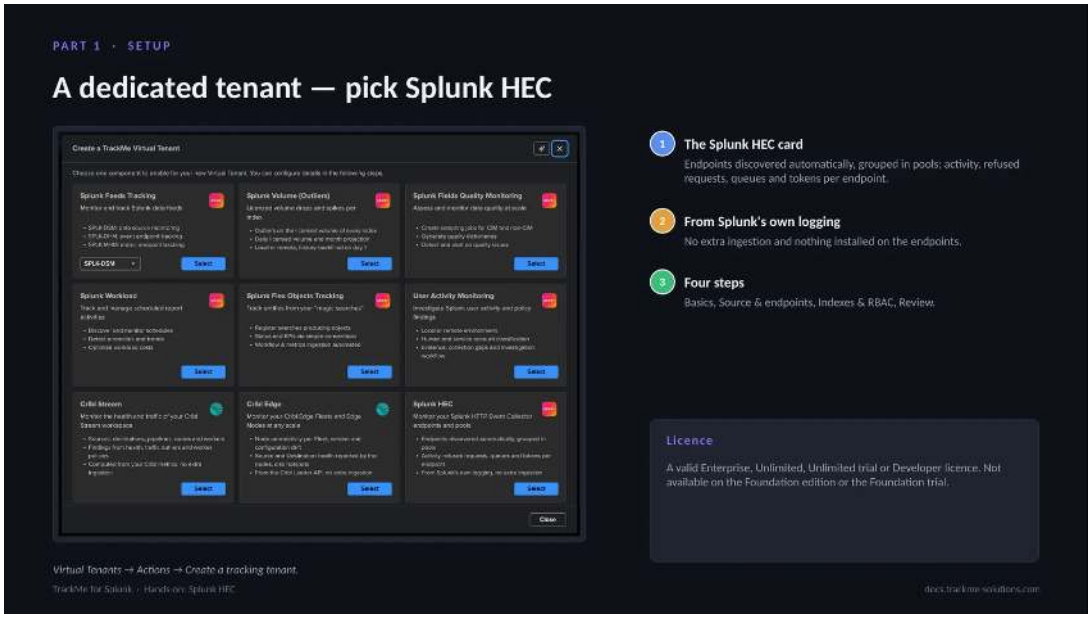
Setup covers the wizard, the pools and the workspace. Endpoints, pools and tokens covers the overview, the endpoints and one endpoint up close, a pool and how it spreads its traffic, and the tokens. Findings follows a heavy forwarder stopped on purpose: what opens, how it is evaluated, the topology and the AI Agent. Operate covers the policies, the tokens that must keep sending, the traffic models and their tuning, collection health and the splunkd API.

Part 1 — Setup



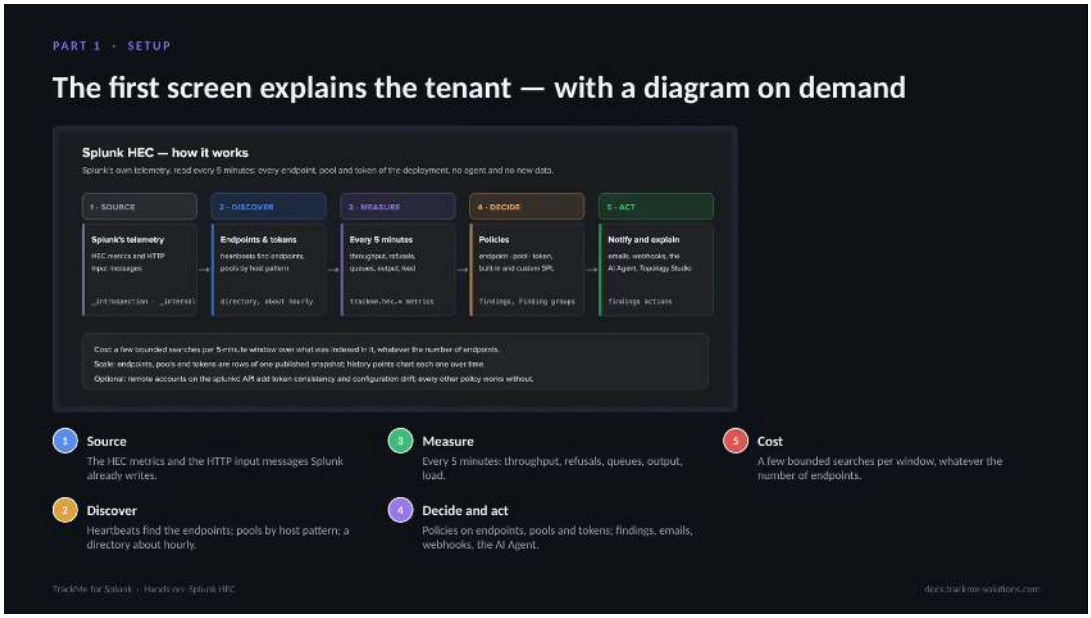
A Splunk HEC tenant reads one deployment: its local search tier, or another deployment through a TrackMe remote account, a Splunk Cloud stack included. This part covers the Splunk HEC card, the source and its endpoints discovered from their heartbeats, the pools of each data centre, and the workspace.

Choosing the Splunk HEC tenant type



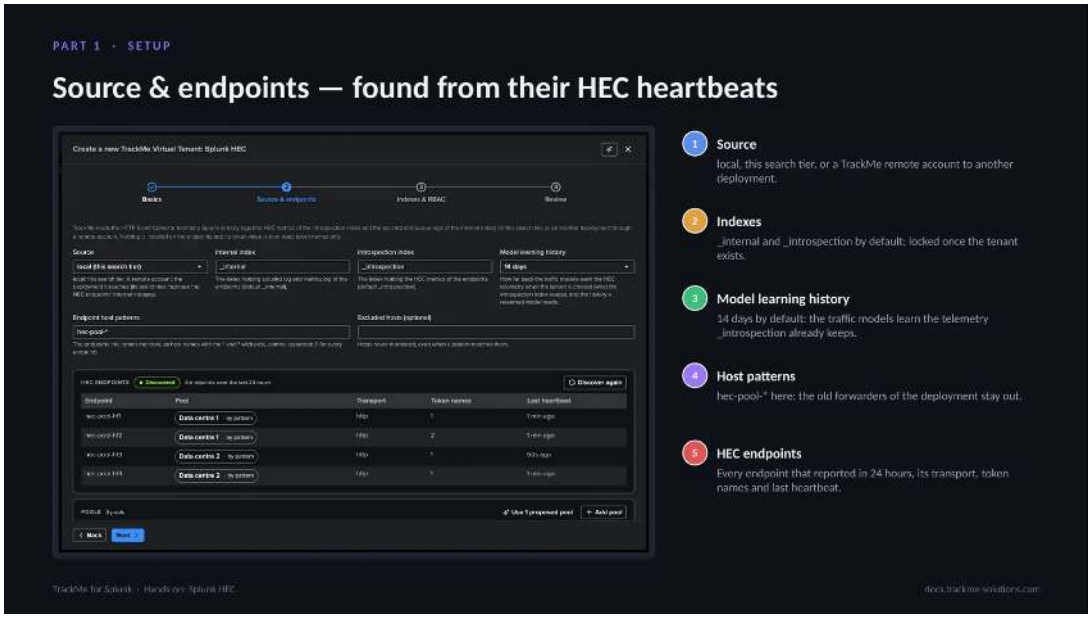
From Virtual Tenants, Actions, Create a tracking tenant, the Splunk HEC card monitors the HTTP Event Collector endpoints and pools of a deployment from Splunk's own logging, with no extra ingestion and nothing installed on the endpoints. The wizard has four steps: Basics, Source & endpoints, Indexes & RBAC, and Review. A Splunk HEC tenant has no entities and no state colour: it is a findings tenant. It needs a valid Enterprise, Unlimited, Unlimited trial or Developer licence.

The How it works diagram



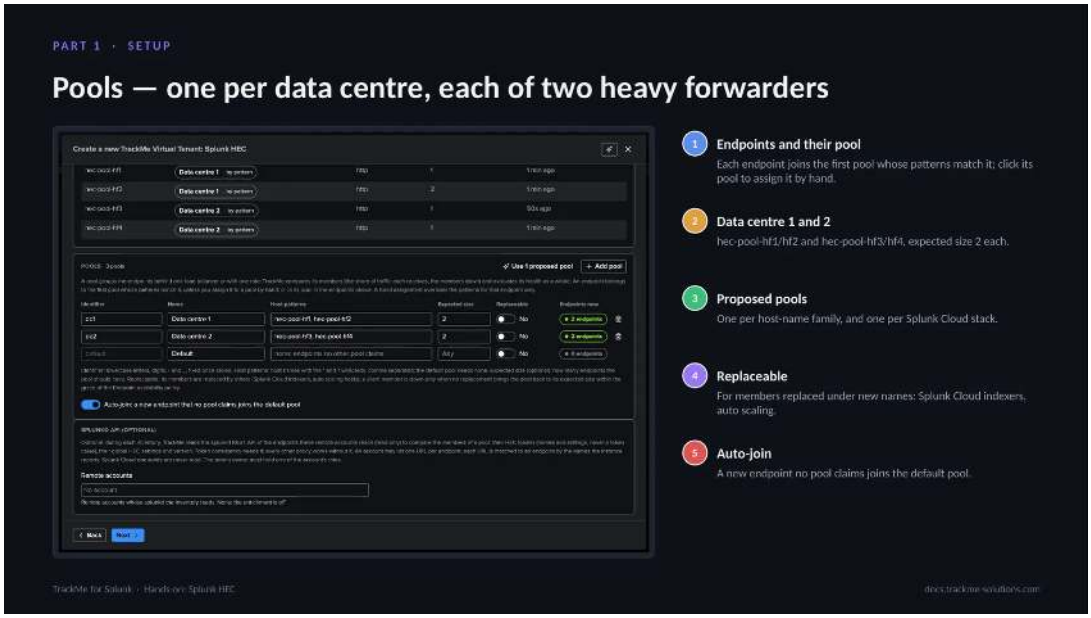
Basics holds the tenant identifier, an alias and a description, under a card that says what the tenant does. How it works draws the five stages: the source, the HEC metrics and HTTP input messages Splunk already writes; discovery of the endpoints from their heartbeats, with pools by host pattern; measurement every five minutes; the policies that decide; and the findings, emails, webhooks and AI Agent that act. The cost stays at a few bounded searches per window, and the optional splunkd API enrichment adds two configuration policies.

Source, indexes and discovered endpoints



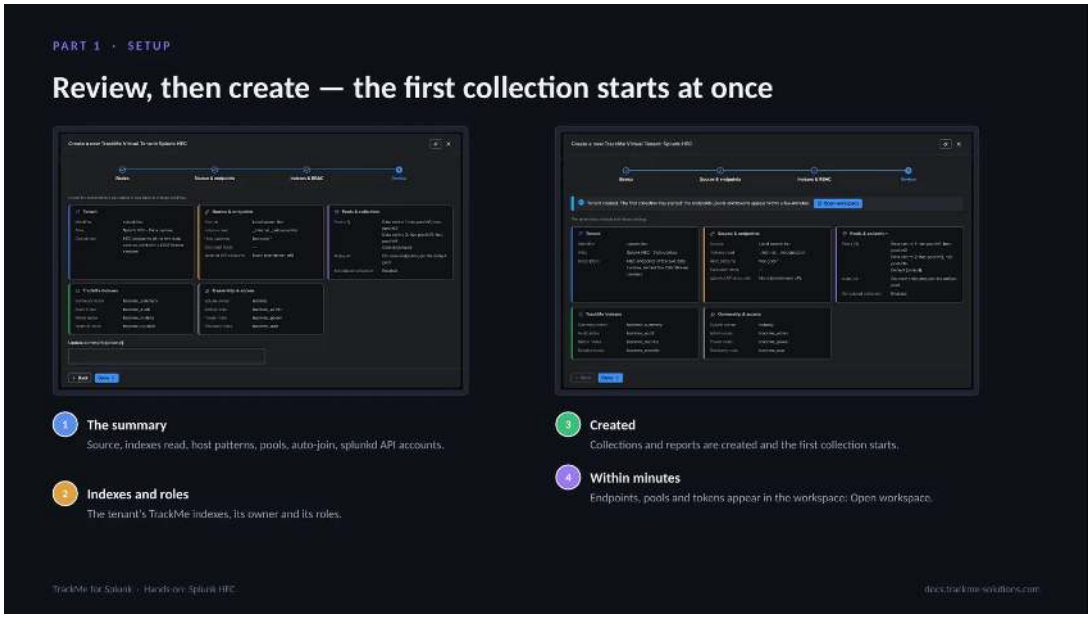
The source is local, this search tier, or a TrackMe remote account to another deployment. The internal and introspection indexes are locked once the tenant exists. The Model learning history, 14 days by default, is how far back the traffic models learn the telemetry _introspection keeps. Host patterns narrow the tenant to the endpoints it follows — hec-pool-* here, which leaves the older forwarders of the deployment out. TrackMe lists every endpoint that reported in the last 24 hours with its transport, token names and last heartbeat.

One pool per data centre



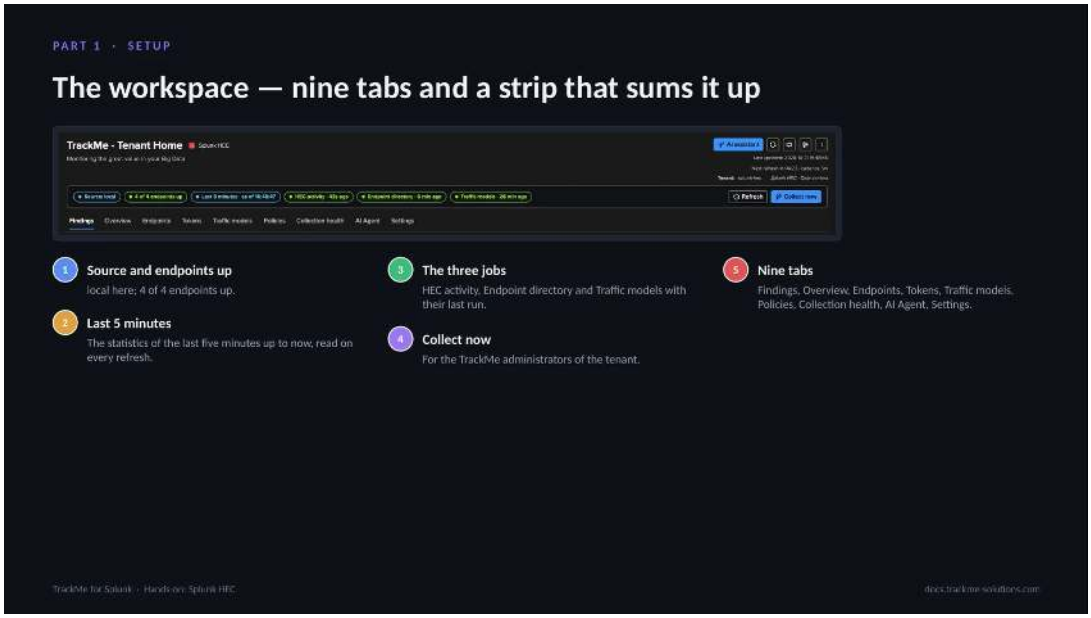
A pool groups the endpoints behind one load balancer or with one role. Each data centre has its own pool, Data centre 1 with hec-pool-hf1 and hec-pool-hf2 and Data centre 2 with hec-pool-hf3 and hec-pool-hf4, with an expected size of two each. An endpoint joins the first pool whose patterns match it, or the pool it is assigned to by hand. The discovery proposes one pool per host-name family and one per Splunk Cloud stack; Replaceable suits members replaced under new names, and Auto-join sends a new endpoint to the default pool.

Review and creation



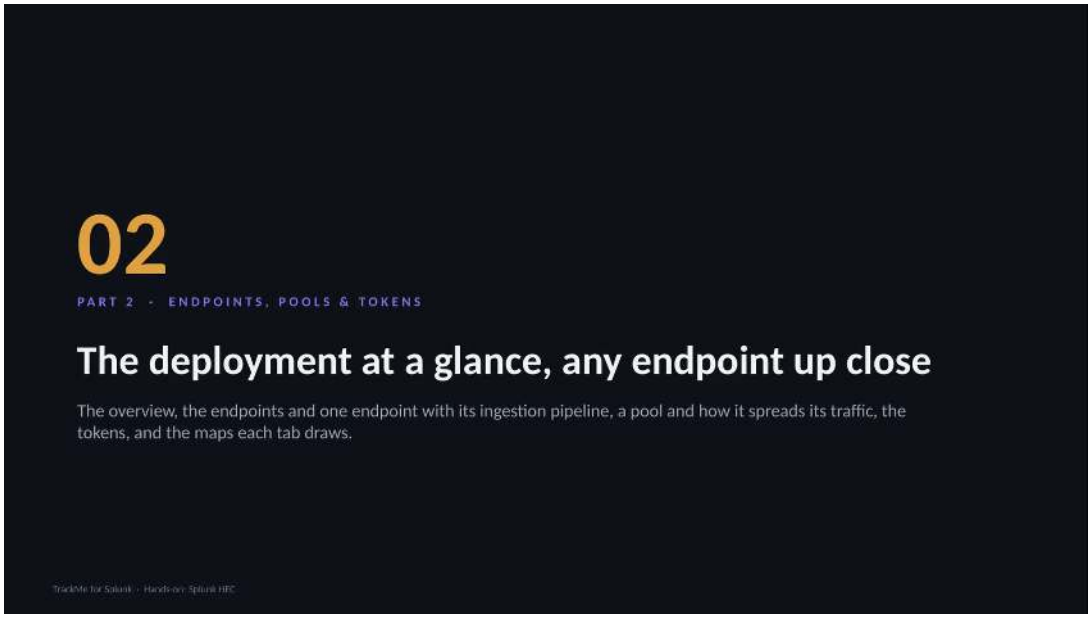
The review summarises the source, the indexes read, the host patterns, the pools, auto-join and the splunkd API accounts, with the tenant's TrackMe indexes, owner and roles. Creating the tenant creates its collections and reports and starts the first collection at once: the endpoints, pools and tokens appear in the workspace within minutes. The HEC activity is read and the policies evaluated every five minutes, the endpoint directory rebuilt about once an hour and the traffic models trained twice an hour.

The workspace and its status strip



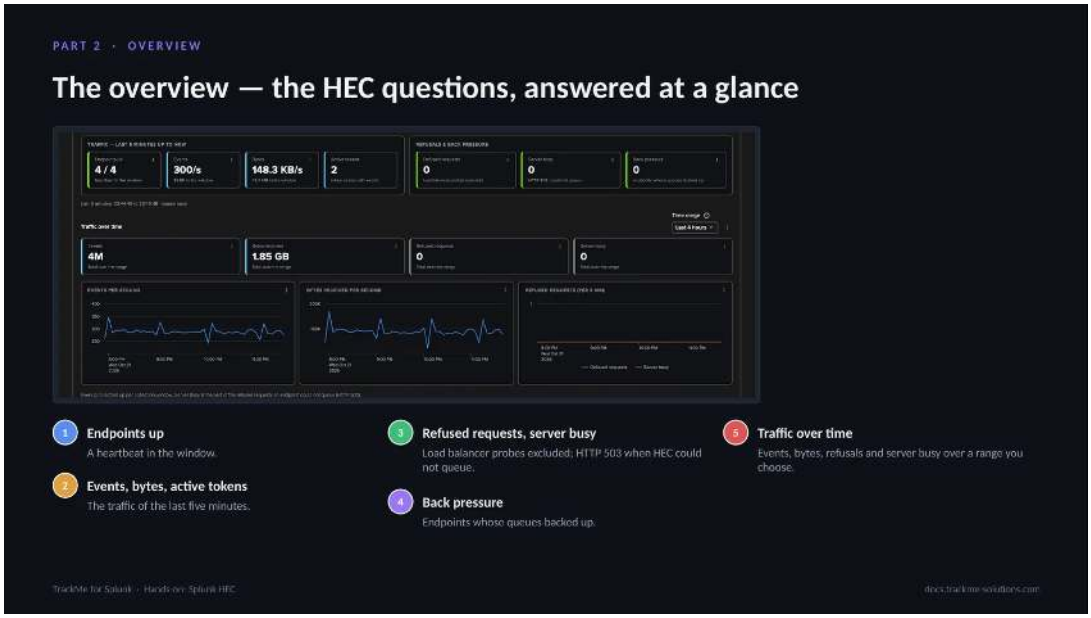
The Splunk HEC workspace is built with the same components as the Cribl workspaces. The status strip shows the source and the endpoints up, the Last 5 minutes badge, the last run of HEC activity, Endpoint directory and Traffic models, Refresh and, for the TrackMe administrators of the tenant, Collect now. Nine tabs follow: Findings, Overview, Endpoints, Tokens, Traffic models, Policies, Collection health, AI Agent and Settings. On every refresh TrackMe reads the last five minutes up to now and lays them over the collected rows.

Part 2 — Endpoints, pools & tokens



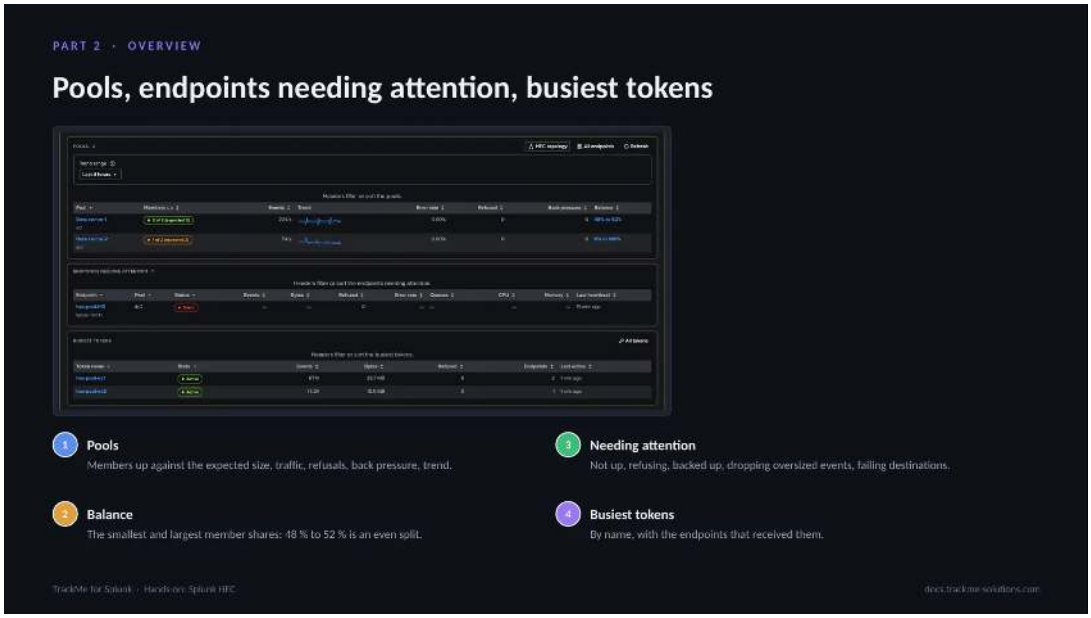
This part covers the deployment at a glance and any endpoint up close: the overview with its tiles and traffic, the pools and the endpoints needing attention, the Endpoints tab, one endpoint with its ingestion pipeline and output, a pool and how it spreads its traffic over its members, the tokens by name, and the live maps each tab draws.

Tiles and traffic over time



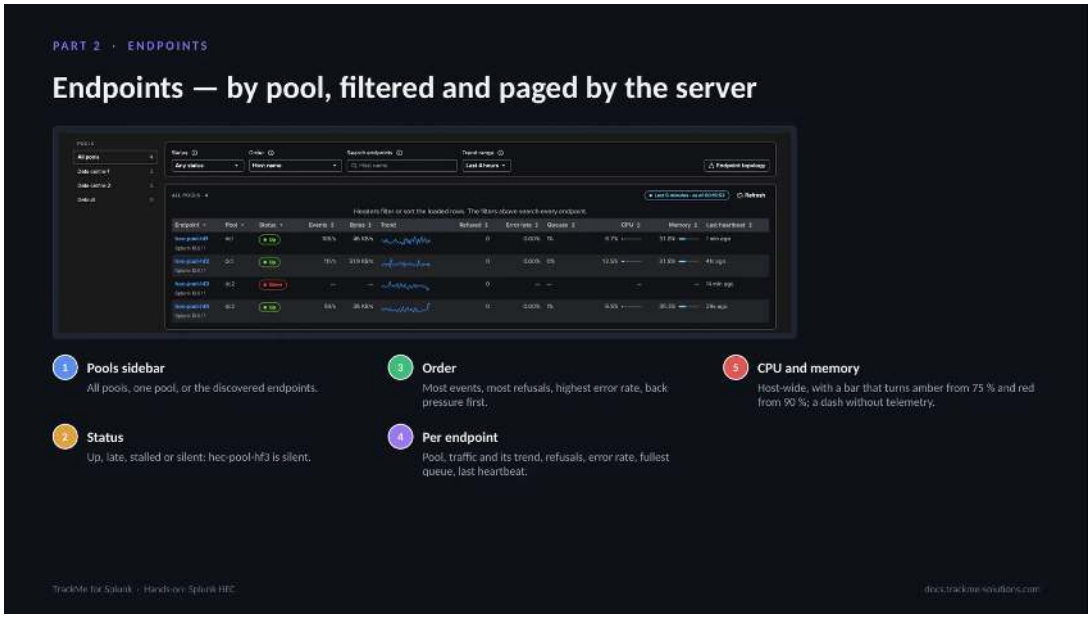
The overview answers the HEC questions at a glance: endpoints up with a heartbeat in the window, events, bytes and active tokens, refused requests with load balancer probes excluded, server busy replies when HEC could not queue a request, and endpoints whose queues backed up. Refused requests, server busy, back pressure and stalled open the Endpoints tab sorted or filtered on them. Traffic over time charts events, bytes, refusals and server busy replies over a chosen range.

Pools and the endpoints needing attention



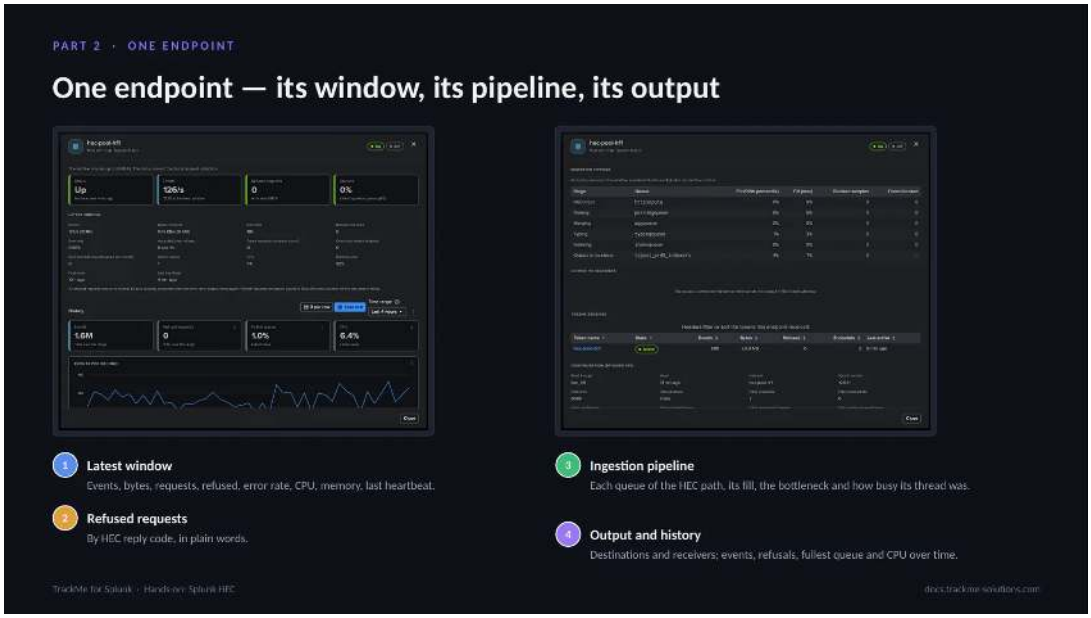
Below the charts, each pool shows its members up against the expected size, its traffic, refusals, back pressure, trend and balance — the smallest and largest member shares, 48 to 52 per cent for an even split. Data centre 2 has one of its two members up: hec-pool-hf3 was stopped, and it is listed as silent among the endpoints needing attention, with no CPU or memory figure. The busiest tokens follow, by name, with the endpoints that received them. A pool name or its balance opens the pool drilldown, and HEC topology draws every pool and its endpoints on a live map.

The Endpoints tab



Every endpoint, by pool, filtered and paged by the server: the sidebar selects all pools, one pool or the discovered endpoints, and the table filters by status and sorts by traffic, refusals, error rate or back pressure. An endpoint is up with a heartbeat in the window, late without one this window but one in the last five minutes, stalled when its output was in trouble and its own telemetry waits behind it, and silent otherwise, as hec-pool-hf3 is here, its trend falling while hec-pool-hf4 takes the traffic. Each row also shows the host's CPU and memory, every process on the host included, with a bar that turns amber from 75 per cent and red from 90; a stopped endpoint shows a dash. Endpoint topology draws the endpoints the tab selects.

One endpoint and its ingestion pipeline

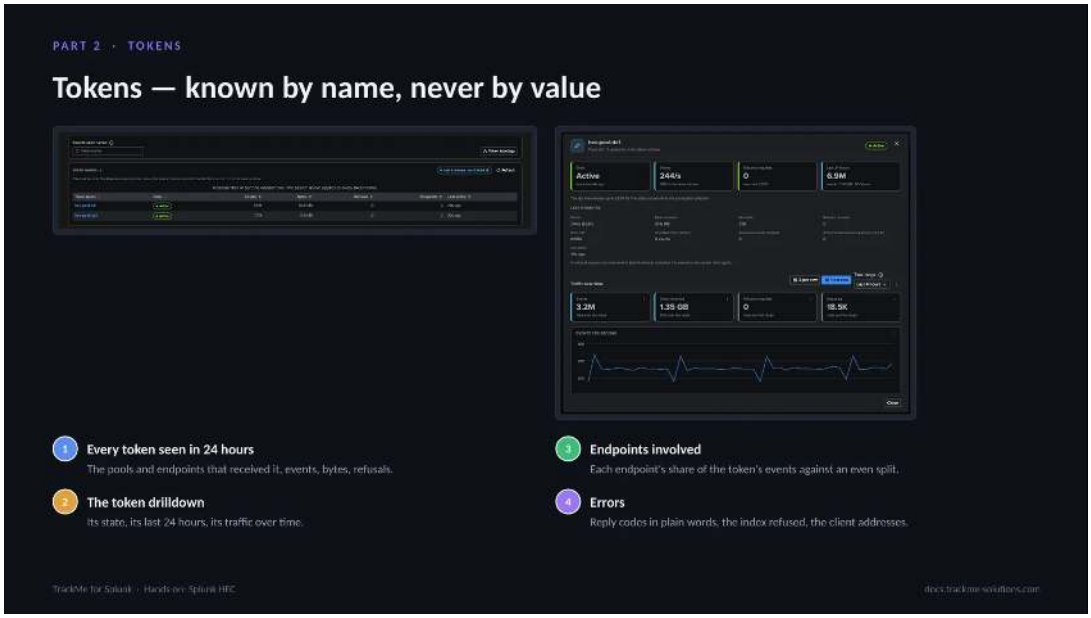


The endpoint drilldown shows the latest window — events, bytes, requests, refused requests, error rate, CPU, memory and last heartbeat — then the refused requests by reply code. The ingestion pipeline lists each queue of the HEC path with its fill, blocked samples, the bottleneck and how busy its thread was: when a stage cannot keep up its queue fills, then the queues before it, until HEC refuses requests. The output to receivers, the tokens received and the history complete it.

A pool and its traffic distribution

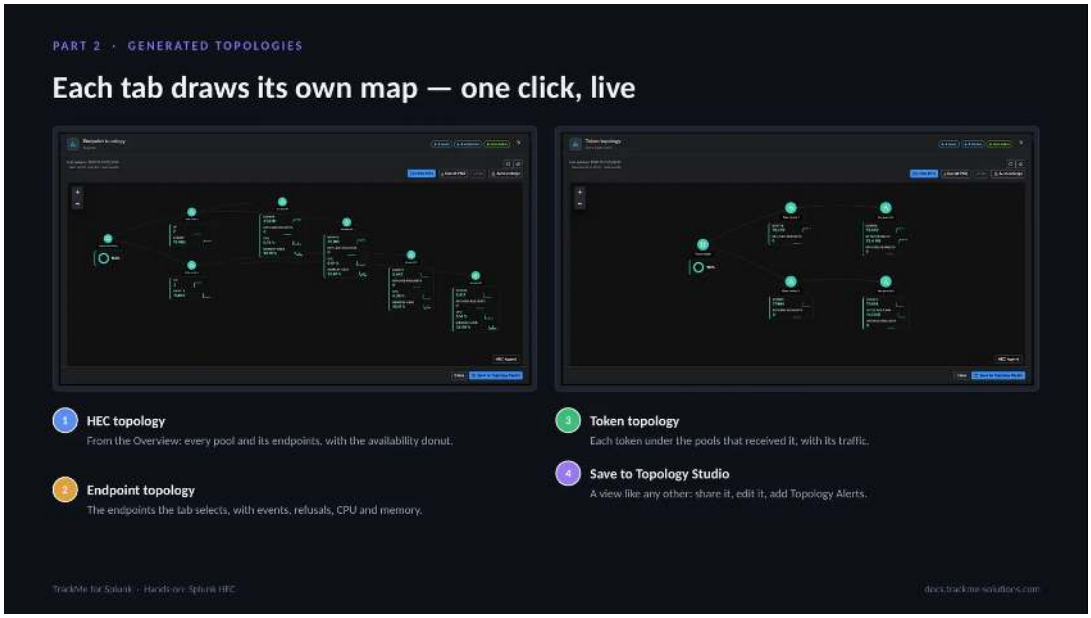
The pool drilldown shows how the members share what the pool receives, against an even split over the members up. Balance is 100 for an even split and 0 when one member takes everything; the tiles add the members carrying traffic, the smallest share against the fair share and the members up that received nothing. Over the last four hours of Data centre 2, the share of hec-pool-hf3 falls to zero while it was stopped, then comes back.

Tokens by name, never by value



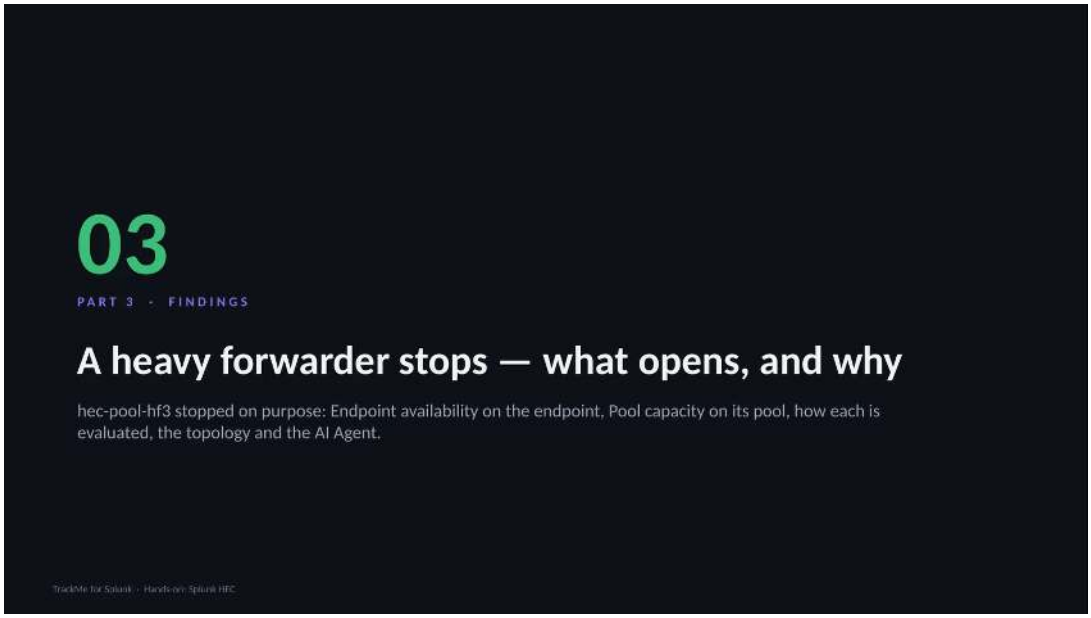
The Tokens tab lists every token name seen in the last 24 hours with the pools and endpoints that received it, its events, bytes and refused requests. A token opens its drilldown: its state, its last 24 hours, its traffic over time, the endpoints involved with each one's share of the token's events against an even split, and the errors in plain words. TrackMe never reads, stores, logs or shows a token value. Here each data centre has its own token, received only by the heavy forwarders of its pool.

Generated topologies



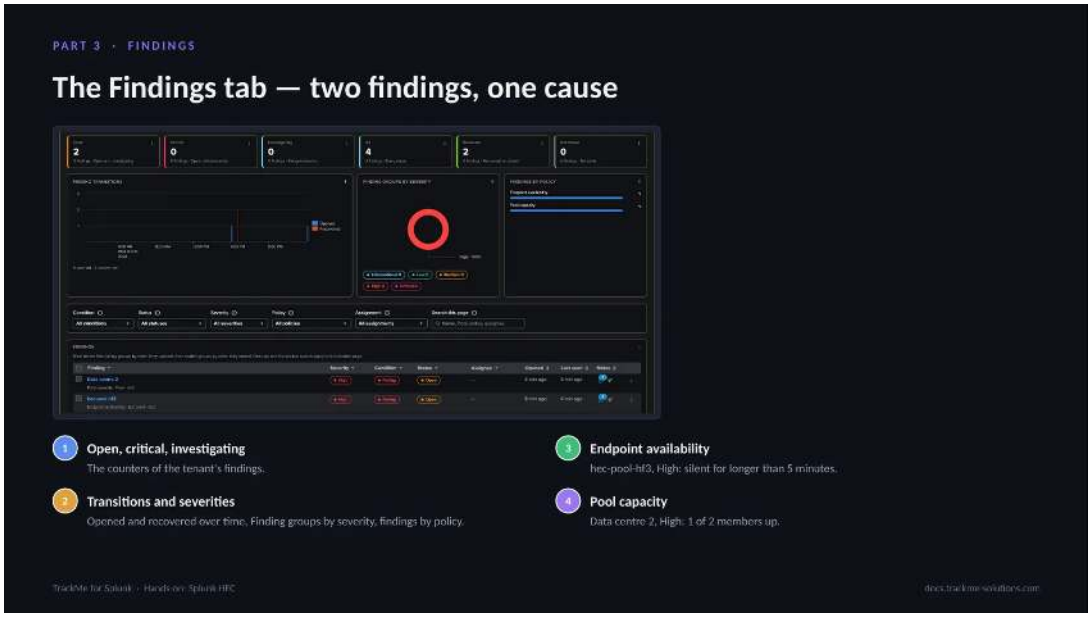
Each workspace tab draws a live map of what it shows, on the Topology Studio canvas. HEC topology, from the Overview, draws every pool and its endpoints with the availability donut. Endpoint topology draws the endpoints the Endpoints tab selects, each with its events, refused requests, CPU and memory. Token topology draws each token under the pools that received it, with its traffic. Every node shows its live status and its twenty-four-hour sparklines, refreshed every minute. Save to Topology Studio keeps the map as a view like any other: share it, edit it, add Topology Alerts.

Part 3 — Findings



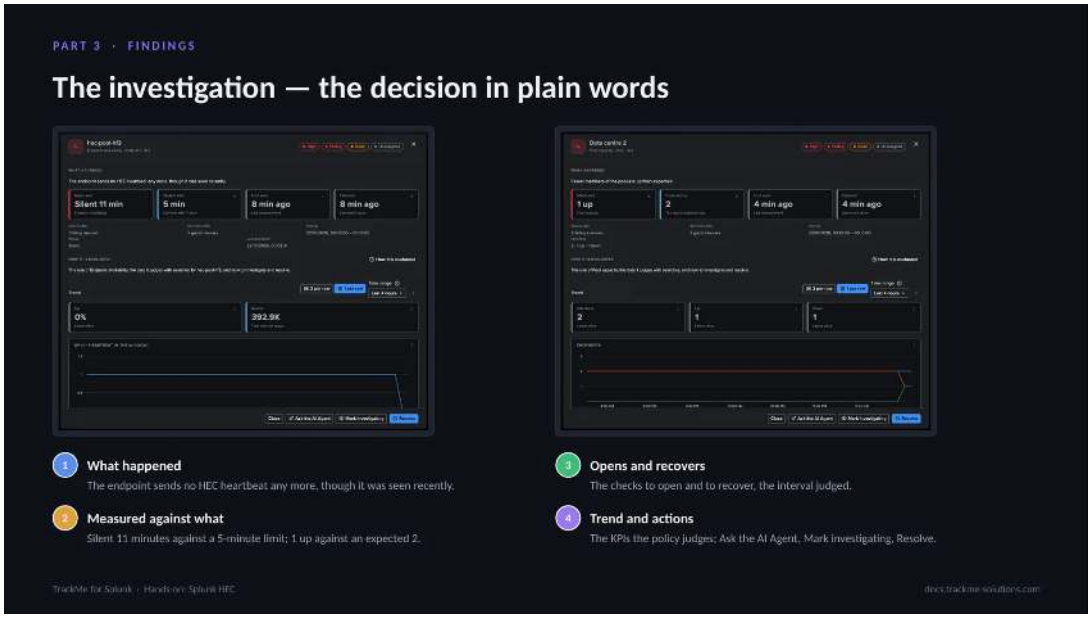
hec-pool-hf3, one of the two heavy forwarders of Data centre 2, was stopped on purpose. This part follows what opened — Endpoint availability on the endpoint and Pool capacity on its pool — how each is evaluated, the topology and the Splunk HEC AI Agent. Findings work as on the Cribl tenants: Finding groups, triage, notifications, assignment and findings actions.

Two findings from one stopped forwarder



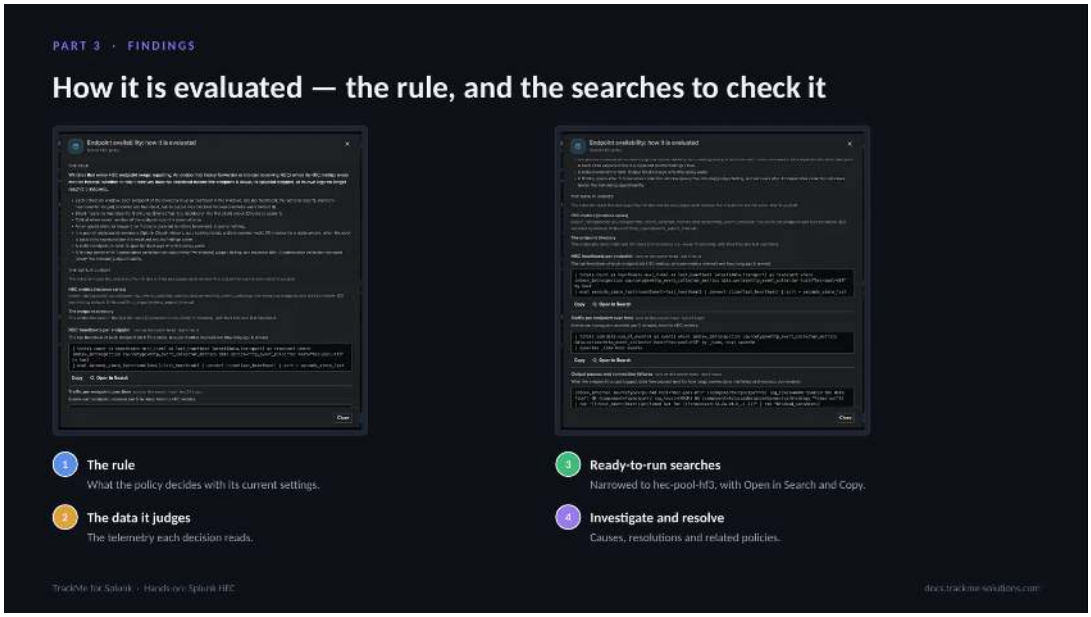
The Findings tab counts the open, critical and investigating findings, charts the transitions over time, the Finding groups by severity and the findings by policy, and lists the findings. Endpoint availability opened on hec-pool-hf3 at the first silent check, High; Pool capacity opened on Data centre 2 after two checks, High, critical only below half the expected size. Each object gathers its findings in one Finding group, the unit that is triaged and notified.

The investigation of each finding



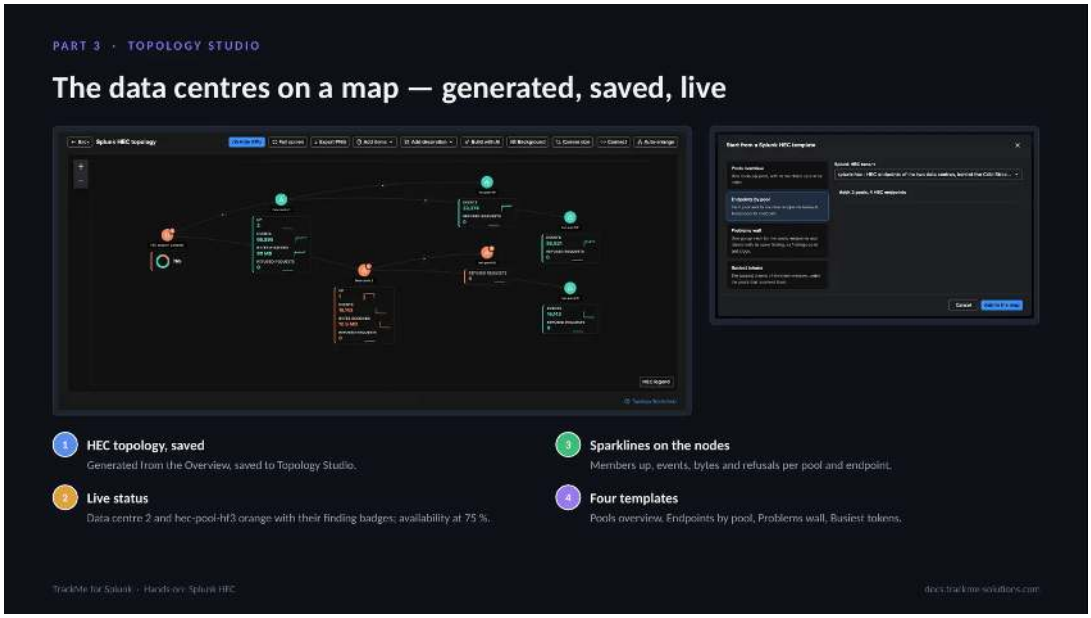
The investigation gives the decision in plain words — the endpoint sends no HEC heartbeat any more, though it was seen recently; fewer members of the pool are up than expected — the measurement and what it was compared with, the checks to open and to recover, the interval judged and the trend of the KPIs the policy judges. Ask the AI Agent, Mark investigating and Resolve sit at the bottom, and Open resource opens the endpoint, pool or token in place.

How a decision is evaluated



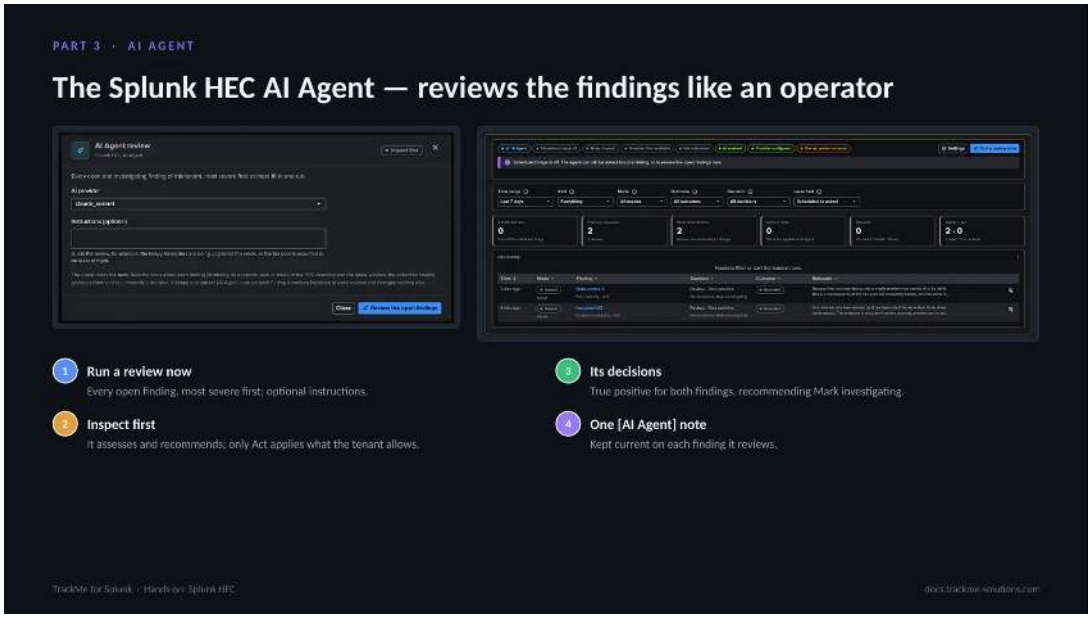
How it is evaluated explains the rule of the policy with its current settings, the data it judges and how to investigate and resolve. Its ready-to-run searches are built from the tenant's own source and, opened from a finding, narrowed to its endpoint or token — here host hec-pool-hf3 — each with Open in Search and Copy. An administrator checks the decision against Splunk's own data in one click.

The data centres in Topology Studio



Splunk HEC pools, endpoints and tokens are Topology Studio objects. This view is the HEC topology generated from the Overview and saved to Topology Studio: Data centre 2 and hec-pool-hf3 are orange with their finding badges while Data centre 1 and its members are green, and the endpoint availability fell to seventy-five per cent. Each node carries its sparklines: members up, events, bytes and refused requests. The templates — Pools overview, Endpoints by pool, Problems wall and Busiest tokens — draw other maps; groups follow their objects as they come and go, and Topology Alerts and Build with AI work on HEC tenants.

The Splunk HEC AI Agent

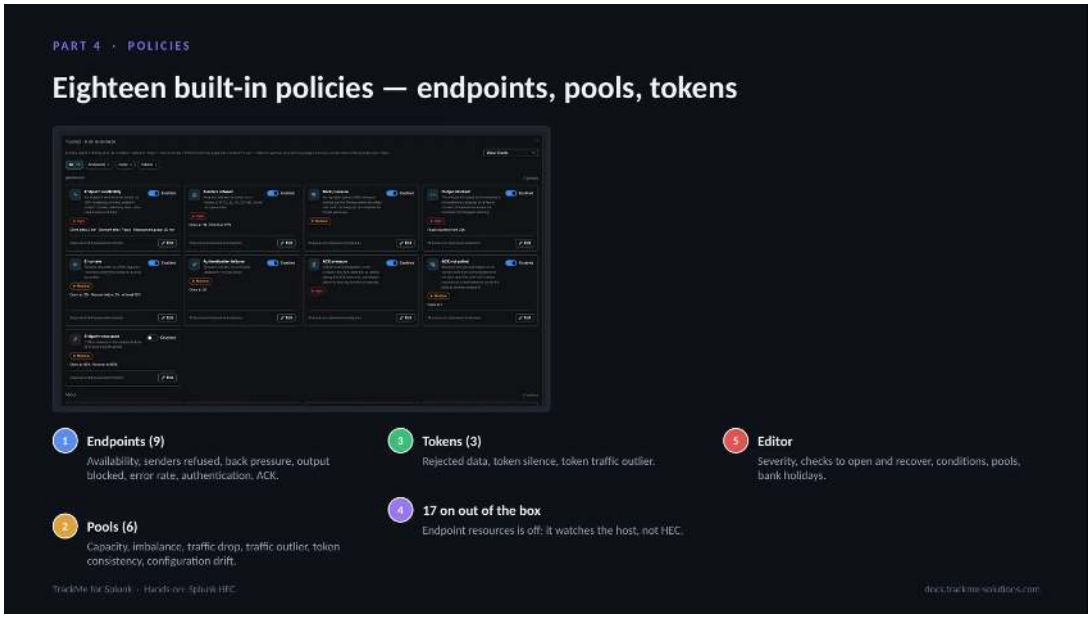


Run a review now reviews every open finding, most severe first, with optional instructions. The agent reads the facts TrackMe holds — the finding and its history, the endpoint or pool in the directory and the latest window, collection health and its own past decisions — and runs no search. It inspects first: here it judged both findings true positives and recommended marking them investigating, recorded without applying anything. Act applies only what the tenant allows, and scheduled triage is off by default.

Part 4 — Operate

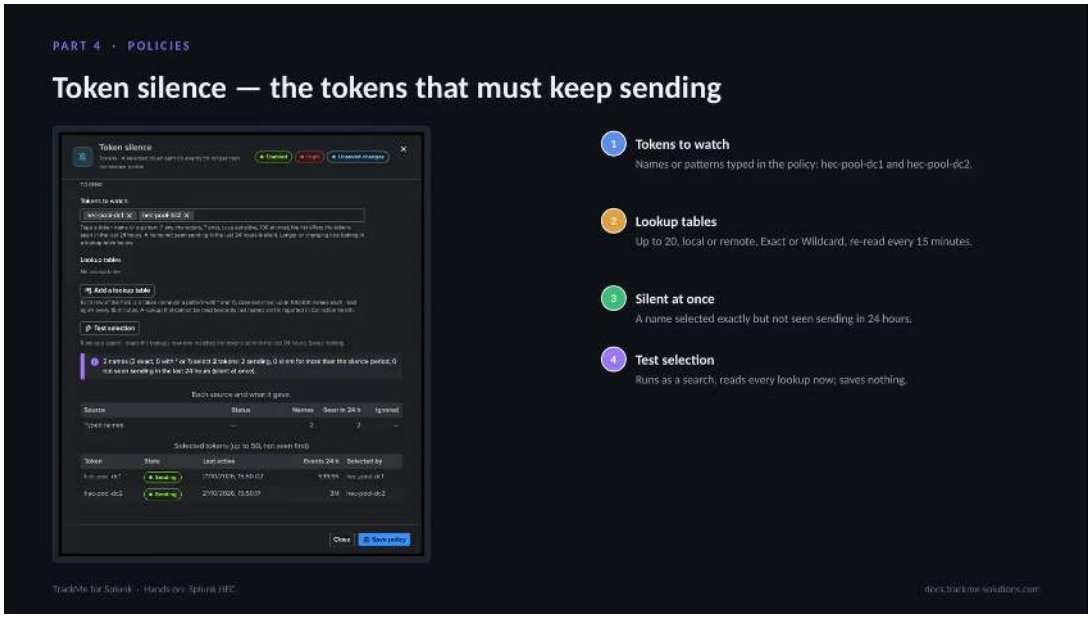
This part covers operating the tenant day to day: the eighteen built-in policies and their editor, the tokens that must keep sending selected by name or from lookups, the traffic models and their tuning, collection health with its run budgets, and the optional splunkd API enrichment of the endpoints.

The built-in policy catalogue



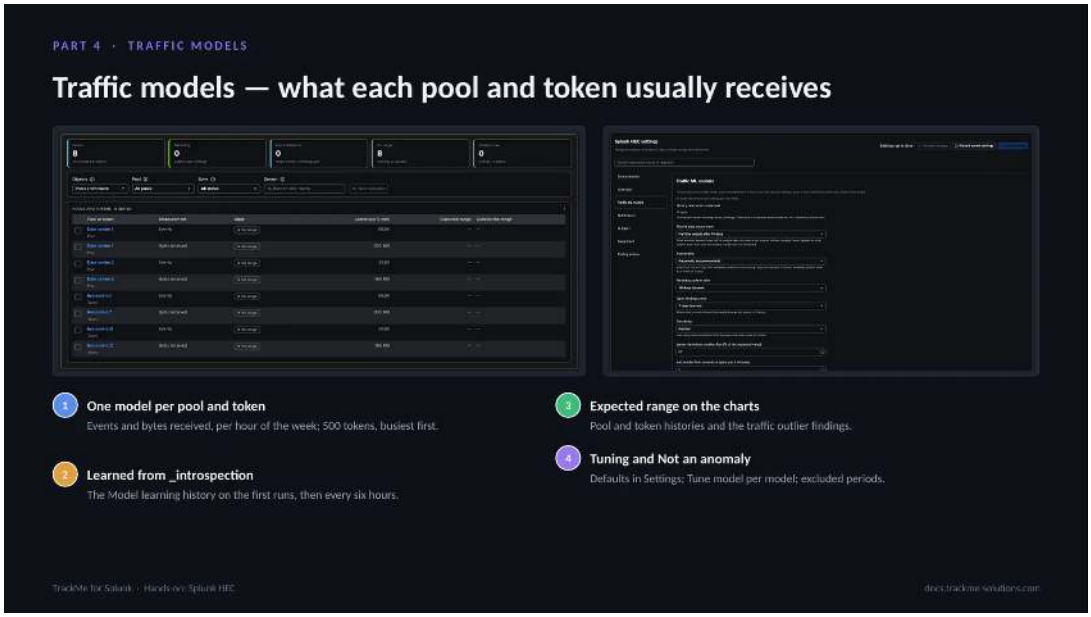
Eighteen built-in policies in three categories: nine on endpoints (availability, senders refused, back pressure, output blocked, error rate, authentication failures, ACK pressure, ACK not polled and endpoint resources), six on pools (capacity, imbalance, traffic drop, traffic outlier, token consistency and configuration drift) and three on tokens (rejected data, token silence and token traffic outlier). Seventeen are on out of the box. A TrackMe administrator of the tenant edits each one's severity, checks, conditions, pools and bank holiday behaviour, and writes custom SPL policies.

Selecting the tokens that must keep sending



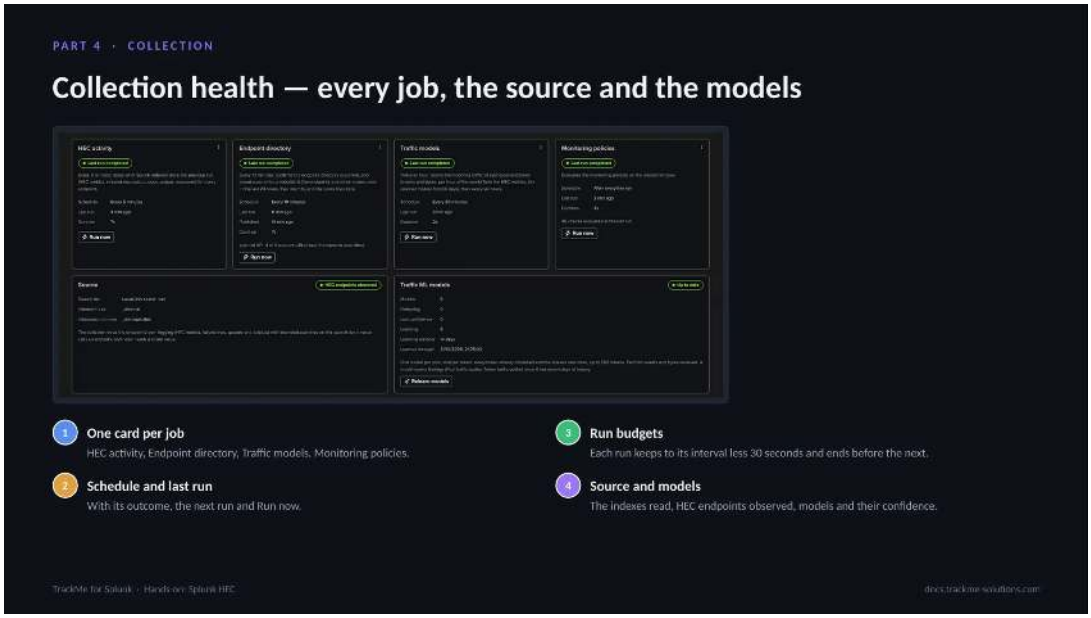
Token silence opens a finding when a selected token sends no event for longer than the silence period, 15 minutes by default. Tokens are typed in the policy — hec-pool-dc1 and hec-pool-dc2 here — or read from up to 20 Splunk lookup tables, local or remote, in Exact or Wildcard mode. A name selected exactly and not seen sending in the last 24 hours is silent at once. Test selection runs as a search, reads every lookup now and saves nothing.

Traffic models and their tuning



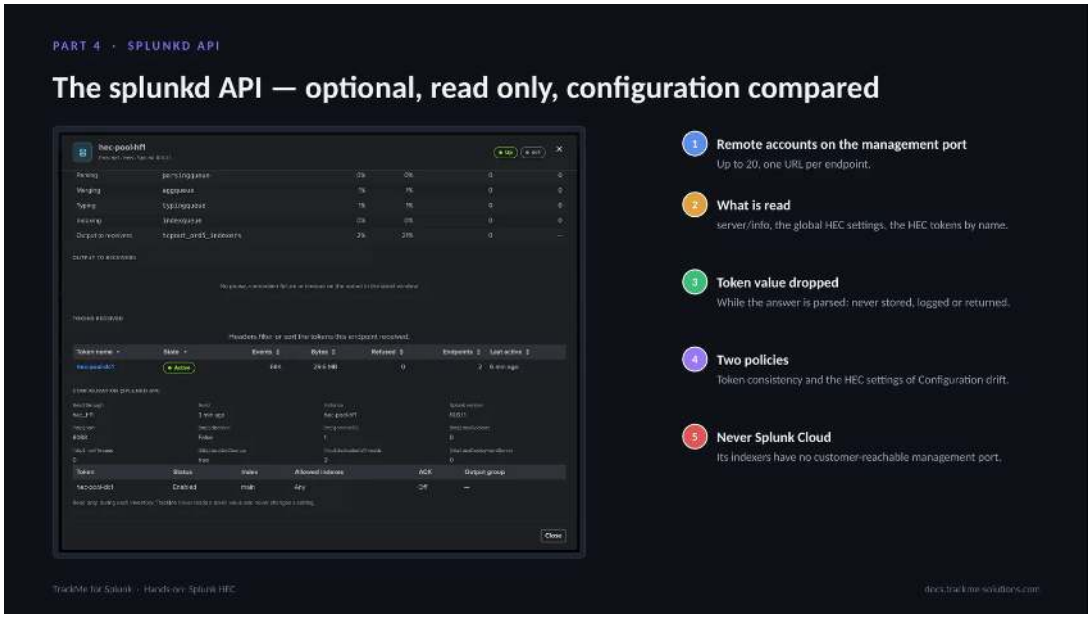
One model per pool and per token, up to 500 tokens busiest first, learns the events and bytes received per hour of the week with the arithmetic of the Cribl Stream traffic models, from the Model learning history on the first runs. The expected range is drawn on the pool and token charts, and Pool traffic outlier and Token traffic outlier open findings once a model detects. Settings, Traffic ML models holds the defaults; Tune model gives a model its own settings and excluded periods, and Not an anomaly excludes an expected episode.

Collection health



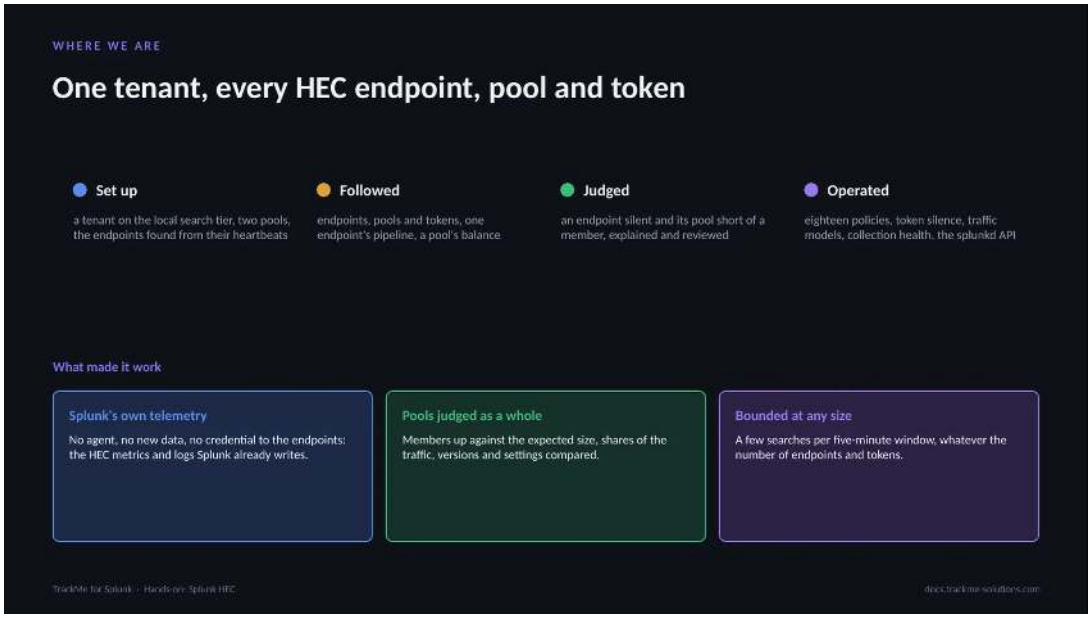
One card per job — HEC activity, Endpoint directory, Traffic models and Monitoring policies — with its schedule, last run, outcome and Run now. Each run keeps to its interval less 30 seconds and ends before the next scheduled run. The Endpoint directory card says what the splunkd API read, the Source panel shows the search tier and indexes read, and the Traffic ML models panel the models and their confidence. When collection does not run as configured, the tab lists the problems and the Configuration Guardian raises an alert.

The optional splunkd API enrichment



With TrackMe remote accounts bound on the endpoints' management port, the endpoint directory reads server/info, the global HEC settings and the HEC tokens by name at each rebuild. The token value is dropped while the answer is parsed: never stored, logged or returned. The endpoint drilldown shows the instance's HEC settings and its tokens with their status, index, allowed indexes and ACK. Token consistency and the HEC settings part of Configuration drift use it; Splunk Cloud is never read.

Where we are



A Splunk HEC tenant was set up on a deployment with two data centres: its endpoints followed from their heartbeats, its pools compared member by member and its tokens by name. A heavy forwarder was stopped, and the two findings it opened were explained, reviewed by the AI Agent and recovered. Three choices make it work: Splunk's own telemetry with no agent and no new data, pools judged as a whole, and a few bounded searches per window at any size.

2.1.12 Splunk S2S

Follow the Splunk-to-Splunk receiving side of a deployment from the telemetry Splunk already writes: the indexer cluster found without configuration as one pool per site and its manager account for planned work, the heavy forwarder tier found as an automatic pool and made a configured one, what is blocked now, a pool's load distribution, a receiver's pipeline queue by queue and the data path from the senders to the indexers; a heavy forwarder stopped on purpose, the three findings it opens, how each is evaluated, the notification email and the Splunk S2S AI Agent; then the twenty-two policies, the traffic models and collection health.

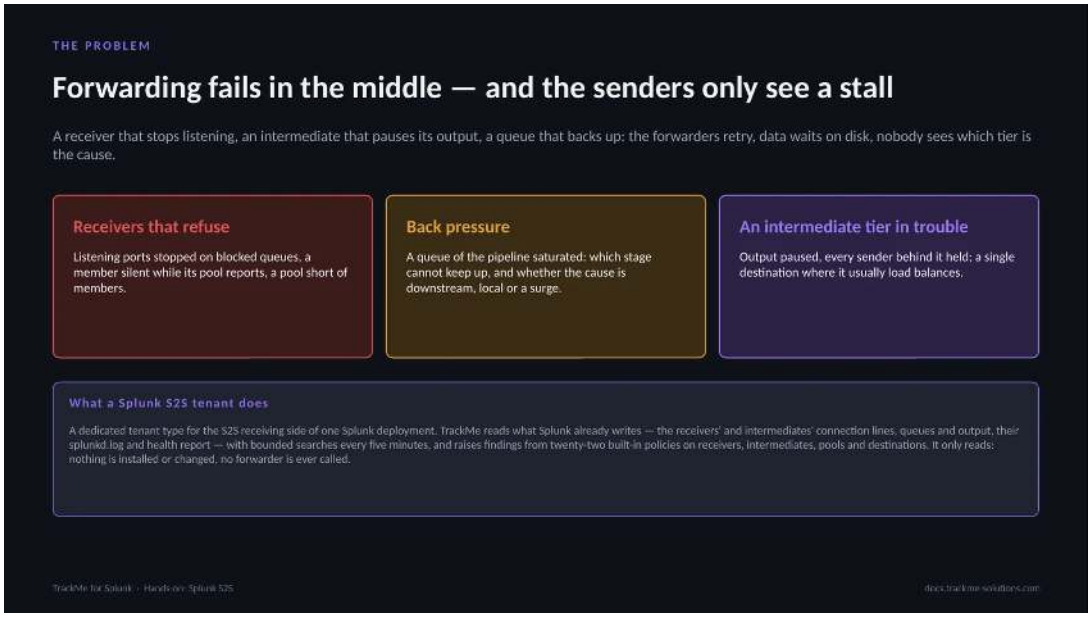
`Download the deck (PDF) · PowerPoint`

about 30 minutes · 26 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

Overview

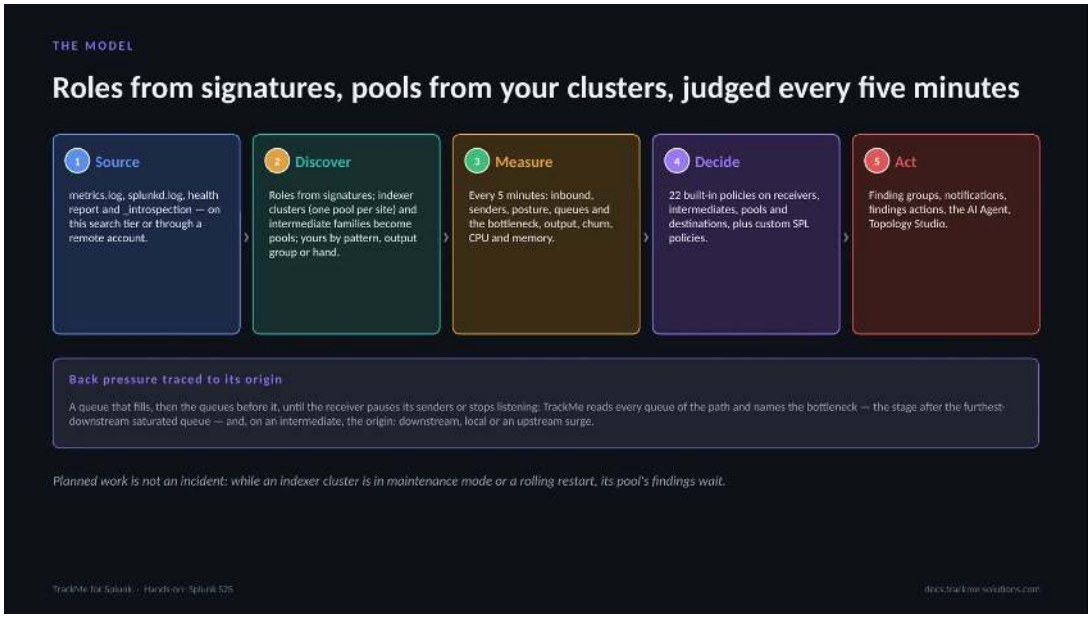
This walkthrough covers the Splunk S2S tenant, generally available in TrackMe 2.4.22. Everything was captured live on a deployment with a four-peer indexer cluster on two sites, a tier of four heavy forwarders, and universal forwarders sending to that tier. In four parts: create the tenant, follow the pools, the hosts and the data path, read the findings of a heavy forwarder stopped on purpose, and operate the tenant.

Why a dedicated Splunk S2S tenant



A Splunk administrator asks the same forwarding questions every day: is every receiver accepting and keeping up, is the intermediate tier blocked, backed up or silent, which tier is the bottleneck when senders are held back, and is the cause downstream, local or an upstream surge. How much flows into each pool, from how many senders, with which TLS and acknowledgement posture? The Splunk S2S tenant answers them with findings raised by twenty-two built-in policies. It only reads the telemetry Splunk already writes: nothing is installed or changed on a forwarder or an indexer.

How a Splunk S2S tenant works

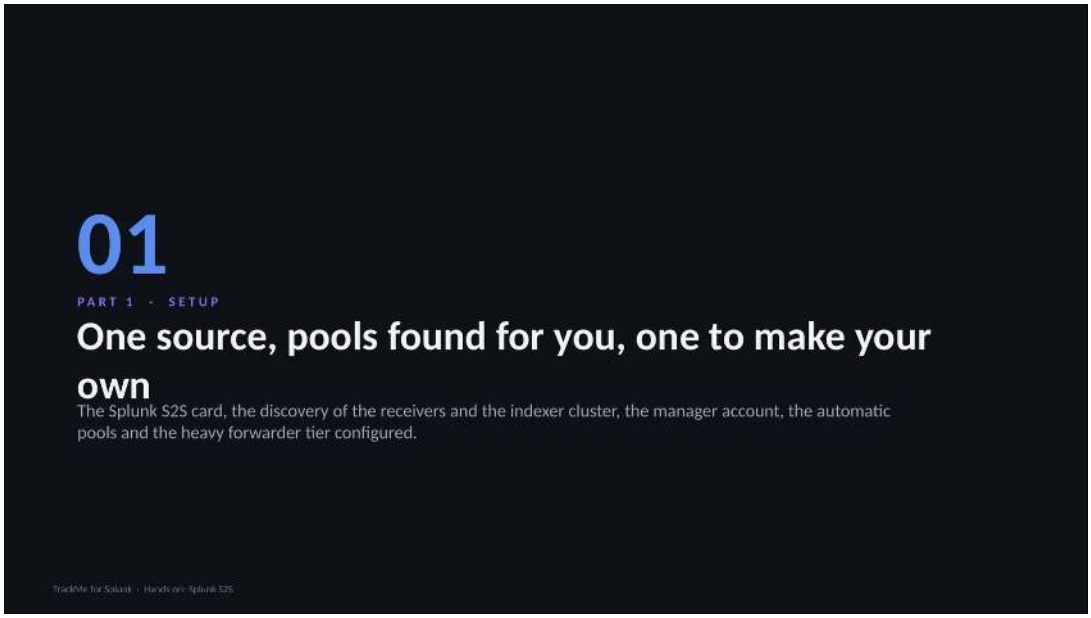


Roles are read from signatures over a day: a host that receives and indexes is a receiver, a host that receives and forwards is an intermediate forwarder. Each indexer cluster the search head is attached to becomes a pool by itself, one per site of a multisite cluster; the intermediate forwarders no pool claims form one automatic pool per host-name family, and other hosts are grouped by host patterns, output groups or hand assignment. Every five minutes the live job reads the last settled index-time window, and the policies decide. Back pressure is traced to its origin: the stage that cannot keep up, and whether the cause is downstream, local or an upstream surge. Planned work is not an incident: an indexer cluster in maintenance mode or a rolling restart holds the pool's findings.

The plan

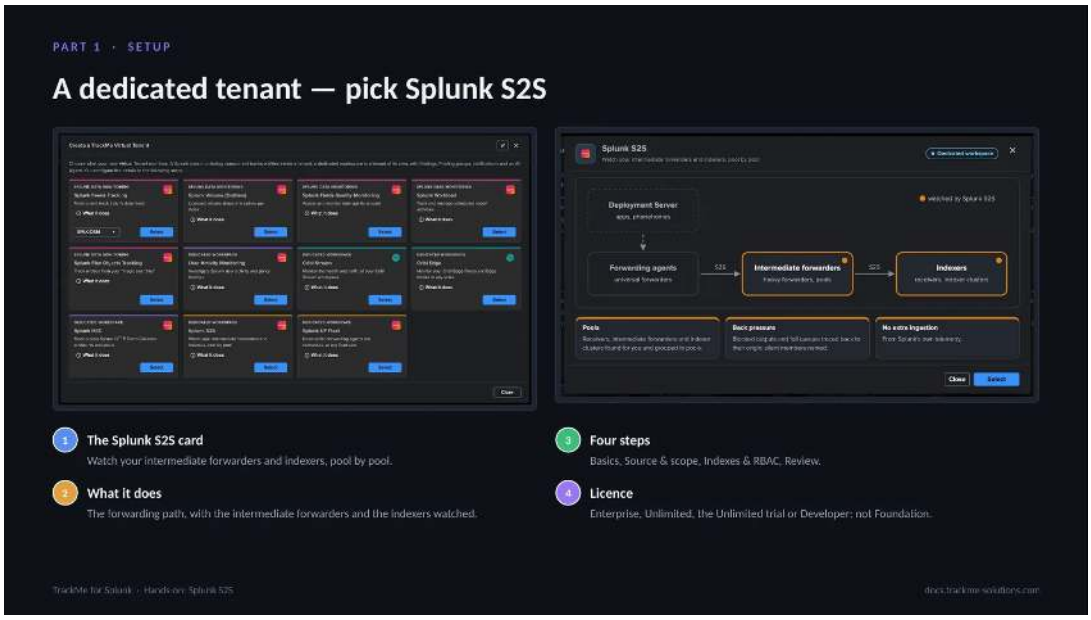
Four parts. Setup: the wizard, the indexer cluster's site pools and their manager account, the automatic pools and the heavy forwarder tier made a configured pool. Pools, hosts and the data path: the Pools tab and Blocked now, a pool's distribution, a receiver's pipeline and the data path. Findings: a heavy forwarder stopped on purpose, what opens and how it is evaluated, the AI Agent and the notification email. Operate: the policies, the traffic models and collection health.

Part 1 — Setup



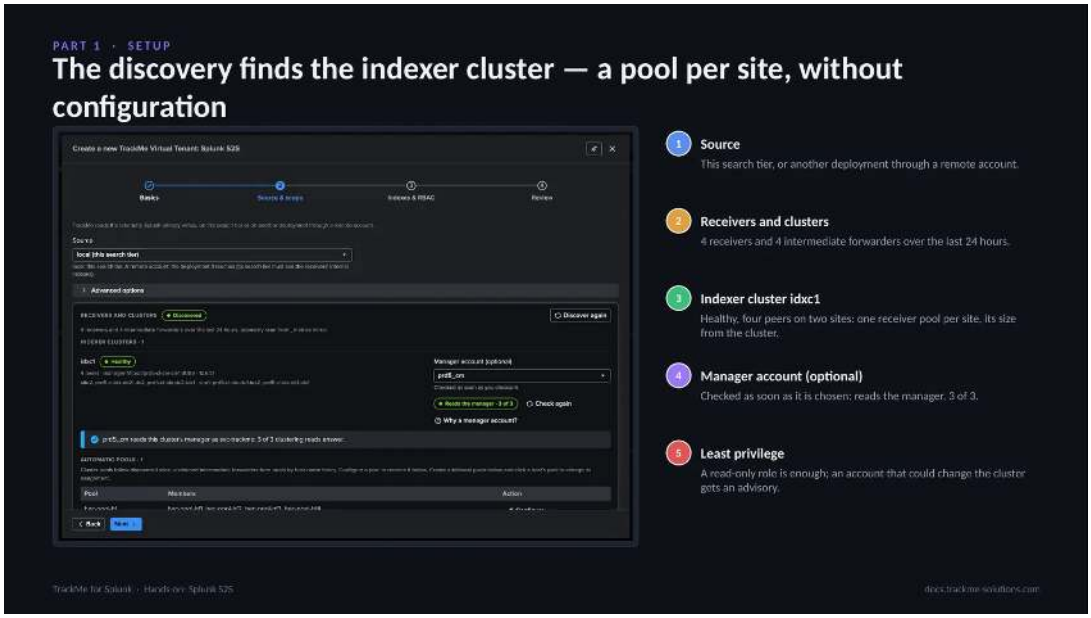
Part one: setup. A Splunk S2S tenant reads one deployment: its local search tier, or another deployment through a TrackMe remote account.

A dedicated tenant — pick Splunk S2S



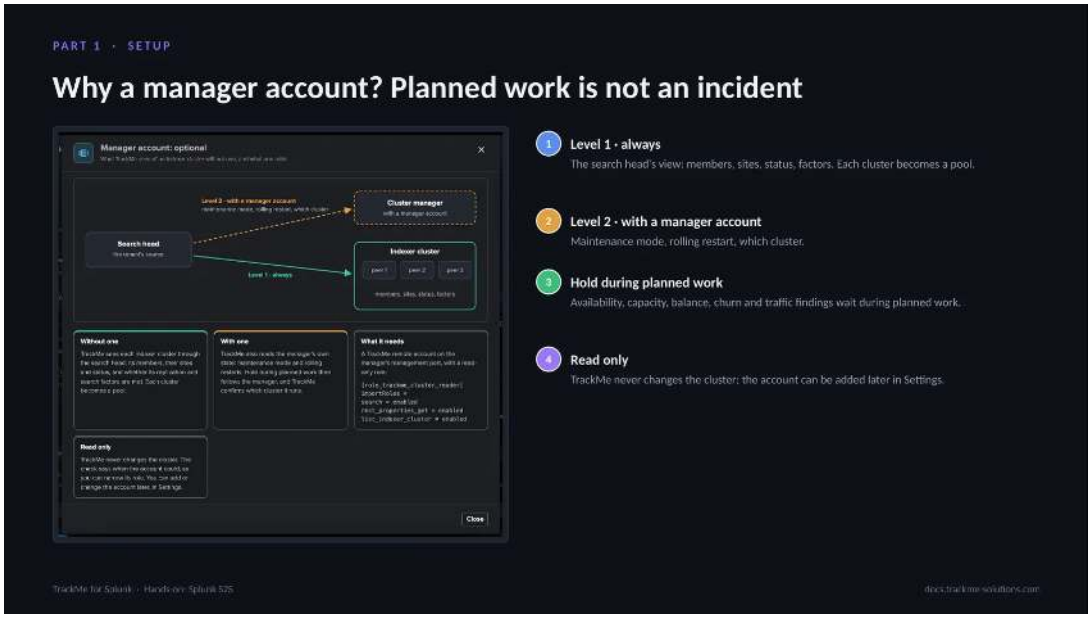
Virtual Tenants, Actions, Create a tracking tenant, then the Splunk S2S card. What it does draws the forwarding path: the forwarding agents send over S2S to the intermediate forwarders, which forward to the indexers, and Splunk S2S watches the intermediates and the indexers. A Splunk S2S tenant has no entities and no state colour: it is a findings tenant, like the Splunk HEC, Cribl and User Activity Monitoring tenants.

The discovery finds the indexer cluster



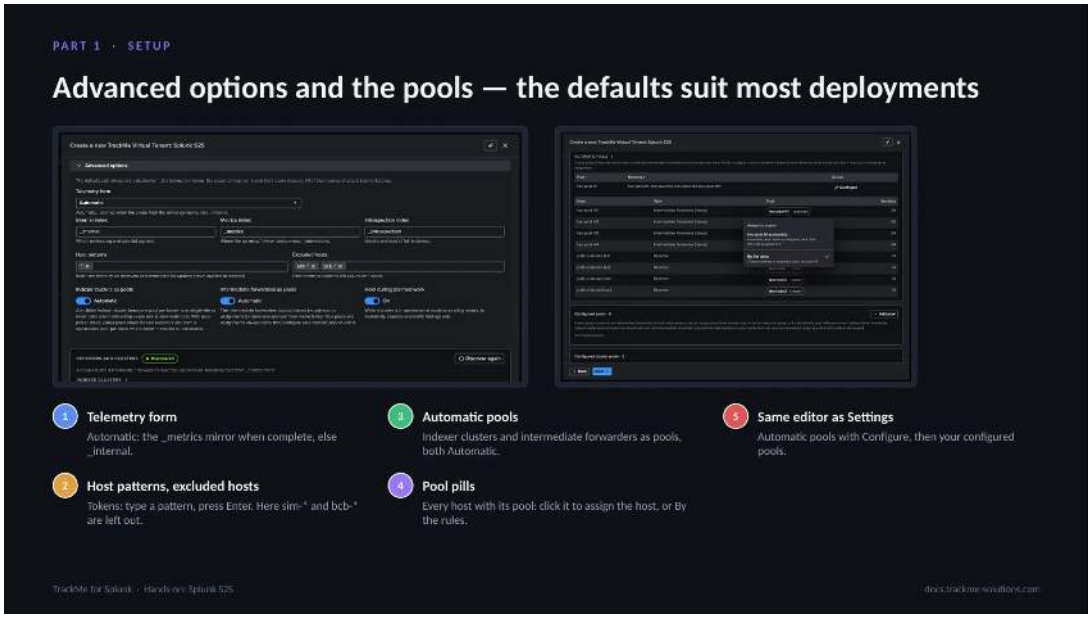
Source and scope. The discovery reads the receivers and intermediates of the last day, and each indexer cluster the search head is attached to: here idxc1, four peers on two sites, which forms one receiver pool per site. The optional manager account lets the tenant read the manager's maintenance mode and rolling restarts. It is checked as soon as it is chosen: here a least-privilege service account reads the manager, 3 of 3 clustering reads. An account that could change the cluster gets an advisory with the read-only role to create: search, rest_properties_get and list_indexer_cluster.

Why a manager account? Planned work is not an incident



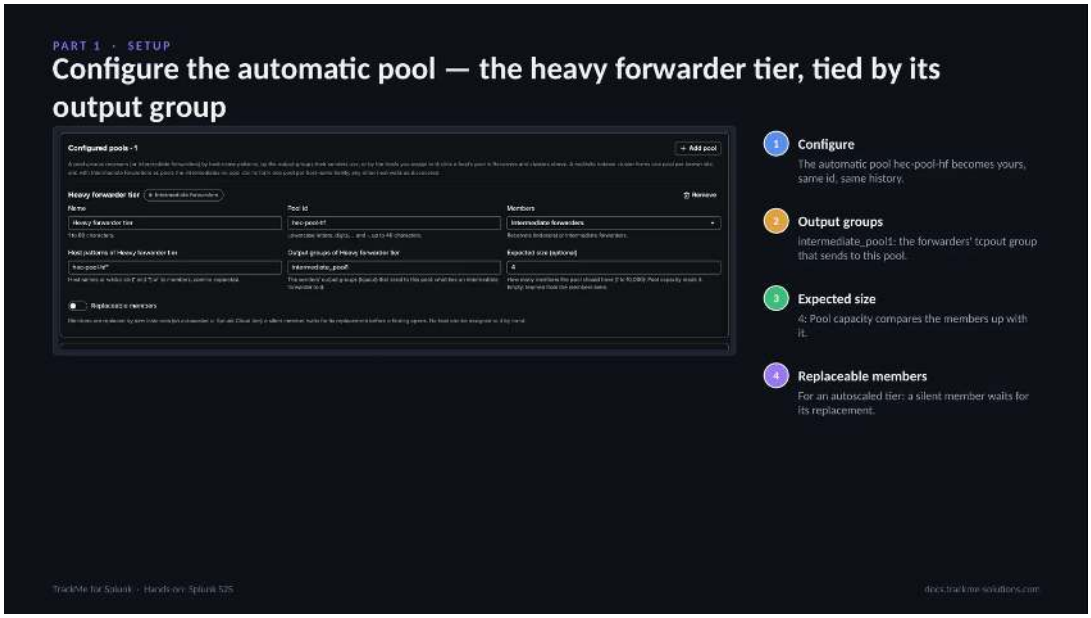
The search head always sees its indexer clusters: their peers, their replication and search factors, whether the data is searchable. A manager account adds the manager's own state, so a rolling restart or a maintenance window holds the pool's findings instead of opening them: an open finding stays open, and a new one waits until the planned work ends. Without it, the tenant works from the search head's view only, and the Review step says so.

Advanced options and the pools



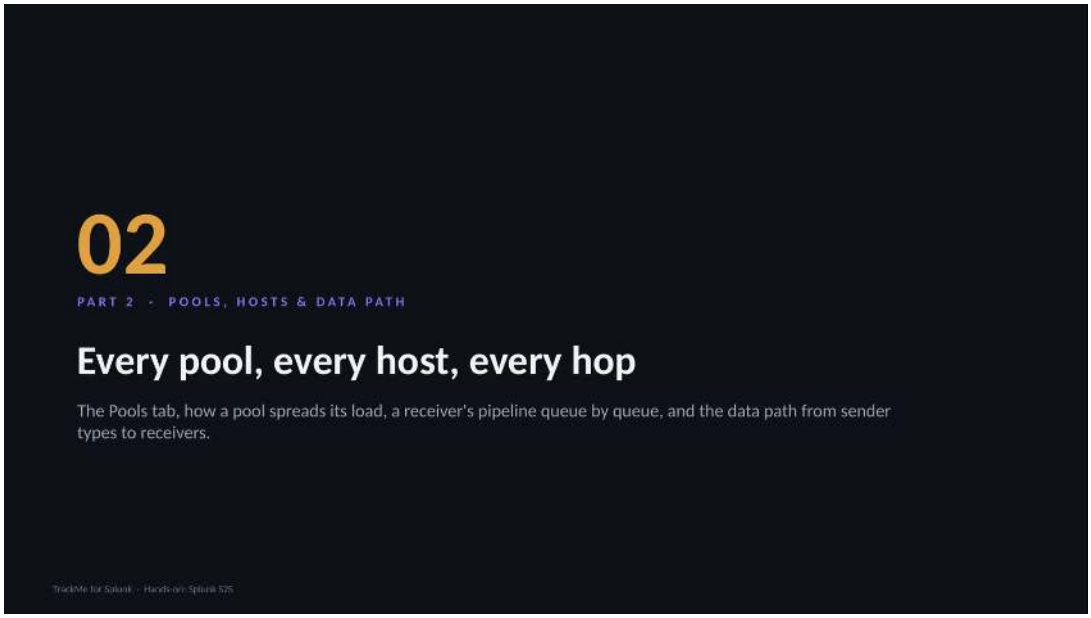
Advanced options stay folded unless a setting needs a fix: the telemetry form, the host patterns and excluded hosts, typed as tokens, and the automatic pools of indexer clusters and intermediate forwarders. Below the clusters, the step shows the pools the tenant starts with: the indexer cluster's two site pools and the automatic pool hec-pool-hf of the four heavy forwarders. Every host carries its pool pill: clicking it assigns the host to another pool, and By the rules gives it back. Nothing needs configuring at creation.

Configure the automatic pool



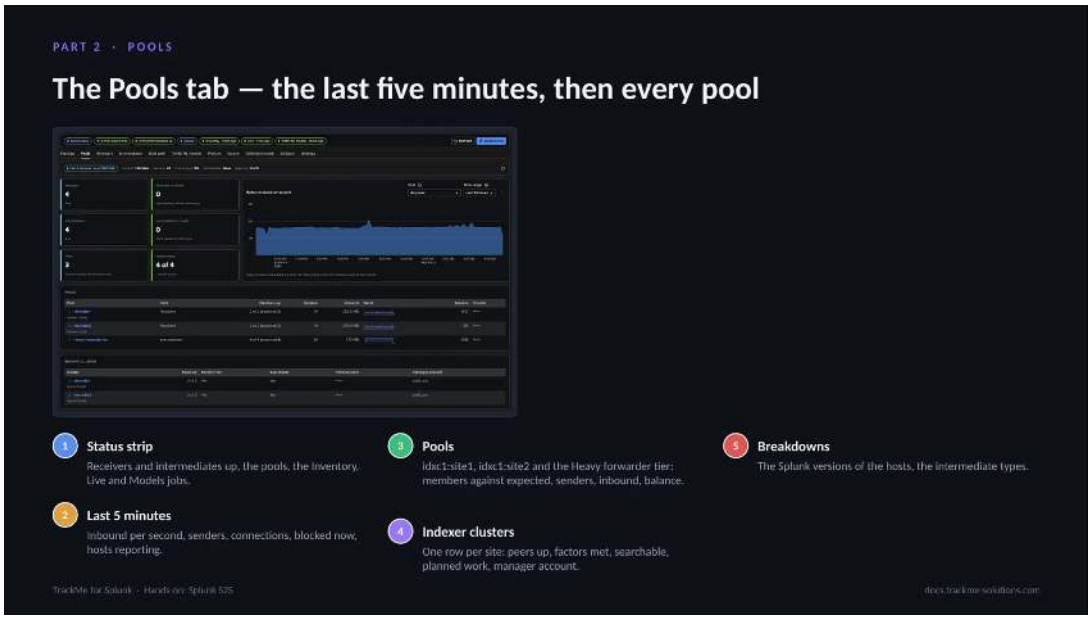
Settings, Pools. The indexer cluster and the heavy forwarder tier are pools from the first run. Configure on the automatic pool hec-pool-hf makes it a configured pool with the same id, so its findings and history continue: here it is named Heavy forwarder tier, given the output group its senders use, which ties the tier to the data path, and its expected size, four. A pool change applies from the next inventory run; Run now on the inventory, then Collect now, shows it at once.

Part 2 — Pools, hosts and data path



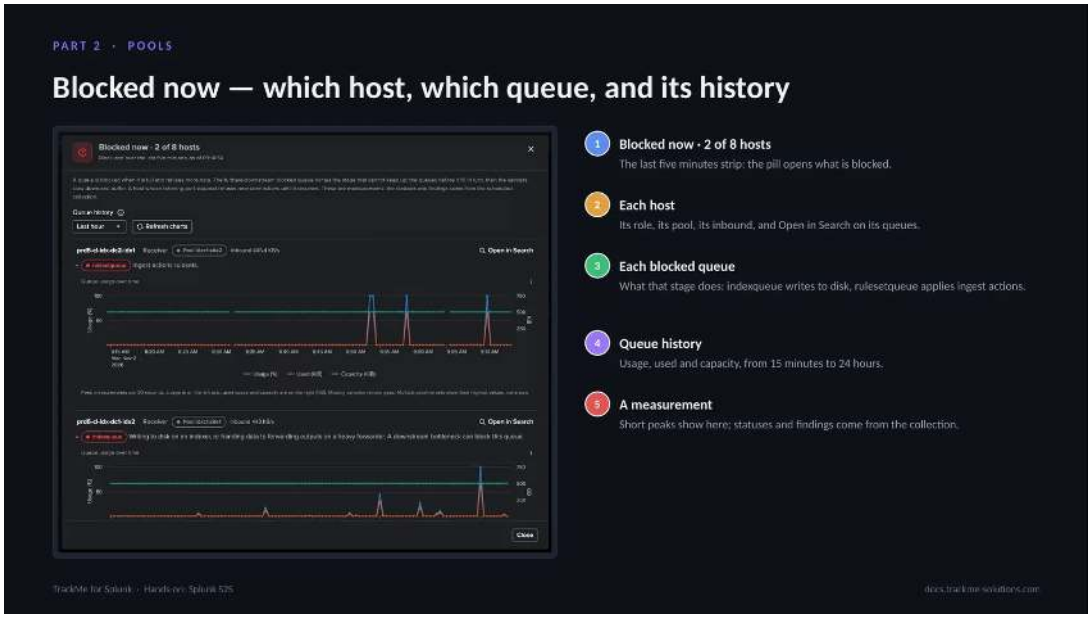
Part two: the workspace. The pools, the receivers and the intermediates, and the data path between them.

The Pools tab



The Pools tab opens on the last five minutes: inbound per second, senders, connections, blocked now and hosts reporting. Then come the host tiles, the pools with their members up against the expected size, their senders, inbound volume, trend and balance: the two site pools idxc1:site1 and idxc1:site2 and the Heavy forwarder tier. The indexer clusters list one row per site with its peers, factors, planned work and manager account. A pool row expands to its members, an indexer cluster pool to its peers.

Blocked now

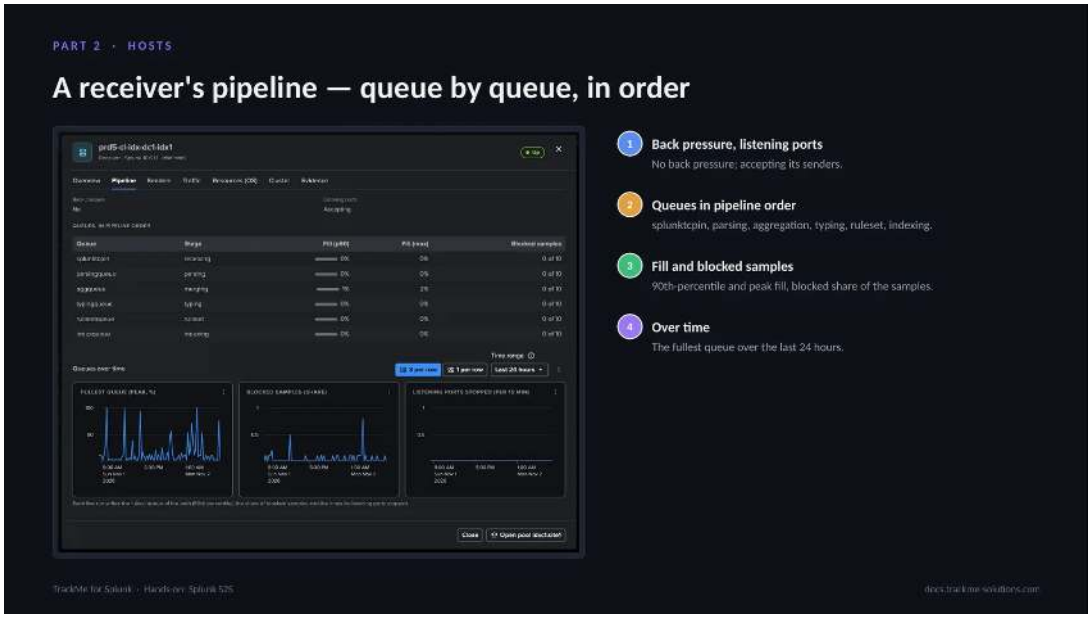


The Blocked now pill of the last five minutes opens what is blocked: each host with its role, its pool and its inbound, every blocked queue with what that stage of the pipeline does, a stopped listening port, Open in Search on the host's queues, and the queue history of each blocked queue, from 15 minutes to 24 hours. Here an indexer of each site shows short peaks of a queue: the index queue on one, the ruleset queue on the other. These are measurements: the statuses and findings come from the scheduled collection.

How the pool spreads its load

The pool modal of the Heavy forwarder tier, Distribution tab. One bar per active member's share of the pool, the fair share, 25 % for four members, and the band of the Receiver imbalance setting. A load balancer that starves one member shows here first, and the policy opens when a member stays below the band. The largest and smallest members are listed with their distance from the fair share.

A receiver's pipeline — queue by queue

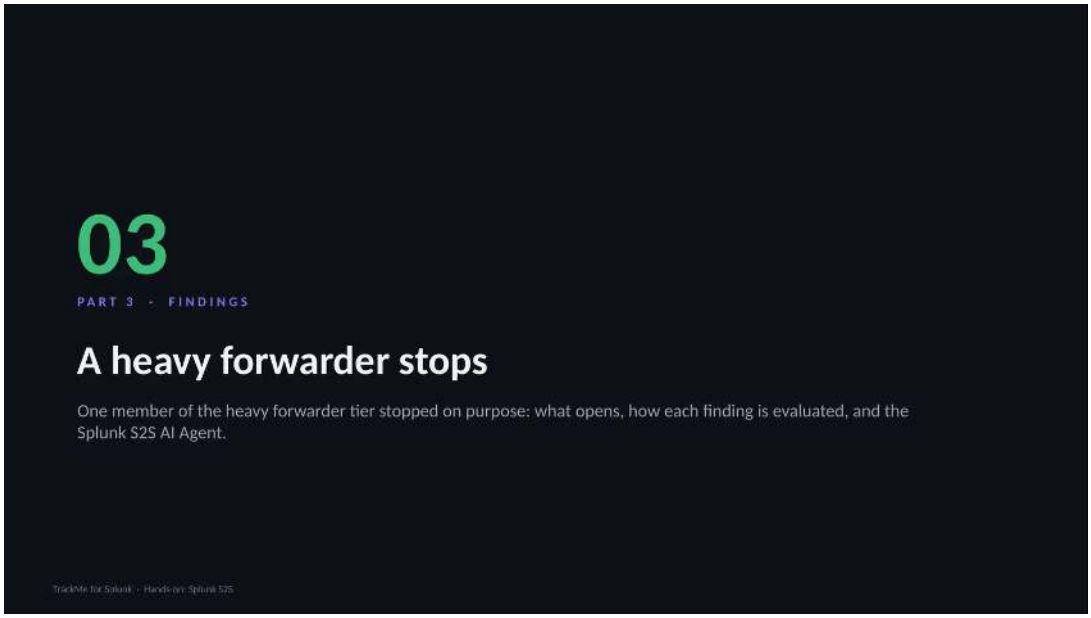


The host modal, Pipeline tab. Each queue of the receiver path, in order, with its fill and its blocked samples. A queue saturated at 80 % or blocked in 30 % of its samples is back pressure: the finding names the stage that cannot keep up, and whether its thread was busy or waiting on the next stage. The chart below follows the fullest queue over time.

The data path

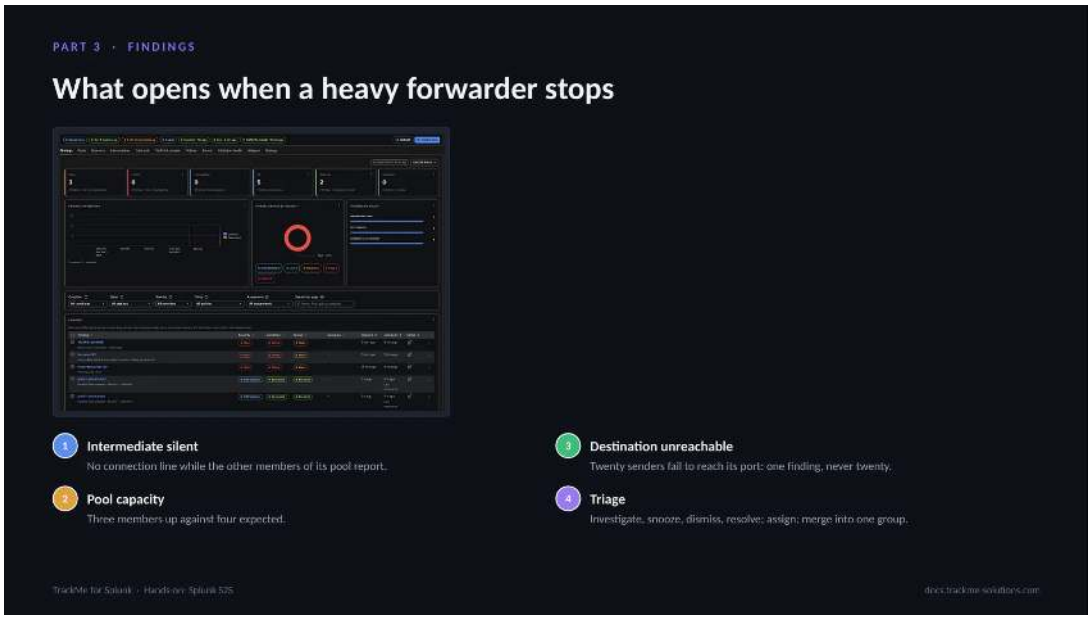
The Data path tab draws the forwarding path from what the receivers report: the universal forwarders into the Heavy forwarder tier, the tier into the two site pools of the indexer cluster, and the full instances sending straight to the indexers. Edges are drawn by volume. A Flows table states every edge in words. An intermediate is tied to its receivers by its output group, never by guessing from a destination address. The topology can be saved to Topology Studio.

Part 3 — Findings



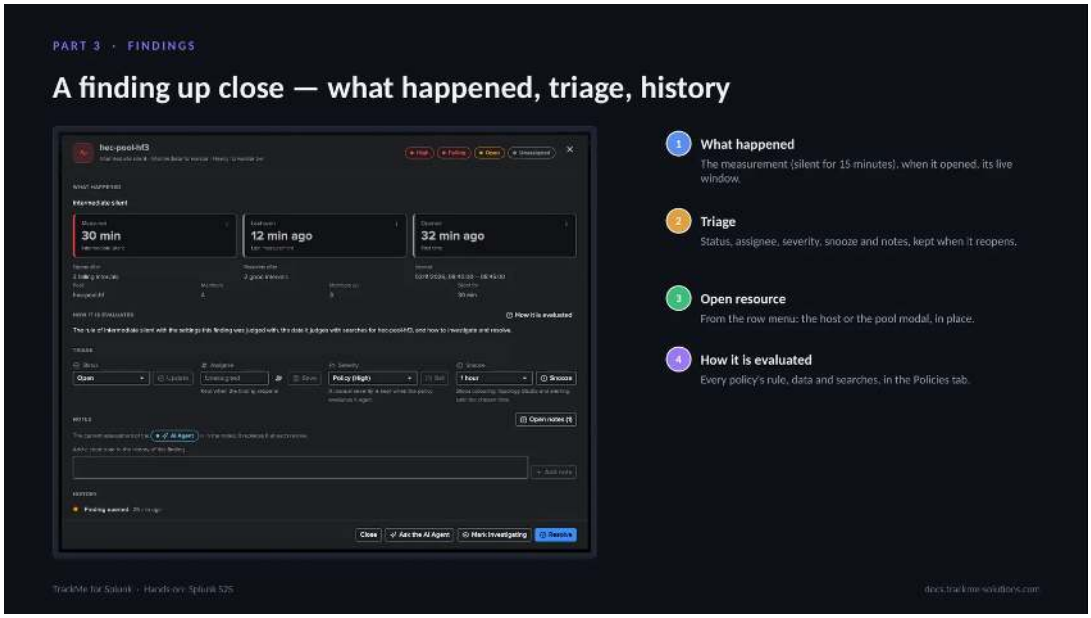
Part three: findings. One heavy forwarder of the tier, hec-pool-hf3, was stopped on purpose for about thirty-five minutes.

What opens when a heavy forwarder stops



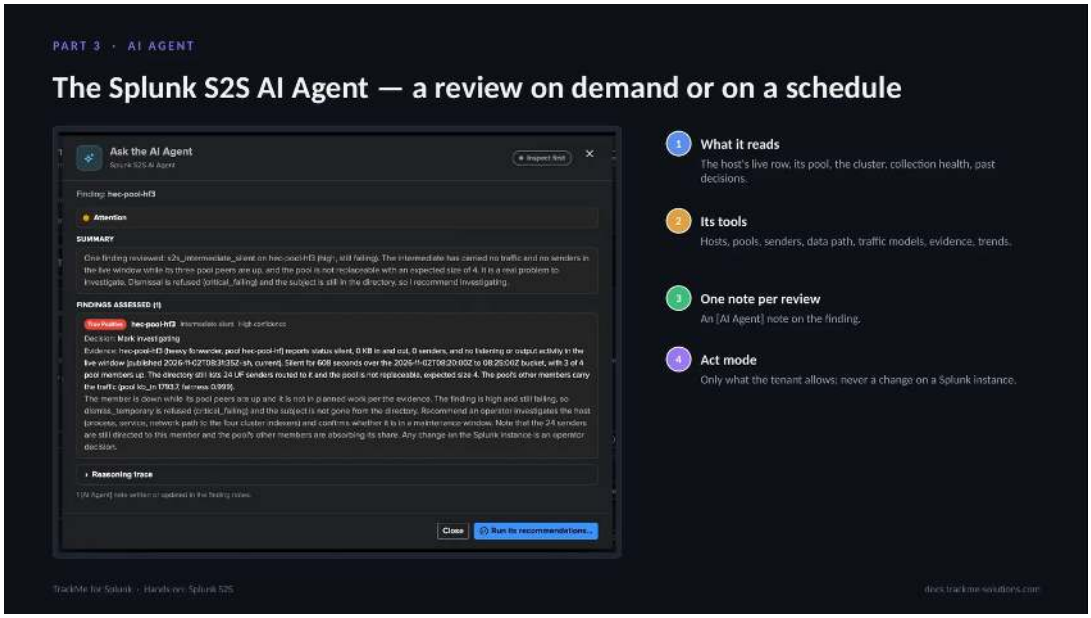
The Findings tab. The stopped heavy forwarder first opens Pool capacity on the Heavy forwarder tier (three members up against four expected), then Intermediate silent on the heavy forwarder and Destination unreachable on its receiving port, measured on the 23 universal forwarders that failed to reach it for 15 minutes or more: one finding on the destination, never one per sender. Each object has its own Finding group; they can be merged by hand when one incident is worked as one. The forwarders load balance to the three other members, so no sender is held: there is no back pressure cascade.

A finding up close



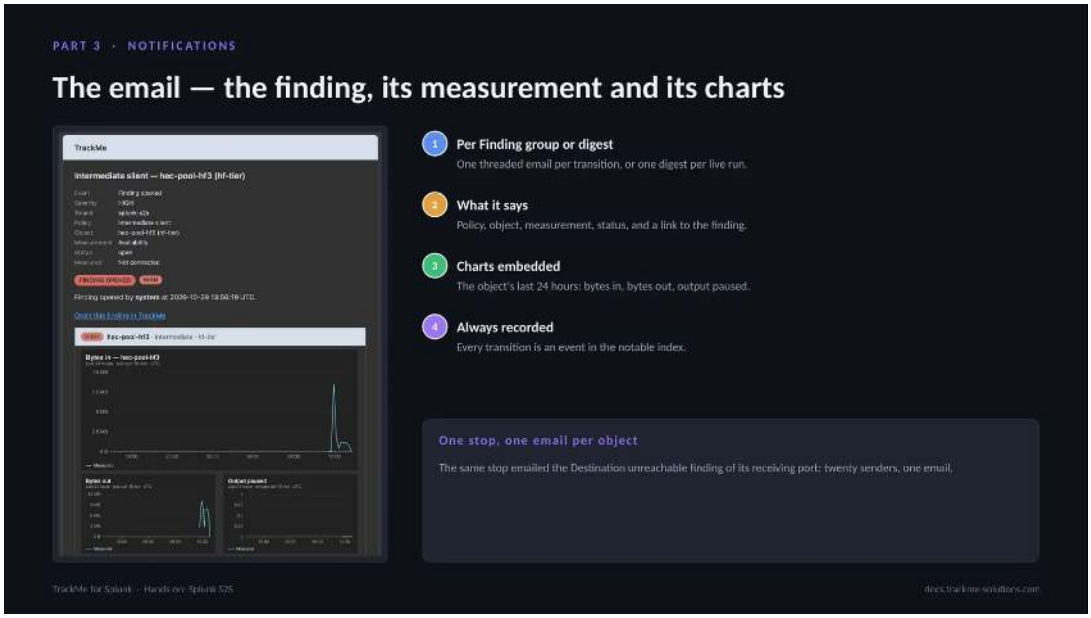
A finding opens with what happened (here the heavy forwarder silent for 10 minutes), when it opened and its live window, its pool with its members up, then its triage — status, assignee, severity, snooze — its notes and its history. Open resource, in the row menu, opens the host or the pool modal in place. How each policy is evaluated — the rule as configured, the data it reads with ready-to-run searches on the tenant's own source, and how to investigate and resolve — is one click away. When the heavy forwarder restarts, the findings recover after two healthy live windows.

The Splunk S2S AI Agent



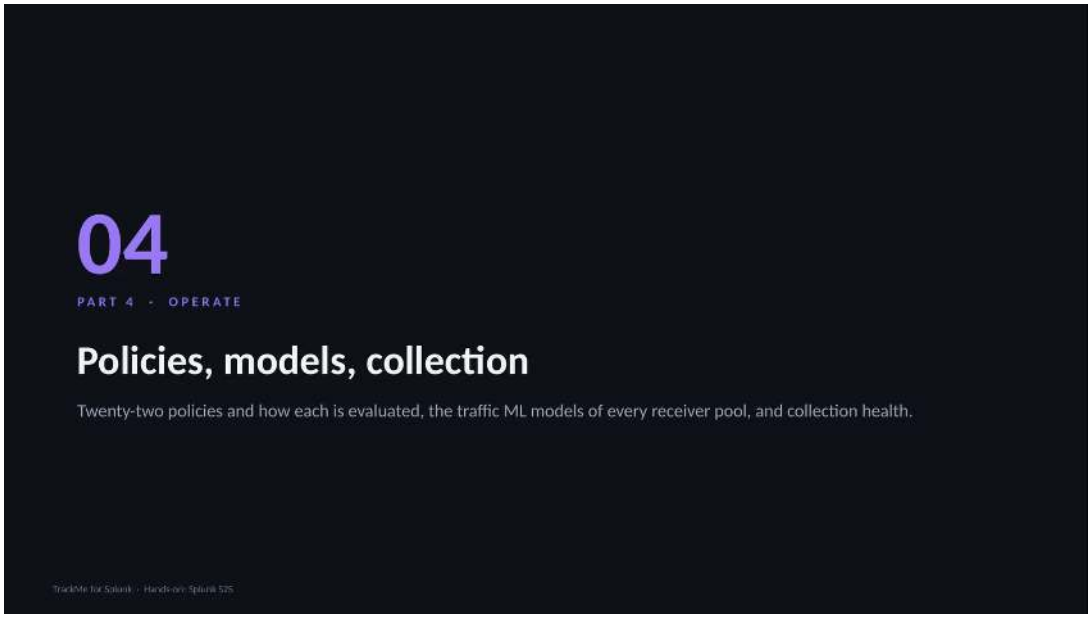
Ask the AI Agent from a finding or a Finding group. The Splunk S2S AI Agent reads the host's live row, its pool, the cluster, collection health and past decisions, and may read further through its tools: hosts, pools, senders, the data path, the traffic models, the evidence and the trends. It knows the pipeline model, the bottleneck and cascade reading, planned cluster work and the TLS and acknowledgement posture. Each review leaves an [AI Agent] note on the finding. Scheduled triage is off by default: hourly, up to ten findings per run, and in act mode only the decisions the tenant allows, never a change on a Splunk instance.

The notification email



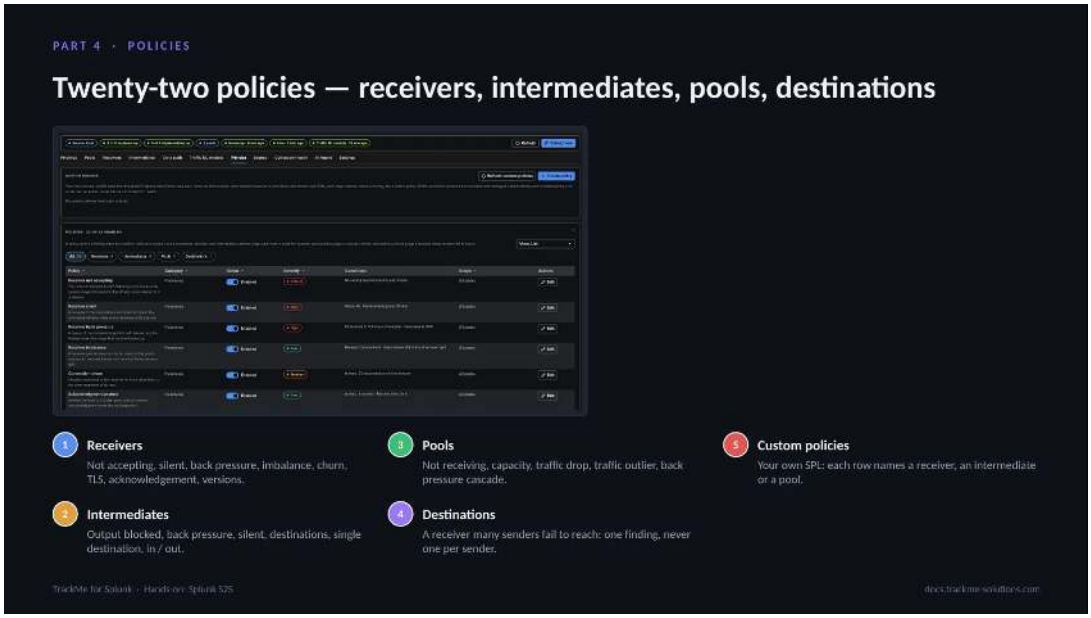
Settings, Notifications sends the transitions of the findings from a minimum severity, for every policy or chosen ones, through an email delivery account: one threaded email per transition of a Finding group, or one digest per live run. Here, the email of the silent heavy forwarder: the policy, the object, its measurement and a link back to the finding, with the intermediate's last 24 hours embedded. The same stop emailed the Destination unreachable finding of its port. Every transition is also an event in the tenant's notable index, whatever the notification settings.

Part 4 — Operate



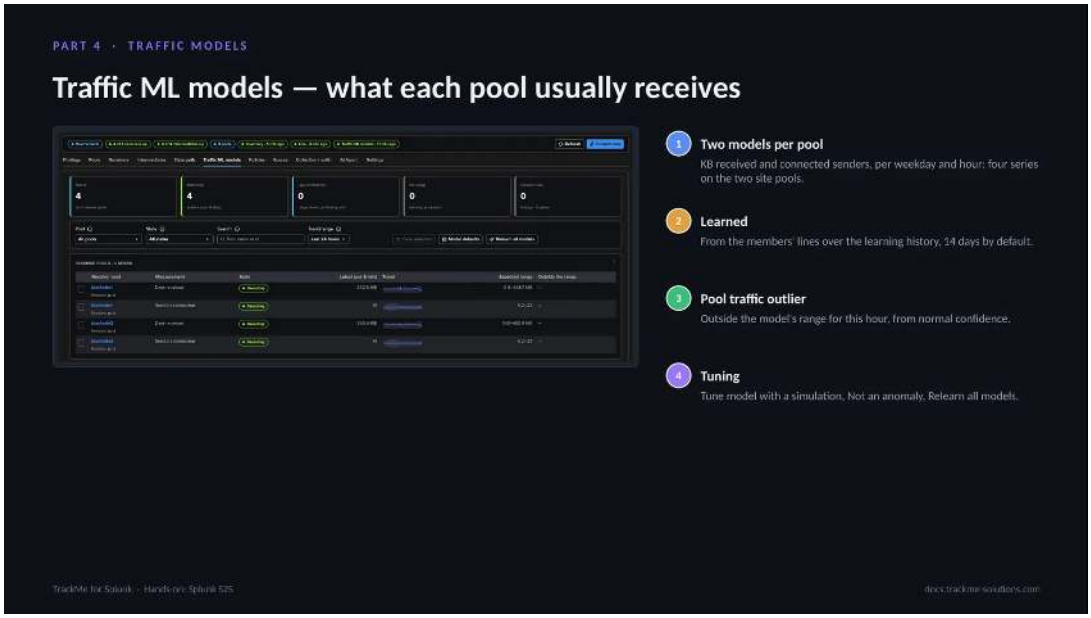
Part four: operate the tenant. The policies, the traffic models and collection health.

Twenty-two policies



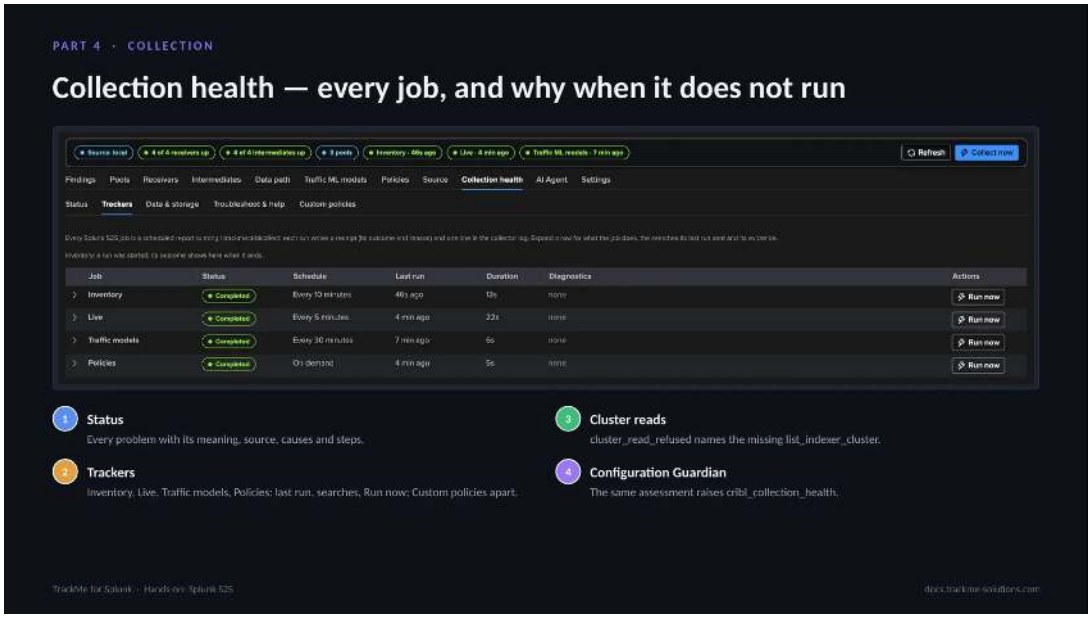
The policy catalogue, by category: receivers, intermediates, pools and destinations. Every policy has its severity, its checks to open and to recover, a scope by pool, a bank holiday hold and How it is evaluated. The ones to know first: Receiver not accepting, Intermediate output blocked and Back pressure cascade, all critical; Pool capacity, the back pressure policies and Destination unreachable, high. Above the catalogue, TrackMe administrators of the tenant write custom SPL policies: each result row names a receiver, an intermediate or a pool.

Traffic ML models



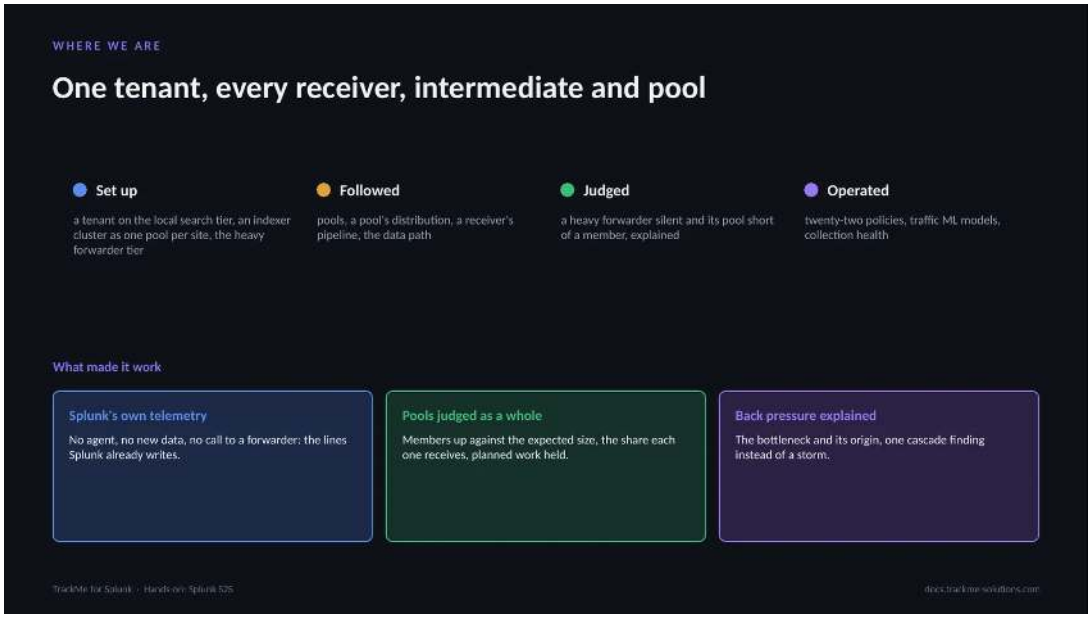
Every receiver pool has two traffic models, KB received and connected senders, learned per weekday and hour over the model learning history, 14 days by default, and refreshed twice an hour: here four series on the two site pools. Pool traffic outlier opens when a pool leaves its range for the hour, from normal confidence. Tune model simulates past windows; Not an anomaly on a finding teaches the model; administrators set the model defaults and relearn all models. Pool traffic drop, the same hour's median over seven days, needs no model.

Collection health



Collection health shows whether the tenant collects as configured: every problem with its meaning, source, causes and steps, and each job — inventory, live, traffic models, policies — with its last run, the searches it sent and Run now; the runs of each custom policy have their own view. The cluster reads need the read-only list_indexer_cluster capability: without it Splunk answers nothing, and Collection health names the missing capability. The Configuration Guardian raises the same assessment.

Where we are



A Splunk S2S tenant set up on a deployment with a four-peer indexer cluster on two sites and a heavy forwarder tier: its cluster found without configuration as one pool per site, its tier an automatic pool made a configured one. The pools, what is blocked, a pool's distribution, a receiver's pipeline and the data path followed. A heavy forwarder stopped, the findings it opened explained and emailed. And the policies, traffic models and collection health that run the tenant. What made it work: Splunk's own telemetry, pools judged as a whole, and back pressure traced to its origin.

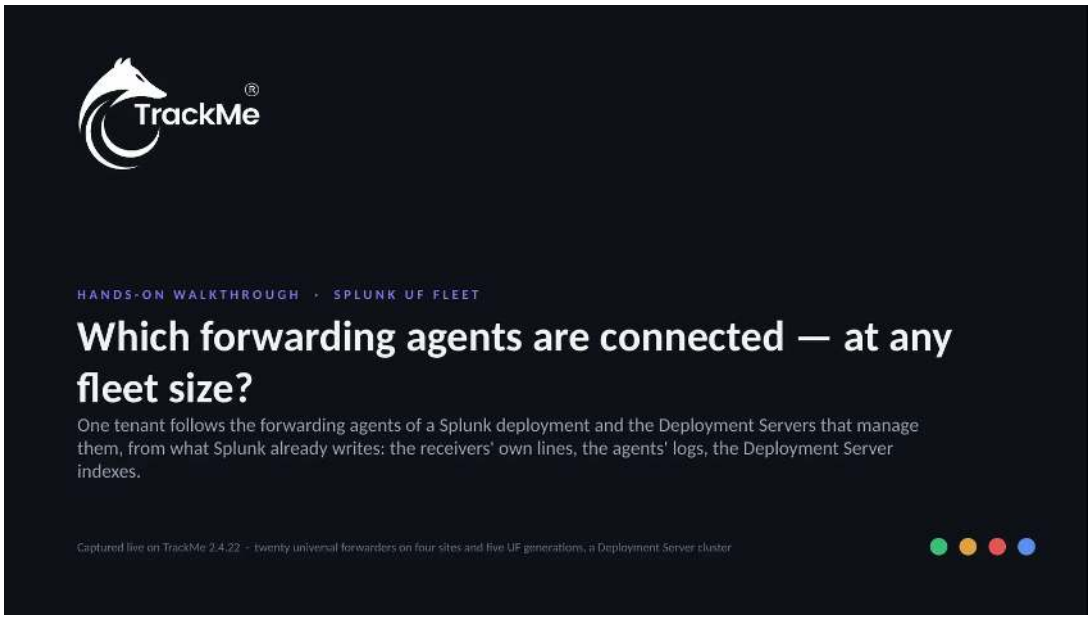
2.1.13 Splunk UF Fleet

Follow every forwarding agent of a Splunk deployment and the Deployment Servers that manage them, from what the receivers, the agents and the Deployment Servers already log: the Deployment Server API accounts, the scope and the discovery, enrichment from a CMDB lookup, groups proposed from the server classes and the enrichment, the agents that must stay connected and the notifications; the fleet, the agents, one agent up close and the Deployment Servers' pace; then four agents of one site stopped on purpose, a mass disconnect per cohort, an expected agent missing, a receiver the agents fail to reach and the Splunk UF Fleet AI Agent.

`Download the deck (PDF) · PowerPoint`

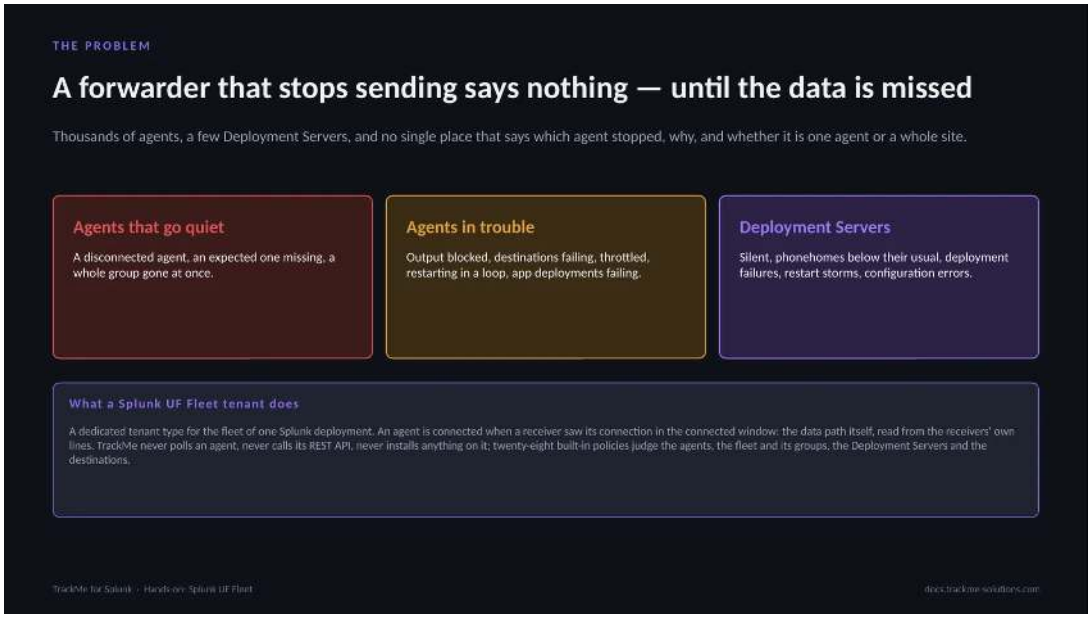
about 30 minutes · 26 slides. Each slide is followed by a description of what it shows — read top to bottom, this page is the walkthrough.

Overview



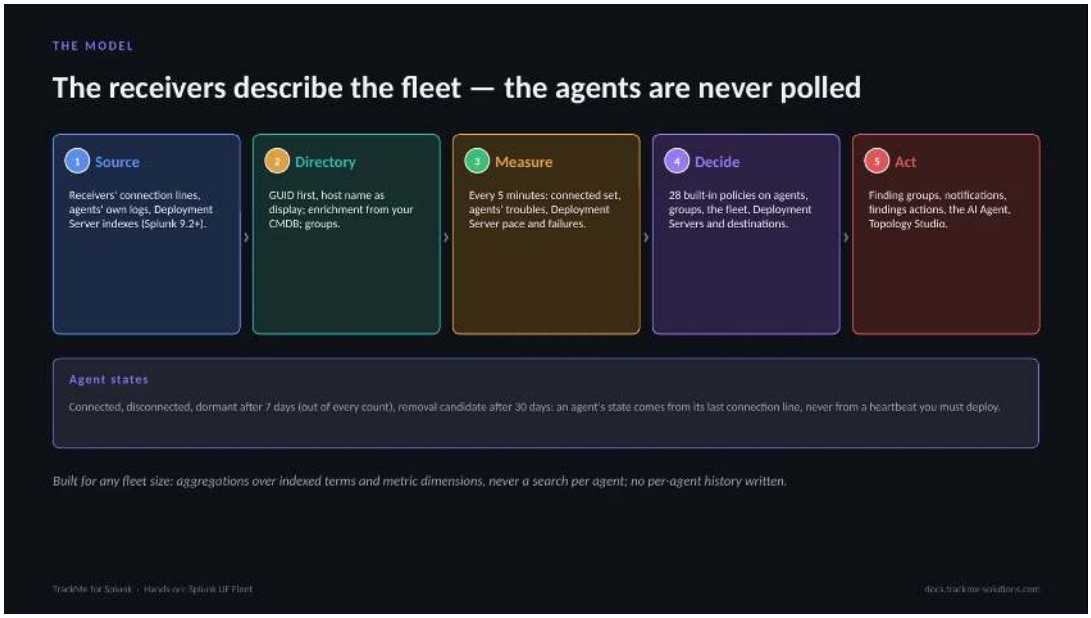
This walkthrough covers the Splunk UF Fleet tenant, generally available in TrackMe 2.4.22. Everything was captured live on a fleet of twenty universal forwarders named after their site and service — London, Paris, New York and a development site — on five UF generations from 9.4 to 10.6, managed by a cluster of two Deployment Servers. In four parts: create the tenant, configure it, follow the fleet and its Deployment Servers, and read the findings of agents stopped on purpose.

Why a dedicated Splunk UF Fleet tenant



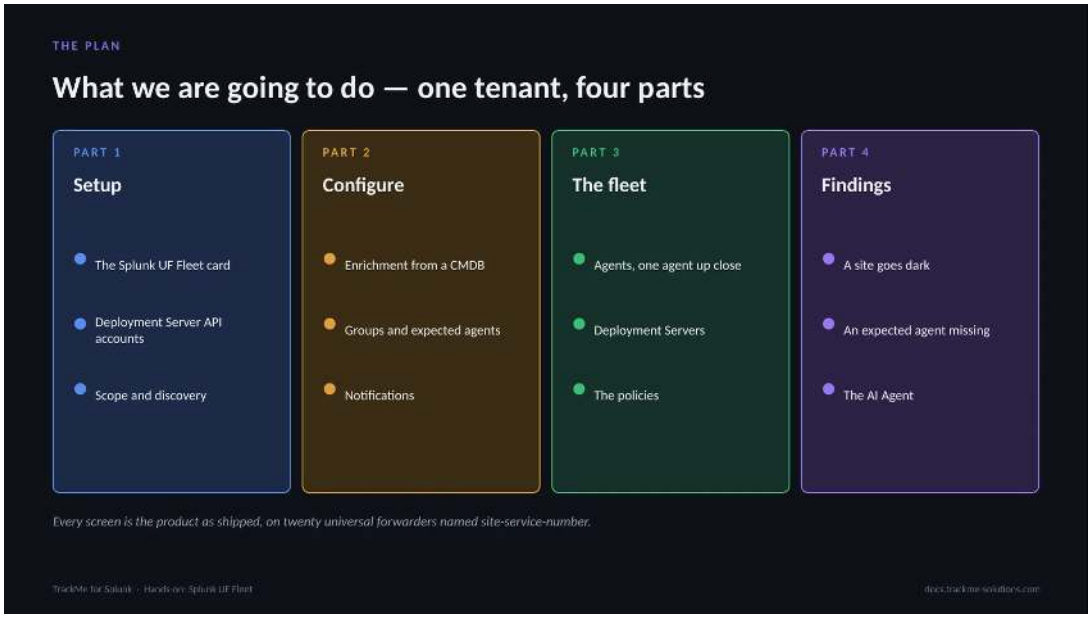
A Splunk administrator asks the same fleet questions every day: how many agents do I have, on which versions and platforms, which are connected, disconnected or dormant, and which of the agents that must stay connected are not. Which agents are blocked, throttled, or failing their destinations or their app deployments? Is each Deployment Server answering its clients at its usual pace? The Splunk UF Fleet tenant answers them with findings raised by twenty-eight built-in policies. It only reads: nothing is installed on an agent, and no agent is ever polled.

How a Splunk UF Fleet tenant works



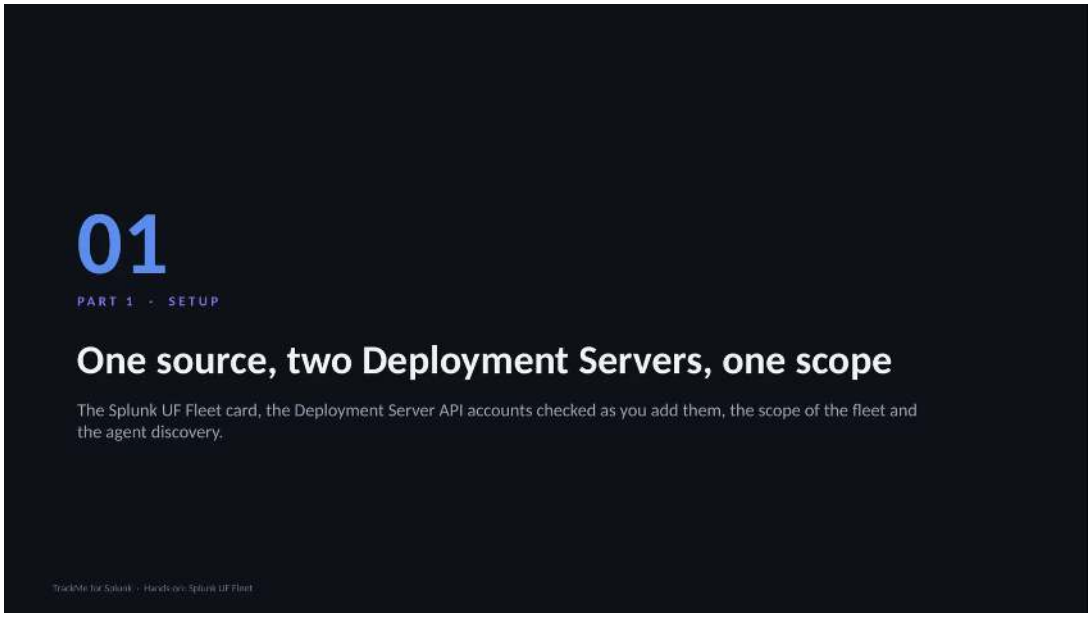
The receivers write a connection line for every sender, the agents forward their own logs, and the Deployment Servers write their phonehomes, their clients and their app events. TrackMe merges the three into one agent directory, reads the connected set every five minutes, and judges the agents, the groups, the fleet and the Deployment Servers. A mass disconnection is one finding on the group, never hundreds of agent findings.

The plan



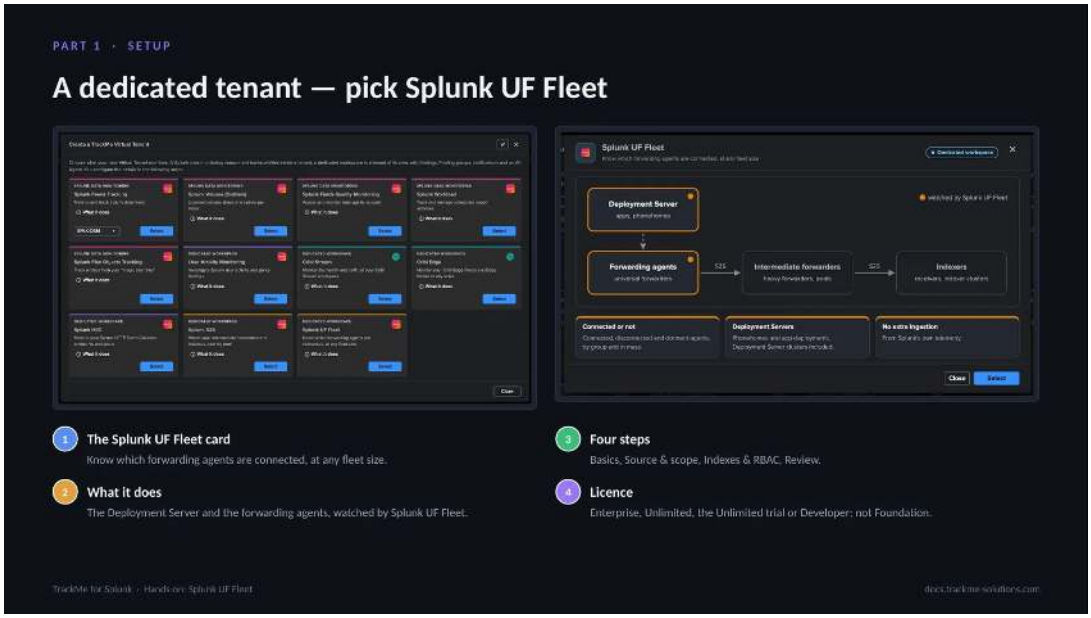
Four parts. Setup: the wizard, the Deployment Server API accounts and the scope. Configure: enrichment from a CMDB, groups proposed from the Deployment Servers and the enrichment, the expected agents and the notifications. The fleet: the Fleet tab, the agents, one agent up close, the Deployment Servers and the policies. Findings: agents stopped on purpose, a site's mass disconnect, an expected agent missing and the AI Agent.

Part 1 — Setup



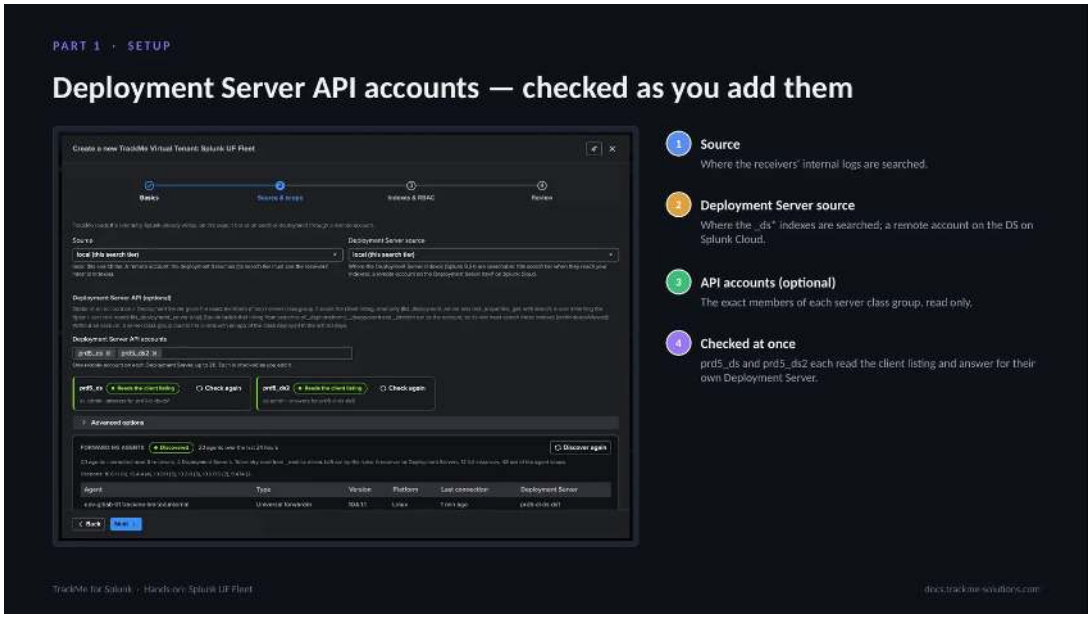
Part one: setup. A Splunk UF Fleet tenant reads one deployment: its local search tier, or another deployment through a TrackMe remote account.

A dedicated tenant — pick Splunk UF Fleet



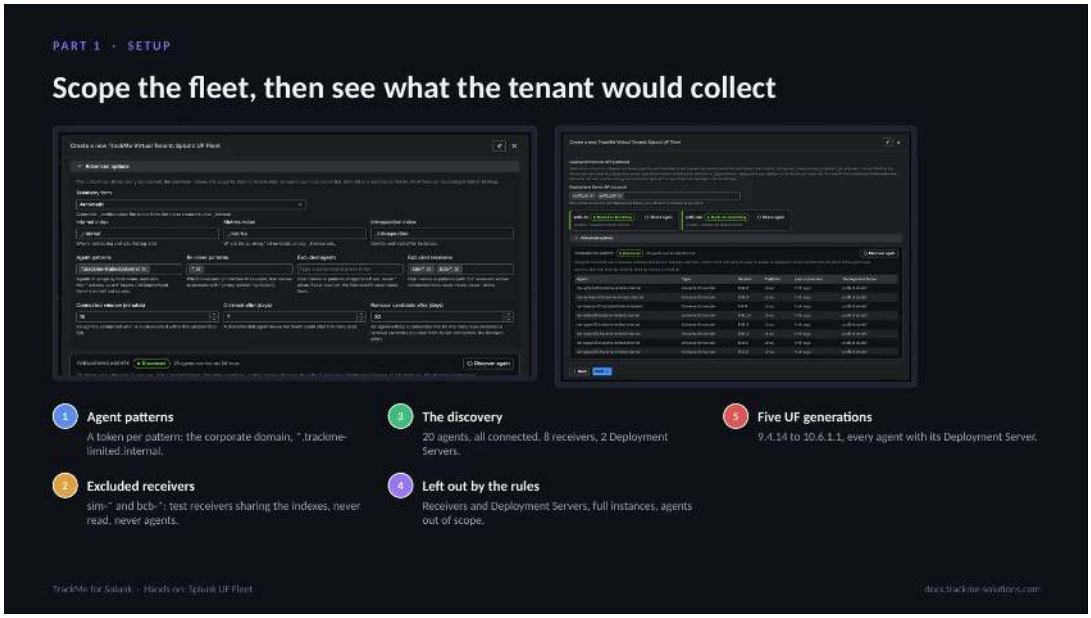
Virtual Tenants, Actions, Create a tracking tenant, then the Splunk UF Fleet card. What it does draws the forwarding path, with the Deployment Server and the forwarding agents watched. The receiving side, the intermediate forwarders and the indexers, has its own tenant type, Splunk S2S; when both read the same source, Topology Studio links them.

Deployment Server API accounts



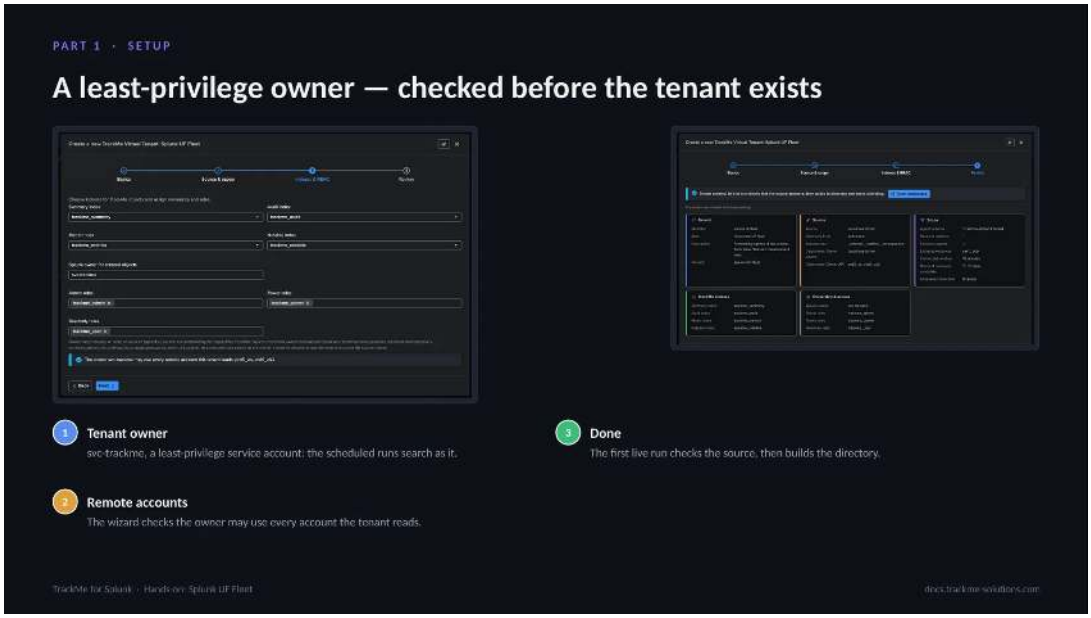
Source and scope. The Deployment Server API accounts are optional: an account on a Deployment Server gives the exact members of each server class group, from its client listing. Its user needs list_deployment_server and rest_properties_get, never an admin role, and its role must be allowed to search the Deployment Server indexes: Splunk builds the client listing from them, as the account. Each account is checked as it is added: here prd5_ds and prd5_ds2 each read the client listing of their own Deployment Server. Without one, a server class group counts the clients with an app of the class deployed in the last 60 days.

Scope the fleet, then see what the tenant would collect



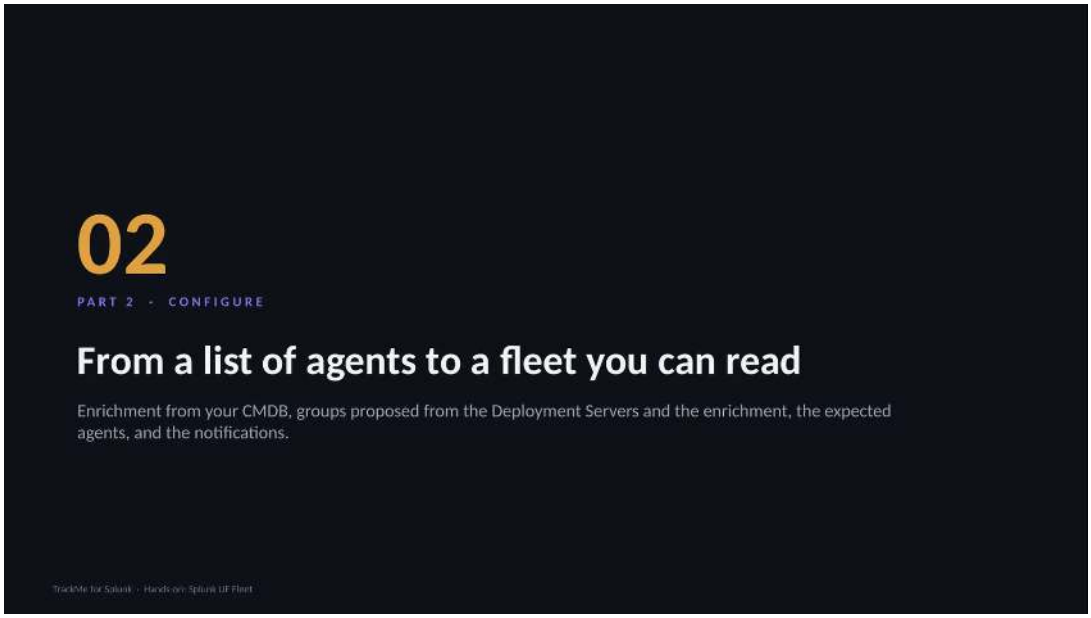
Advanced options: the agent patterns scope the tenant to the corporate domain, here *.trackme-limited.internal, and the excluded receivers leave out two families of test receivers sharing the same indexes; each pattern is a token, typed and added with Enter. Then the connected window and the dormancy and removal delays. The discovery runs the tenant's own rules with your rights over the last day: here twenty universal forwarders on five UF generations, all connected, and what the rules left out.

A least-privilege owner



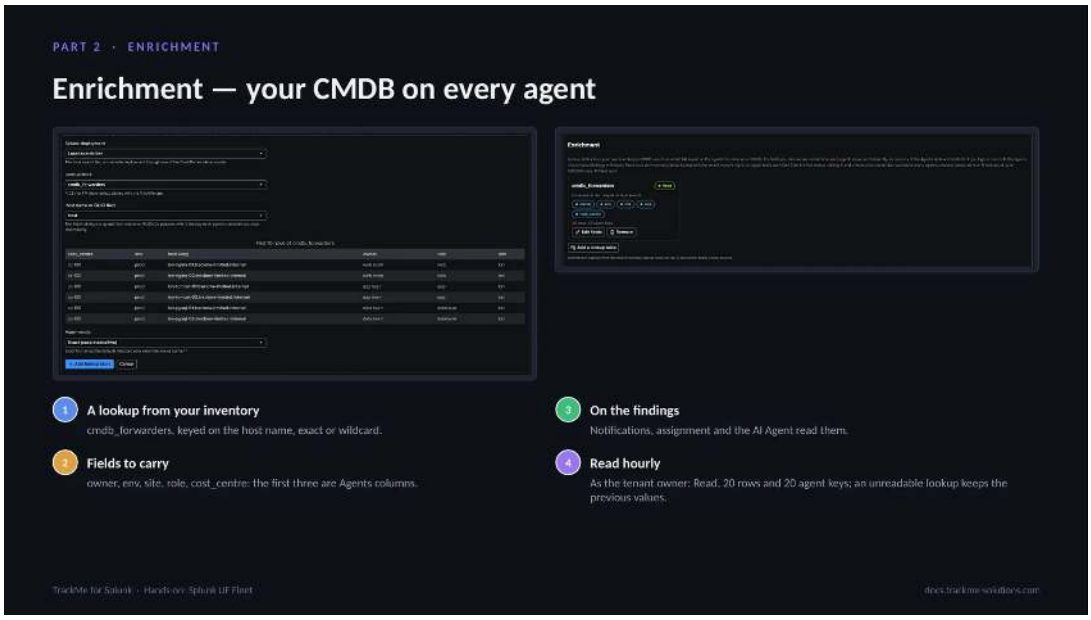
Indexes and RBAC, then Review and Done. The owner must be able to use every remote account the tenant reads, the Deployment Server API accounts included; otherwise the wizard names the fix before the save. The Review lists the source, the scope, the Deployment Server API accounts, the indexes and the ownership. The first live run starts at once.

Part 2 — Configure



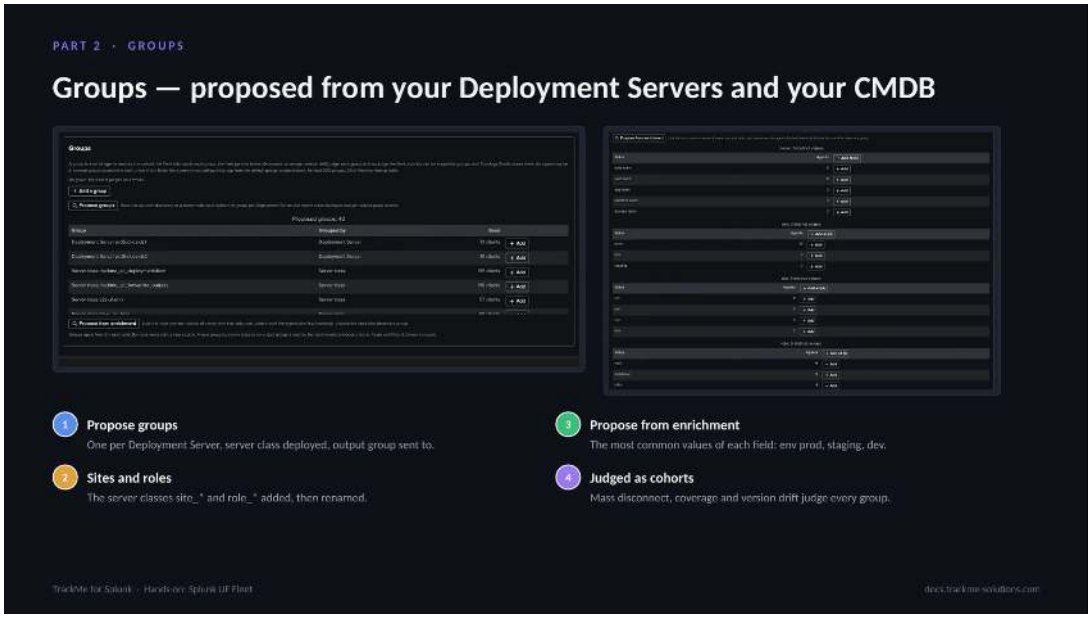
Part two: configure the tenant. Three settings turn a list of agents into a fleet: enrichment, groups and expected agents. Notifications then deliver its findings.

Enrichment — your CMDB on every agent



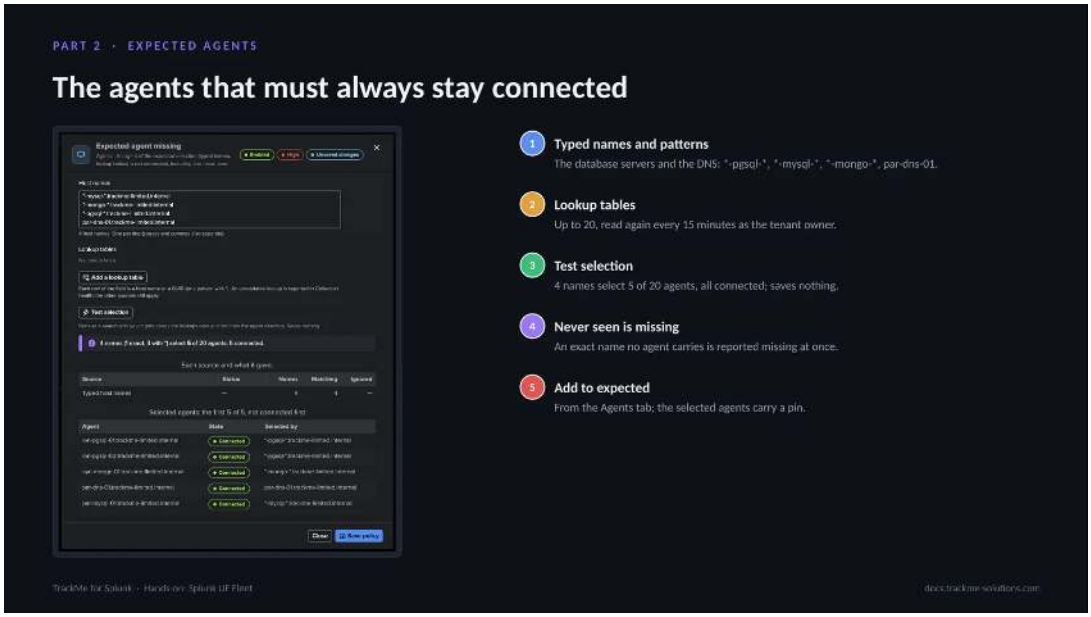
Settings, Enrichment. Up to five lookup tables of up to 500,000 rows, local or through a remote account, carry fields from your own inventory onto each agent: here the owner, the environment, the site, the role and the cost centre from a CMDB lookup, read by the last inventory, 20 rows for 20 agents. Enrichment applies from the next inventory and never starts a new source.

Groups — proposed from your Deployment Servers and your CMDB



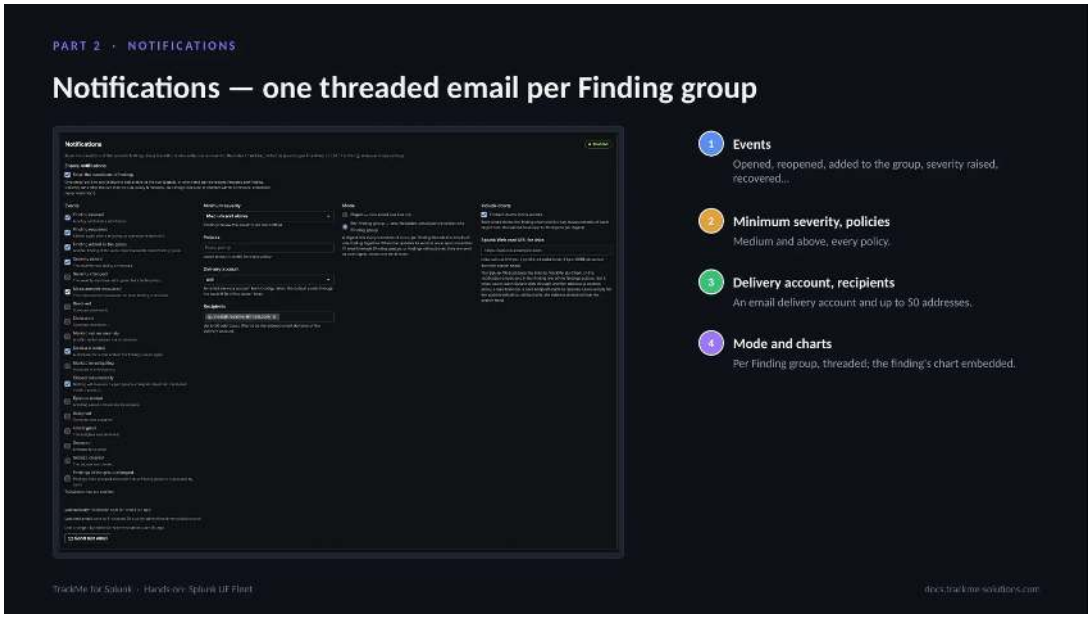
Settings, Groups. A group reads a set of agents as one cohort: the Fleet tab counts it, the fleet policies judge it, a policy can be scoped to it, and Topology Studio draws it. Groups are proposed from the Deployment Server classes and from the enrichment values: here four sites and five roles from the server classes, and three environments from the CMDB. A new group is pending until the next collection; Run now on the inventory shows it at once.

The agents that must always stay connected



The expected agents are selected in the Expected agent missing policy: typed host names or GUIDs with wildcards, and lookup tables. Here the database servers and the Paris DNS server. Test selection runs as a search with your rights and shows the selected agents by state. Dormancy never closes an expected agent's finding.

Notifications — one threaded email per Finding group

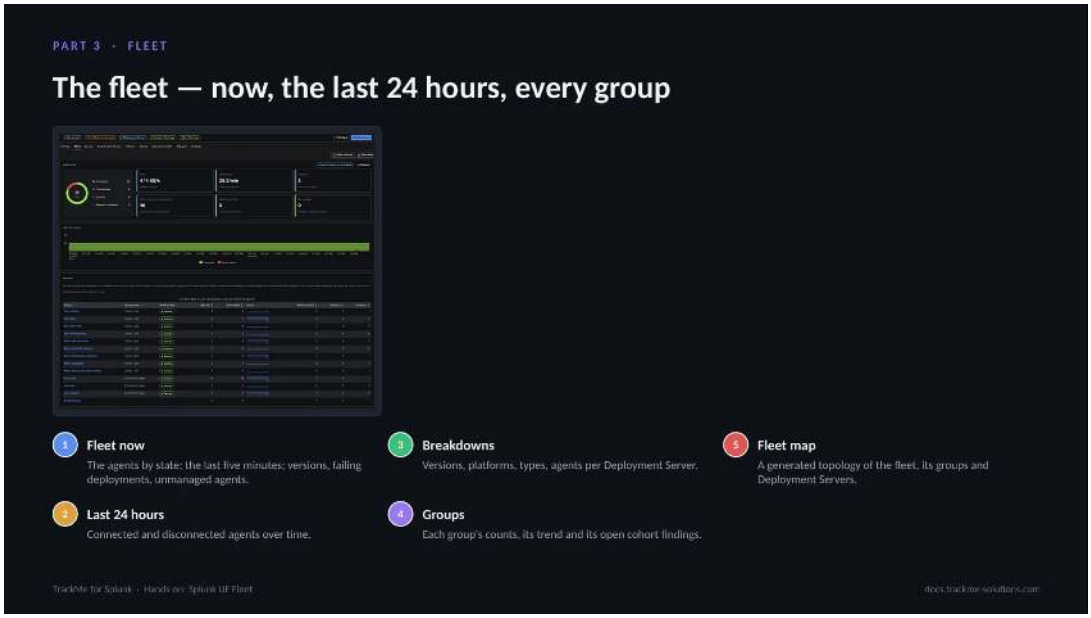


Settings, Notifications: the events notified, the minimum severity, the policies, the email delivery account and the recipients, and the mode — one digest per live run, or one threaded email per transition of a Finding group — with the finding's chart and key measurements embedded. Every transition is also written as an event to the tenant's notable index, whatever these settings.

Part 3 — The fleet

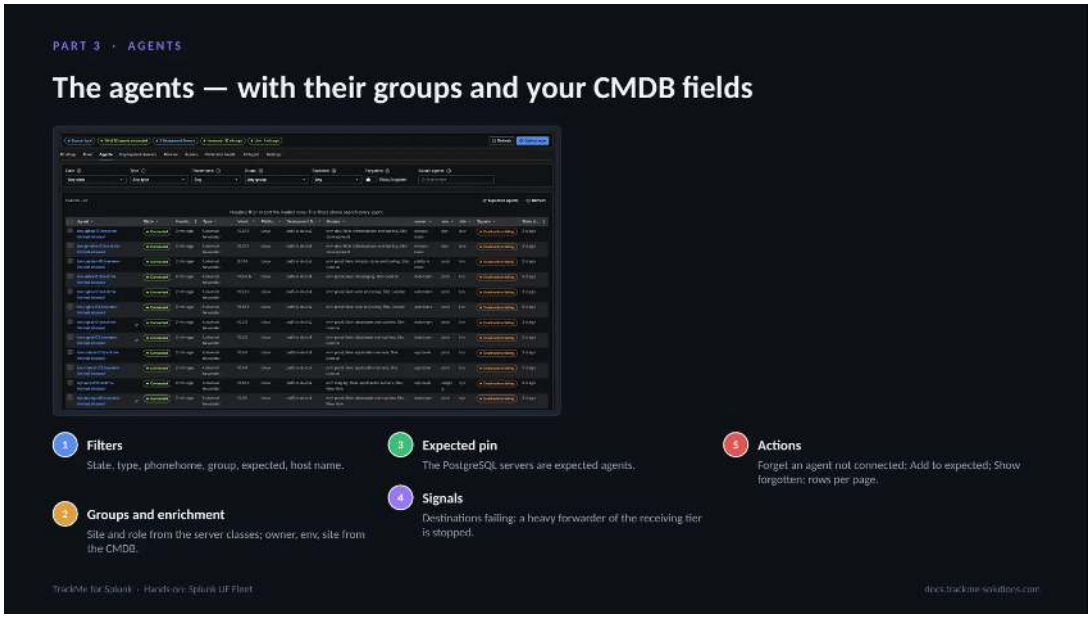
Part three: the workspace. The fleet, its agents, its Deployment Servers and its policies.

The fleet — now, the last 24 hours, every group



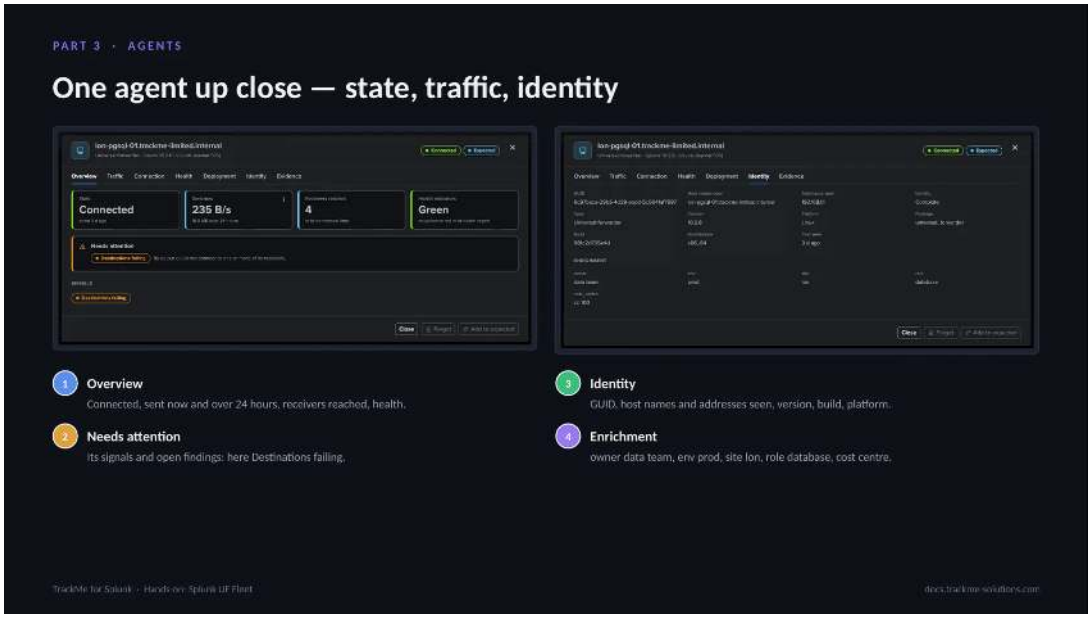
The Fleet tab shows every figure once: the agents by state, the last five minutes (data sent, phonehomes, the receivers that saw the fleet), the fleet's management (the agents not on the most common version, the deployments failing, the agents served by no Deployment Server), the last 24 hours, the breakdowns by version, platform, agent type and Deployment Server, each opening the Agents tab filtered, the groups with their membership state, counts and open cohort findings, the recently disconnected agents, and the Fleet map, a generated topology of the fleet, its groups and its Deployment Servers. Here the Paris site is down: 16 of 20 agents connected.

The agents — with their groups and your CMDB fields



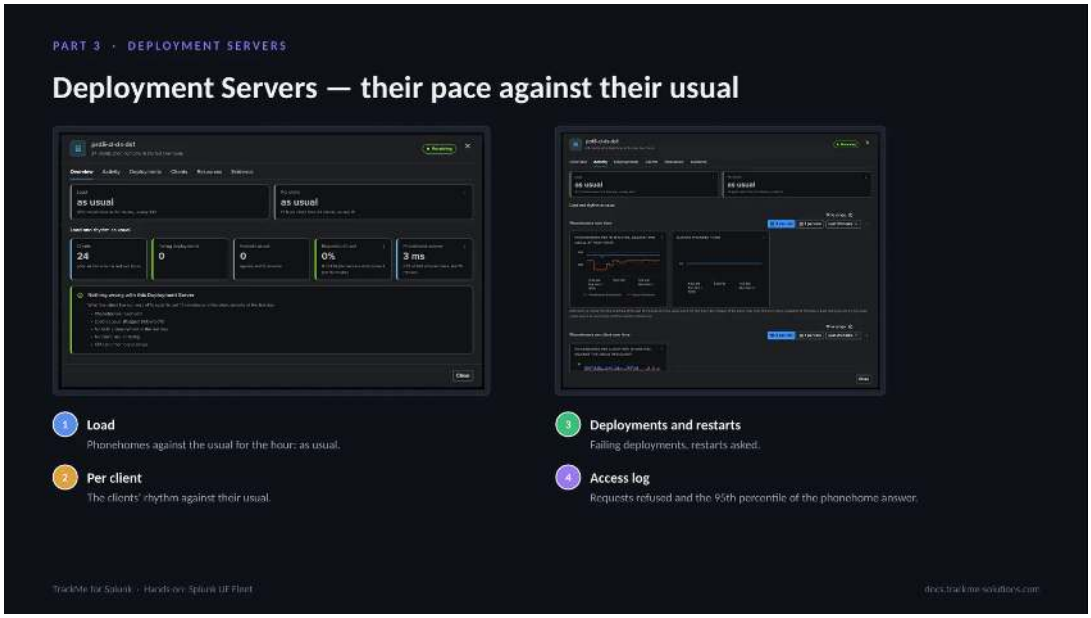
The Agents tab, paged on the server, with filters on state, type, phonehome, group, expected and host name; forgotten agents are listed only with Show forgotten. Each agent with its state, heartbeat, type, version, platform, Deployment Server, groups, the first three enrichment fields and its signals: here Destinations failing on every agent, while a heavy forwarder of the receiving tier is stopped. A signal pill opens its facts and evidence; Forget, for an agent not connected, and Add to expected act on the selection, and the footer sets the rows per page.

One agent up close — state, traffic, identity



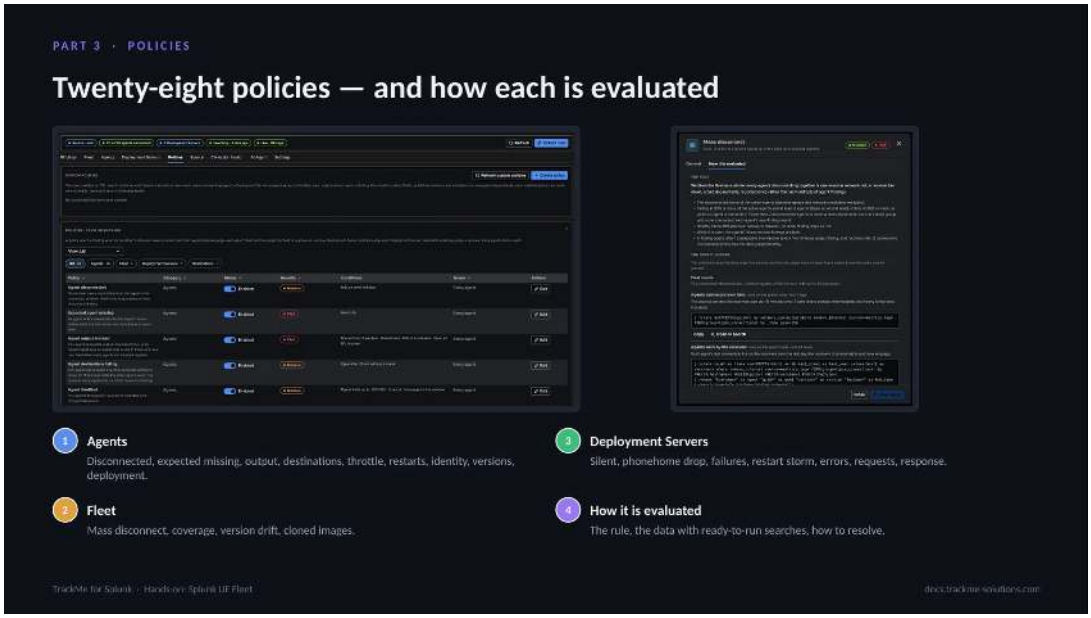
The agent modal: Overview, Traffic, Connection, Health, Deployment, Identity and Evidence. Its Overview shows what needs attention, here Destinations failing; Forget and Add to expected are disabled with their reason for a connected, expected agent. The Identity tab shows the host names and GUIDs the agent was seen with, and the enrichment fields from your CMDB. Its charts read Splunk's own lines on demand: no per-agent history is written, whatever the fleet size.

Deployment Servers — their pace against their usual



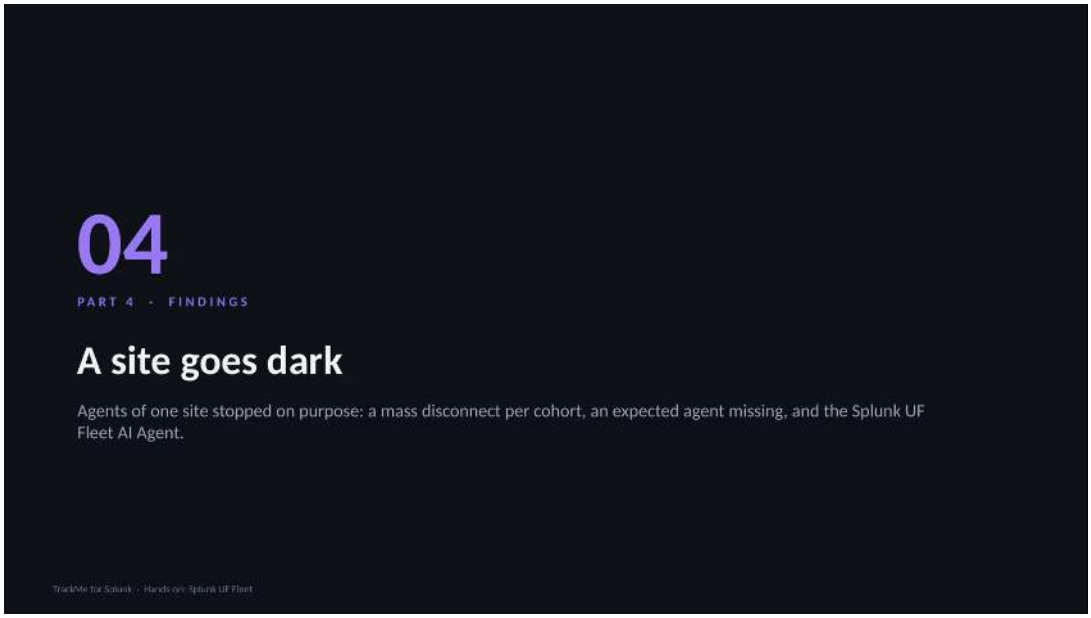
The Deployment Server is a first-class subject: its clients, phonehomes, pace against its usual, failing deployments, restarts asked, CPU and memory. Load and Per client read together: load up with a stable rhythm means more clients; both up, clients phoning home more often; load down with a stable rhythm, clients that left.

Twenty-eight policies — and how each is evaluated



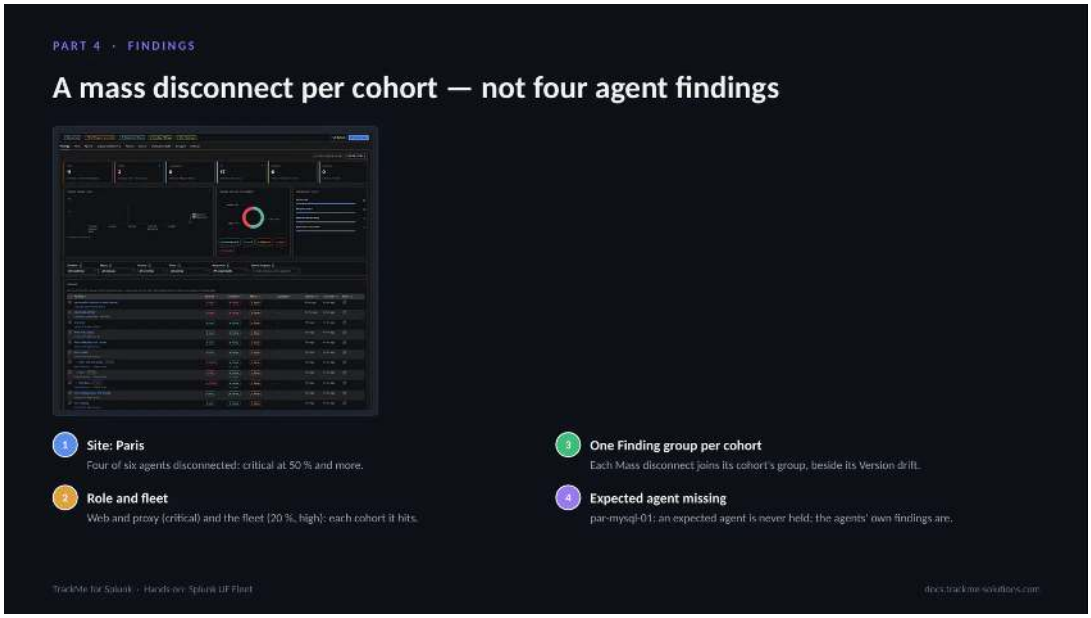
The policy catalogue, by category: agents, the fleet, Deployment Servers and destinations. Every policy has its severity, its checks to open and to recover, a scope by group, a bank holiday hold and How it is evaluated. Mass disconnect opens when twenty per cent of a group, and at least two agents, disconnect together, critical at half; the agents' own findings are held while it is open. Above the catalogue, TrackMe administrators of the tenant write custom SPL policies.

Part 4 — Findings



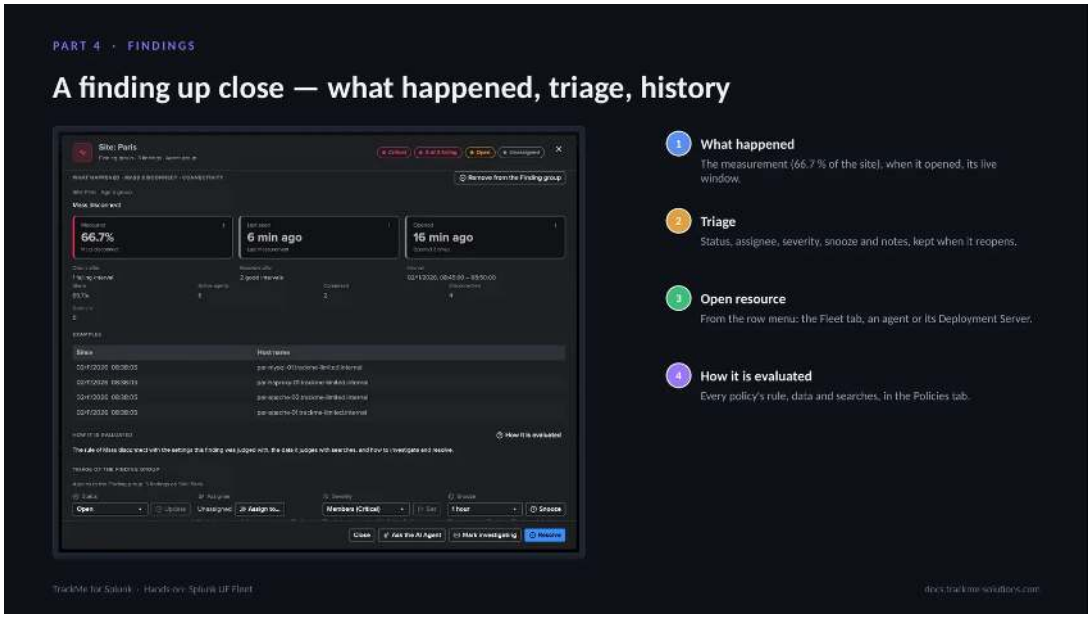
Part four: findings. Four agents of the Paris site were stopped on purpose, one of them an expected database server.

A mass disconnect per cohort — not four agent findings



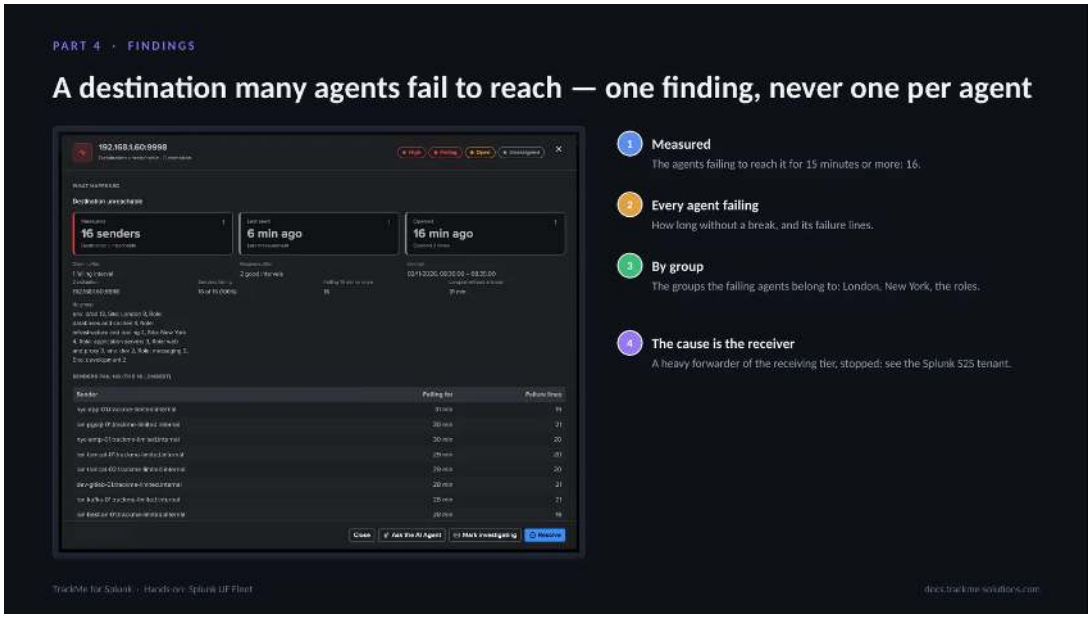
Four agents of the Paris site stopped together. Mass disconnect opens on each cohort they are a large share of: the Paris site group, critical as two thirds of the site is down, the web and proxy role group, critical too, and the fleet at twenty per cent, high; each joins the Finding group of its cohort, beside its Version drift finding. The agents' own disconnection findings are held, never opened one by one. par-mysql-01 is an expected agent: Expected agent missing opens for it whatever the cohort.

A finding up close



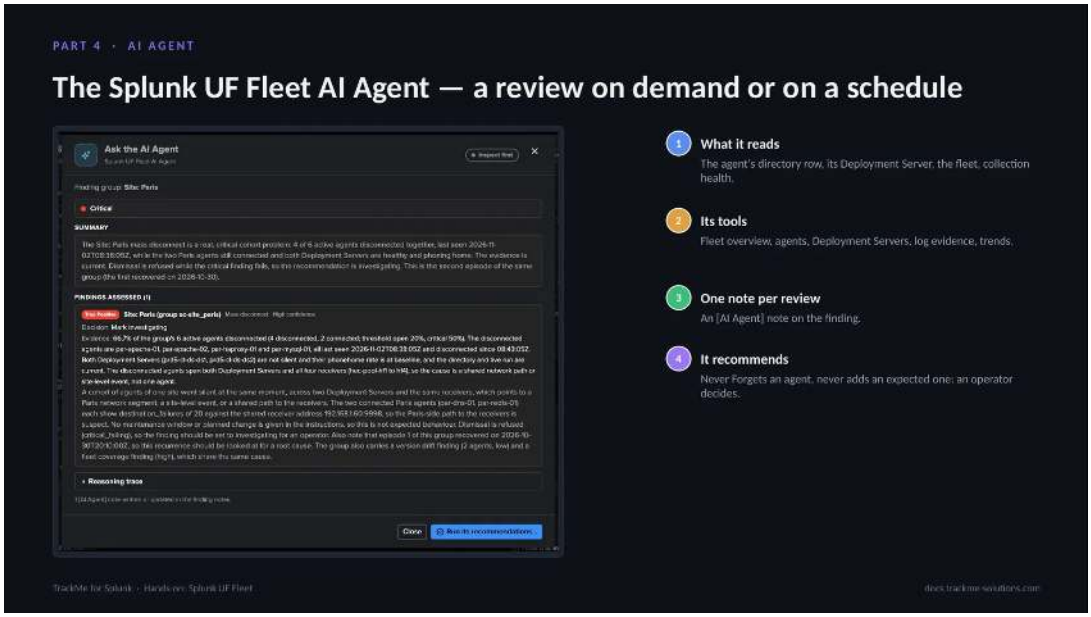
A finding opens with what happened (here 66.7 per cent of the Paris site disconnected), when it opened and its live window, then its triage — status, assignee, severity, snooze — its notes and its history. Open resource, in the row menu, opens the Fleet tab, an agent or its Deployment Server in place. How each policy is evaluated — the rule as configured, the data it reads with ready-to-run searches, and how to investigate and resolve — is in the Policies tab. When the agents reconnect, the mass disconnect recovers below ten per cent for two runs; an agent still disconnected then opens its own finding.

A destination many agents fail to reach



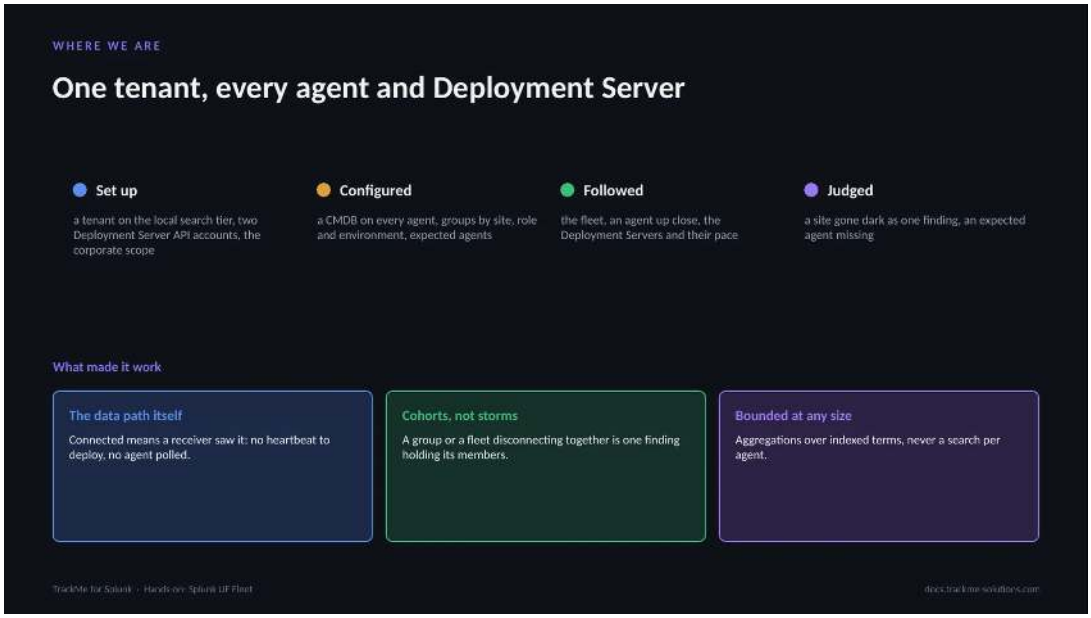
A heavy forwarder of the receiving tier was stopped at the same time. The agents that send to it failed to reach its port: one Destination unreachable finding opened on the receiver, measured on the 16 agents failing for 15 minutes or more, with each agent, how long it failed, its failure lines and the groups the failing agents belong to, never one finding per agent. The receiving side of the same stop is in the Splunk S2S walkthrough.

The Splunk UF Fleet AI Agent



Ask the AI Agent from a finding or a Finding group. The Splunk UF Fleet AI Agent reads the finding, the agent or group, the Deployment Servers and collection health, and may read further through its tools. Each review leaves an [AI Agent] note on the finding. Scheduled triage is off by default: hourly, up to ten findings per run. In act mode it applies only what the tenant allows, and never changes anything on an agent or a Deployment Server.

Where we are



A Splunk UF Fleet tenant set up on twenty universal forwarders and a Deployment Server cluster, enriched from a CMDB, grouped by site, role and environment, its critical agents expected. The fleet, the agents and the Deployment Servers followed. A site gone dark read as a mass disconnect per cohort, an expected agent missing, and the AI Agent's review.

2.1.14 Reference white papers

The former quickstart tutorials remain available as reference material.

QUICK START - Starting with TrackMe: (feed tracking quickstart)

Starting with TrackMe!

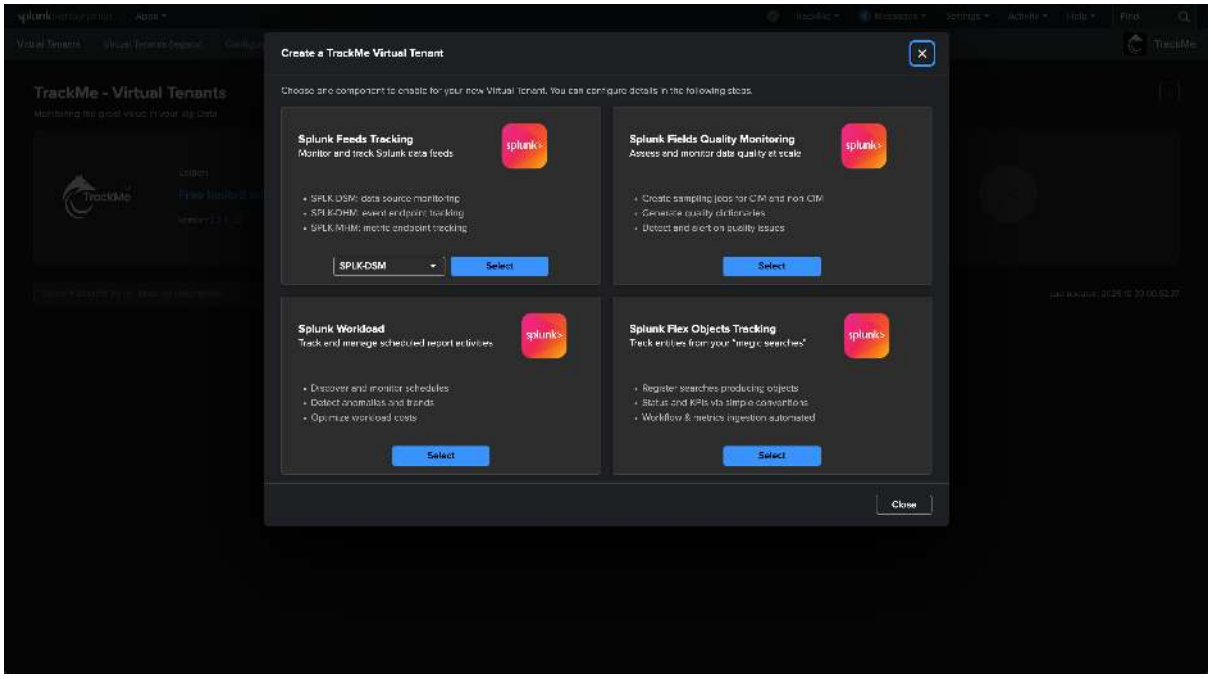
- This tutorial is a starting point for TrackMe new joiners!
- The objective is to help you get started with TrackMe, understand the basic concepts and focus on feeds Tracking for Splunk.
- In this tutorial, we will assume that you are starting entirely from scratch, and we will cover the essential steps to set up feed tracking in TrackMe, with main best practices.
- **This tutorial works in 3 main steps and can be used by all users, including Foundation Edition trial users:**
  - **Step 1:** Create a Virtual Tenant for data sources tracking
  - **Step 2:** Create a Virtual Tenant for data hosts tracking
  - **Step 3:** Alerting and notifications
- This quickstart tutorial was last updated on the 25th of May 2025, to reflect the latest TrackMe releases and especially the new Stateful Alerting features.

TrackMe is installed, what now?

Once TrackMe is installed, the following wizard will guide you through the initial setup of a new Virtual Tenant:

About Virtual Tenants:

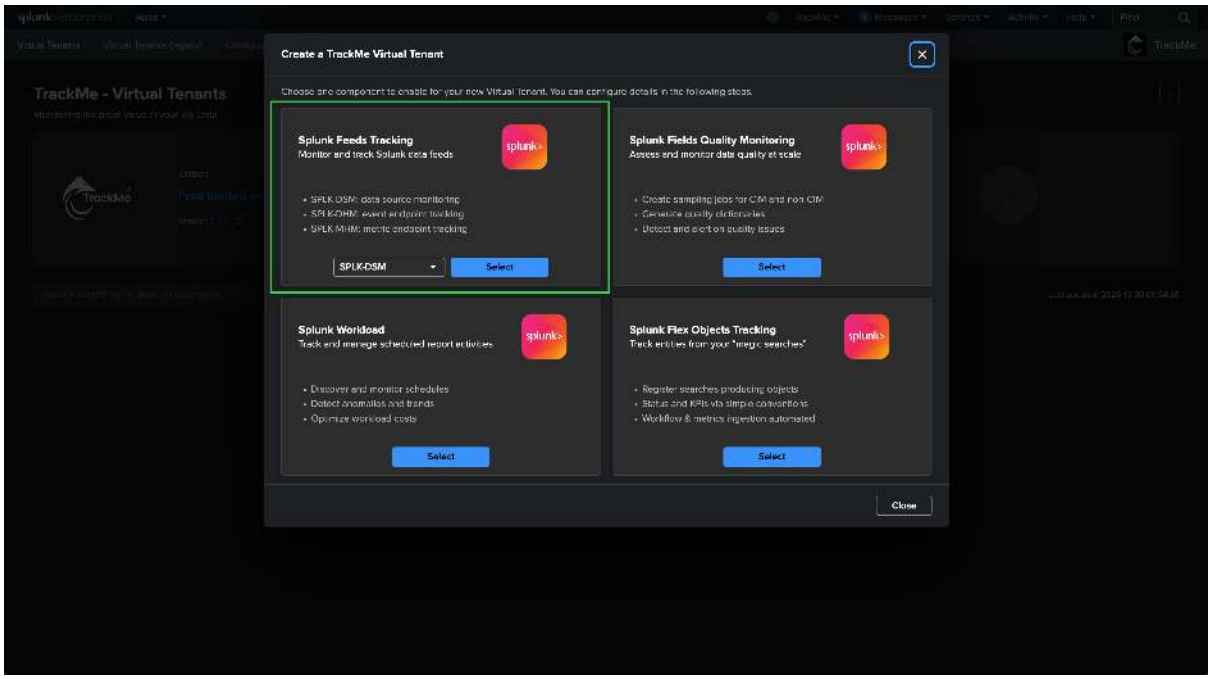
- Virtual Tenants are an essential core feature in TrackMe, this allows TrackMe to orchestrate and manage TrackMe-related knowledge objects and configuration, and address many powerful concepts such as multi-tenancy, data isolation, and more.
- You can also understand this concept as virtual instances of TrackMe within TrackMe, which you can create, destroy, and restart as needed.
- Virtual Tenants enable TrackMe components, which are designed to address use cases, such as **splk-dsm** which is the essential component for feed tracking.



Step 1: Let's create a Virtual Tenant for data sources tracking

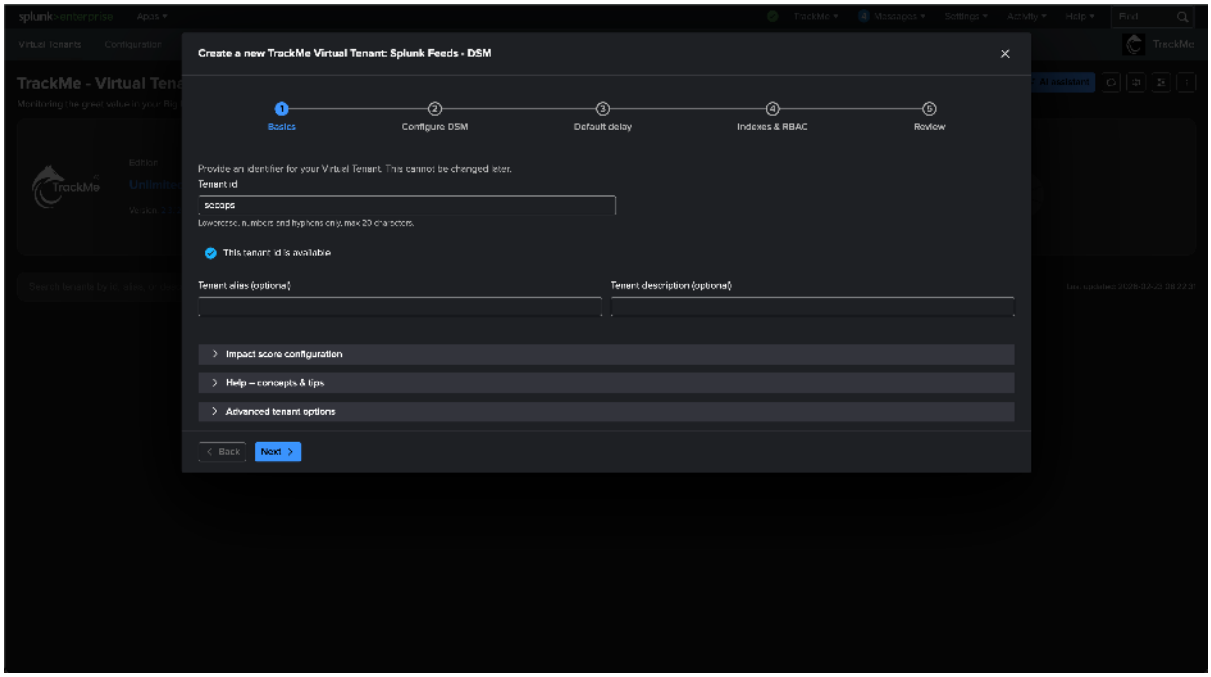
We will now create a Virtual Tenant to start tracking data sources:

- component: `Splunk Feeds Tracking`



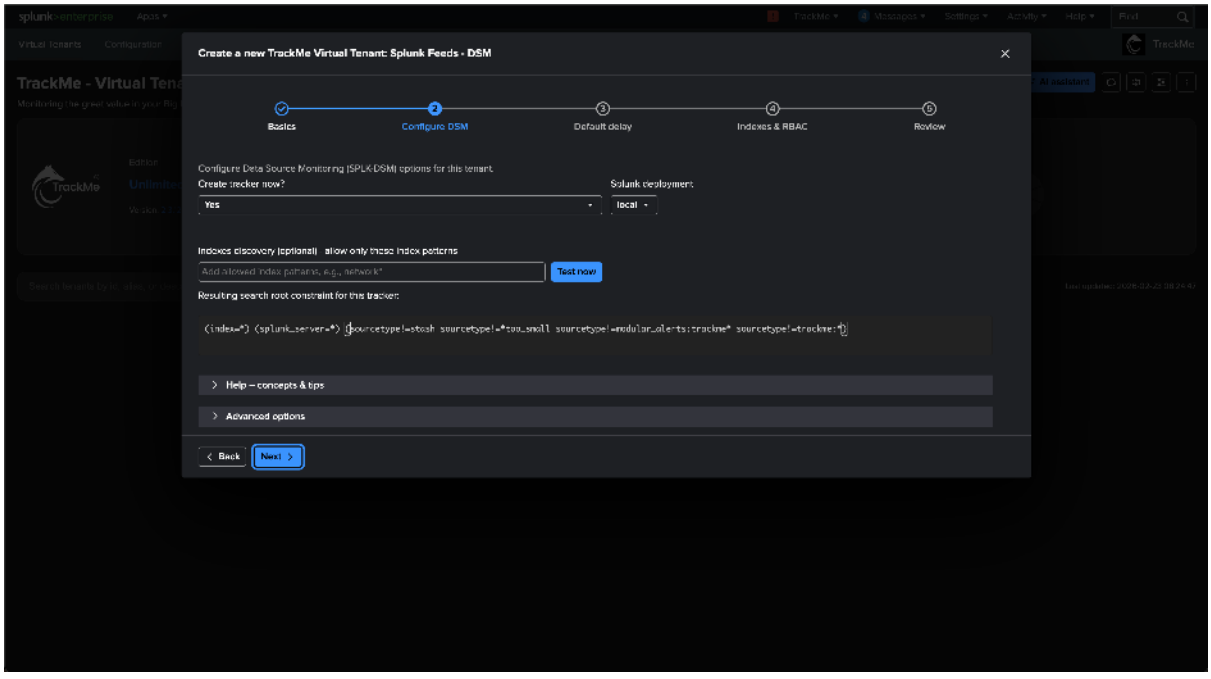
- tenant name: `secops`

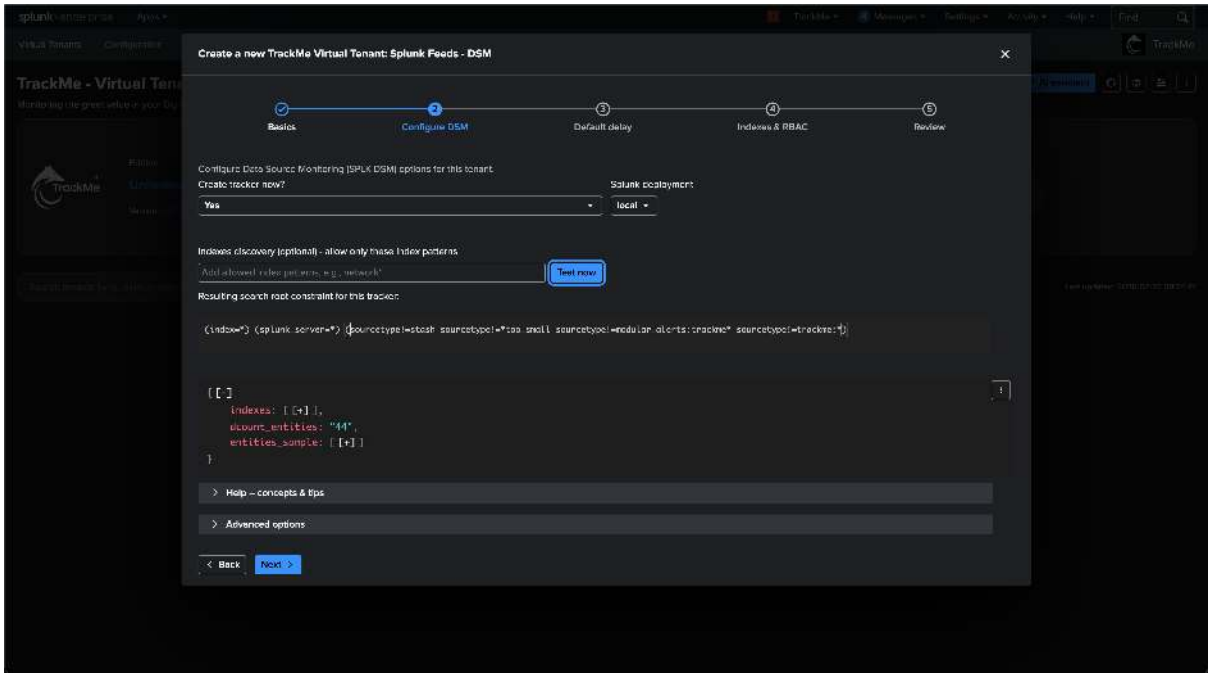
- tenant alias: This is optional and can be updated at any time. If set, the alias replaces the tenant identifier in the Virtual Tenants UI.
- tenant description: This is optional and can be updated at any time. If set, the description is displayed in the Virtual Tenants UI.



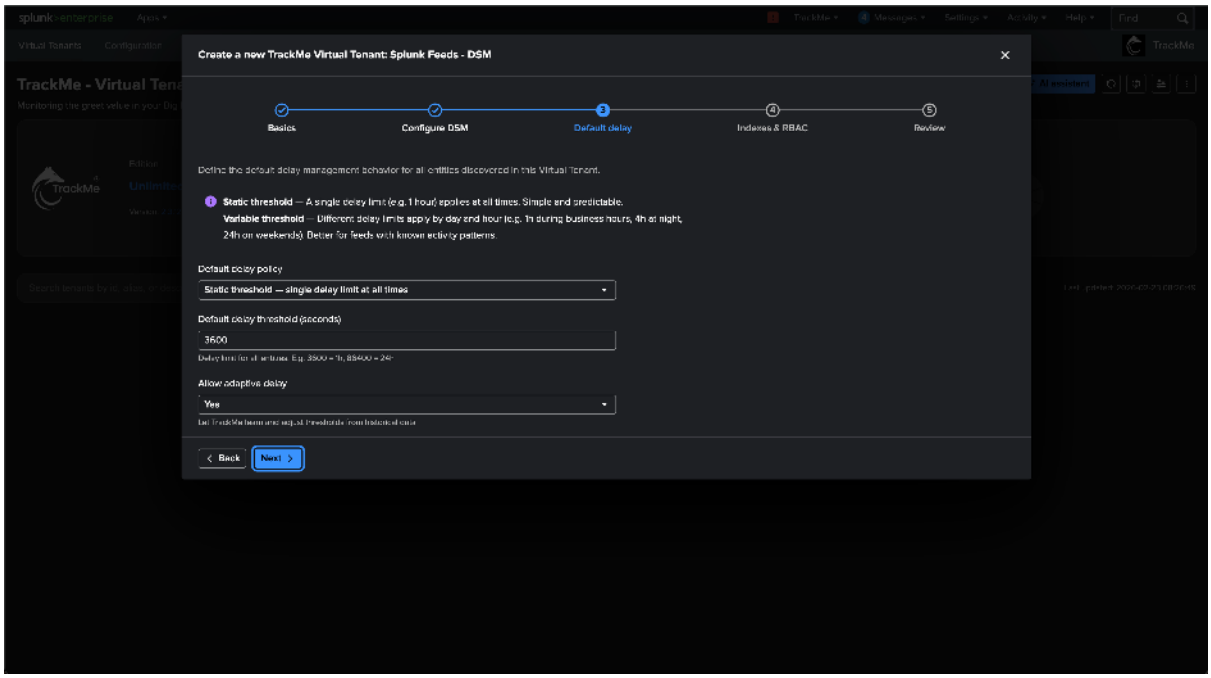
Creating tracker during the Virtual Tenant creation, or later on via the Hybrid Tracker management UI

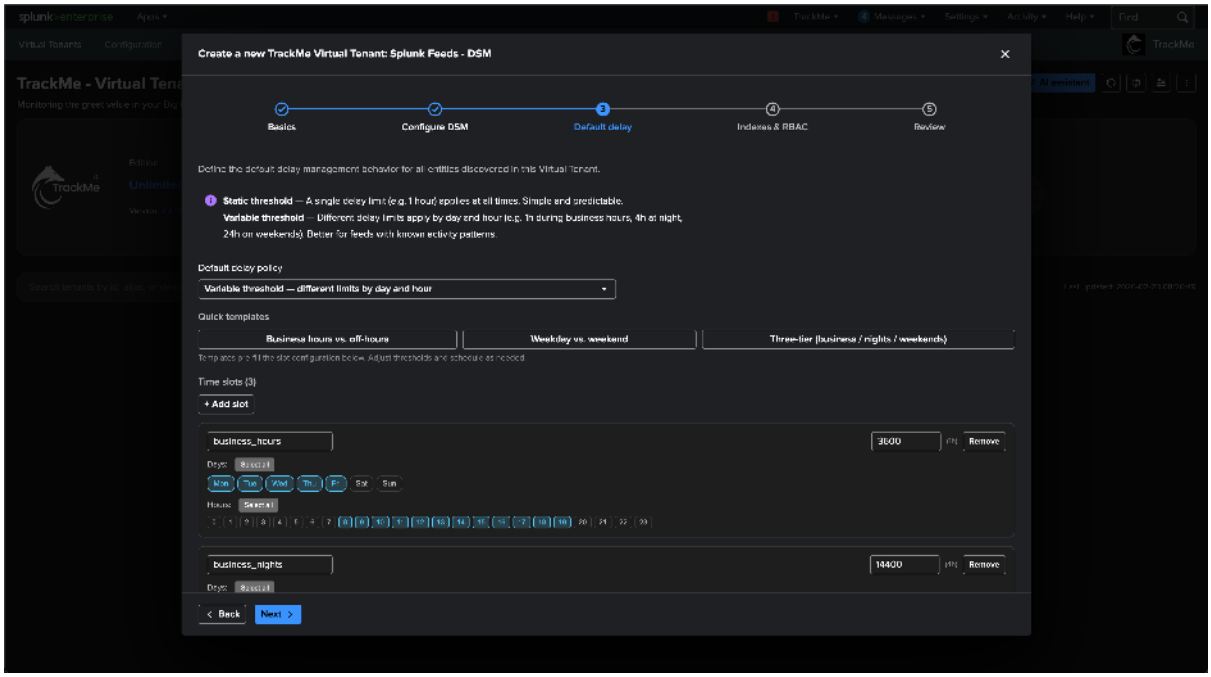
- If your environment is small enough (less than 2/3 TB per day of ingestion), you can leave the default configuration and create the tracker during this stage (so leave "Yes" for Create Hybrid tracker).
- For larger environments, and up to any super large environments, we recommend disabling the creation of the Virtual Tenant and creating the tracker later on manually via the Hybrid Tracker management UI.



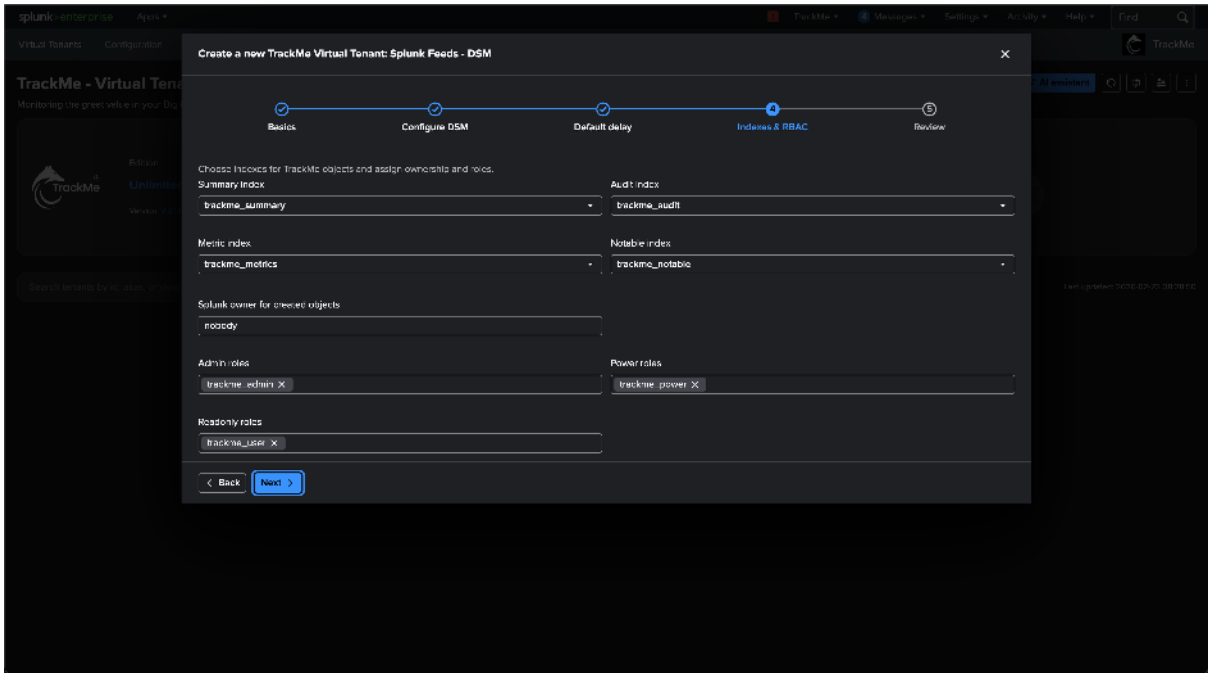


- **The next screen allows defining the default delay threshold behavior, TrackMe allows two different delay threshold policies:**
  - Static delay threshold: A single fixed threshold value that applies at all times. This is the default and traditional behavior in TrackMe.
  - Variable delay threshold: Time-aware thresholds that change dynamically based on the day of the week and the hour of the day. This allows defining tighter thresholds during business hours and more relaxed thresholds during nights, weekends, or known quiet periods.





- The final configuration screen and its top section allows defining TrackMe indexes, in most cases, the default indexes are fine, and we can leave the default configuration.



- The second part of that same screen allows defining ownership and permissions, all of these can be easily modified via TrackMe at any point in time, in short:

Owner:

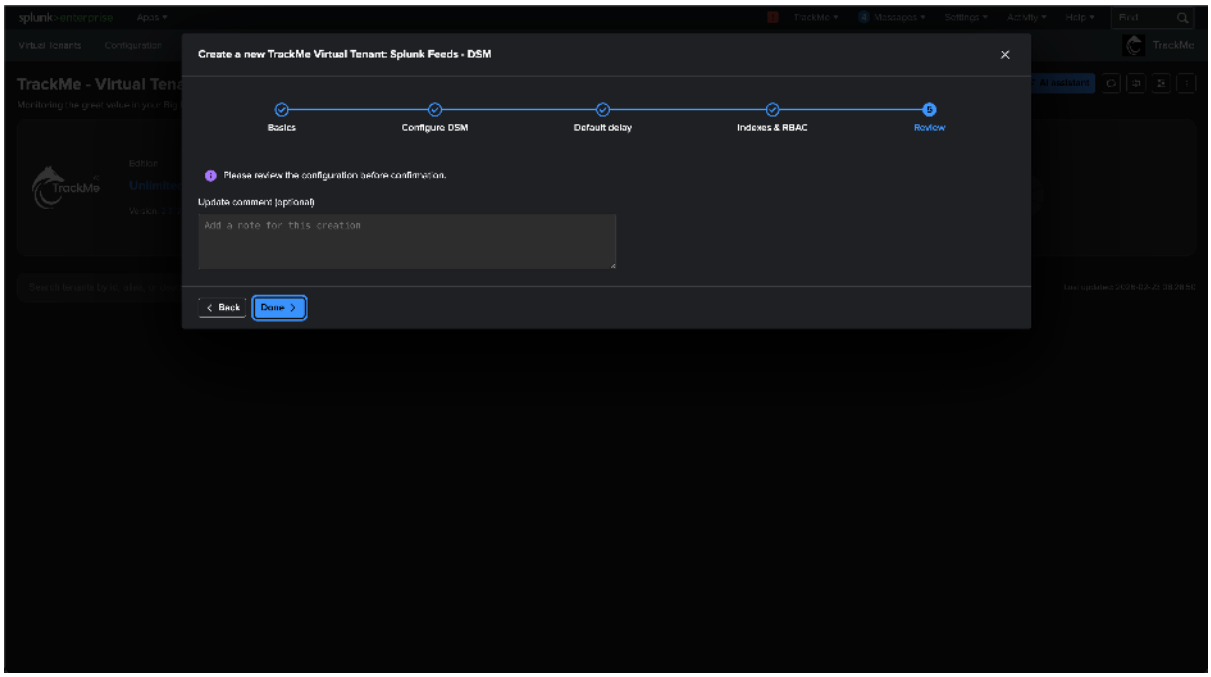
- Default owner is nobody, which refers to the splunk-system-user, this means that TrackMe will automatically reassign the ownership of the knowledge objects to the splunk-system-user.
- This is fine for most cases and is a common practice in Splunk.
- On large or strict environments, creating a service account can be considered as good practice and notably allows tracking TrackMe's related activity easily, leveraging Splunk Workload Management, see: :ref: *trackme_admin_config* for more information.

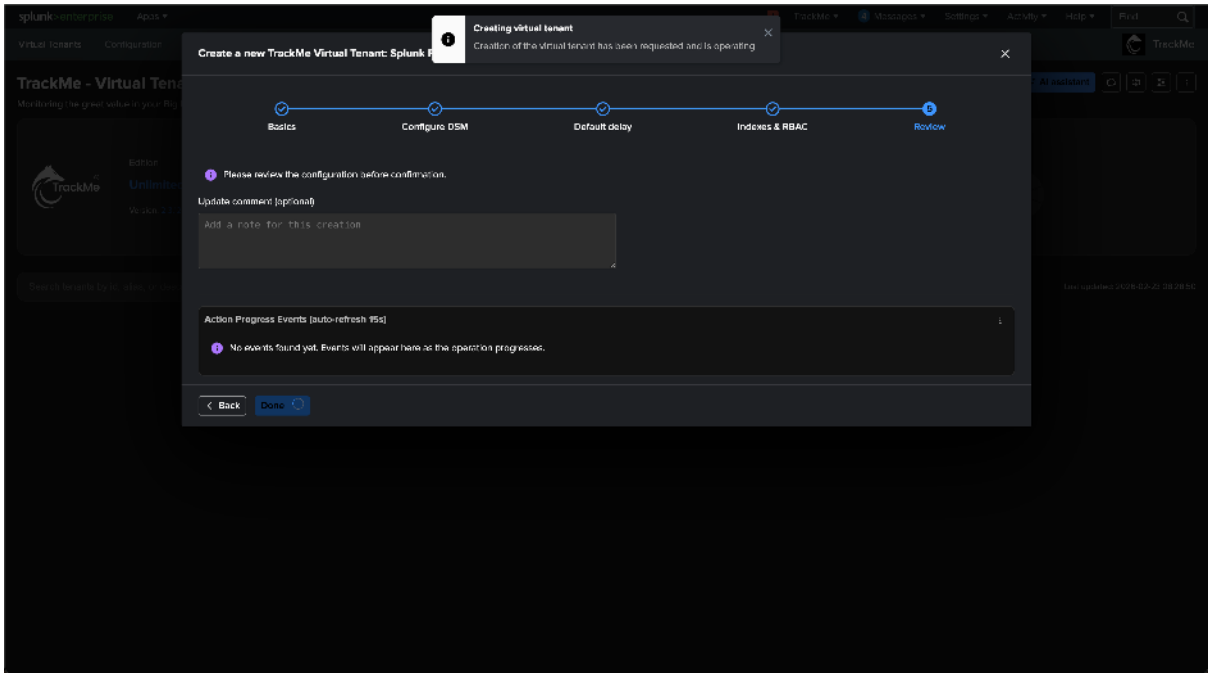
Permissions:

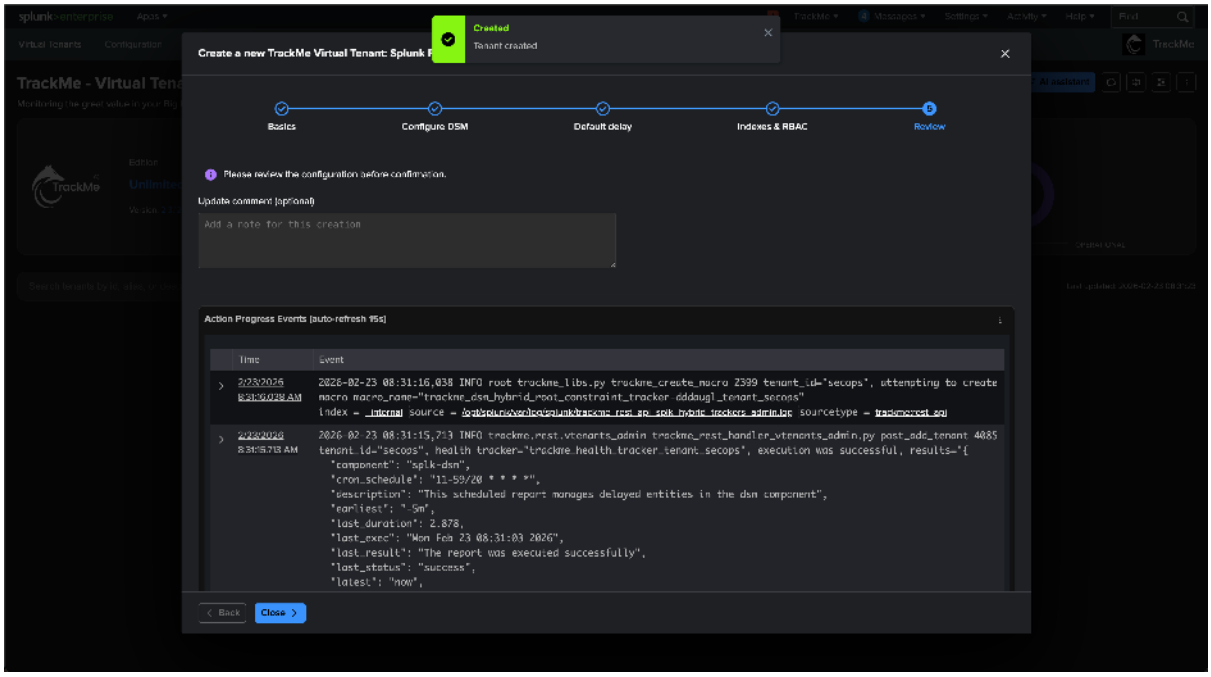
- The default permissions leverage a 3-dimensional model, from admin to power and finally read-only users.
- As a start, you generally can leave everything as default

Validate the creation of the Virtual Tenant:

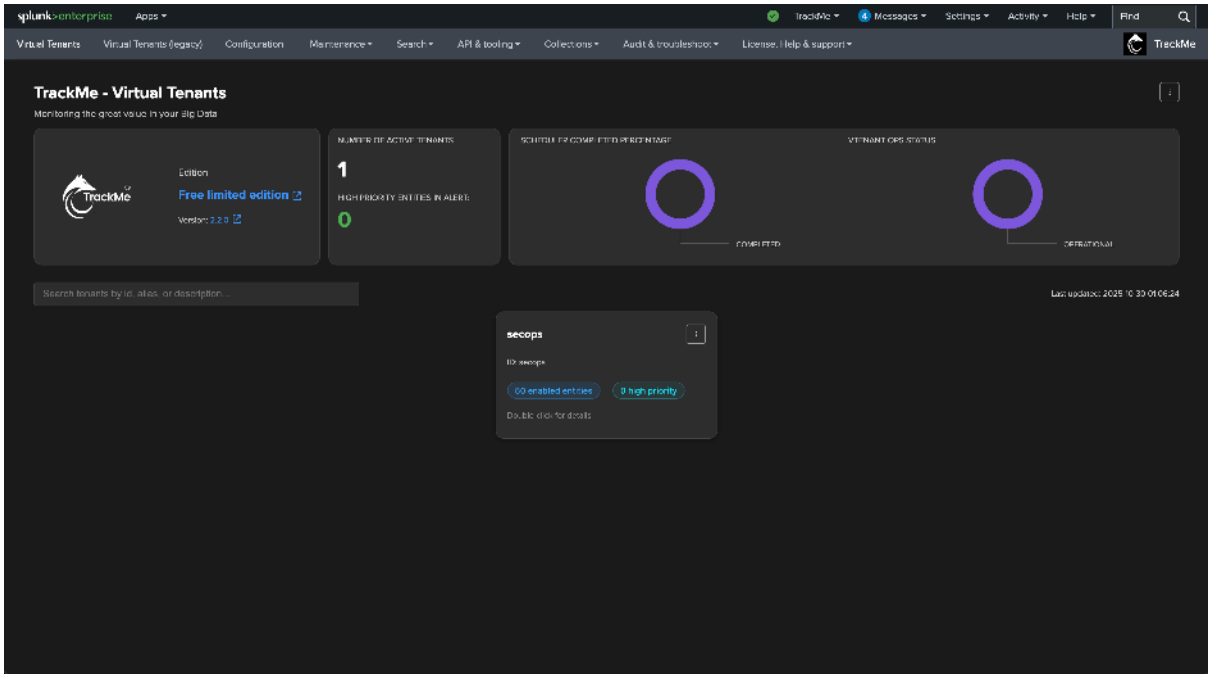
We can now validate the creation of the Virtual Tenant, after a short moment, the Virtual Tenant UI will be refreshed and a Virtual Tenant will now be available:



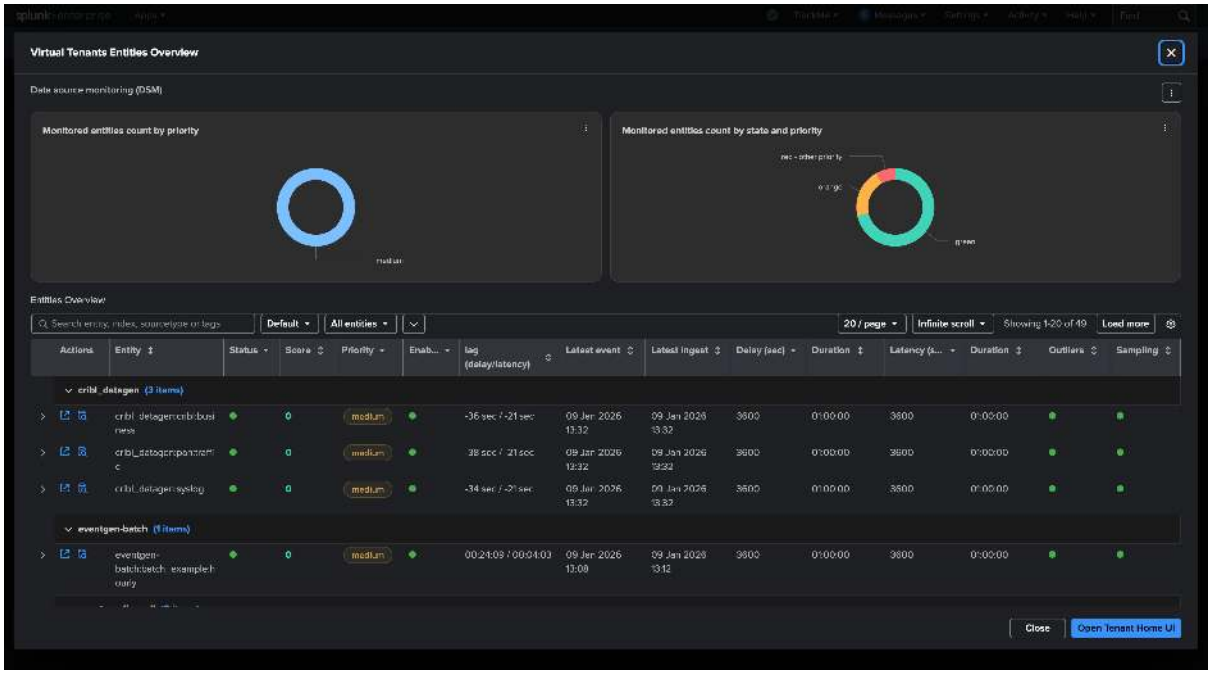




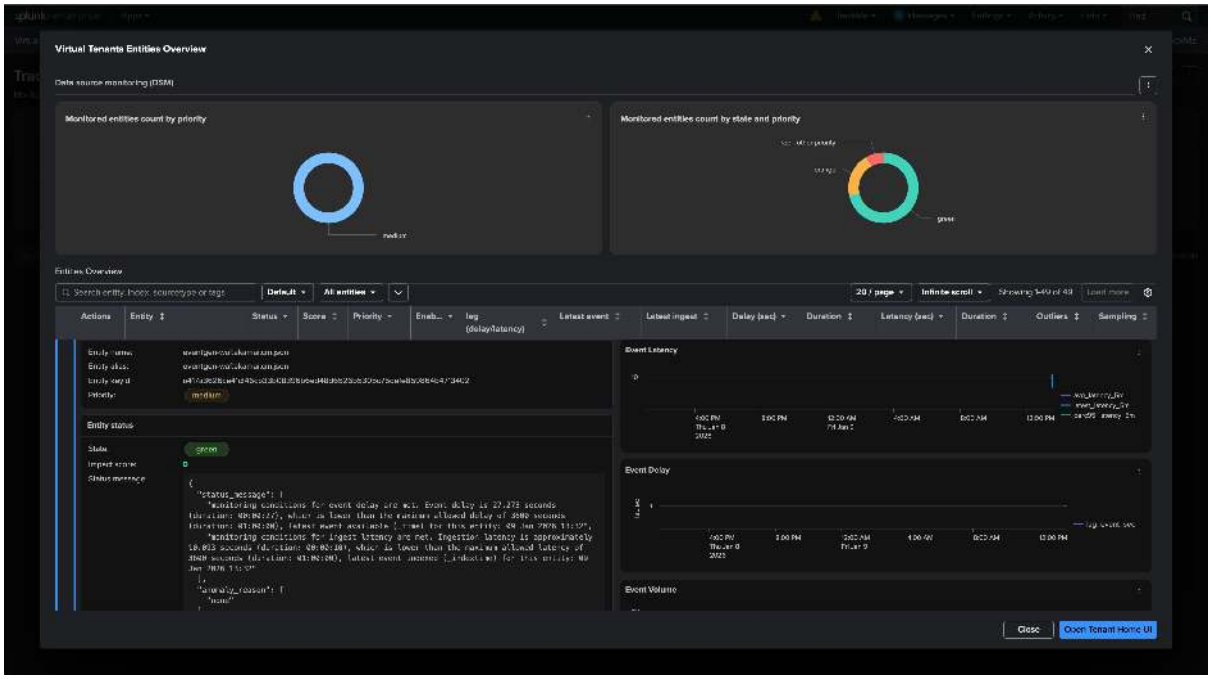
After a few minutes, the Virtual Tenant user interface will show activity of the tenant and eventually entities that were discovered:



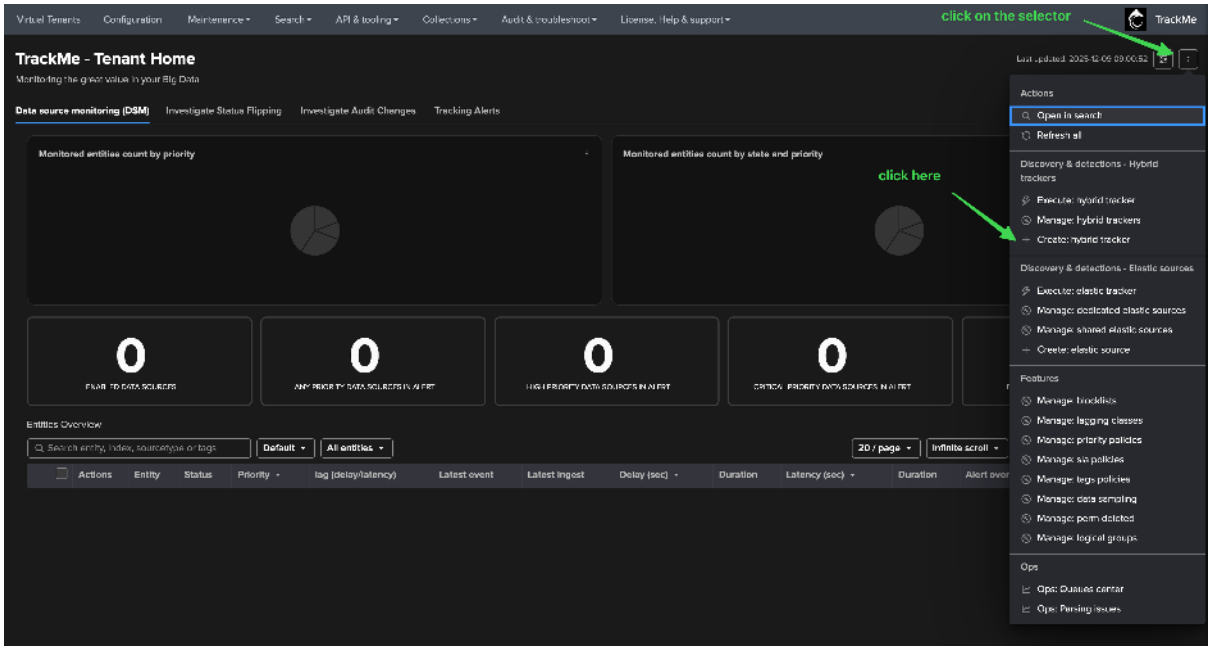
Double click on the Virtual Tenant box to open the following screen:

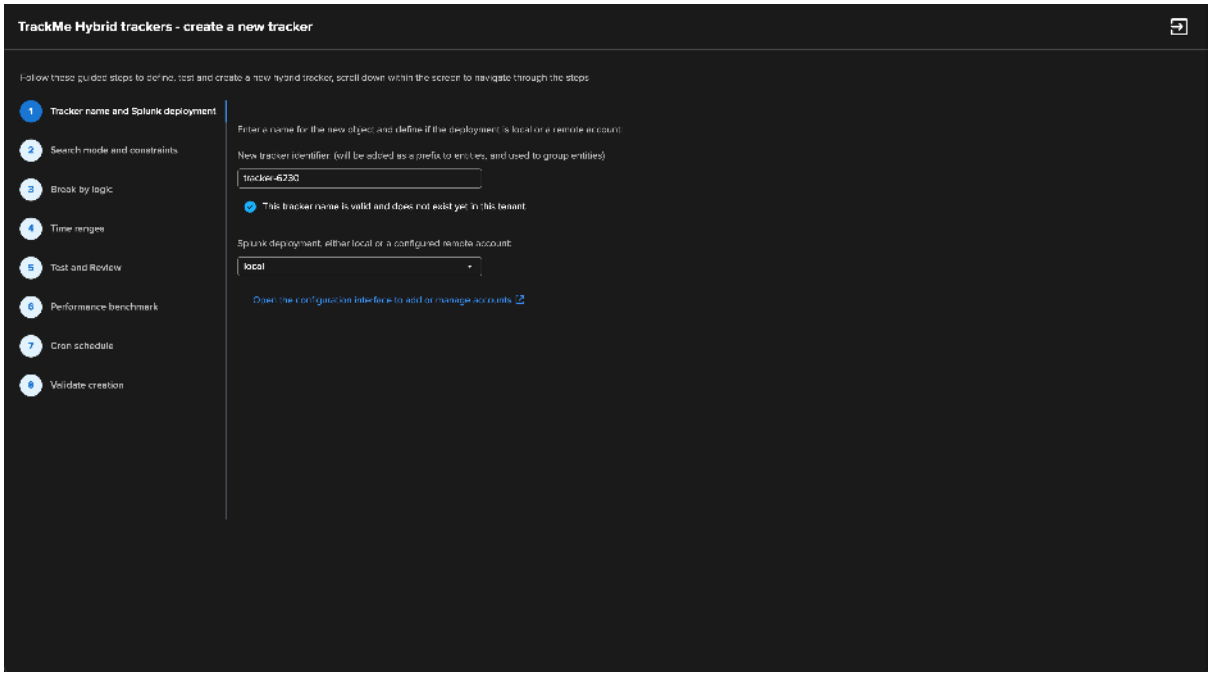


You can preview various information about the entities, and access the Home user interface for the tenant:

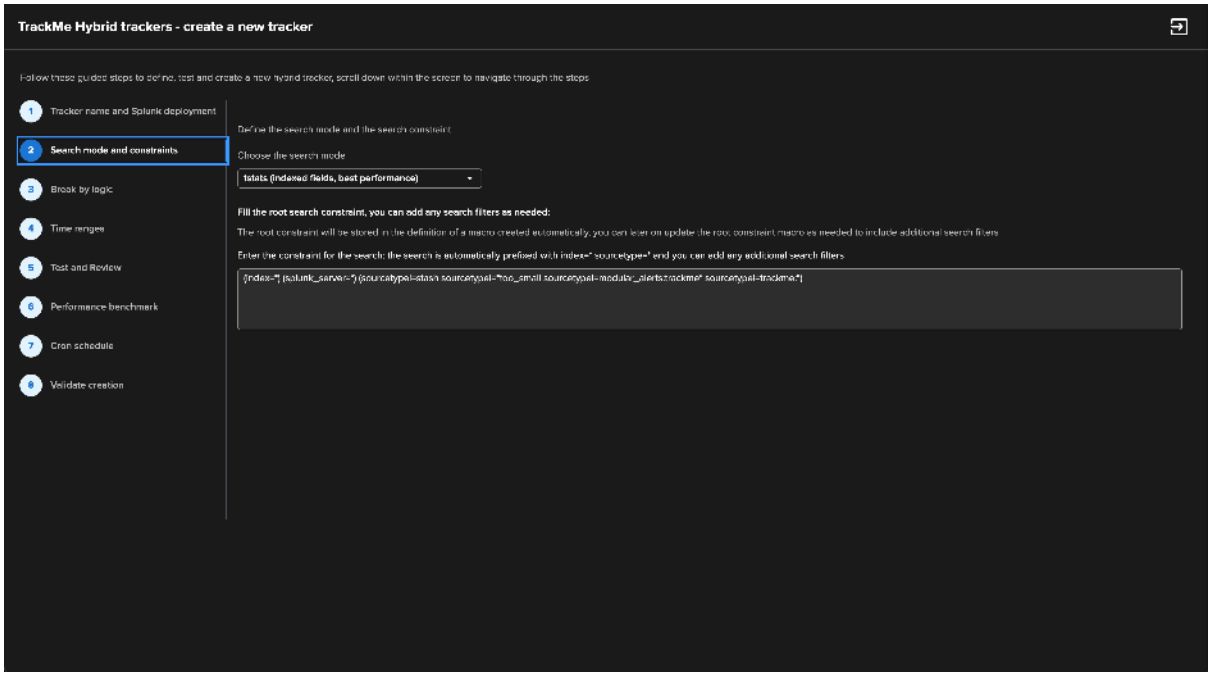


Optional: Create a hybrid tracker for splk-dsm after the creation of the Virtual Tenant





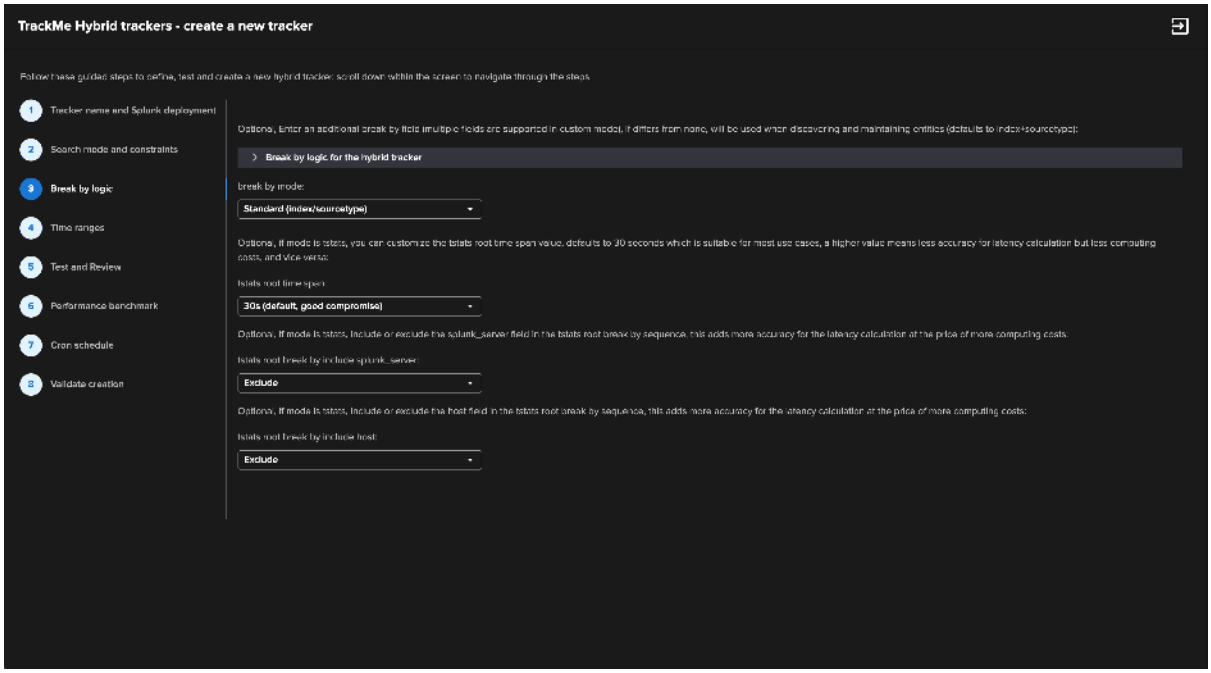
- Go to Step 2: (Search mode and constraints)
  - The default root constraint tracks all indexers, and excludes summary data (stash) and TrackMe-related data.
  - On large environments, the scaling concept for TrackMe is to dedicate Hybrid Trackers to specific indexes scope, so trackers can share the load and be executed concurrently, allowing TrackMe to scale at any level.
  - On relatively small environments, the default configuration for a single tracker is in most cases able to cope with the load with no issues.
  - Finally, if you are a Foundation Edition trial user, you can create up to eight Hybrid Trackers in total.
  - For more information about scaling TrackMe for high-scale environments, please refer to the TrackMe documentation, notably: *Large-scale environments*



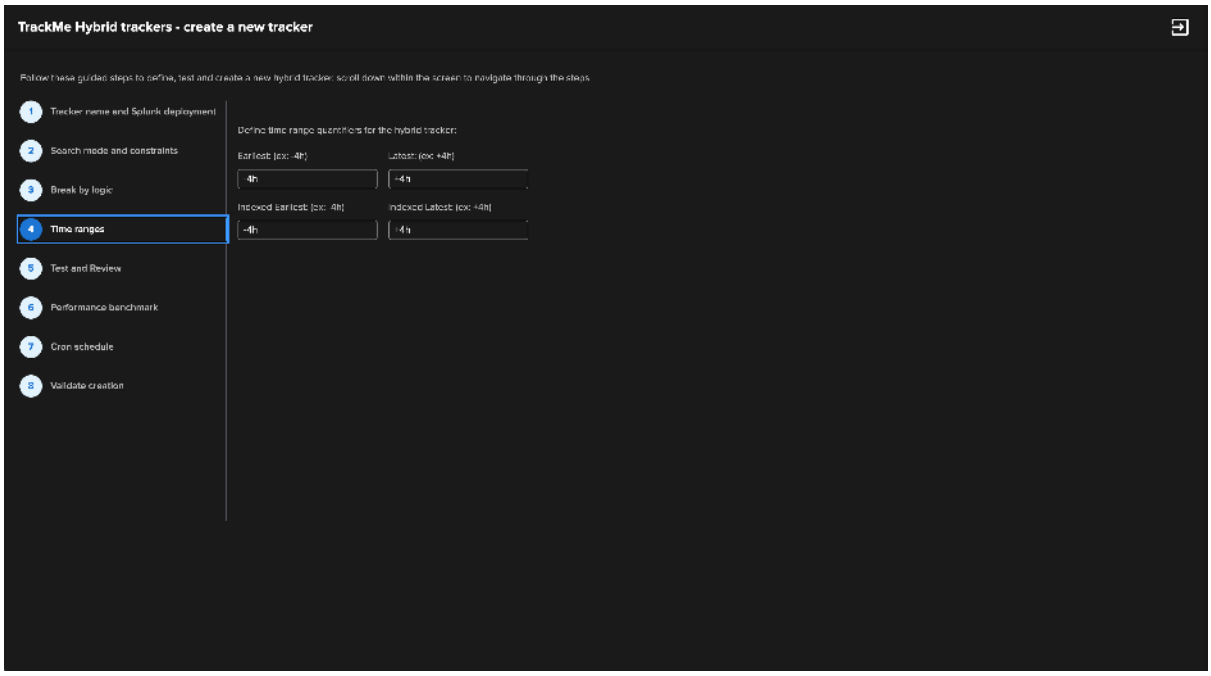
About Trackers scope:

- When creating a Hybrid Tracker, TrackMe creates a dedicated Splunk macro which contains the scope of the tracker.
- You can therefore easily start with a restricted scope such as a list of index patterns, then modify this macro at any point in time to include additional contexts.
- To retrieve the macro name after the tracker is created, click on Manage Hybrid tracker from the home UI.

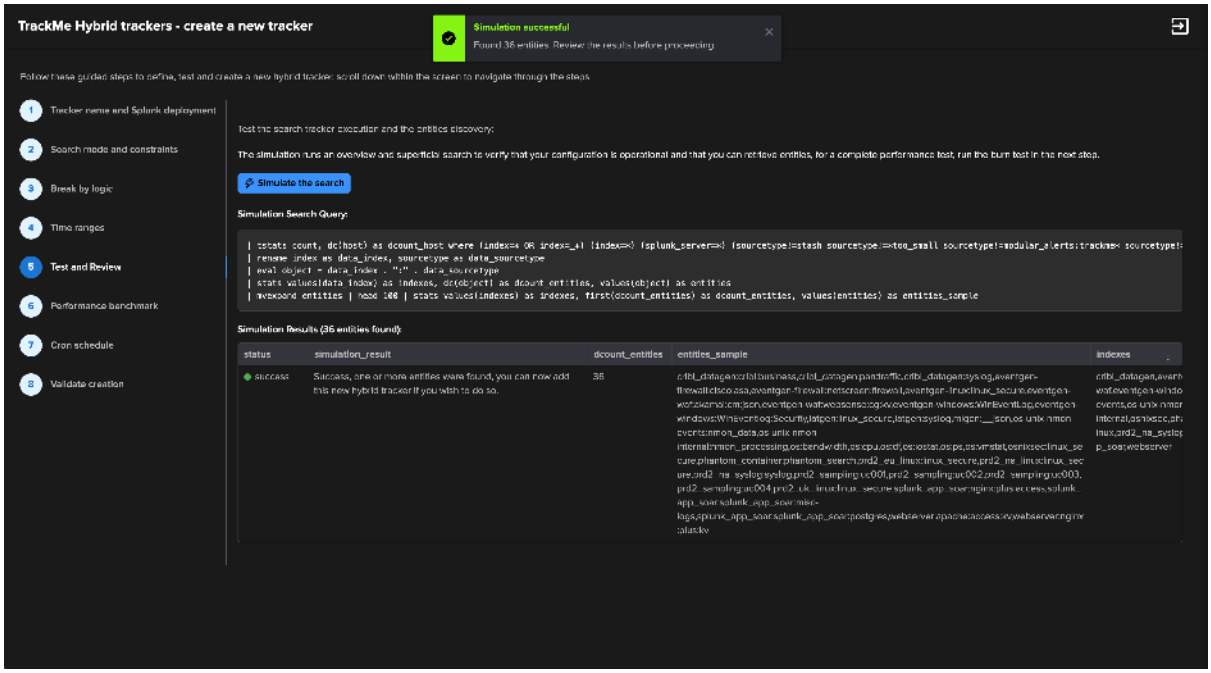
- Go to Step 3: (Break by logic)
  - By default, the behavior is to create TrackMe entities as the combination of indexes and sourcetypes, therefore: `<index>:<sourcetype>`, in most cases, this is what you want.
  - An alternative, and depending on your requirements, is to use the `merge` mode, in this case TrackMe will create one entity per index: `<index>`.
  - Finally, you can also specify a custom list (comma-separated format) of fields as part of a custom break by, this is more sophisticated and is generally used for specific use cases such as leveraging custom indexed fields in large-scale environments.



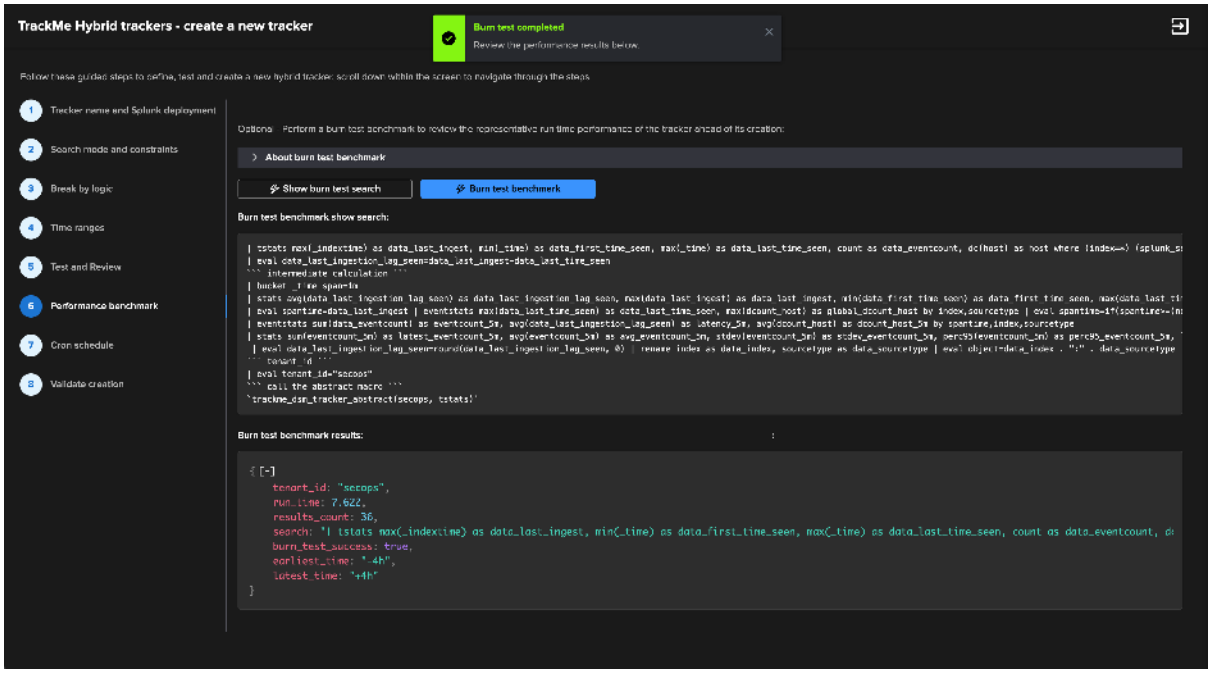
- Go to Step 4: (Time ranges)
  - By default, TrackMe uses a -4h/+4h time range for the search logic, this is generally fine for most cases.
  - In some contexts such as very high-scale contexts, or limited capacity contexts, you can eventually reduce the earliest to reduce the associated costs and run time (most likely for splk-dhm than splk-dsm).



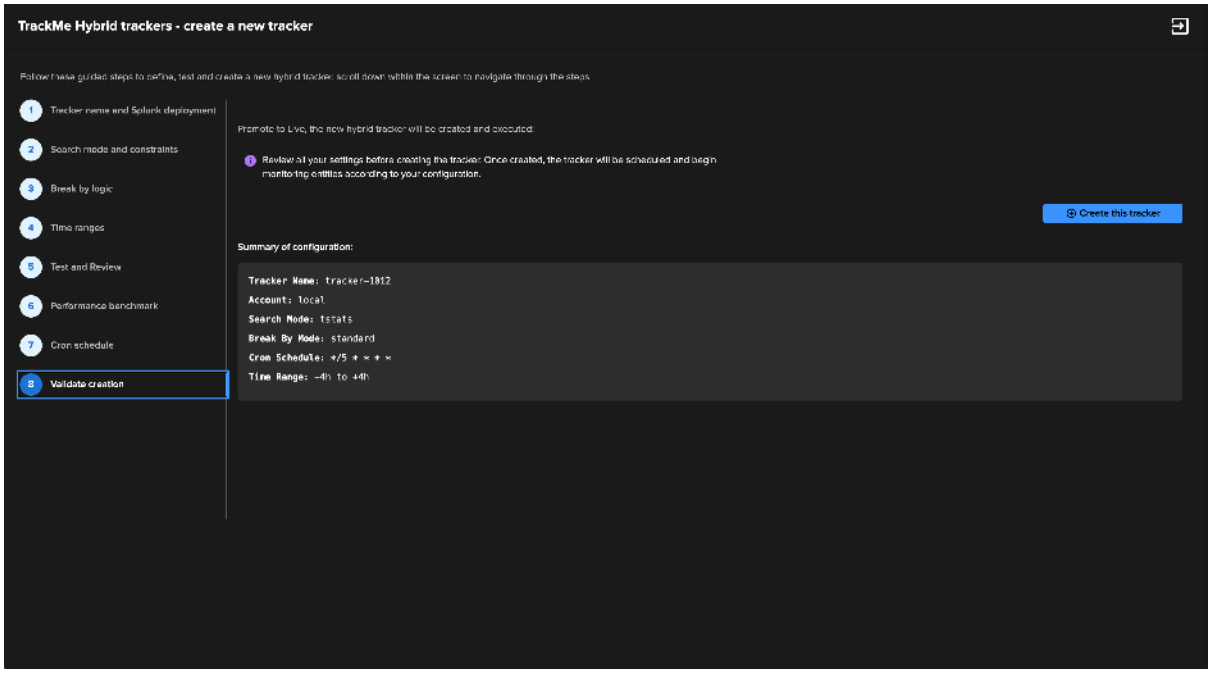
- Go to Step 5: (Test & Review)
  - This steps allows simulating the search logic and its parameters, to preview the results and notably the number of entities that would be created.

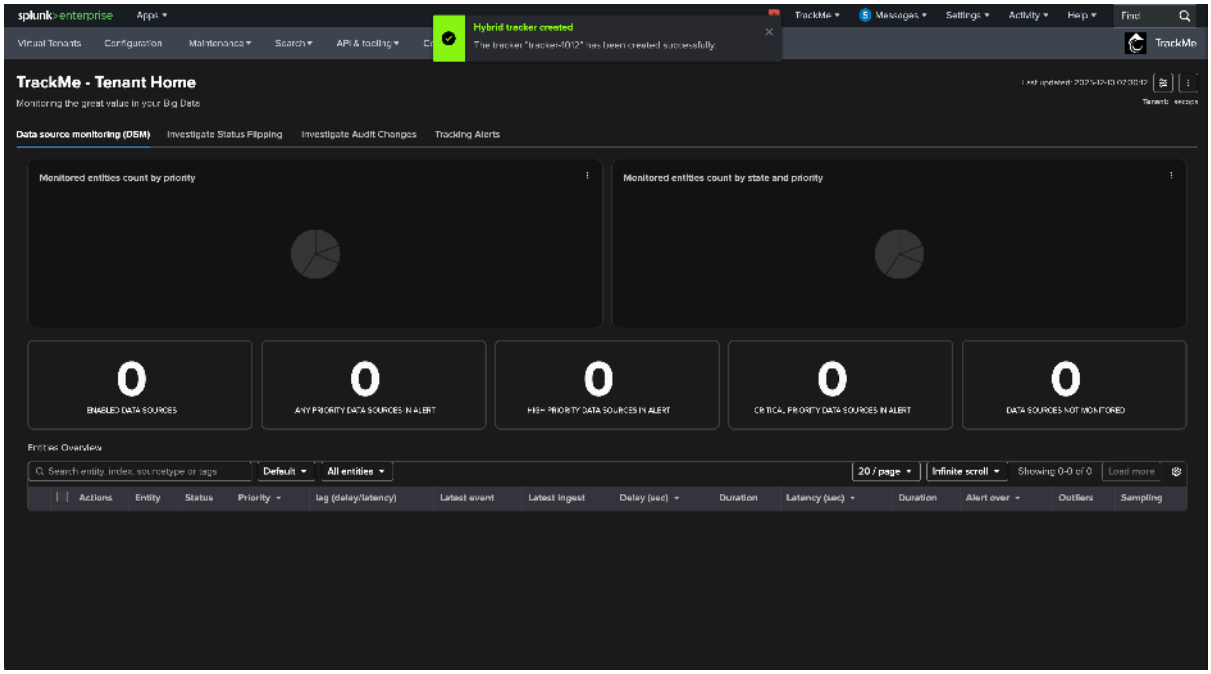


- Go to Step 6: (Performance benchmark)
  - TrackMe allows benchmarking the most expensive part of the search logic, this provides an accurate enough idea of how long the tracker will take to execute.
  - The target is to execute the search every 5 minutes (while this is under your control, in most cases we want to get as close as possible to this frequency, especially for feeds tracking).
  - This means that the search needs to be executed in less than 300 seconds to avoid generating skipping searches and missing executions.
  - The scaling idea underneath is to create multiple trackers with a reduced scope, so they can be executed concurrently, and therefore reduce the execution time.



- Finally, go step “Validate creation” to create the tracker





- Once created, you can from the main menu selector request the immediate execution of the tracker:

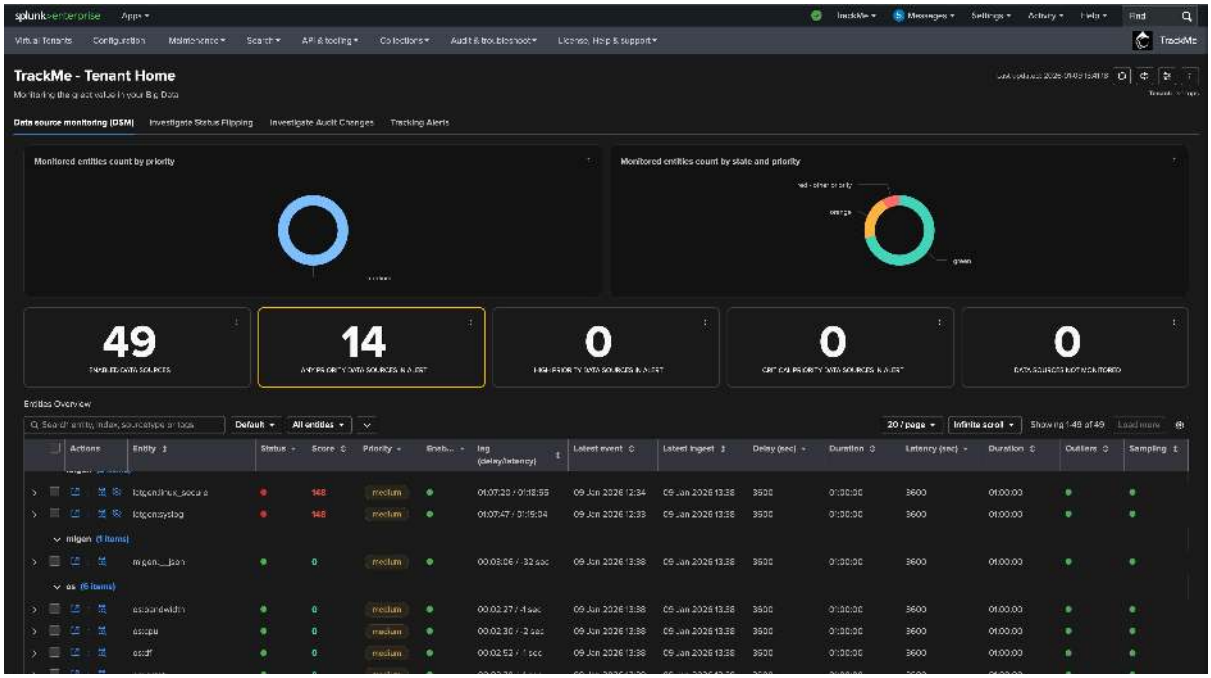
- After the tracker for first executed, entities will be created and visible in the main user interface:



Step 2: Let's create a Virtual Tenant for data host sources

We will now create a Virtual Tenant to start tracking hosts, we recommend to setup hosts tracking in a dedicated tenant, so we can easily manage various features such as disabling ML Outliers:

- component: `splk-dhm`
- tenant name: `endpoints`

Repeat the same process for data hosts tracking:

- We recommend being very strict with splk-dhm, notably we recommend restricting the scope as much as possible, and ensuring to allow only indexes that related to data generated by endpoints themselves.
- You totally can start with a certain scope, so you can first monitor the costs of the associated backends in

TrackMe, then gradually increase the scope as needed.

- Finally you can also choose to include or not splunkd itself, if you wish to monitor the availability of Splunk UFs/UFs internals, which reflect a healthy connectivity and status of Splunk agents.

Step 3: Alerting and notifications

Hint

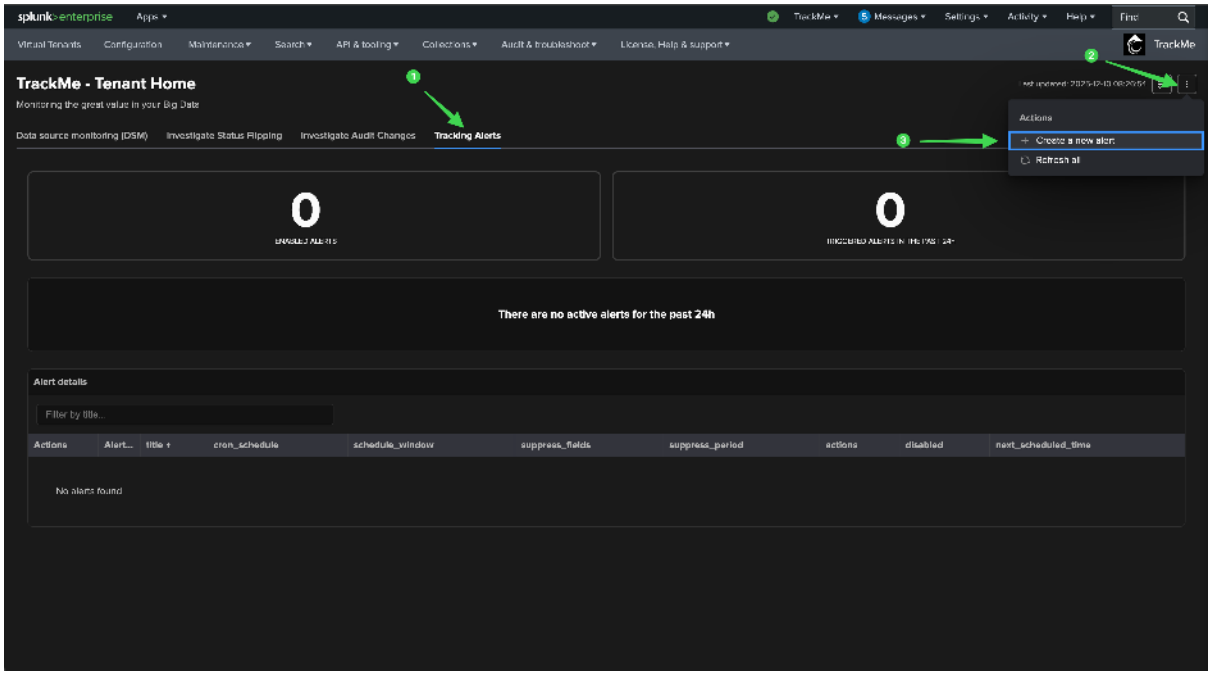
This quickstart was updated to use TrackMe's new StateFul Alerting features:

- Since TrackMe 2.1.11, a new concept of StateFul Alerting is available as the main alerting mechanism in TrackMe.
- These features provides a powerful, flexible and easy alerting capabilities as well as enhanced Email delivery notifications.
- For more information about this new concept, please refer to the *Stateful alerting* documentation.

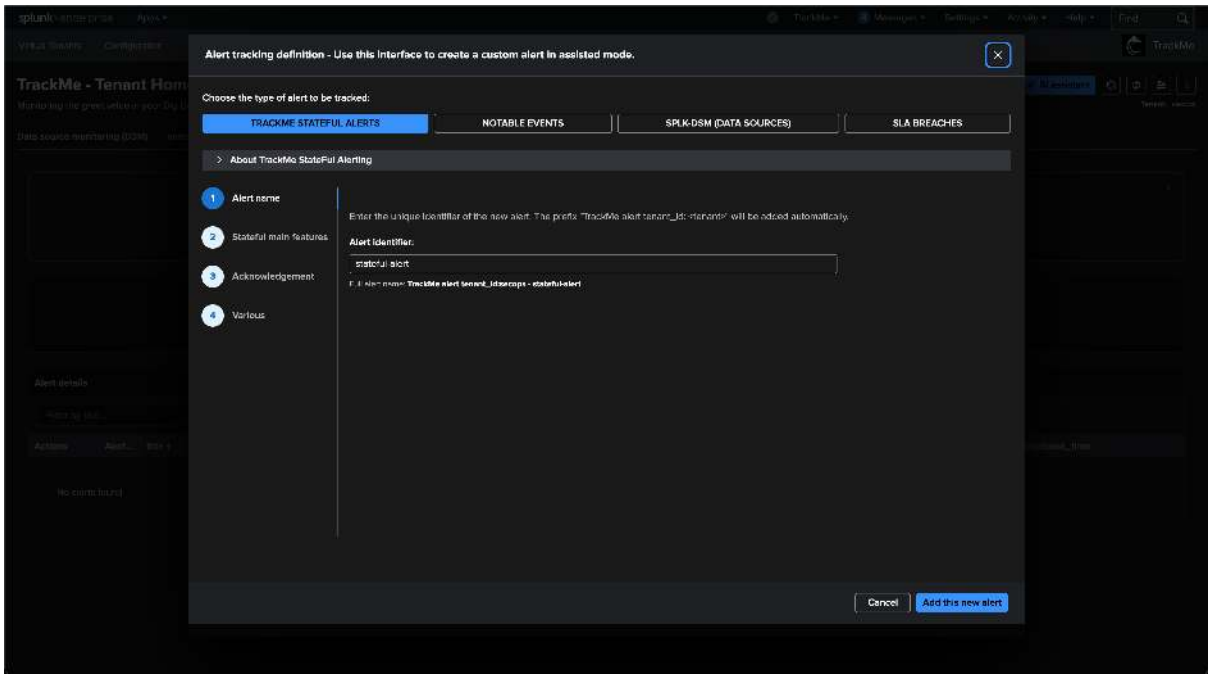
About Alerting recommendations:

- In a Production context, a true challenge is the massive number of entities, from hundreds if not not many thousdands of sources, hosts and so forth, it can be overwhelming to manage.
- We recommend a selective approach which used in conjonction with TrackMe and Splunk capabilities allow you to tackle these challenges.
- What we recommend is notably to leverage the `priority` concepts, and alert only on properly qualified entities leveraging `high` and `critical` priorities.
- This approach allows you to focus on the most important entities, and to avoid alerting fatigue by progressively qualifying your alerting logic and maturity in TrackMe over time.

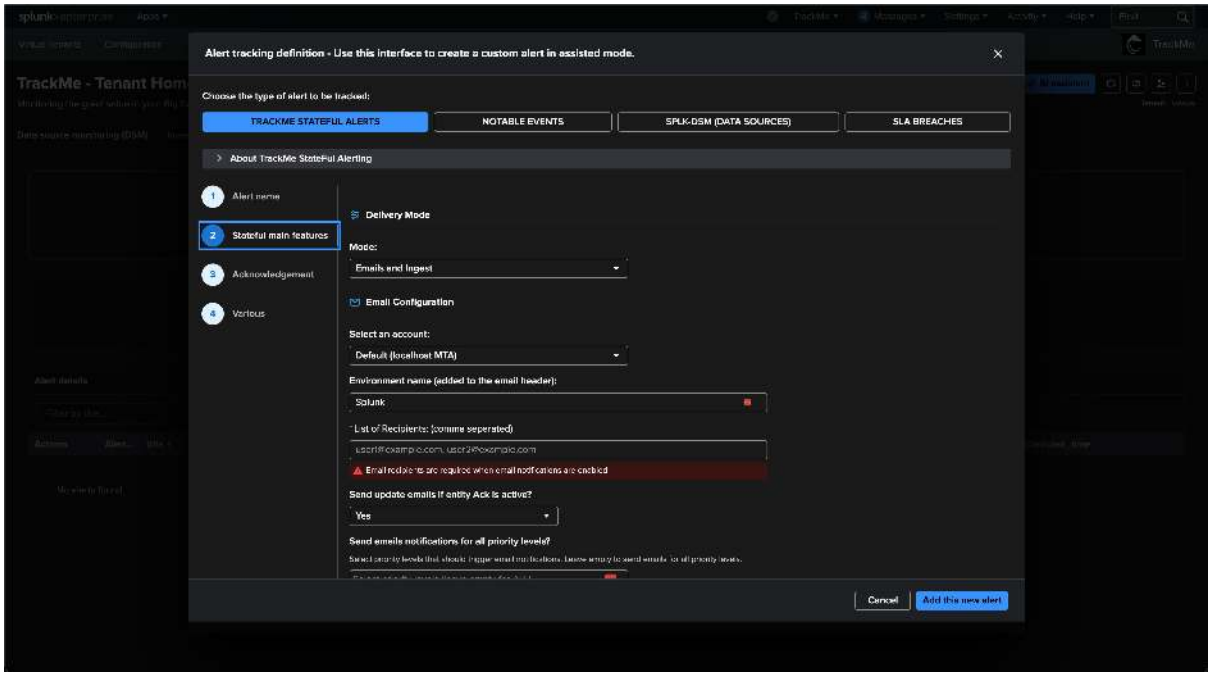
Access the Alerts creation wizard:



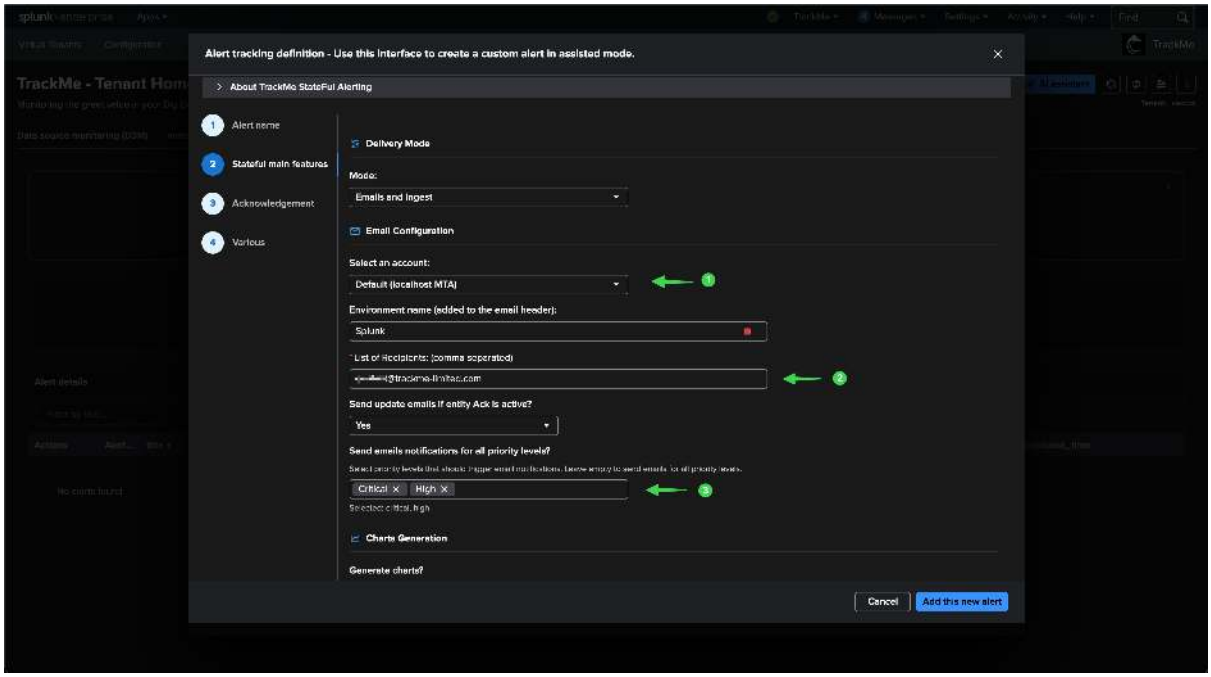
Welcoming screen for the alerts creation wizard:



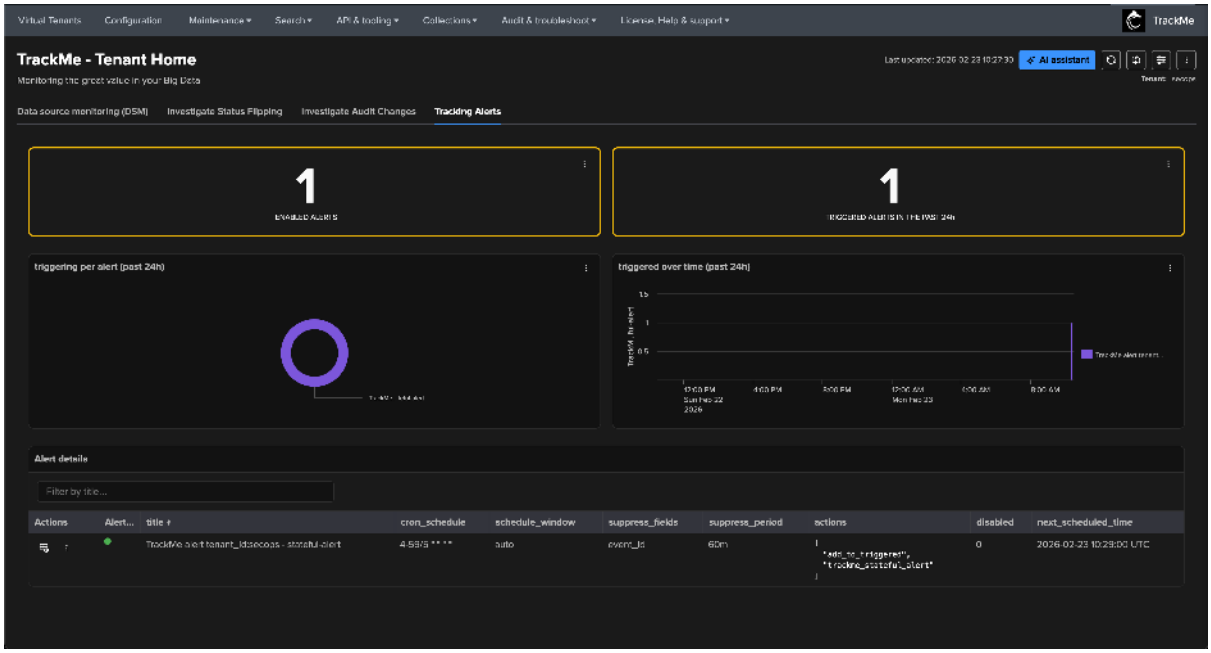
Go in step2, the default name of the alert is fine, we can leave it as is.



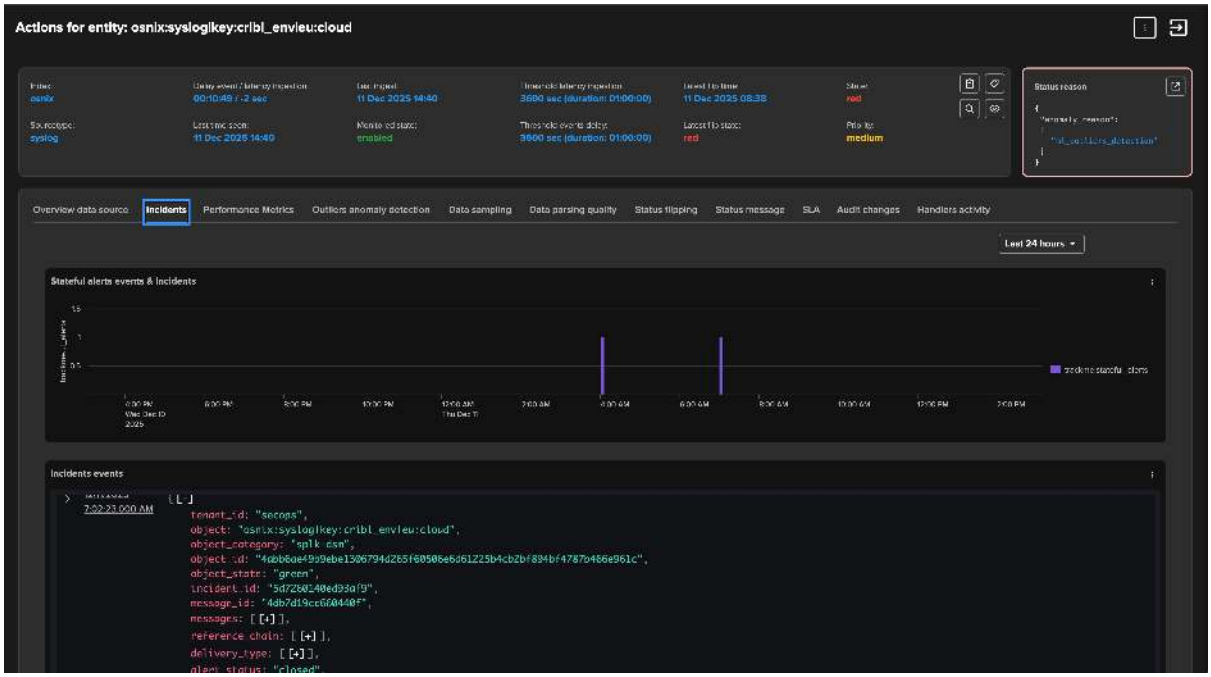
Configure the email delivery account, recipients and priority levels for email notifications:



Then validate the alerting creation:



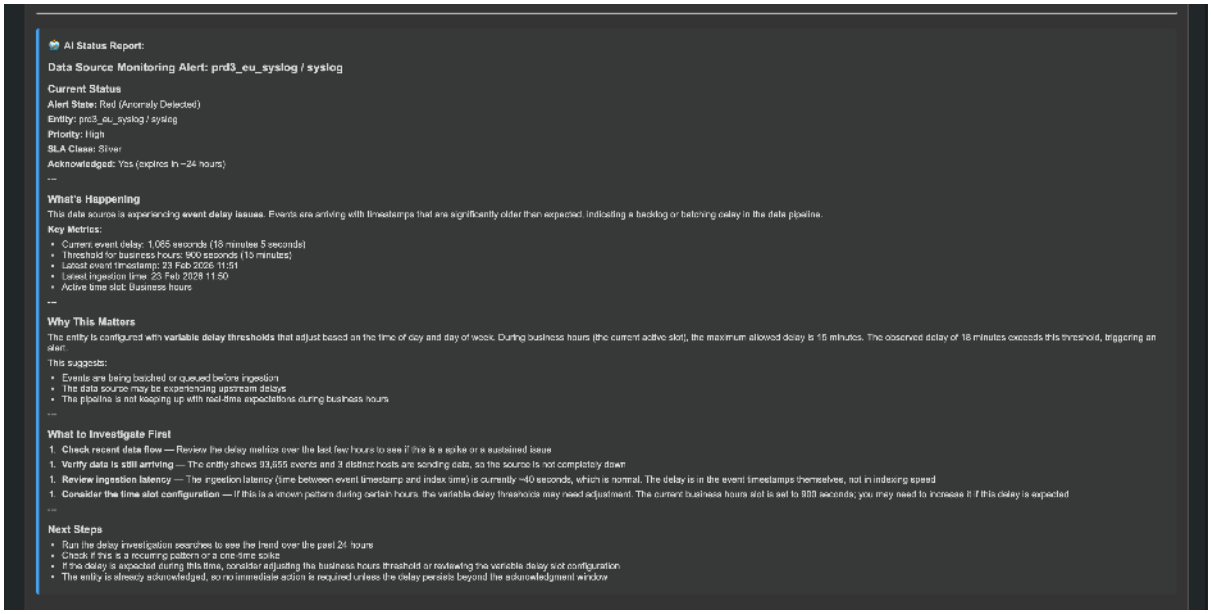
We are good to go now, if things are working as expected, any entity matching priority high or critical and currently in anomaly state, will trigger an alert!



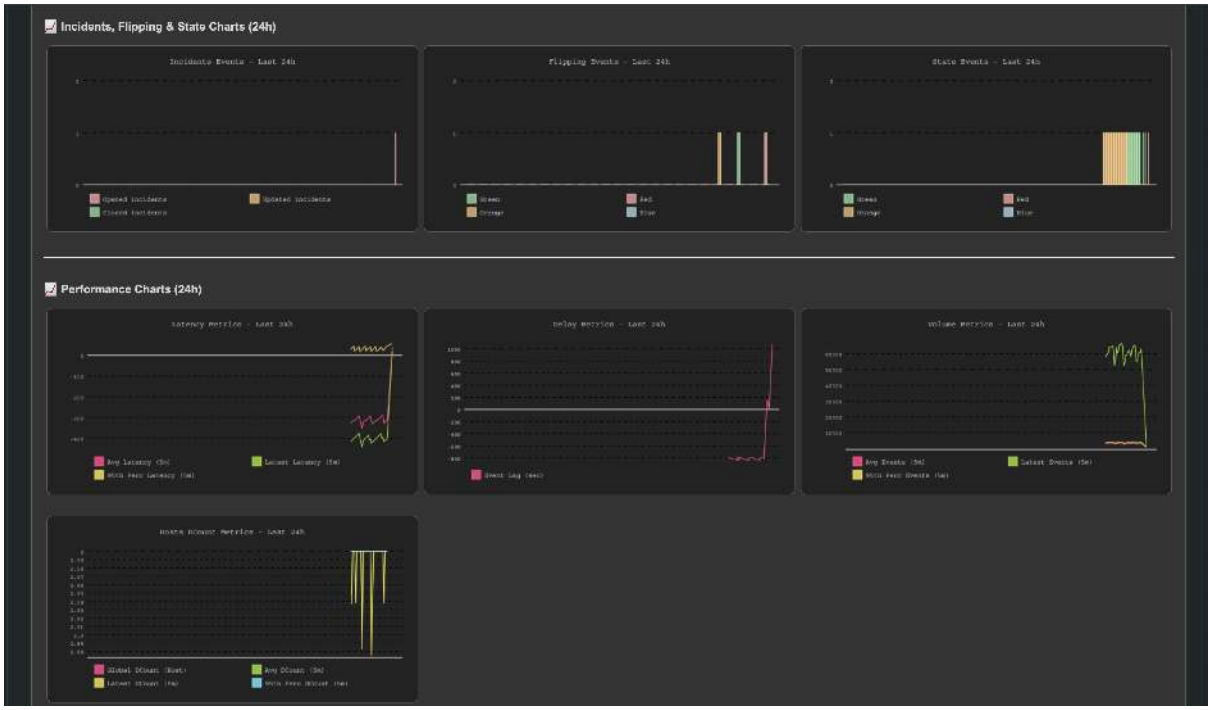
And if we did right, we also have a very nice Email notification!

Note: The AI status report requires an AI provider to be configured, if you haven't done so yet, please refer to the :ref:`ai_providers` documentation.

TrackMe Notification
Environment: Splunk
Detection Time: Mon Feb 23 12:14:06 2026 UTC
Alert Status: opened
Tenant: secops
Alias: prd3_eu_syslog:syslog
Object: prd3_eu_syslog:syslog
Priority: high
Unknown Link
Status: red
Impact score: 100
Incident ID: 5839a93aef88608e
Detailed Information:
The entity has transitioned to an alerting state:
Alias: prd3_eu_syslog:syslog
Object: prd3_eu_syslog:syslog
Object ID: 2b5c4151054 1a2be341a2b9c73e55462c549b7b4ef622b46ee8b1818beeda995
Category: splk-dsm
Anomaly Reason(s):
variable_delay_threshold_breached
Message(s):
Monitoring conditions are not met due to delay issues. Event delay is 1085.0 seconds (duration: 00:18:05), which is higher than the maximum allowed variable delay threshold (active slot: 'business_hours') of 900 seconds (duration: 00:15:00), latest event available (_time) for this entity: 23 Feb 2026 11:51, latest event ingested (_indextime) for this entity: 23 Feb 2026 11:50. This indicates that the source is receiving events with timestamps older than the threshold defined for this entity.
Message source: trackme:state
Message source ID: 8b6be13Bb2c9c7c656b970b5b00d0188e20bbcfcef1d68bf5278ad834b218982



AI Status Report:
Data Source Monitoring Alert: prd3_eu_syslog / syslog
Current Status
Alert State: Red (Anomaly Detected)
Entity: prd3_eu_syslog / syslog
Priority: High
SLA Class: Silver
Acknowledged: Yes (expires in ~24 hours)
What's Happening
This data source is experiencing event delay issues. Events are arriving with timestamps that are significantly older than expected, indicating a backlog or batching delay in the data pipeline.
Key Metrics:
Current event delay: 1,085 seconds (18 minutes 5 seconds)
Threshold for business hours: 900 seconds (15 minutes)
Latest event timestamp: 23 Feb 2026 11:51
Latest ingestion time: 23 Feb 2026 11:50
Active time slot: Business hours
Why This Matters
The entity is configured with variable delay thresholds that adjust based on the time of day and day of week. During business hours (the current active slot), the maximum allowed delay is 15 minutes. The observed delay of 18 minutes exceeds this threshold, triggering an alert.
This suggests:
Events are being batched or queued before ingestion
The data source may be experiencing upstream delays
The pipeline is not keeping up with real-time expectations during business hours
What to Investigate First
1. Check recent data flow — Review the delay metrics over the last few hours to see if this is a spike or a sustained issue
1. Verify data is still arriving — The entity shows 93,655 events and 3 distinct hosts are sending data, so the source is not completely down
1. Review ingestion latency — The ingestion latency (time between event timestamp and index time) is currently ~40 seconds, which is normal. The delay is in the event timestamps themselves, not in indexing speed
1. Consider the time slot configuration — If this is a known pattern during certain hours, the variable delay thresholds may need adjustment. The current business hours slot is set to 900 seconds; you may need to increase it if this delay is expected
Next Steps
Run the delay investigation searches to see the trend over the past 24 hours
Check if this is a recurring pattern or a one-time spike
If the delay is expected during this time, consider adjusting the business hours threshold or reviewing the variable delay slot configuration
The entity is already acknowledged, so no immediate action is required unless the delay persists beyond the acknowledgment window



Adapt to your preferences, repeat as needed, TrackMe is now Production ready!

QUICK START - TrackMe Impact-Based Alerting (IBA)

Impact-Based Alerting (IBA)

- Impact-Based Alerting (IBA) is a new core alerting model introduced in TrackMe 2.3.5.
- IBA transforms how TrackMe determines entity status by using a flexible, configurable scoring system instead of hardcoded rules.
- Inspired by Risk-Based Analysis (RBA) in security contexts, IBA allows administrators to fine-tune how different anomalies contribute to entity health status.
- IBA provides complete transparency through detailed score breakdowns, making it easy to understand why an entity is in a particular state.
- For users migrating from previous versions, the transition is seamless and requires no manual intervention.
- This guide focuses on feeds tracking (DSM and DHM components) as the primary use case, with extensions to other TrackMe components covered in later sections.

What is Impact-Based Alerting?

Impact-Based Alerting (IBA) is TrackMe's intelligent scoring system that determines entity health status based on a cumulative impact score. Instead of using fixed rules, IBA aggregates scores from various anomaly types over a 24-hour rolling window, providing a flexible and tunable approach to alerting.

Domain Positioning

- Inspired by security-grade risk scoring, IBA brings impact-driven alerting to data monitoring. IBA applies risk-based scoring principles to data reliability and observability in TrackMe.

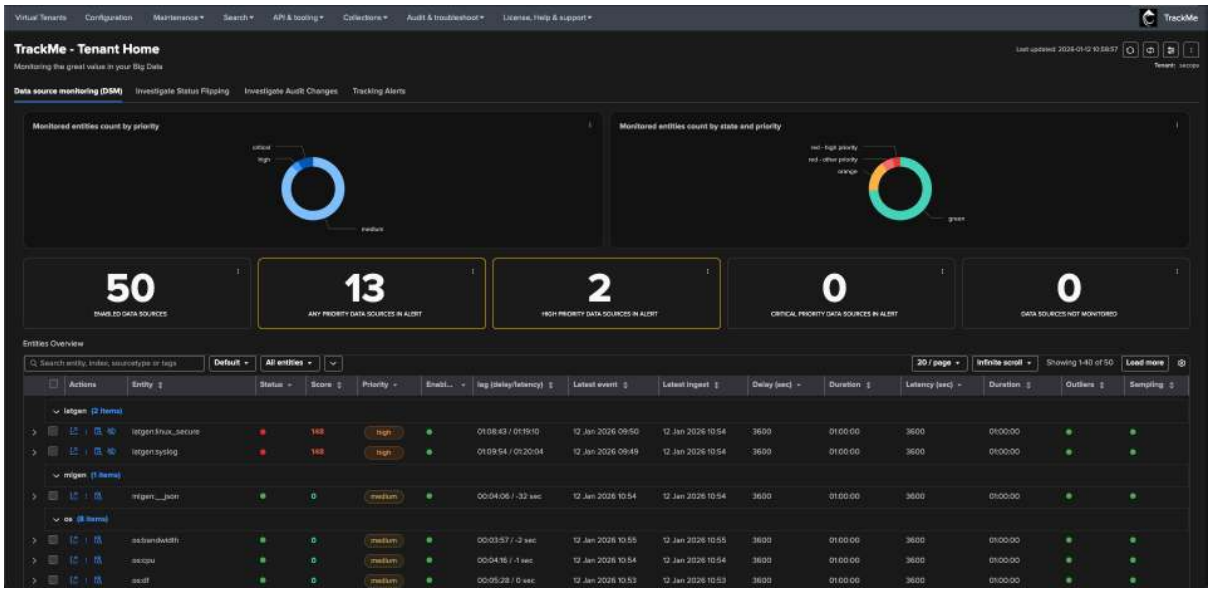
Key Concepts:

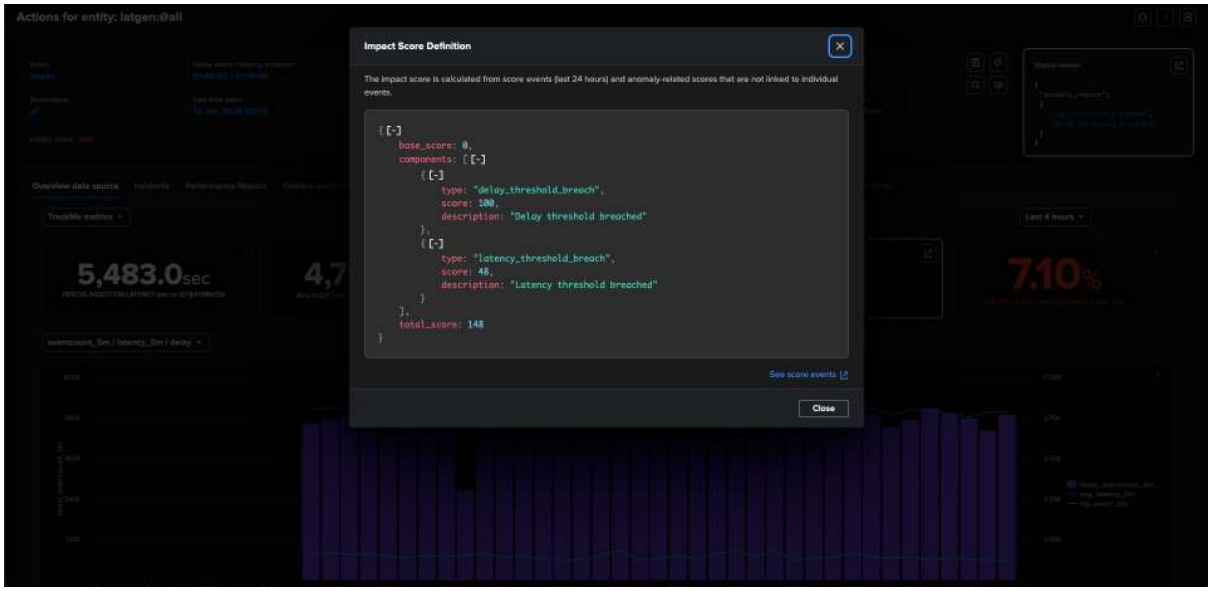
- **Impact Score**: A numeric value (0-100) assigned to each anomaly type when detected

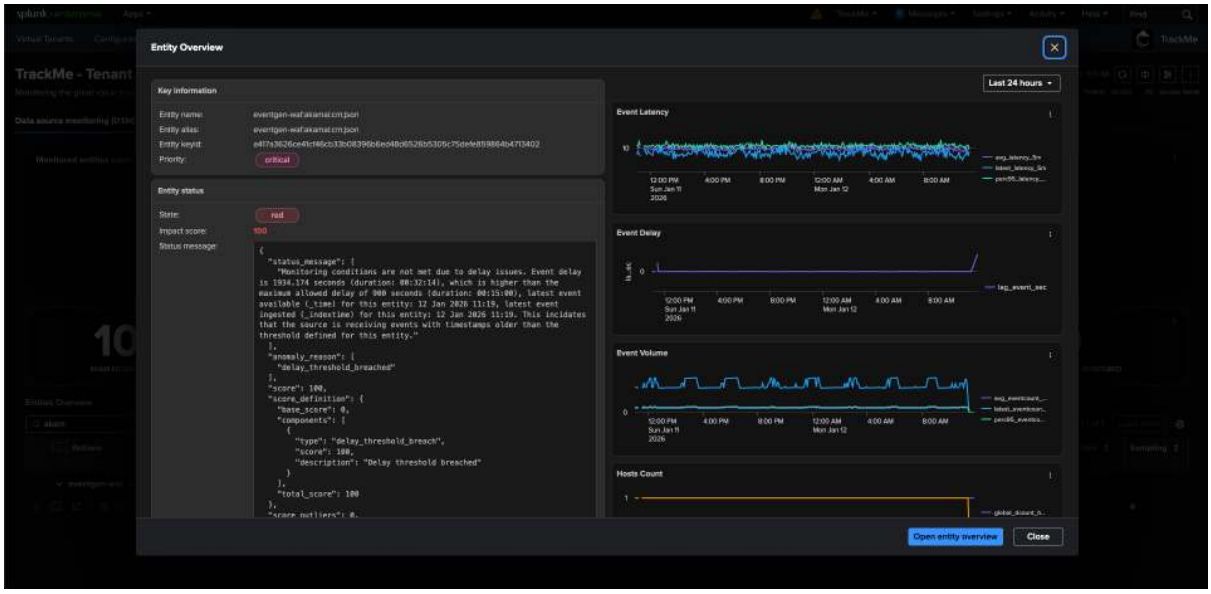
- **Total Score**: The cumulative sum of all impact scores for an entity
- **Score Aggregation**: Scores are aggregated over a 24-hour rolling window
- **Status Determination**: Entity status (green, orange, red, blue) is determined by the total score
- **Score Transparency**: Every score includes a detailed breakdown showing exactly which anomalies contributed

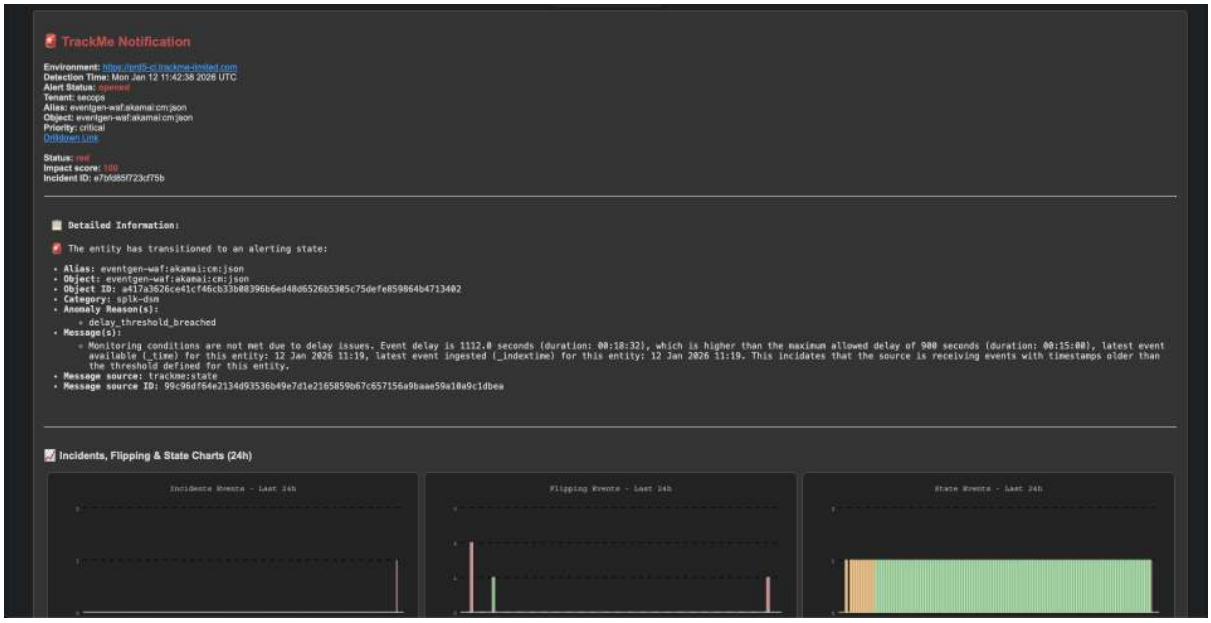
Why IBA Matters:

- **Smarter Alerting**: Fine-tune impact scores per tenant, component, and anomaly type to match your environment's priorities
- **Reduced False Positives**: One-click suppression capabilities allow you to mark outliers or entire entities as false positives
- **Complete Transparency**: Detailed score breakdowns show exactly why an entity is in a particular state
- **Flexible Configuration**: Adjust impact scores through an intuitive UI without code changes
- **Audit Trail**: Full traceability of score events and anomaly reasons, even when suppressed









Understanding Entity Status in IBA

TrackMe entities can have four possible statuses, each determined by the total impact score:

Green Status

- **Condition**: Total score = 0 (no anomalies detected)
- **Meaning**: The entity is healthy and operating normally
- **Visual Indicator**: Green status dot

Orange Status

- **Condition**: Total score > 0 and < 100 (anomalies present but below critical threshold)
- **Meaning**: Potential issues detected that require attention but don't warrant a critical alert
- **Visual Indicator**: Orange status dot
- **Use Case**: Early warning for issues that may escalate if not addressed

Red Status

- **Condition**: Total score >= 100 (critical threshold breached)
- **Meaning**: Critical issues detected that require immediate attention
- **Visual Indicator**: Red status dot
- **Use Case**: Triggers alerts and notifications for immediate action

Blue Status

- **Condition**: Special state (e.g., logical group protection, minimal disruption time)
- **Meaning**: Entity is part of a logical group that provides protection
- **Visual Indicator**: Blue status dot

How Impact Scoring Works for Feeds Tracking (DSM)

The Data Sources Monitoring (DSM) component tracks data sources (index/sourcetype combinations) and uses IBA to determine entity status based on various anomaly types.

DSM Anomaly Types and Default Impact Scores:

Anomaly Type	Default Score	Description
Delay Threshold Breach	100	Data flow is interrupted - no new events received (static delay policy)
Variable Delay Threshold Breach	100	Data flow is interrupted - no new events received within the active variable delay slot threshold (variable delay policy, since v2.3.12)
Latency Threshold Breach	48	Events are being indexed but with high latency
Data Sampling Anomaly	36	Quality issues detected in event format recognition
Min Hosts Dcount Breach	100	Minimum number of distinct hosts threshold breached
Future Tolerance Breach	36	Events detected with timestamps too far in the future
ML Outliers Detection	36 (default)	Machine Learning models detected abnormal volume patterns

Score Calculation Example:

Let's consider a DSM entity with multiple anomalies:

1. **Base Score**: 0 (no upstream threshold breaches from hybrid trackers)
2. **Delay Threshold Breach** (or **Variable Delay Threshold Breach**): Score = 100 (default)
3. **ML Outliers Detection**: Score = 36 (default)
4. **Total Score**: 136

Result: Red status (score >= 100)

Score Definition Breakdown:

The system maintains a detailed breakdown of the score:

```
{
  "base_score": 0,
  "components": [
    {
      "type": "delay_threshold_breach",
      "score": 100,

    }
  ],
  "score_outliers": 36.0,
  "score_source": ["lowerbound_outlier"],
  "total_score": 136.0
}
```

Understanding the Score Components:

- **base_score**: Score from upstream tracker/search results (e.g., threshold breaches detected by hybrid trackers)
- **components**: Array of anomaly components contributing to the score, each with: - **type**: The anomaly type (e.g., "delay_threshold_breach") - **score**: The impact score for this anomaly - **description**: Human-readable description
- **score_outliers**: Cumulative outlier score (if ML outliers are detected)
- **score_source**: Array of score sources (e.g., "lowerbound_outlier", "false_positive", "manual_score")
- **total_score**: Final calculated score used for status determination

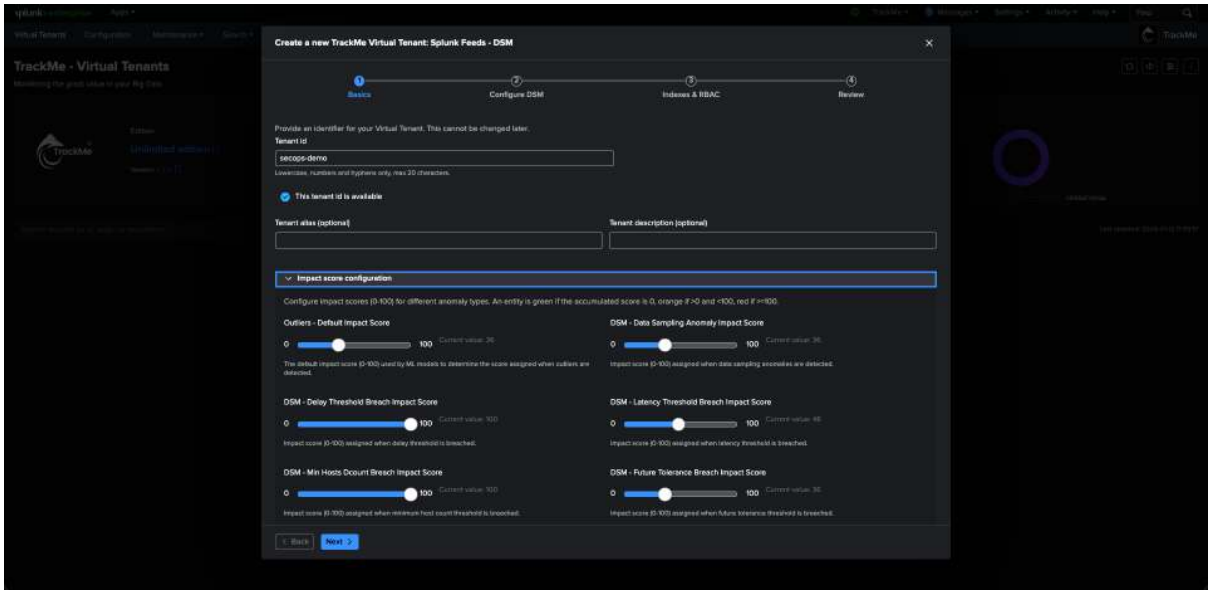
Configuring Impact Scores for DSM

Impact scores are configured per Virtual Tenant account, allowing you to customize how different anomaly types contribute to entity status for each tenant.

During Virtual Tenant Creation:

When creating a new Virtual Tenant for DSM (Data Sources Monitoring), you can configure impact scores in the wizard:

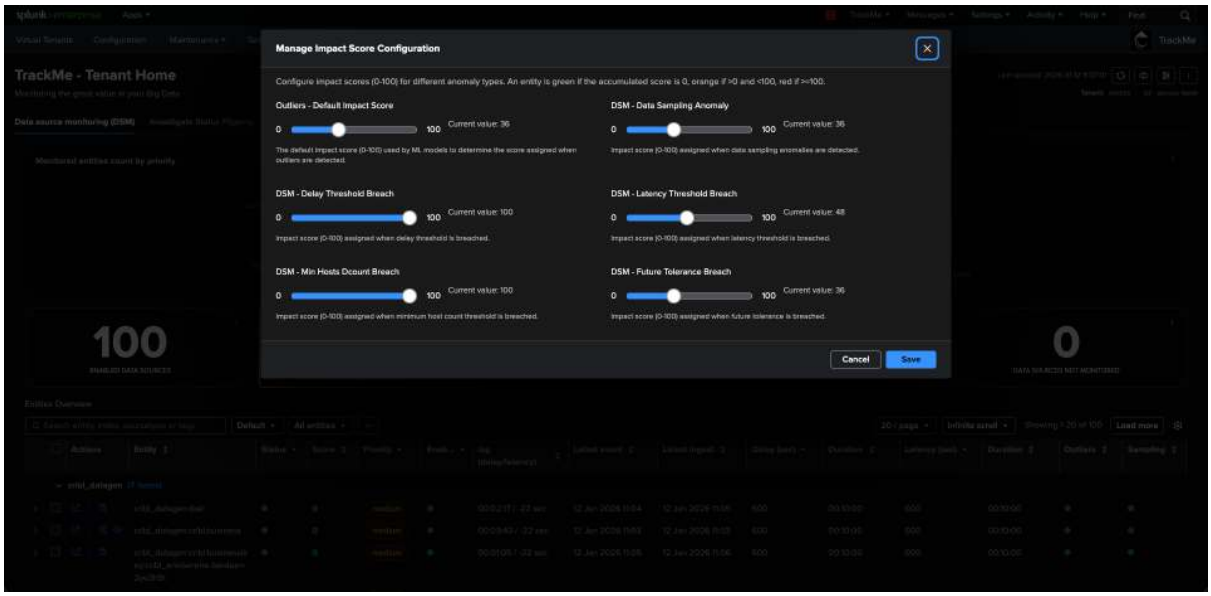
1. Navigate to the "Impact score configuration" section (collapsible panel)
2. Adjust sliders (0-100) for each anomaly type:
   - **Outliers - Default Impact Score**: Applies to ML outlier detections (default: 36)
   - **DSM - Data Sampling Anomaly Impact Score**: Quality issues (default: 36)
   - **DSM - Delay Threshold Breach Impact Score**: Data flow interruption (default: 100) - applies to both static and variable delay policies
   - **DSM - Latency Threshold Breach Impact Score**: High indexing latency (default: 48)
   - **DSM - Min Hosts Dcount Breach Impact Score**: Minimum hosts threshold (default: 100)
   - **DSM - Future Tolerance Breach Impact Score**: Future timestamp issues (default: 36)



After Virtual Tenant Creation:

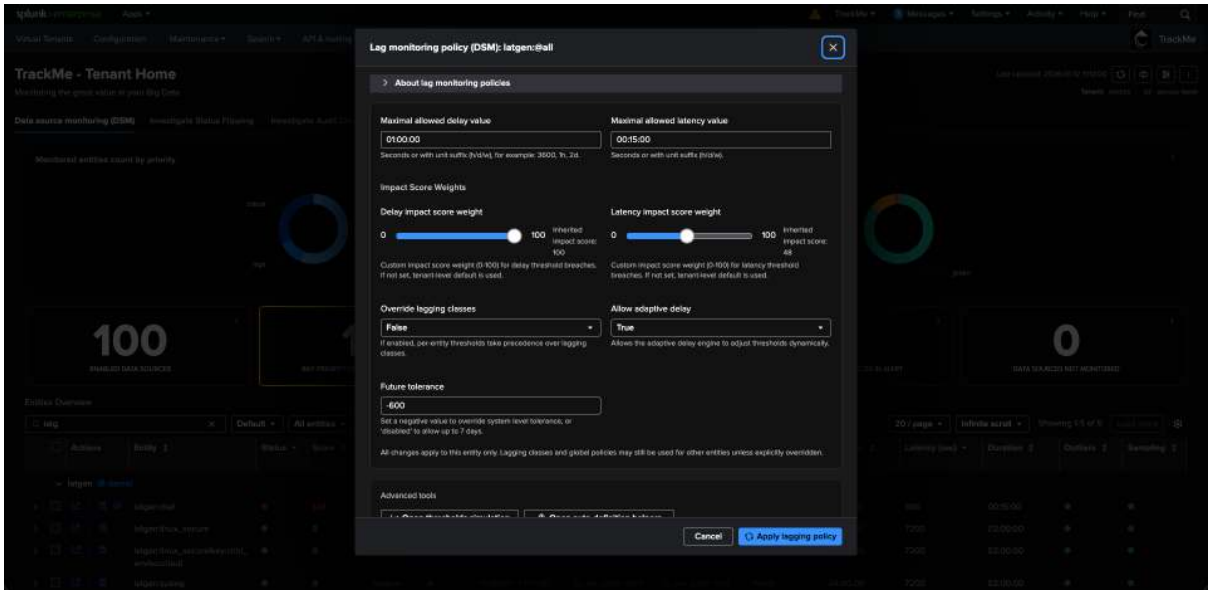
You can update impact scores for existing tenants:

1. Navigate to the Virtual Tenant home interface
2. Click the kebab menu (three dots) for the tenant
3. Select “Manage: Impact score”
4. Adjust the sliders for each anomaly type
5. Save the configuration



Per-Entity Score Weight Overrides (DSM and DHM):

For DSM and DHM components, you can override impact score weights on a per-entity basis through the lagging policy configuration. This allows fine-grained control for specific entities that may have different priorities or requirements than the tenant-level defaults.



How to Configure Per-Entity Score Weights:

1. Navigate to the entity detail modal for the DSM or DHM entity you want to configure
2. Click on "Manage lagging policy" (or access via the entity kebab menu)
3. In the lagging policy modal, locate the "Impact Score Weights" section
4. Adjust the sliders for: - **Delay impact score weight**: Custom impact score (0-100) for delay threshold breaches - **Latency impact score weight**: Custom impact score (0-100) for latency threshold breaches
5. The modal displays the "Inherited impact score" value, showing the tenant-level default
6. Click "Apply lagging policy" to save the entity-specific overrides

Important Notes:

- Per-entity score weights override tenant-level defaults for that specific entity only
- Other entities continue to use tenant-level defaults unless they also have per-entity overrides
- Per-entity overrides apply only to delay and latency threshold breaches (not other anomaly types)
- These overrides are stored in the entity's lagging policy configuration
- Other TrackMe components (MHM, FLX, FQM, WLK) use different mechanisms for per-entity customization

Use Cases for Per-Entity Overrides:

- **Critical Data Sources**: Increase delay/latency scores for mission-critical feeds
- **Low-Priority Sources**: Decrease scores for less critical feeds to reduce alert noise
- **Special Handling**: Adjust scores for entities with known patterns or maintenance windows
- **Gradual Rollout**: Test new score configurations on specific entities before applying tenant-wide

Best Practices for DSM Impact Score Configuration:

- **Delay Threshold Breach** (and **Variable Delay Threshold Breach**): Keep at 100 (default) - this is a critical indicator of data flow interruption
- **Latency Threshold Breach**: Consider 48-60 range - high latency is important but less critical than delay
- **Data Sampling Anomaly**: Adjust based on your quality requirements (default: 36)
- **ML Outliers**: Start with default (36) and adjust based on false positive rates
- **Future Tolerance Breach**: Keep at default (36) unless you have specific requirements

Example Configuration Scenarios:

Scenario 1: High-Volume, Low-Latency Tolerance Environment

- Delay Threshold Breach: 100 (critical)
- Latency Threshold Breach: 60 (increased importance)
- Data Sampling Anomaly: 50 (quality is important)
- ML Outliers: 30 (reduce false positives)

Scenario 2: Quality-Focused Environment

- Delay Threshold Breach: 100 (critical)
- Latency Threshold Breach: 40 (less critical)
- Data Sampling Anomaly: 60 (quality is paramount)
- ML Outliers: 40 (balance detection and false positives)

Understanding Score Aggregation and Time Windows

Impact scores are aggregated over a **24-hour rolling window**, meaning:

- Scores from anomalies detected in the last 24 hours contribute to the total score
- Older scores automatically expire after 24 hours
- The total score reflects the current state of the entity over this window

How Score Events Work:

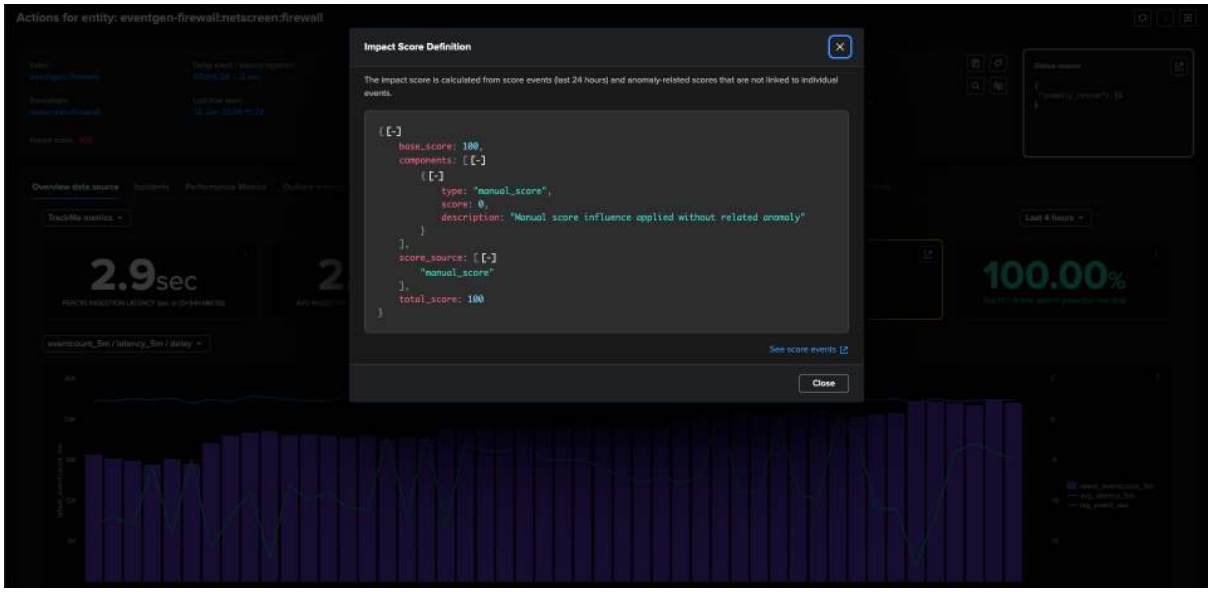
Score events are generated when anomalies are detected and stored in TrackMe's metrics store. These events include:

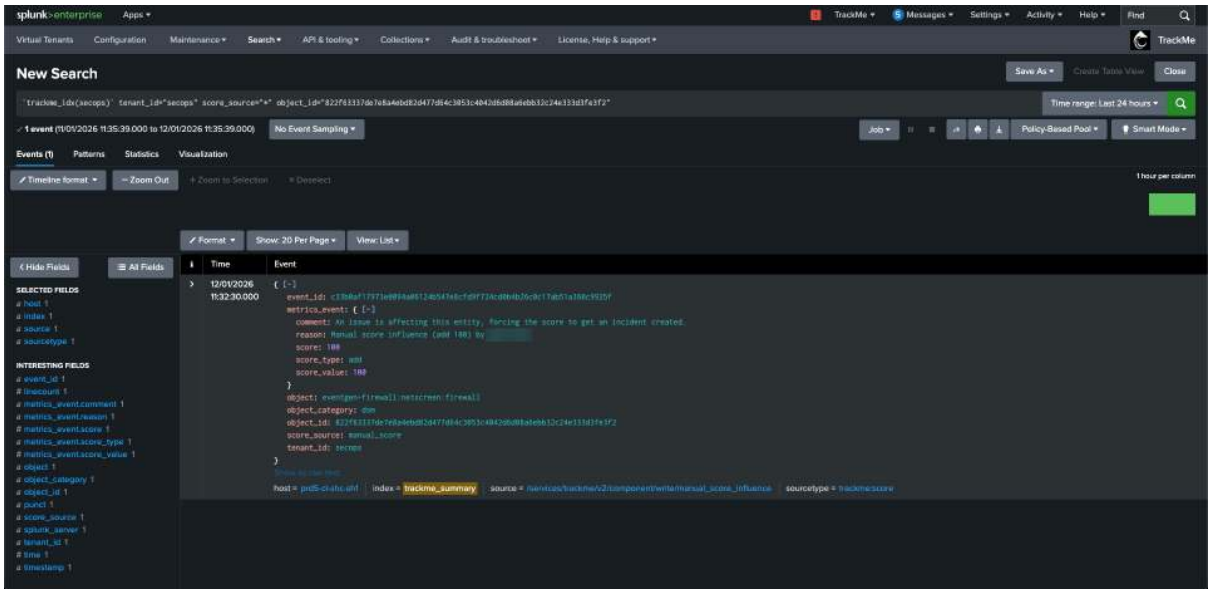
- **Timestamp**: When the anomaly was detected
- **Score Value**: The impact score for this anomaly
- **Score Source**: The source of the score (e.g., "delay_threshold_breach", "ml_outliers_detection")
- **Anomaly Details**: Additional context about the anomaly

Viewing Score Events:

You can view the underlying score events for any entity:

1. Click on the impact score value in the entity detail modal or overview table
2. This opens the Score Definition Modal showing the breakdown
3. Click "See score events" link at the bottom
4. This opens a Splunk search showing all score events for the entity in the last 24 hours





Score Event Query Example:

The score events search query looks like:

```
`trackme_idx(tenant_id)` tenant_id="your_tenant_id" score_source="*"␣
↪object_id="your_object_id"
```

The query filters score events for the specific entity and shows: - When each score event was generated - The score value (positive or negative) - The score source - Additional metadata

False Positive Management

IBA provides powerful false positive management capabilities, allowing you to suppress alerts while maintaining full audit trail transparency.

Global False Positive (Entity-Level):

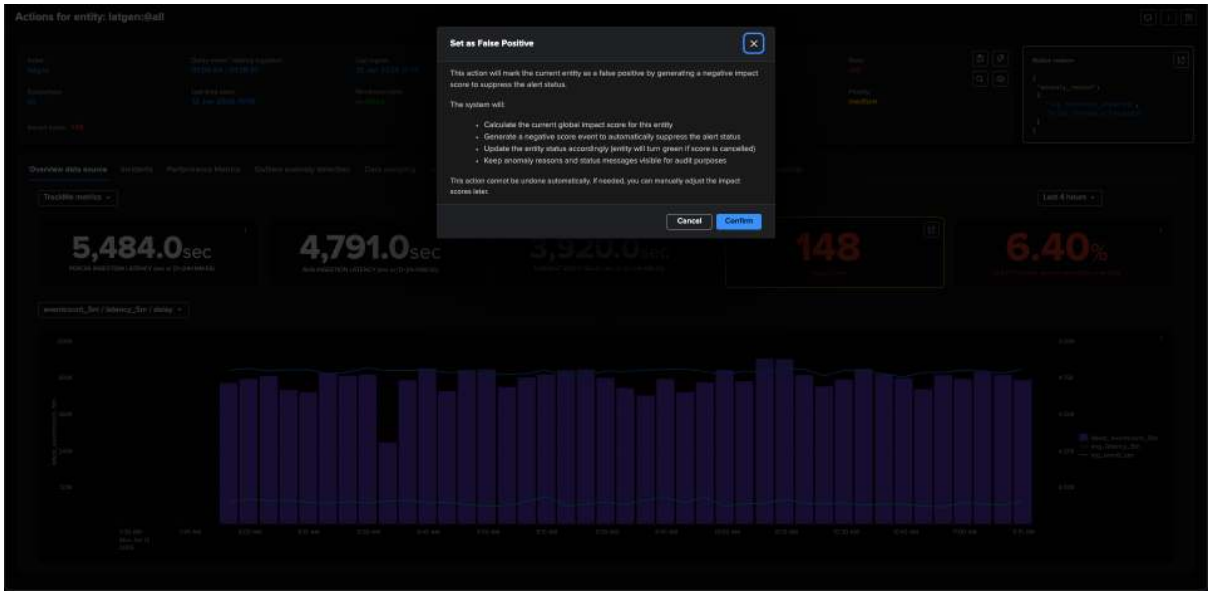
To suppress all alerts for an entity:

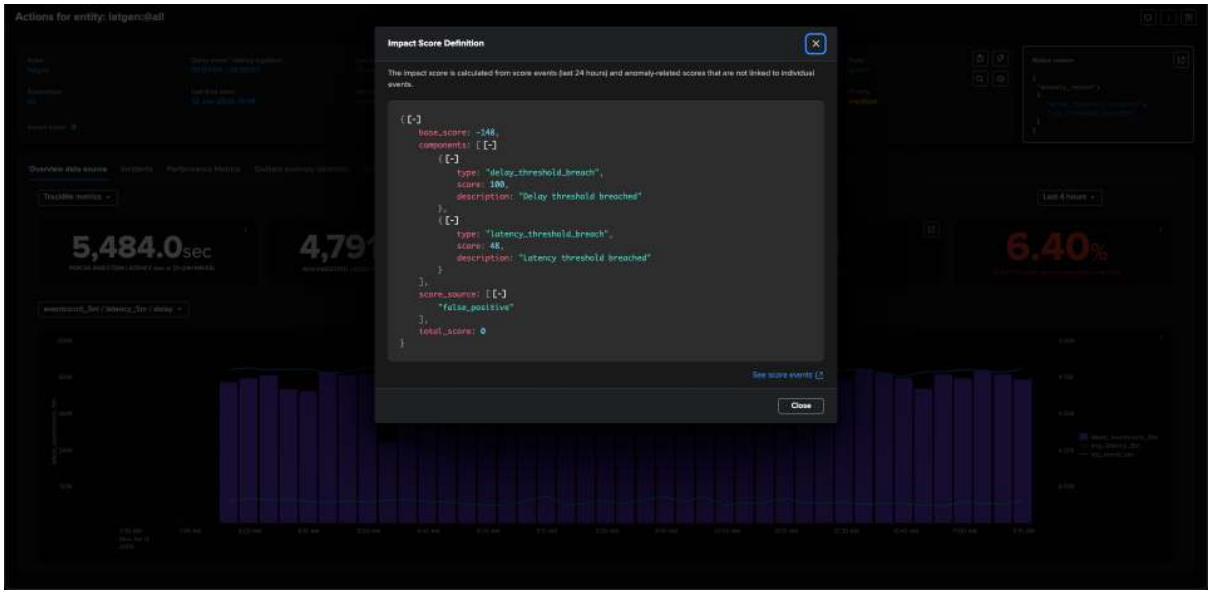
1. Open the entity detail modal
2. Click the kebab menu (three dots)

3. Select “Set as false positive” (first action in “Actions” category)
4. The system generates a negative score event that cancels out all positive scores
5. The entity transitions to green status when *total_score <= 0*
6. Anomaly reasons remain visible for audit purposes

Important Notes:

- False positive actions require power/admin user privileges
- Anomaly reasons are preserved even when suppressed (for audit trail)
- Score events are traceable - you can see what was suppressed and when
- False positives can be reversed by adjusting scores manually if needed





Outliers False Positive:

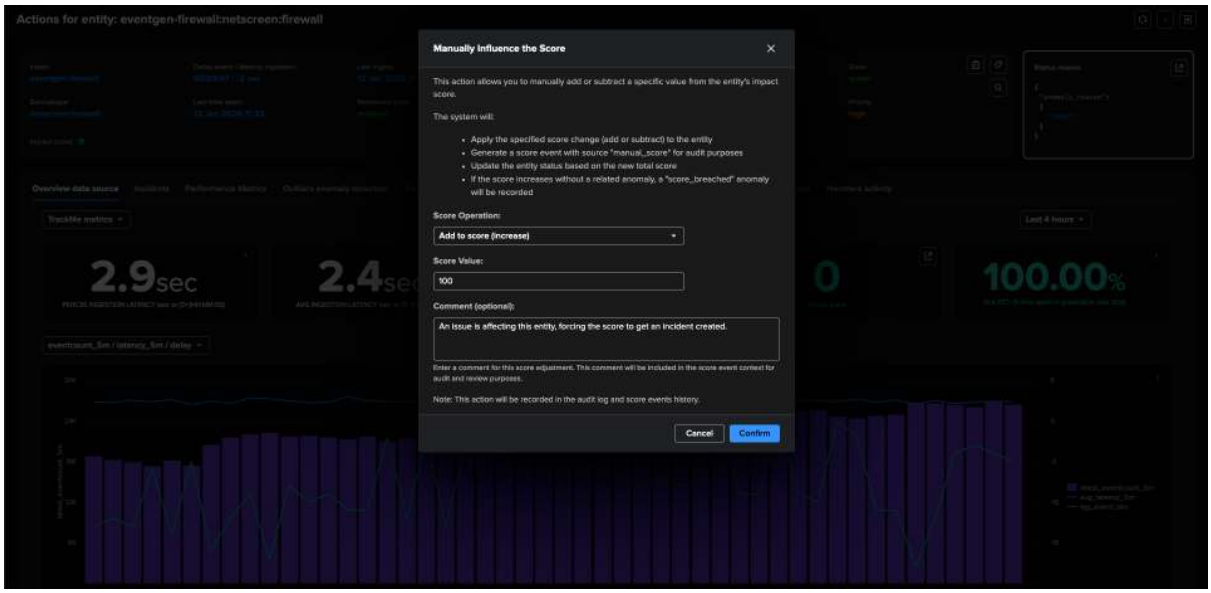
When ML outliers are detected but you determine they are false positives:

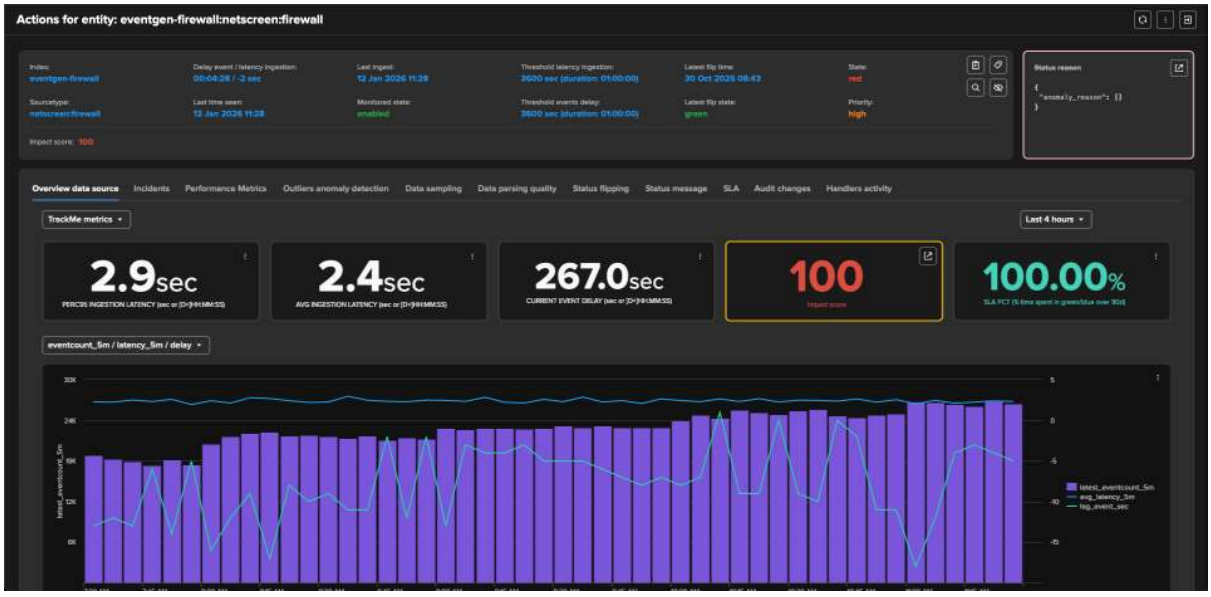
1. Navigate to the Outliers overview tab
2. Click “Set as false positive” button (or use the kebab menu)

3. The system generates a negative score event that cancels out the positive outlier score
4. The entity state transitions based on the resulting score: - If *score_outliers* >= *100*: Red status - If *score_outliers* > *0* and < *100*: Orange status (with *ml_outliers_detection* in anomaly reasons) - If *score_outliers* <= *0*: Green status (outliers suppressed)

Manual Score Influence

For fine-grained control, power/admin users can manually add or subtract specific values from an entity's impact score.





Use Cases:

- Manually adjusting scores for entities that need special attention
- Fine-tuning entity status without triggering false positive suppression
- Adding temporary score adjustments for testing or investigation
- Subtracting scores to reduce alert severity

How to Use Manual Score Influence:

1. Open the entity detail modal

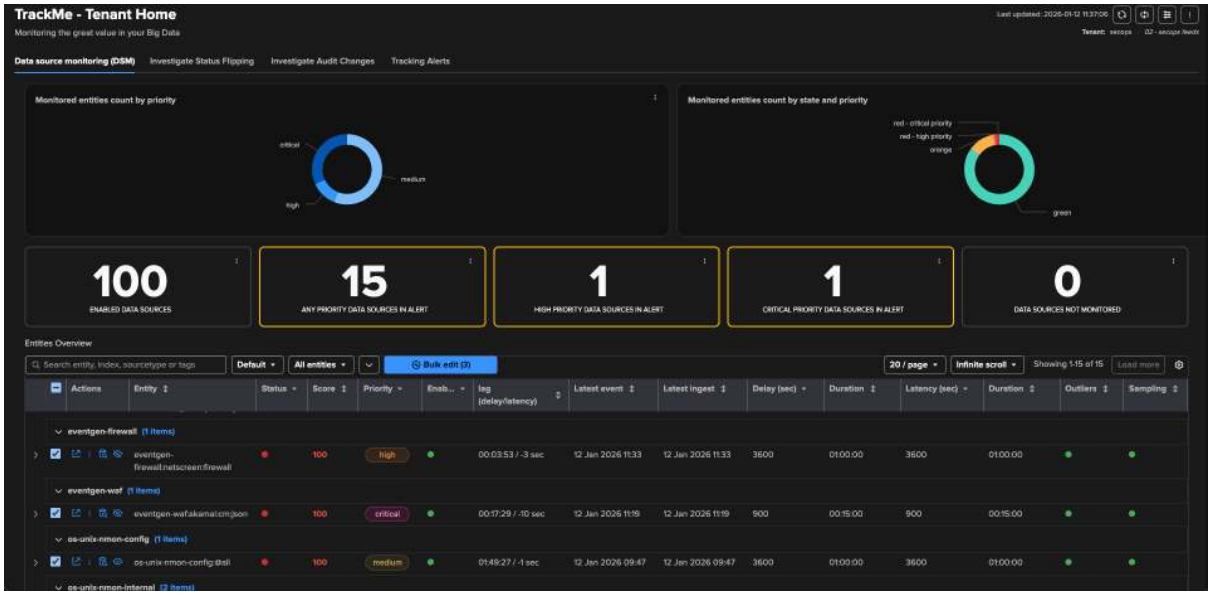
2. Click the kebab menu (three dots)
3. Select “Manually influence the score” (second action in “Actions” category)
4. Choose operation type: - **Add to score**: Increase the score (positive value) - **Subtract from score**: Decrease the score (negative value)
5. Enter a value (1-100)
6. The system generates a score event with *score_source=”manual_score”*
7. Entity status updates based on the new total score

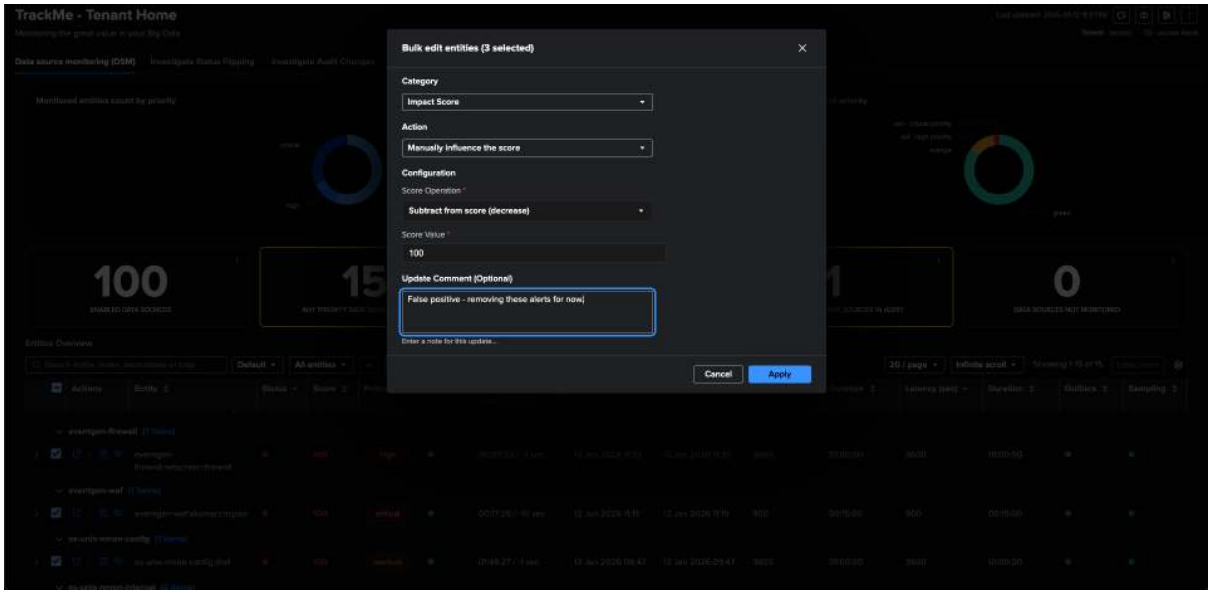
Important Notes:

- Manual score events are included in the score definition breakdown
- If manual score increases cause positive score without related anomalies, a *score_breached* anomaly is recorded
- Manual score events are traceable in score events search
- Manual scores persist until they expire (24-hour window) or are adjusted

Bulk Operations

IBA supports bulk operations for managing impact scores across multiple entities efficiently.





Bulk False Positive:

1. Select multiple entities in the overview table
2. Click “Bulk edit” button
3. Select “Set as false positive” action (first in “Impact Score” category)
4. The system sequentially processes each entity
5. Summary toast notification shows success/skip/error counts

Bulk Manual Score Influence:

1. Select multiple entities in the overview table
2. Click “Bulk edit” button
3. Select “Manually influence the score” action (second in “Impact Score” category)
4. Choose operation type (add/subtract) and enter score value
5. The system sequentially processes each entity
6. Summary toast notification shows success/skip/error counts

Important Notes:

- Bulk operations include a 500ms delay between successful calls to allow Splunk to ingest metrics
- Individual failures don’t stop the entire operation
- API responses indicating “no action needed” are ignored (counted as skips)
- Summary notifications provide clear feedback on the operation results

Impact Scoring for Data Hosts Monitoring (DHM)

The Data Hosts Monitoring (DHM) component tracks data from a host perspective (sourcetypes associated with hosts) and uses similar IBA principles as DSM.

DHM Anomaly Types and Default Impact Scores:

Anomaly Type	Default Score	Description
Delay Threshold Breach	100	Data flow is interrupted - no new events from host (static delay policy)
Variable Delay Threshold Breach	100	Data flow is interrupted - no new events from host within the active variable delay slot threshold (variable delay policy, since v2.3.12)
Latency Threshold Breach	48	Events from host are being indexed but with high latency
Future Tolerance Breach	36	Events detected with timestamps too far in the future
ML Outliers Detection	36 (default)	Machine Learning models detected abnormal volume patterns

Key Differences from DSM:

- DHM focuses on host-level tracking rather than index/sourcetype combinations
- DHM does not include "Data Sampling Anomaly" or "Min Hosts Dcount Breach" anomaly types
- Otherwise, the scoring mechanism works identically to DSM

Configuring Impact Scores for DHM:

The configuration process is identical to DSM:

1. During Virtual Tenant creation, select "splk-dhm" component
2. Configure impact scores in the "Impact score configuration" section: - **Outliers - Default Impact Score**: Default: 36 - **DHM - Delay Threshold Breach Impact Score**: Default: 100 - **DHM - Latency Threshold Breach Impact Score**: Default: 48 - **DHM - Future Tolerance Breach Impact Score**: Default: 36

Per-Entity Score Weight Overrides:

Like DSM, DHM also supports per-entity score weight overrides through the lagging policy configuration. You can override delay and latency impact score weights for individual host entities using the same process described in the DSM section above.

Best Practices for DHM:

- Similar to DSM, keep Delay Threshold Breach at 100 (critical)
- Adjust Latency Threshold Breach based on your requirements (default: 48)
- Consider host-specific requirements when configuring scores
- Use false positive management for known host maintenance windows

Extending IBA to Other TrackMe Components

While this guide focuses on feeds tracking (DSM and DHM), IBA extends to all TrackMe components. Here's a brief overview:

Metrics Host Monitoring (MHM):

- **Metric Alert**: Default score 100 (critical metric threshold breached)
- **Future Tolerance Breach**: Default score 36

Flex Objects (FLX):

- **Inactive**: Default score 100 (entity is inactive)
- **Status Not Met**: Default score 100 (custom status condition not met)
- **Threshold Breach**: Configurable per threshold (default: 100)

Fields Quality Monitoring (FQM):

- **Status Not Met**: Default score 100 (quality condition not met)

- **Threshold Breach**: Configurable per threshold (default: 100)

Workload (WLK):

- **Skipping Searches**: Default score 100
- **Execution Errors**: Default score 100
- **Orphan Search**: Default score 100
- **Execution Delayed**: Default score 100
- **Out of Monitoring Times**: Default score 100
- **Status Not Met**: Default score 100

Configuration for Other Components:

The impact score configuration process is similar across all components:

1. Create or manage a Virtual Tenant for the component
2. Configure impact scores in the wizard or management UI
3. Adjust scores based on your priorities and requirements
4. Use false positive management and manual score influence as needed

Score Definition Modal and Transparency

The Score Definition Modal provides complete transparency into how impact scores are calculated.

Accessing the Score Definition Modal:

- Click on the impact score value in the entity detail modal (cartouche)
- Click on the impact score value in the overview table
- Click the link icon on the Impact Score single view card in overview tabs

What the Modal Shows:

1. **Explanation Text**: "The impact score is calculated from score events and anomaly-related scores that are not linked to individual events."
2. **Score Definition Breakdown**: JSONTree component showing: - *base_score*: Base score from score events - *components*: Array of anomaly components with scores - *score_outliers*: Outlier score if present - *score_source*: Array of score sources - *total_score*: Final calculated score
3. **Score Events Link**: "See score events" link that opens a Splunk search showing all score events for the entity in the last 24 hours

Understanding the Breakdown:

Each component in the score definition includes: - **type**: The anomaly type (e.g., "delay_threshold_breach") - **score**: The impact score for this anomaly - **description**: Human-readable description

This breakdown makes it easy to understand: - Why an entity is in a particular state - Which anomalies are contributing to the score - How much each anomaly contributes - Whether false positives or manual scores are affecting the total

Best Practices and Recommendations

Getting Started:

1. **Start with Defaults**: Begin with default impact scores and observe behavior
2. **Monitor False Positives**: Track false positive rates and adjust scores accordingly
3. **Use Score Definition Modal**: Regularly review score breakdowns to understand entity states
4. **Leverage False Positive Management**: Use false positive suppression for known issues

5. **Gradual Tuning**: Adjust scores incrementally based on your environment's needs

Scoring Strategy:

- **Critical Anomalies**: Keep at 100 (e.g., delay threshold breach, inactive entities)
- **Warning Anomalies**: Use 36-60 range (e.g., latency, outliers, future tolerance)
- **Quality Anomalies**: Adjust based on quality requirements (e.g., data sampling)
- **Balance Detection and False Positives**: Adjust ML outlier scores based on detection accuracy

Operational Practices:

- **Regular Review**: Periodically review score definitions to ensure they match your priorities
- **Documentation**: Document any custom score configurations for your team
- **Audit Trail**: Use score events search to investigate entity state changes
- **Testing**: Use manual score influence to test alerting thresholds before making permanent changes

Troubleshooting:

- **Unexpected Red Status**: Check score definition modal to see which anomalies contributed
- **False Positives**: Use false positive management to suppress known issues
- **Score Not Updating**: Verify score events are being generated (check score events search)
- **Configuration Not Applied**: Ensure Virtual Tenant account has impact score fields configured

Conclusion

Impact-Based Alerting (IBA) represents a fundamental shift in how TrackMe evaluates and alerts on data quality issues. By providing:

- **Flexible Configuration**: Fine-tune impact scores per tenant, component, and anomaly type
- **Complete Transparency**: Detailed score breakdowns and traceable score events
- **False Positive Management**: One-click suppression with full audit trail
- **Manual Control**: Fine-grained score adjustments for special cases
- **Bulk Operations**: Efficient management across multiple entities

IBA puts you in complete control of how TrackMe evaluates entity health, making alerting smarter, more tunable, and far more actionable.

Next Steps:

- Create or update Virtual Tenants with impact score configuration
- Monitor entity states and review score definitions regularly
- Adjust impact scores based on your environment's priorities
- Leverage false positive management and manual score influence as needed
- Explore IBA features for other TrackMe components (MHM, FLX, FQM, WLK)

For more information about specific TrackMe components and advanced IBA features, refer to the TrackMe administration and user guides.

QUICK START - Design and automate through lookup knowledge

Automate priority, tags and SLA management through a single lookup

- This quickstart guides you through the design and implementation of **lookup-based policies** in TrackMe, a powerful approach to automate the management of priority, tags, and SLA classes across your monitored entities.
- The key idea: **a single lookup file** (CSV or KVstore) containing your knowledge about your Splunk environment can drive **all three policy types** at once — priority assignment, tag automation, and SLA classification.
- **This quickstart provides two end-to-end examples:**
  - **Data source monitoring (DSM):** Using an index-based lookup to assign priorities, tags, and SLA classes to data source entities
  - **Data host monitoring (DHM):** Using a host-based lookup to assign priorities, tags, and SLA classes to data host entities
- **Prerequisites:** An existing Virtual Tenant with discovered entities, and a lookup file uploaded to Splunk (via the Splunk App for Lookup File Editing or any other method).

Hint

For detailed documentation on each individual policy type, refer to:

- *Managing priority via policy* — Priority policies
- *Accessing, defining and managing tags policies* — Tags policies
- *Defining SLA policies to assign SLA classes automatically* — SLA policies

The concept: one lookup, three policies

The idea behind lookup-based policies is simple: you maintain a single lookup file that contains your knowledge about your Splunk environment, and TrackMe uses it to automate the management of priority, tags, and SLA classes across your monitored entities.

Consider the following lookup file `example_cmdb_indexes.csv` with three columns:

Example:

index	priority	tags
os	low	os
prd*_*_linux	critical	production
webserver	critical	web

From this single lookup, TrackMe can create three policies:

- **Priority policy:** Map the `index` column to entity fields, and use the `priority` column to assign priority levels (low, medium, high, critical) to matching entities.
- **Tags policy:** Using the same lookup and field mapping, use the `tags` column with a comma separator to assign one or more tags to matching entities.
- **SLA policy:** Using the same lookup and field mapping, use the `priority` column with **value mappings** to translate priority levels into SLA classes (e.g., `critical` → `gold`, `high` → `silver`, `low` → `platinum`).

Hint

This approach is particularly powerful because:

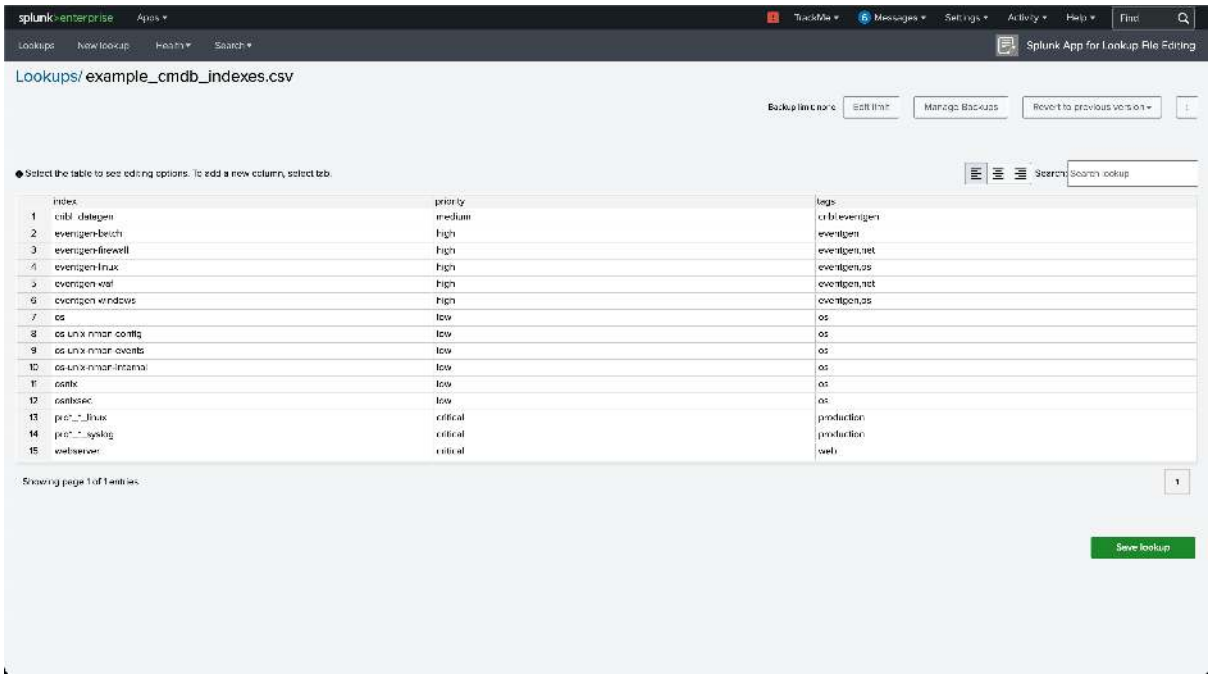
- All three policies share the same lookup file — a single source of truth for your Splunk knowledge.
- Updates to the lookup are automatically reflected when the policy trackers run.
- Field mappings support **wildcard** matching (using `*` and `?` patterns), so you can match complex index or host naming conventions with simple patterns.
- Each policy includes a **simulation mode** that lets you preview the results before applying changes.

Data source monitoring (DSM) example

In this example, we will demonstrate the complete workflow for data source monitoring, using the `example_cmdb_indexes.csv` lookup shown above. We will map the `index` field in the lookup to the `data_index` entity field, which allows matching data source entities by the index they belong to.

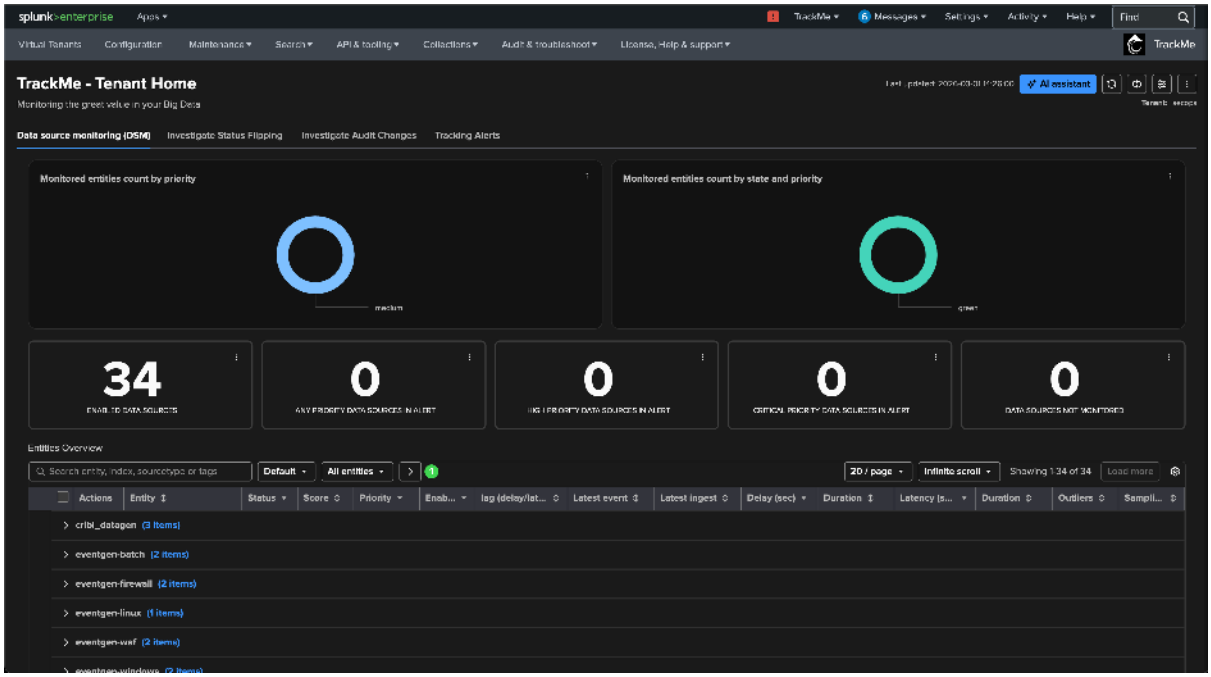
The lookup file

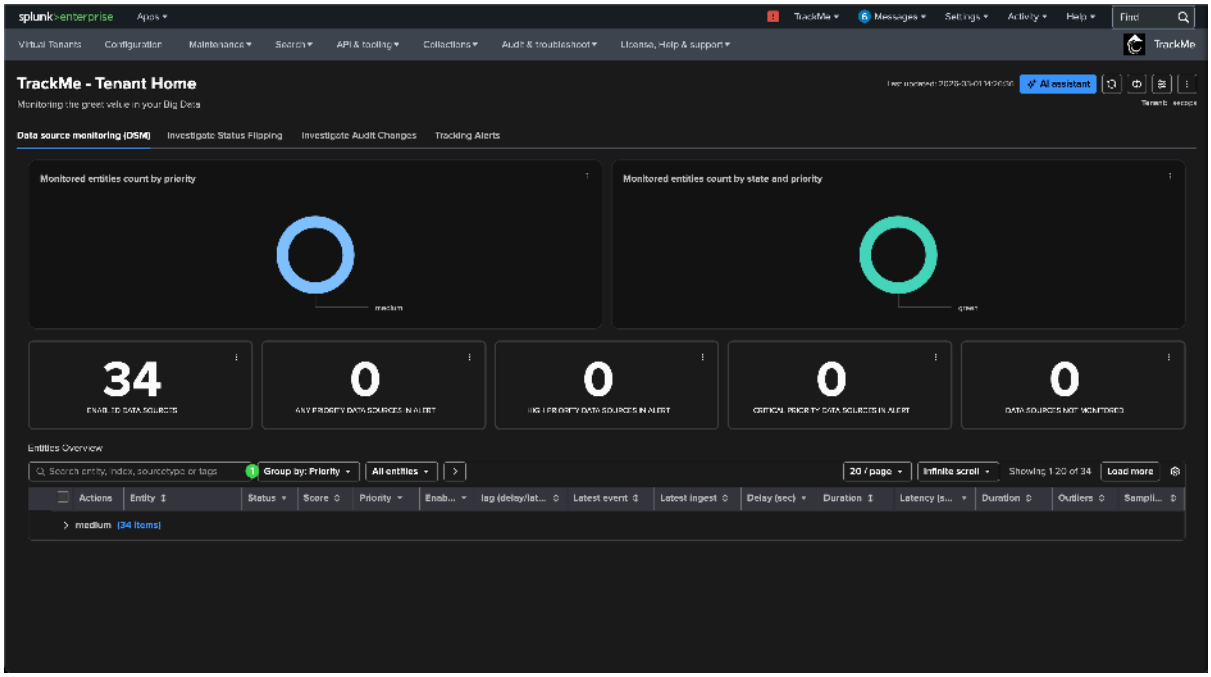
The lookup file `example_cmdb_indexes.csv` is uploaded to Splunk and contains 15 rows mapping indexes to priorities and tags:



Initial state

Before creating any policies, all 34 data source entities are at the default priority level (medium) and have no tags or SLA classes assigned:

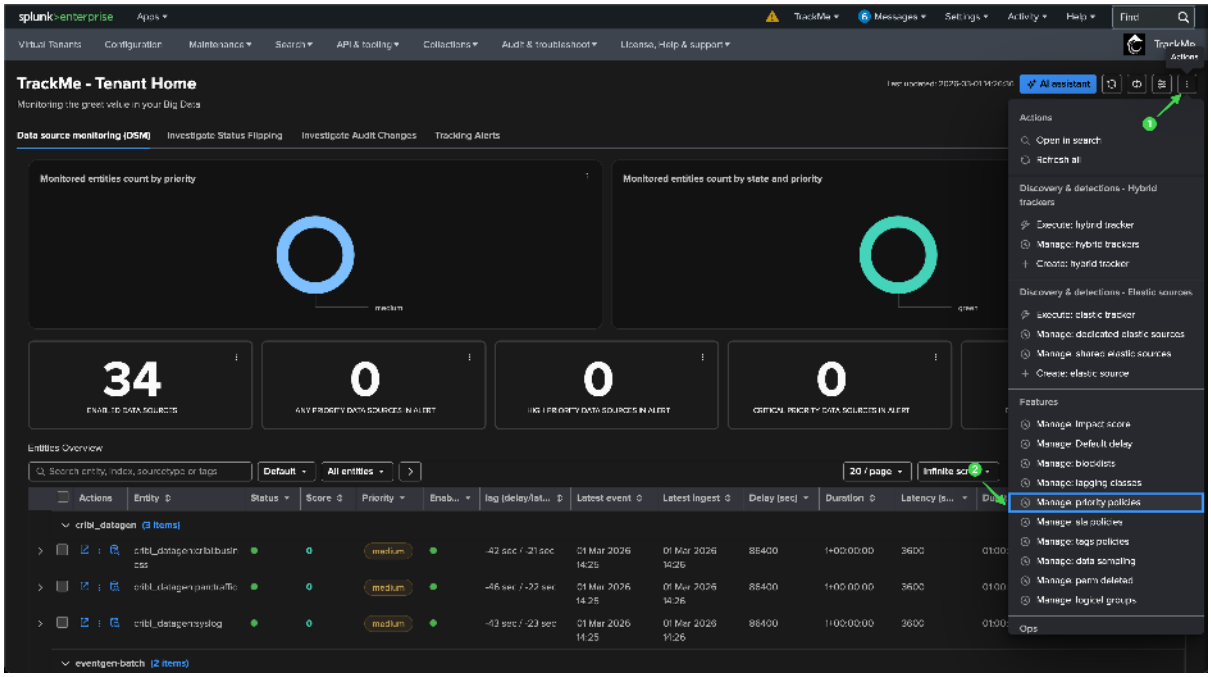


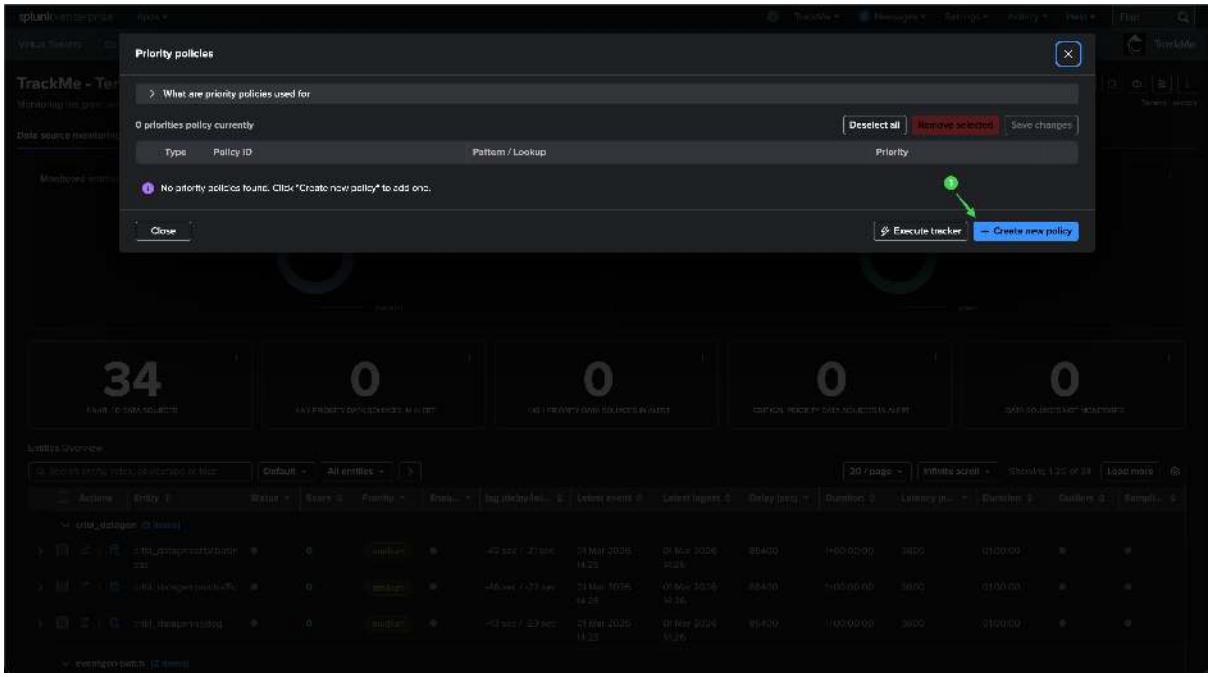


Step 1: Create a priority policy

Access the priority policies screen:

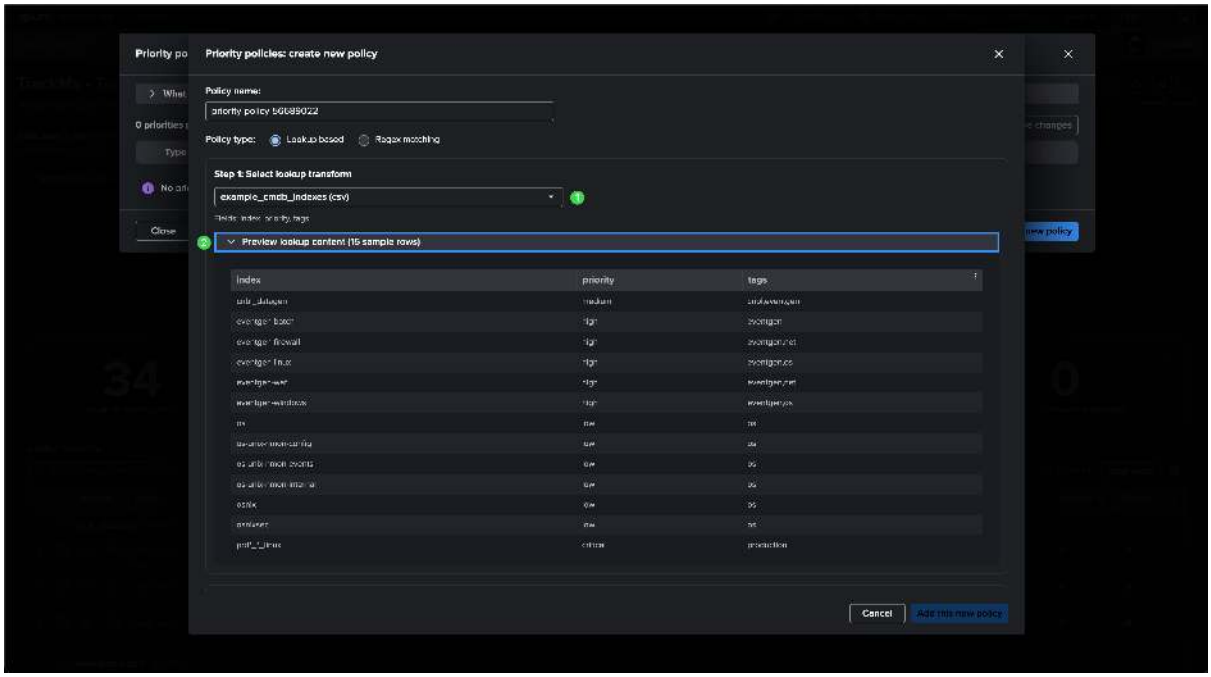
From the Tenant Home page, click the **Actions** button in the top-right corner, then select **Manage priority policies**.



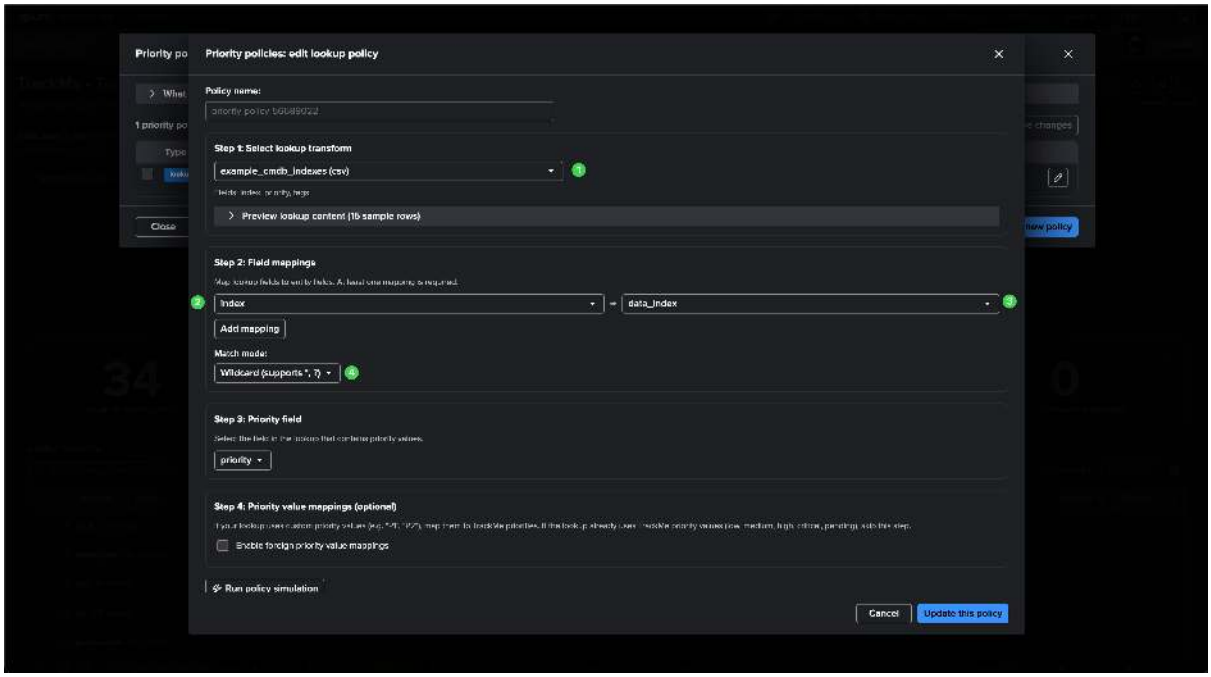


Create a lookup-based priority policy:

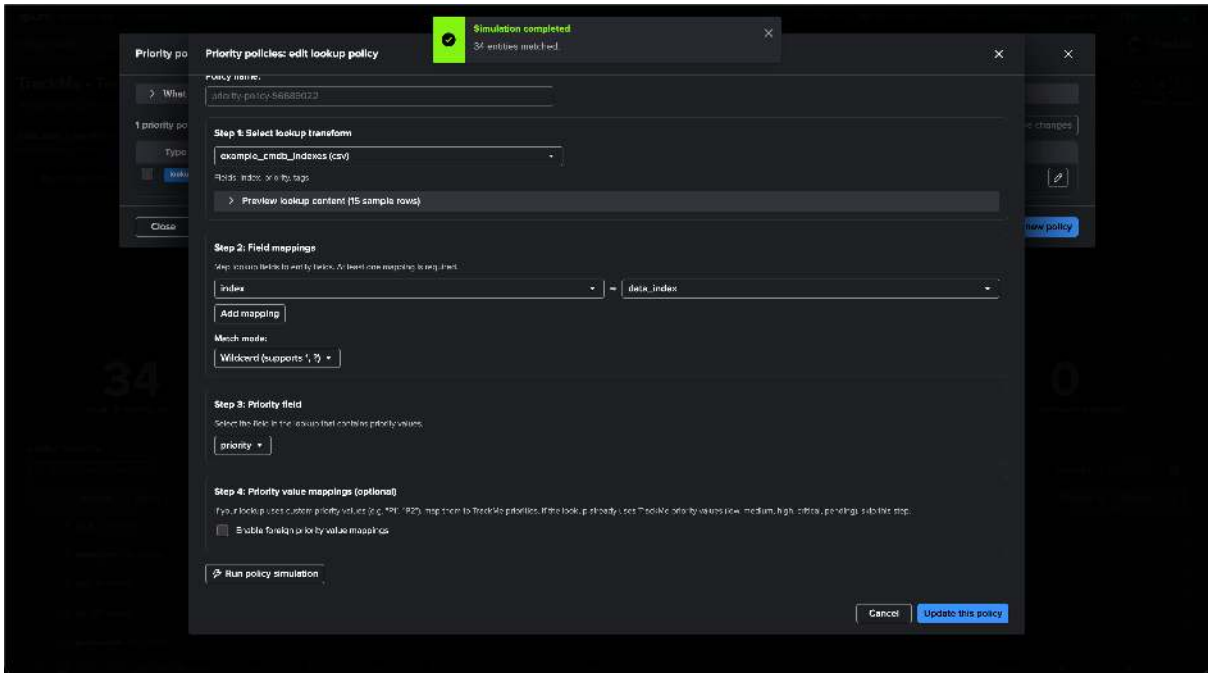
- Click **Create new policy** and select the **Lookup based** mode
- In **Step 1**, select the lookup transform `example_cmdb_indexes (csv)` — TrackMe lists all available lookup transforms and shows a preview of sample rows
- In **Step 2**, configure the **field mapping**: map the lookup field `index` to the entity field `data_index`, and select the **match mode** (Wildcard or Exact)
- In **Step 3**, select `priority` as the **priority field** — the lookup already uses TrackMe priority values (low, medium, high, critical), so no value mappings are needed
- In **Step 4**, priority value mappings are optional and not required in this example since the lookup already uses TrackMe-compatible priority values



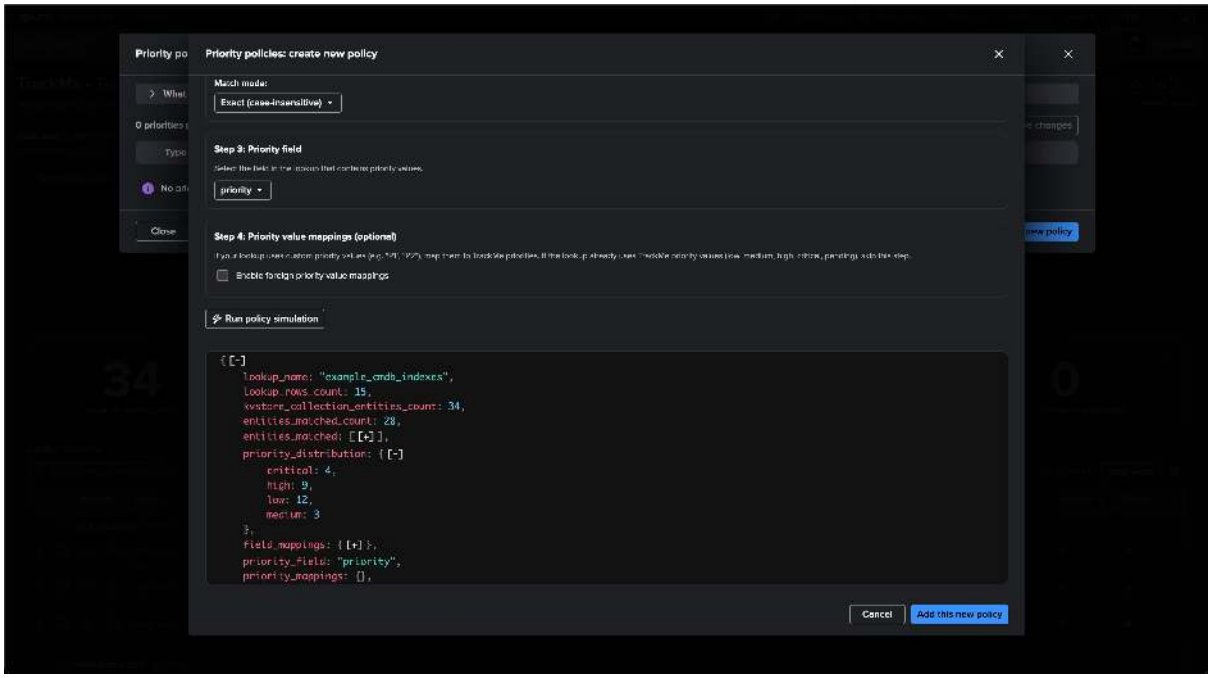
Priority policies: create new policy
Policy name:
Policy type:
Lookup based
Regex matching
Step 1: Select lookup transform
example_cmdb_indexes (csv)
Preview lookup content (15 sample rows)
index
priority
tags
Cancel



Priority policies: edit lookup policy
Policy name:
Step 1: Select lookup transform
example_cmdb_indexes (csv)
Preview lookup content (15 sample rows)
Step 2: Field mappings
index
data_index
Add mapping
Match mode:
Wildcard (supports *, ?)
Step 3: Priority field
priority
Step 4: Priority value mappings (optional)
Enable foreign priority value mappings
Run policy simulation
Cancel
Update this policy

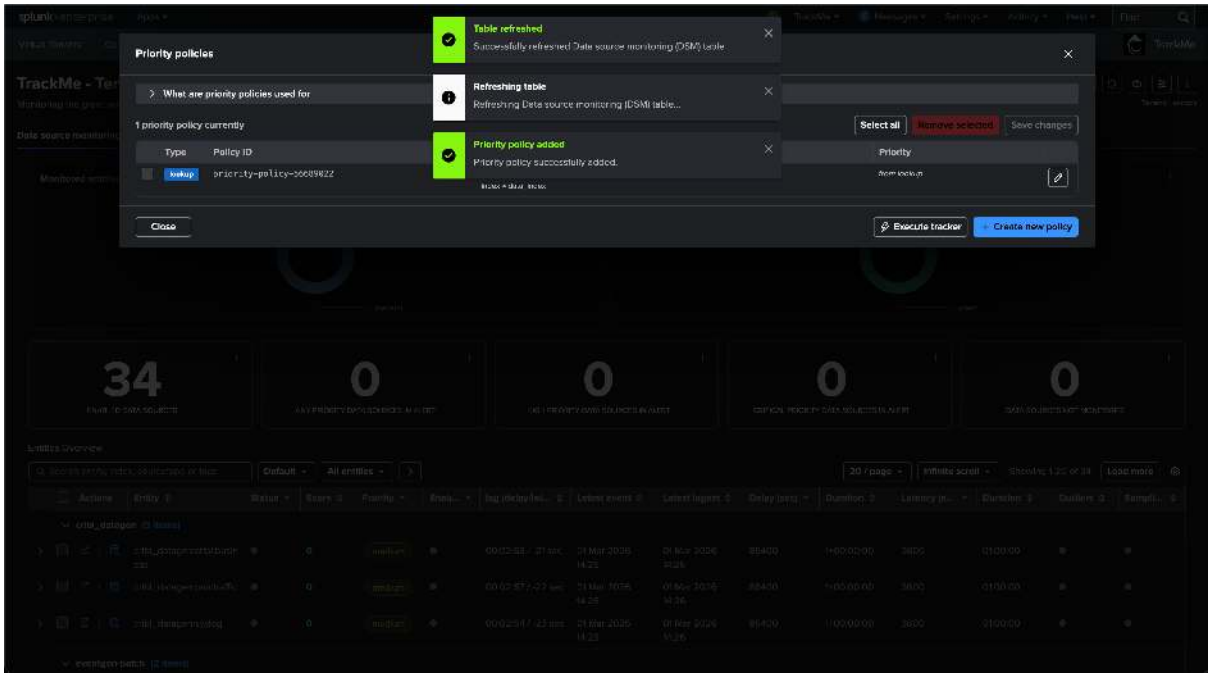


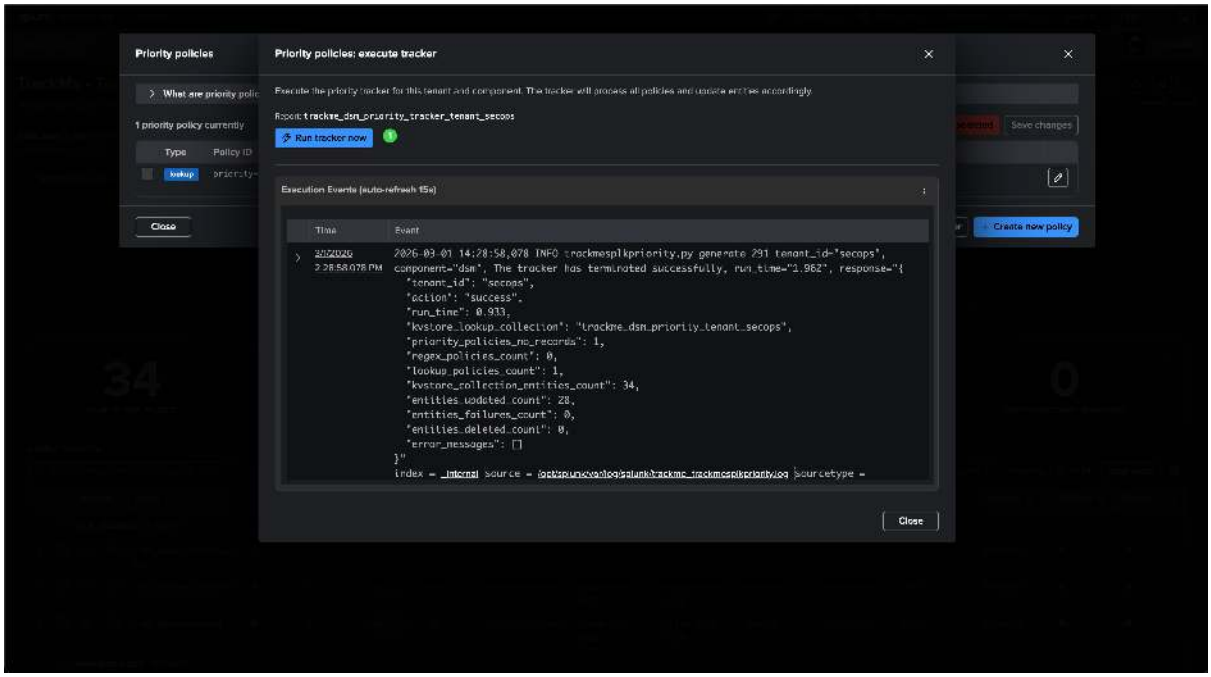
Run the simulation to preview which entities would be matched and what priorities would be assigned. The simulation results show the number of matched entities and the priority distribution:



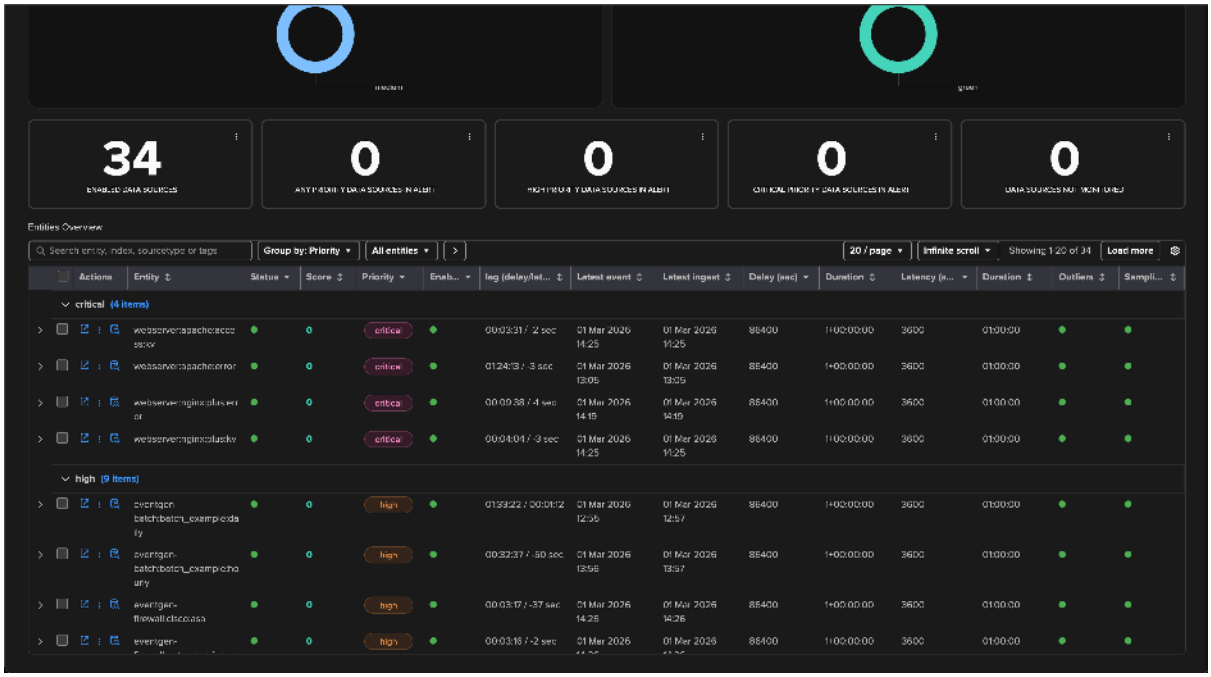
Add the policy and execute the tracker:

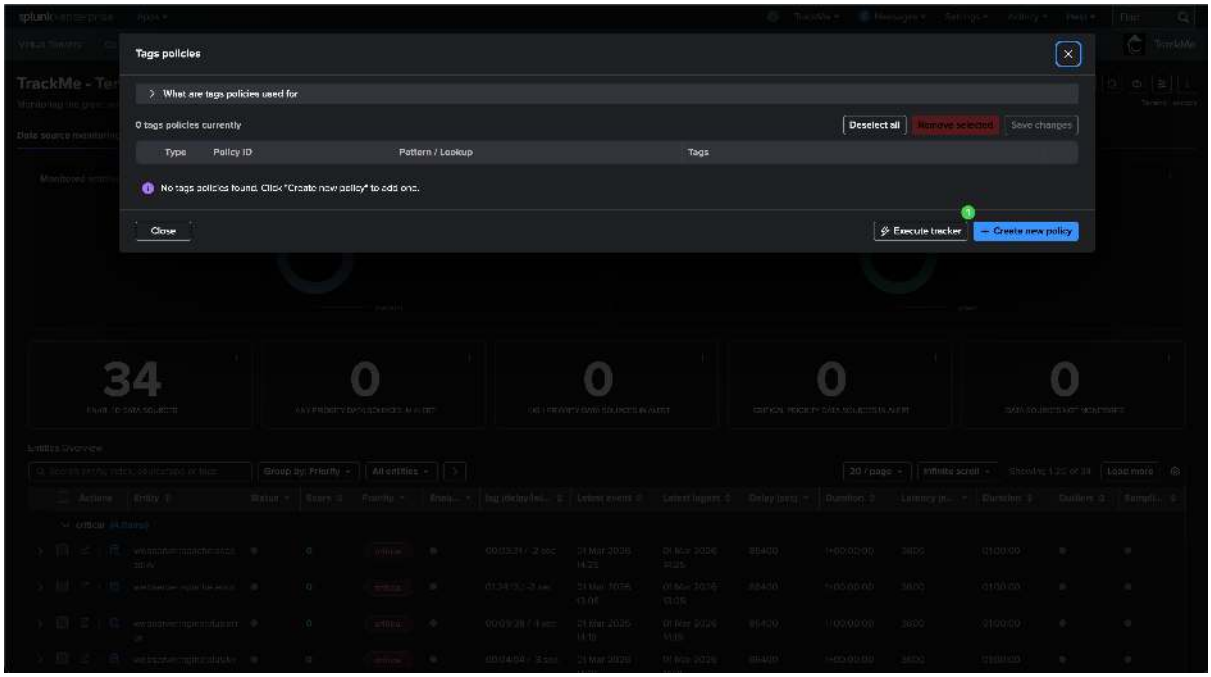
Once the policy is created, click **Execute tracker** to apply the priority assignments to all matching entities:





Result: Entities are now assigned the correct priority levels based on the lookup — the Tenant Home reflects the new priority distribution (critical, high, medium, low):

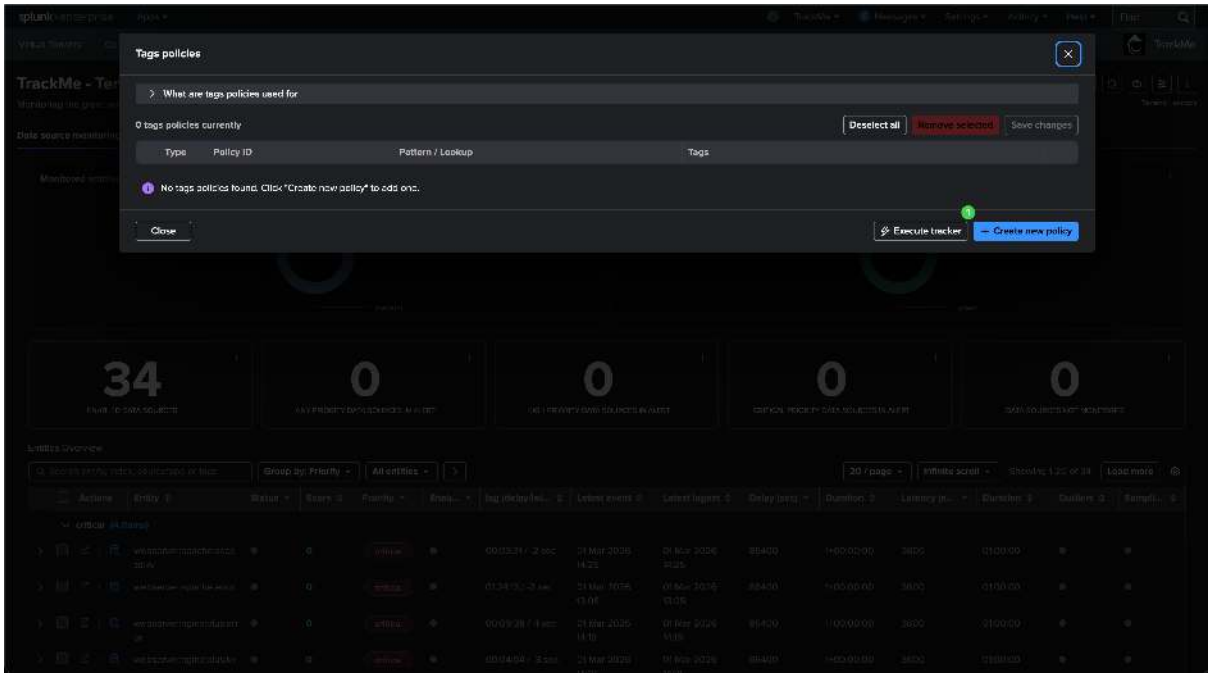




Step 2: Create a tags policy

Access the tags policies screen:

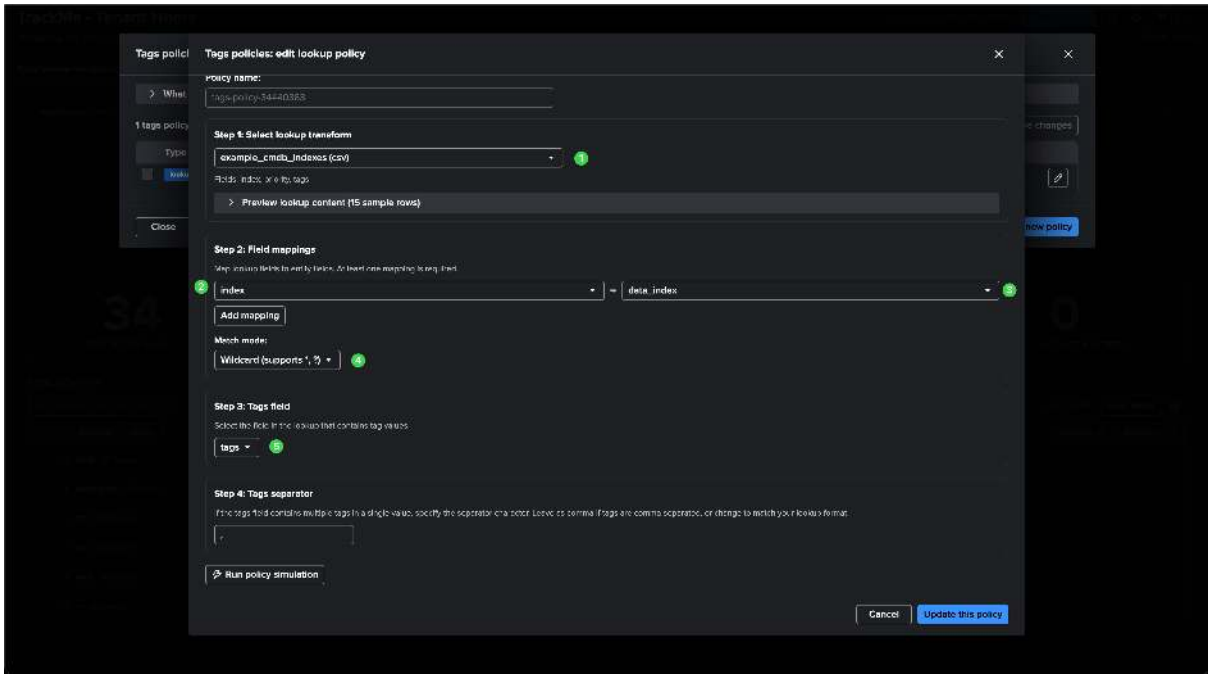
From the Tenant Home page, click the **Actions** button, then select **Manage tags policies**.



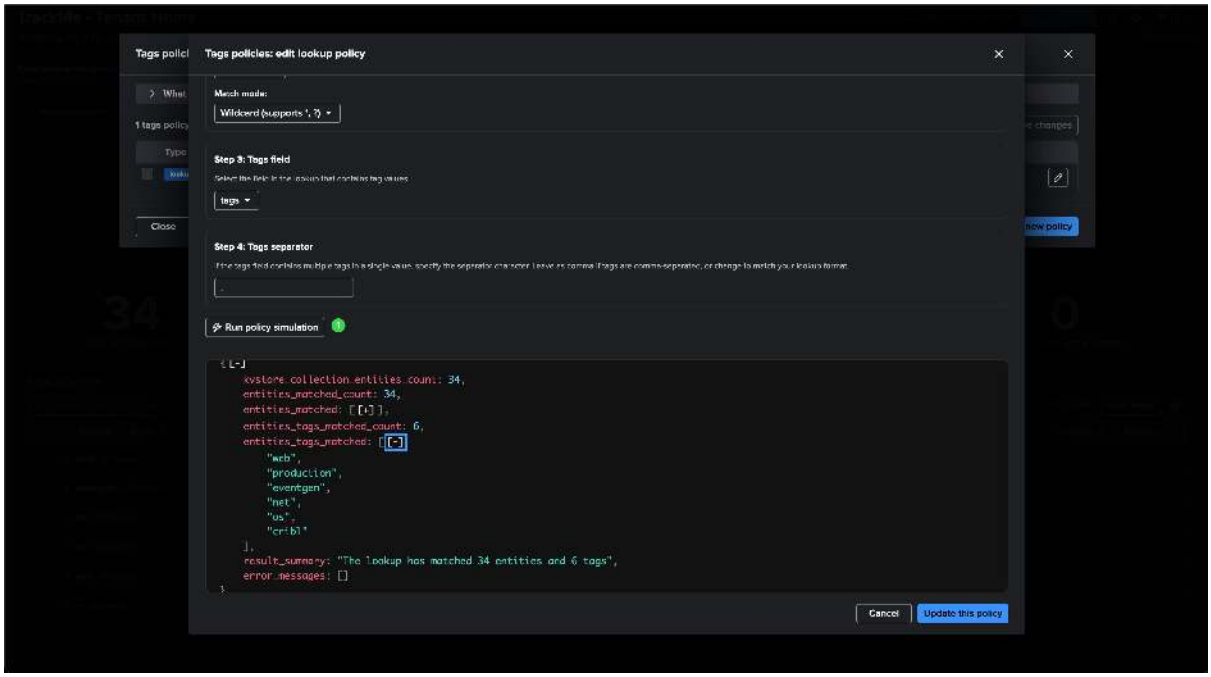
Create a lookup-based tags policy:

Using the same lookup transform, configure the tags policy:

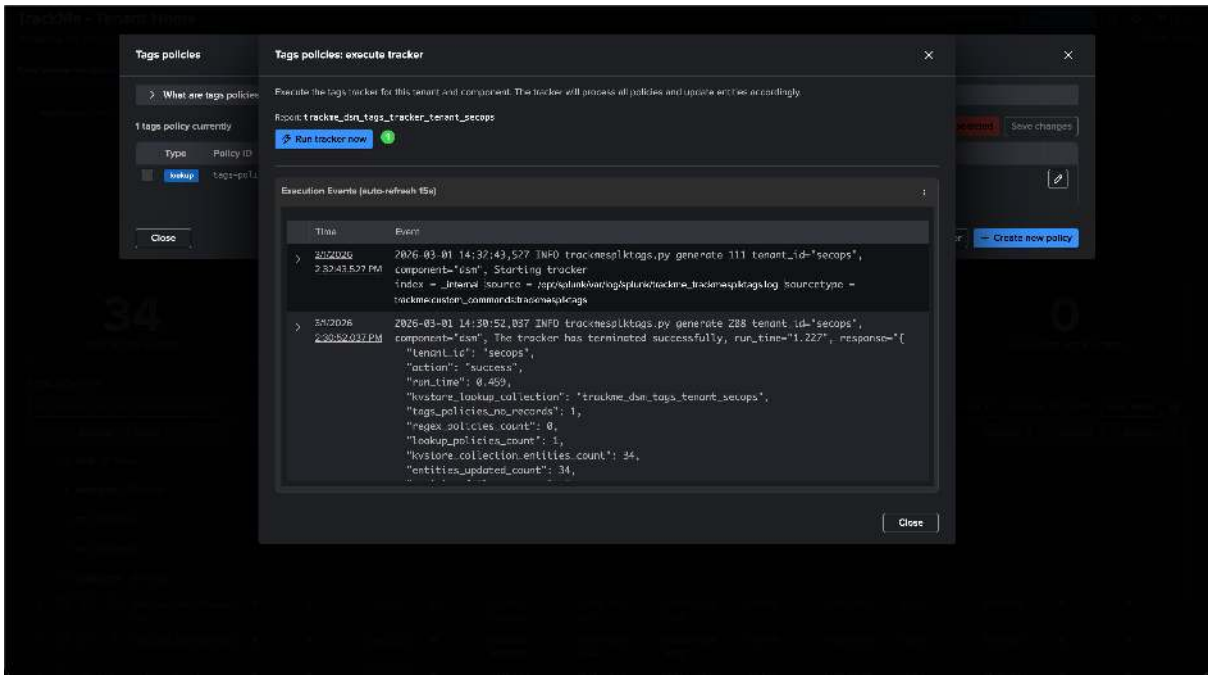
- In **Step 1**, select the same lookup transform `example_cmdb_indexes (csv)`
- In **Step 2**, configure the same **field mapping**: `index` → `data_index`, with **Wildcard** match mode
- In **Step 3**, select `tags` as the **tags field**
- In **Step 4**, set the **tags separator** to `,` (comma) — this tells TrackMe to split the tags column value into individual tags (e.g., `eventgen,os` becomes two separate tags: `eventgen` and `os`)



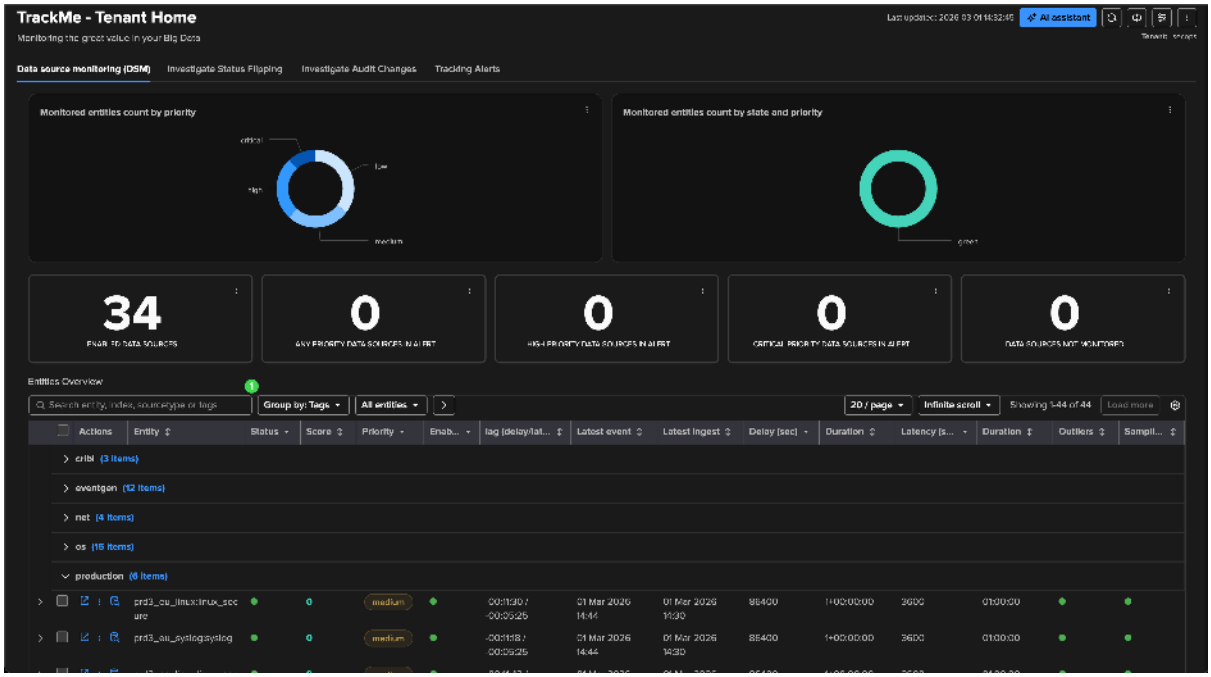
Run the simulation to preview tag assignments. The simulation shows 34 matched entities and 6 distinct tags discovered:

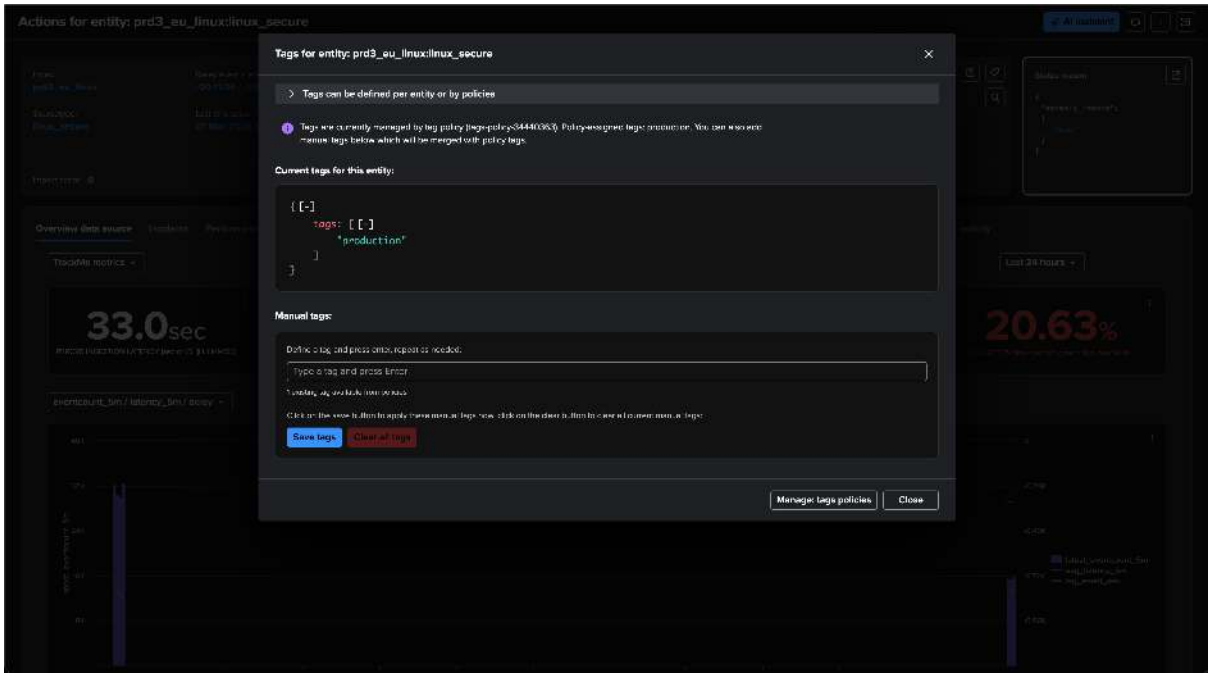


Execute the tracker to apply the tag assignments:



Result: Entities are now tagged, and you can group the Tenant Home by tags to see the tag distribution. Clicking on an entity's tags dialog shows the tags assigned by the policy:

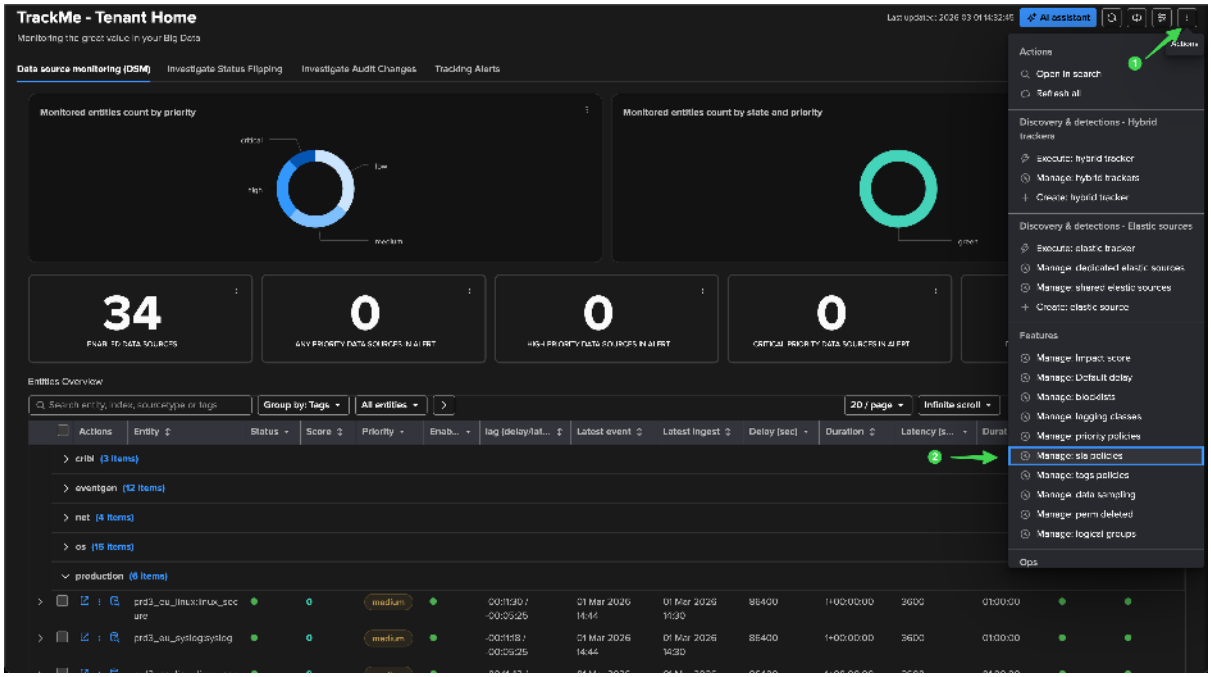




Step 3: Create an SLA policy

Access the SLA policies screen:

From the Tenant Home page, click the **Actions** button, then select **Manage SLA policies**.

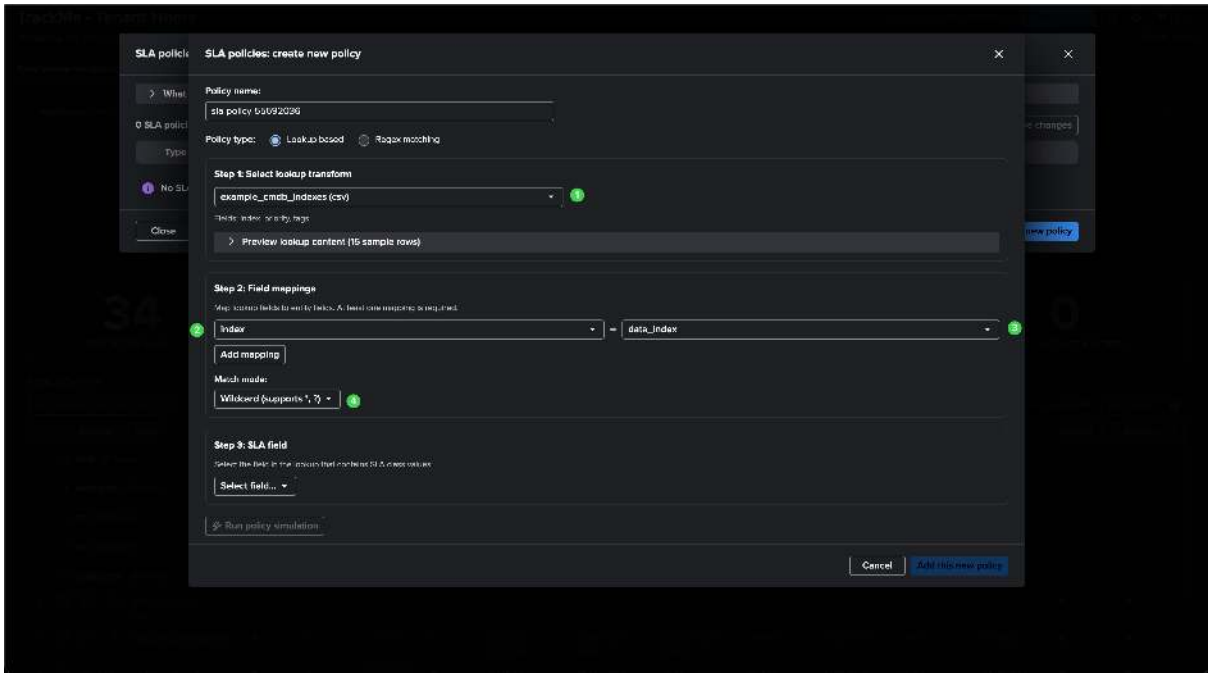


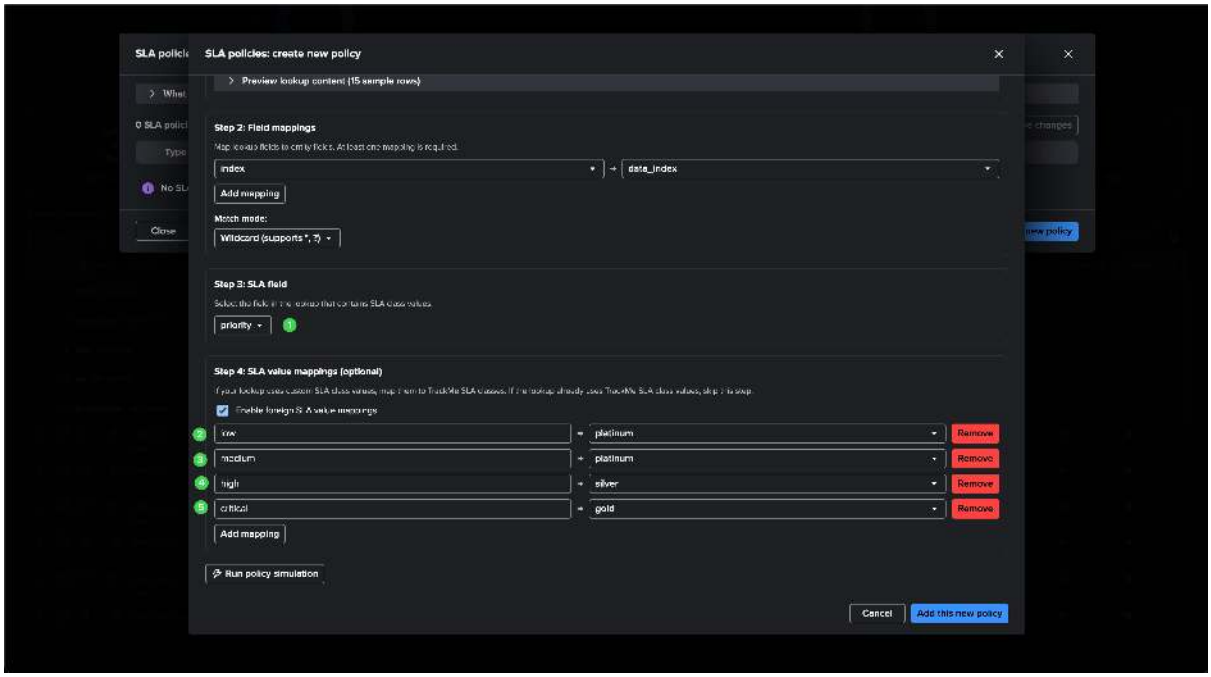
Create a lookup-based SLA policy:

Using the same lookup transform, configure the SLA policy — but this time, we leverage **value mappings** to translate the priority column into SLA classes:

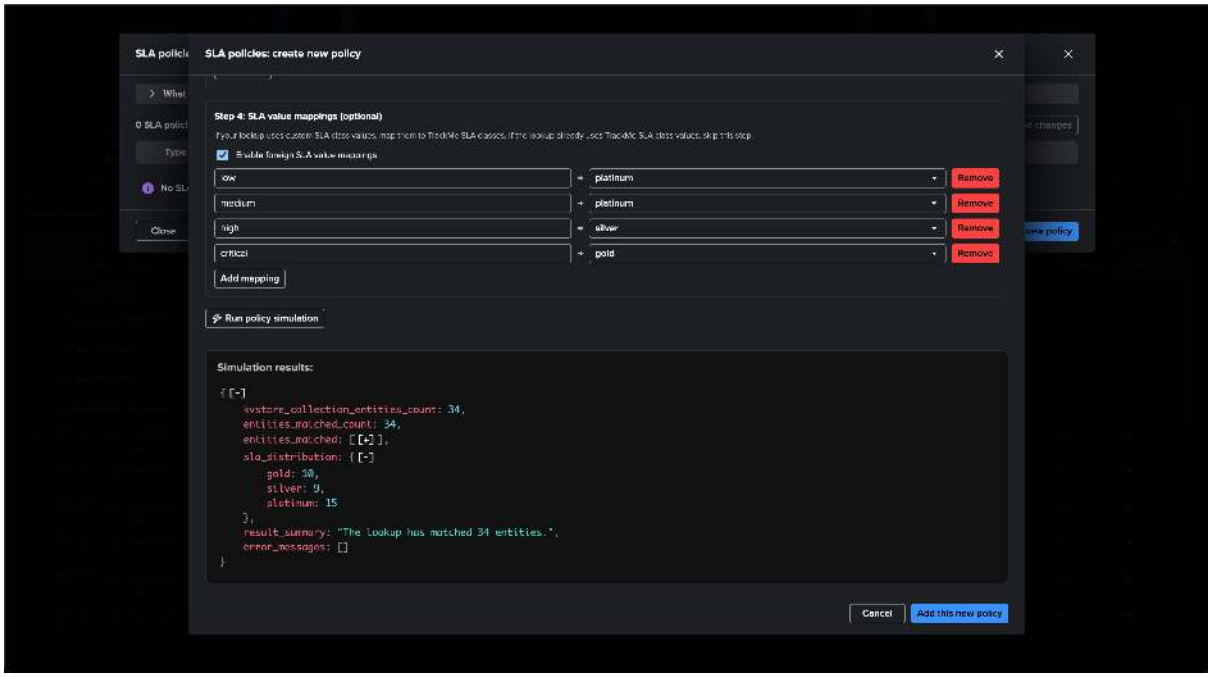
- In **Step 1**, select the same lookup transform `example_cmdb_indexes (csv)`
- In **Step 2**, configure the same **field mapping**: `index` → `data_index`, with **Wildcard** match mode
- In **Step 3**, select `priority` as the **SLA field** — since the lookup does not have a dedicated SLA column, we reuse the priority column and translate values via mappings
- In **Step 4**, enable **SLA value mappings** and define the translation:

Lookup value (priority)	→	SLA class
low	→	platinum
medium	→	platinum
high	→	silver
critical	→	gold

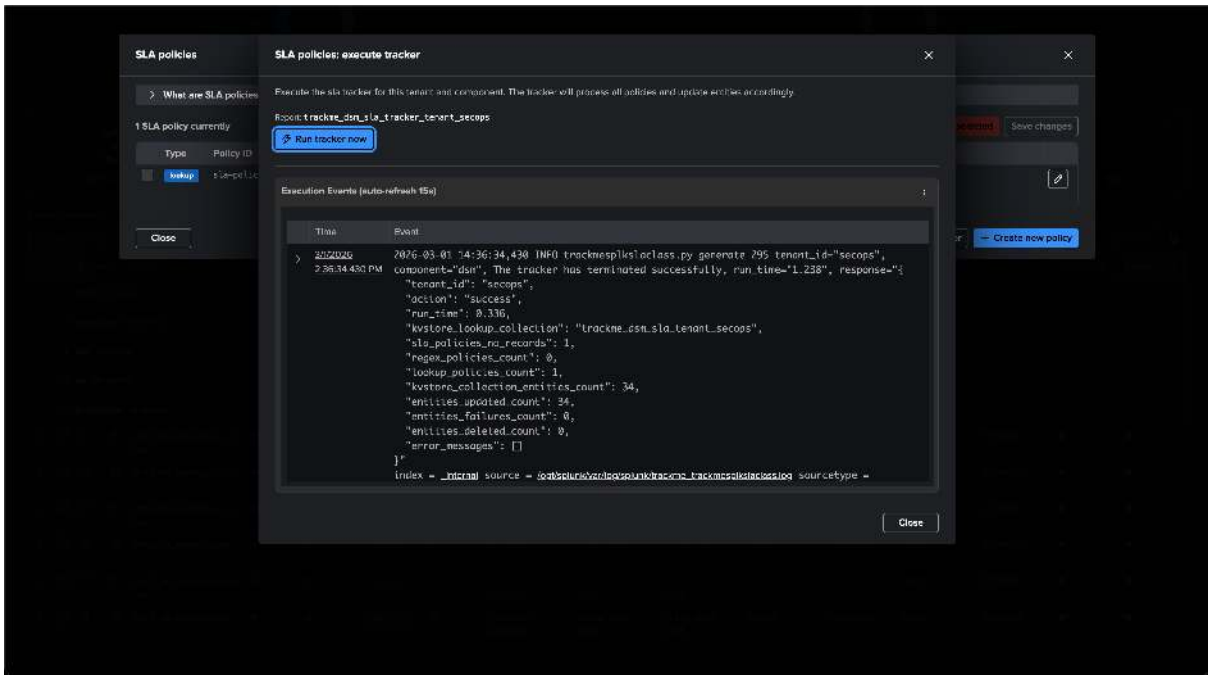




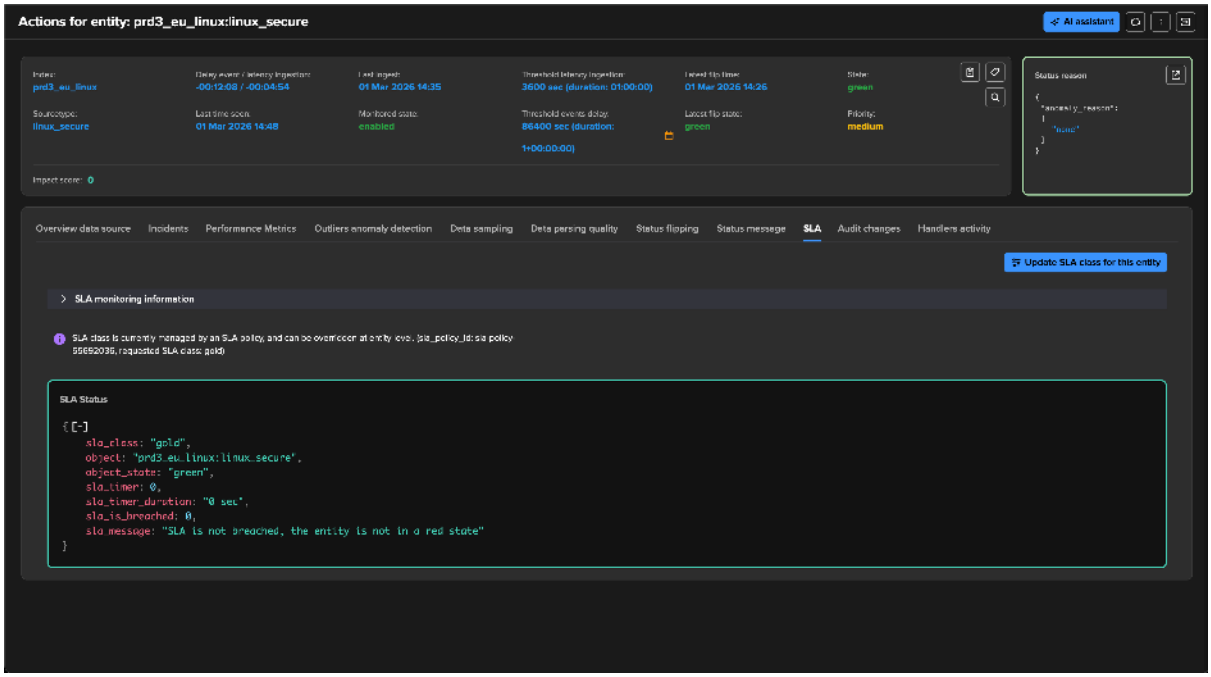
Run the simulation to preview SLA class assignments. The simulation shows the SLA distribution across all 34 entities:



Execute the tracker to apply the SLA class assignments:



Result: Opening an entity's SLA tab confirms the SLA class has been assigned by the policy. In this example, `prd3_eu:linux:linux_secure` is assigned the `gold` SLA class, as its index matches the `prd*_*_linux` wildcard pattern with a `critical` priority mapped to `gold`:



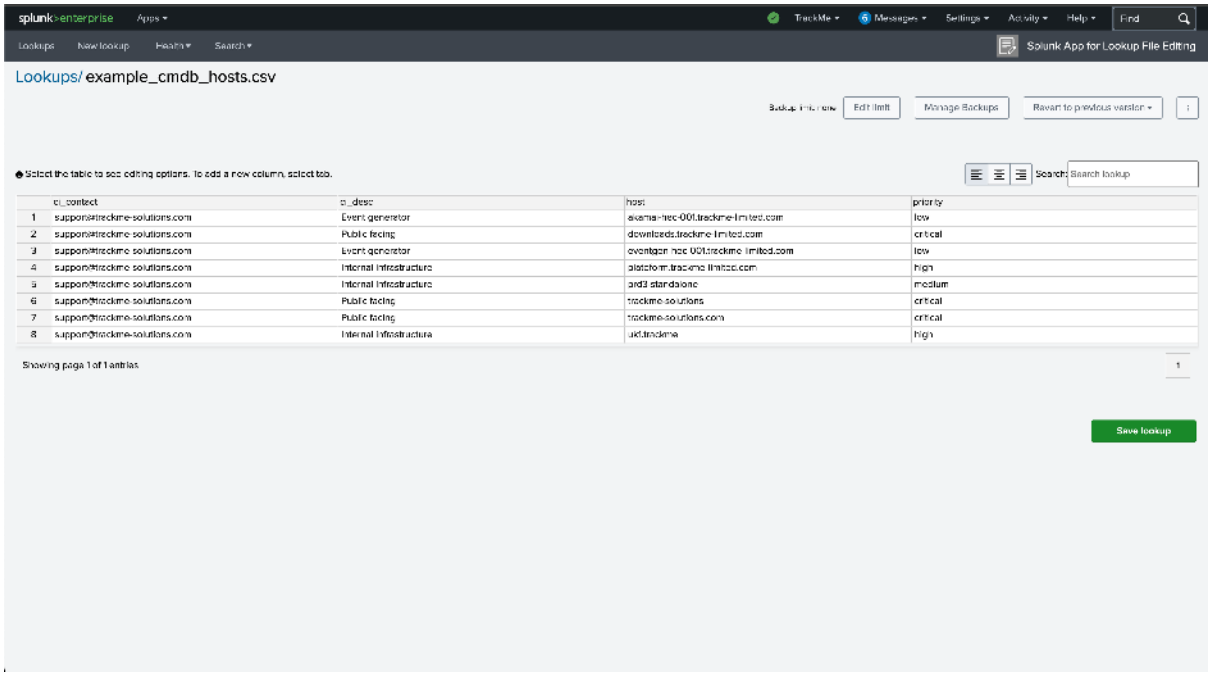
Data host monitoring (DHM) example

In this example, we demonstrate the same workflow for data host monitoring, using a host-based lookup `example_cmdb_hosts.csv`. The key differences from the DSM example are:

- The lookup maps **hosts** (by FQDN) instead of indexes
- The field mapping uses `host` → `alias` (the entity alias field in DHM)
- The match mode is **Exact** (hosts have specific FQDNs, no wildcards needed)
- The **tags field** uses the `ci_desc` column (leveraging an existing CMDB description field as tags)

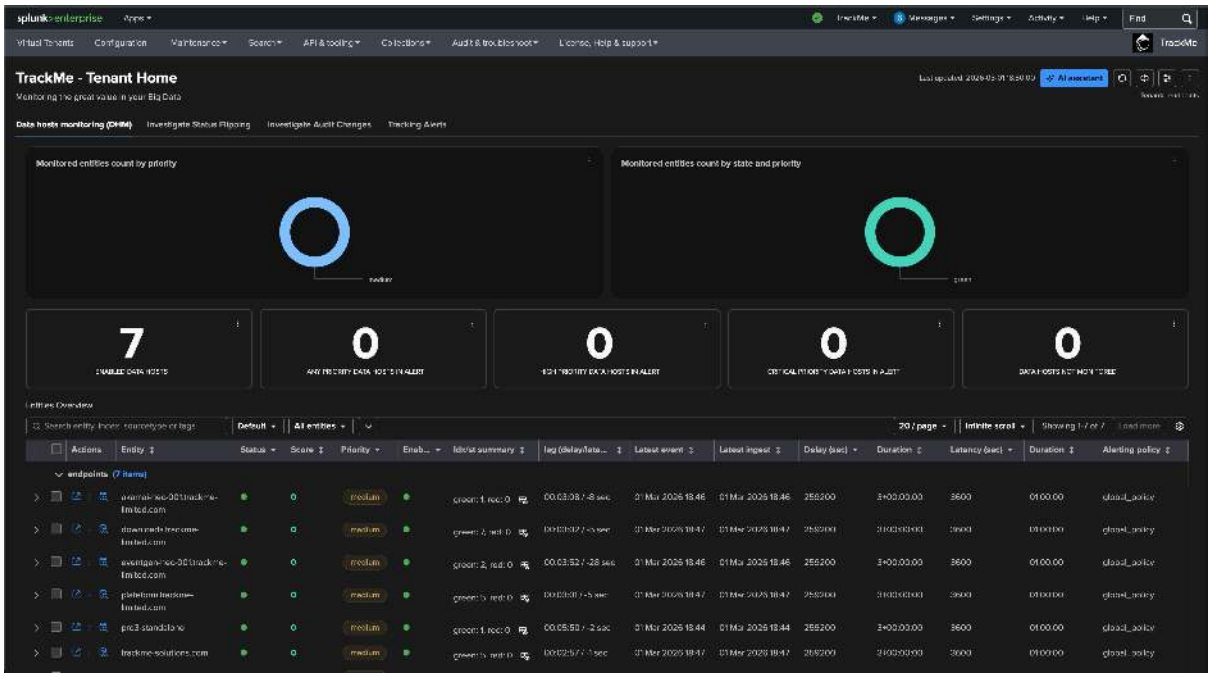
DHM - The lookup file

The lookup file `example_cmdb_hosts.csv` is uploaded to Splunk and contains 8 rows with columns `ci_contact`, `ci_desc`, `host`, and `priority`:



DHM - Initial state

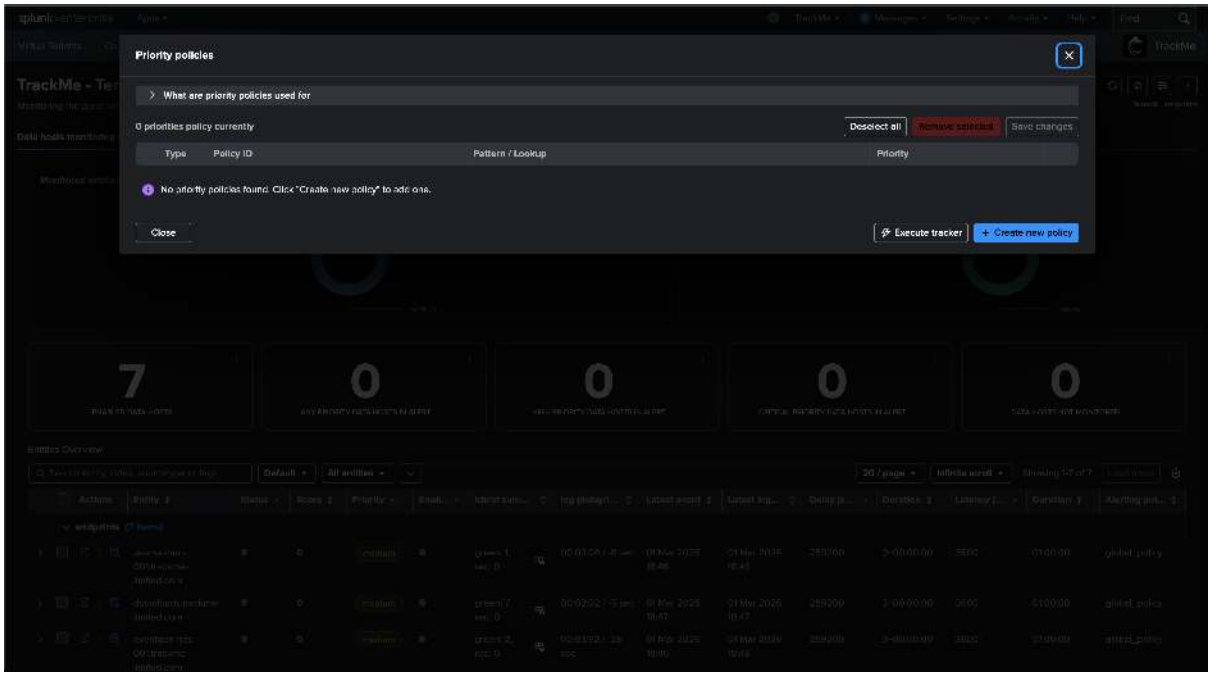
Before creating any policies, all 7 data host entities are at the default priority level (medium):

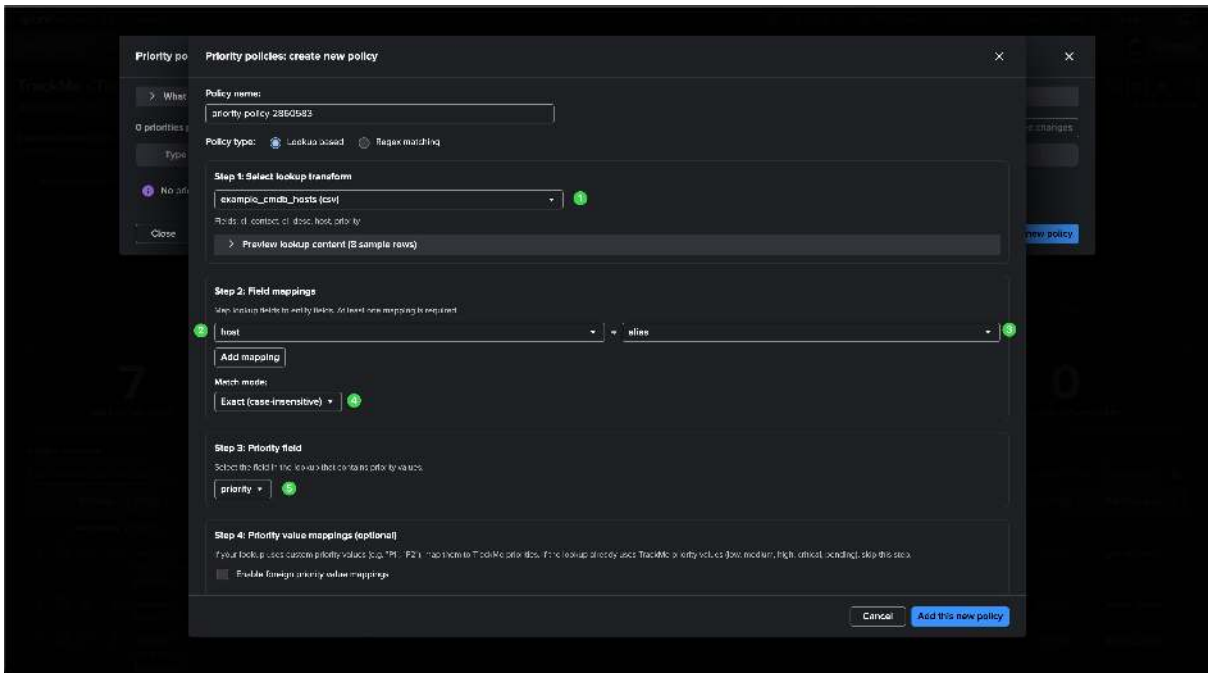


DHM - Step 1: Create a priority policy

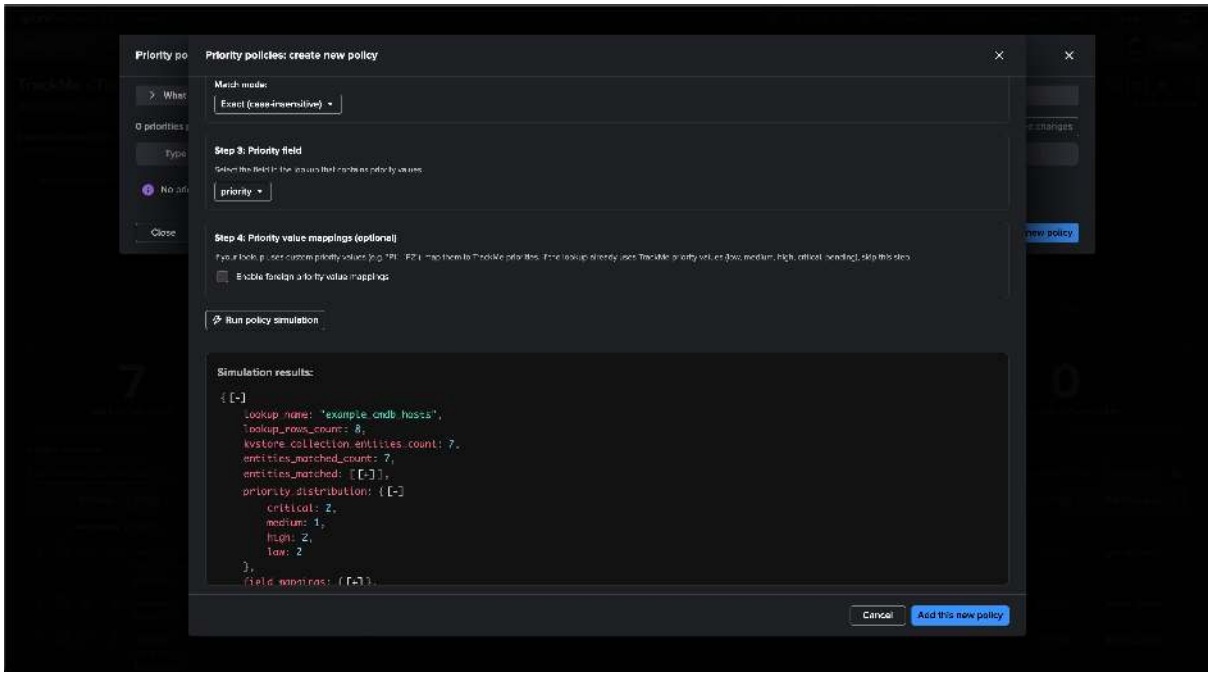
Access the priority policies screen and create a lookup-based policy:

- Select the lookup transform `example_cmdb_hosts (csv)`
- Configure the **field mapping**: `host` → `alias`, with **Exact (case-insensitive)** match mode
- Select `priority` as the **priority field**

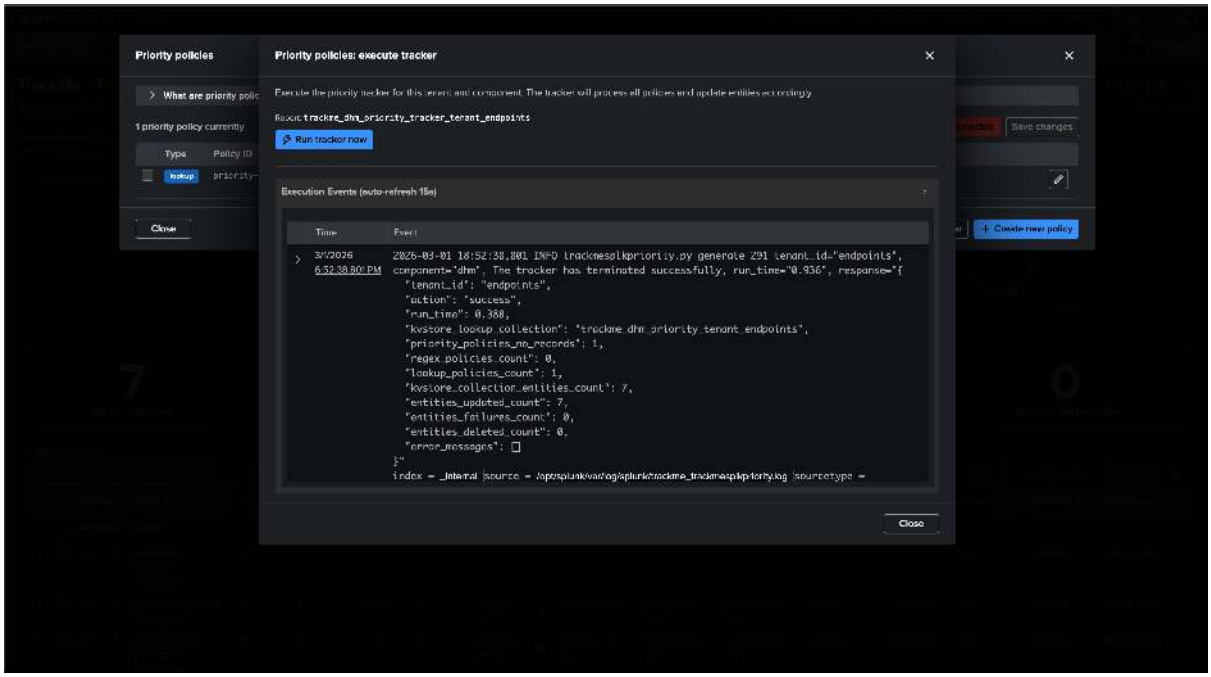




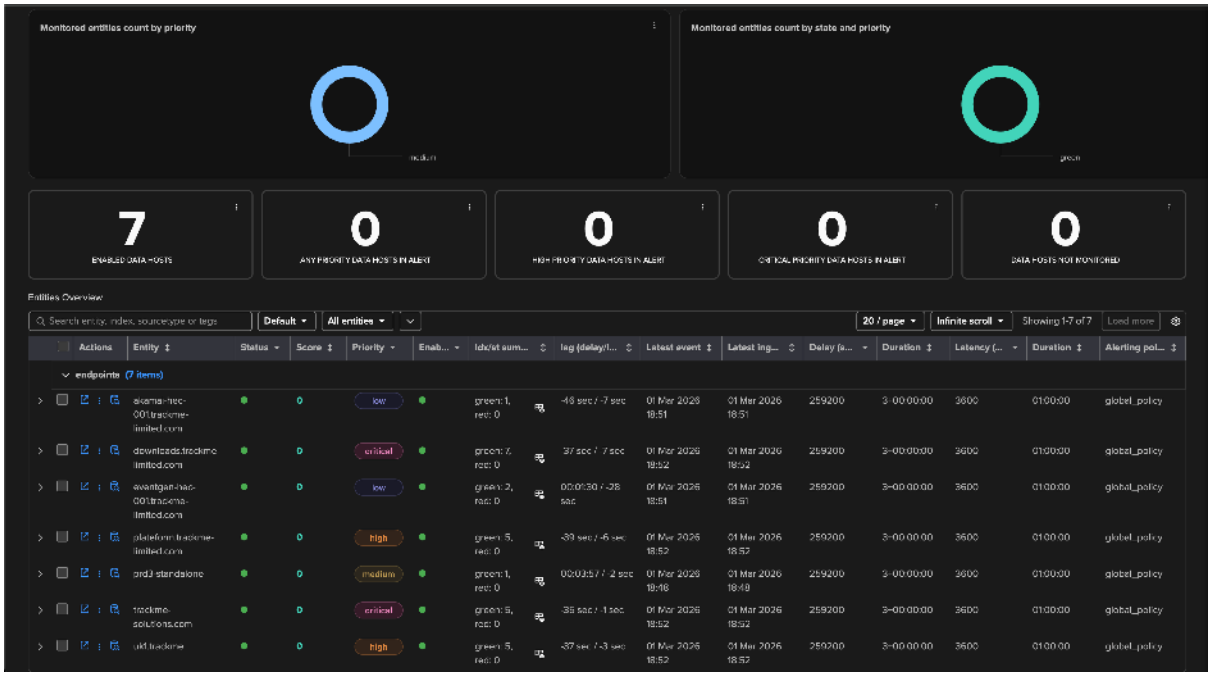
Run the simulation — all 7 entities are matched with the correct priority distribution (critical: 2, high: 2, medium: 1, low: 2):

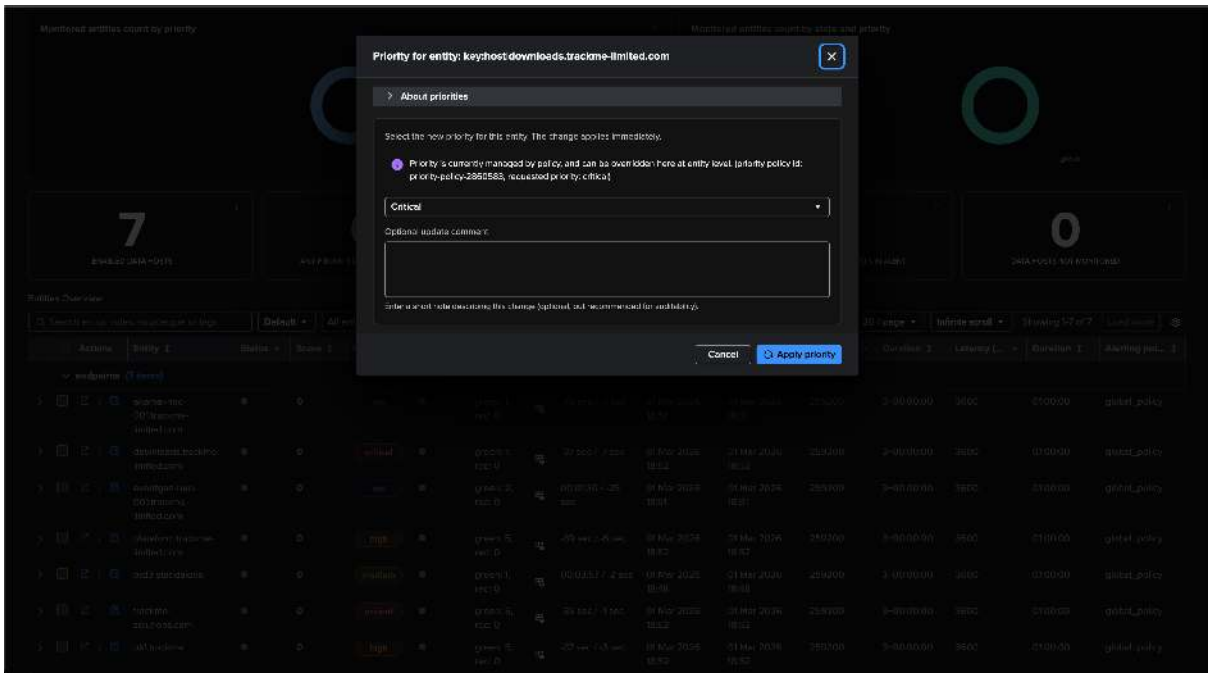


Execute the tracker to apply the priority assignments:



Result: Entities are now assigned the correct priority levels. The entity-level priority dialog shows the priority is managed by the policy and can be overridden at entity level:

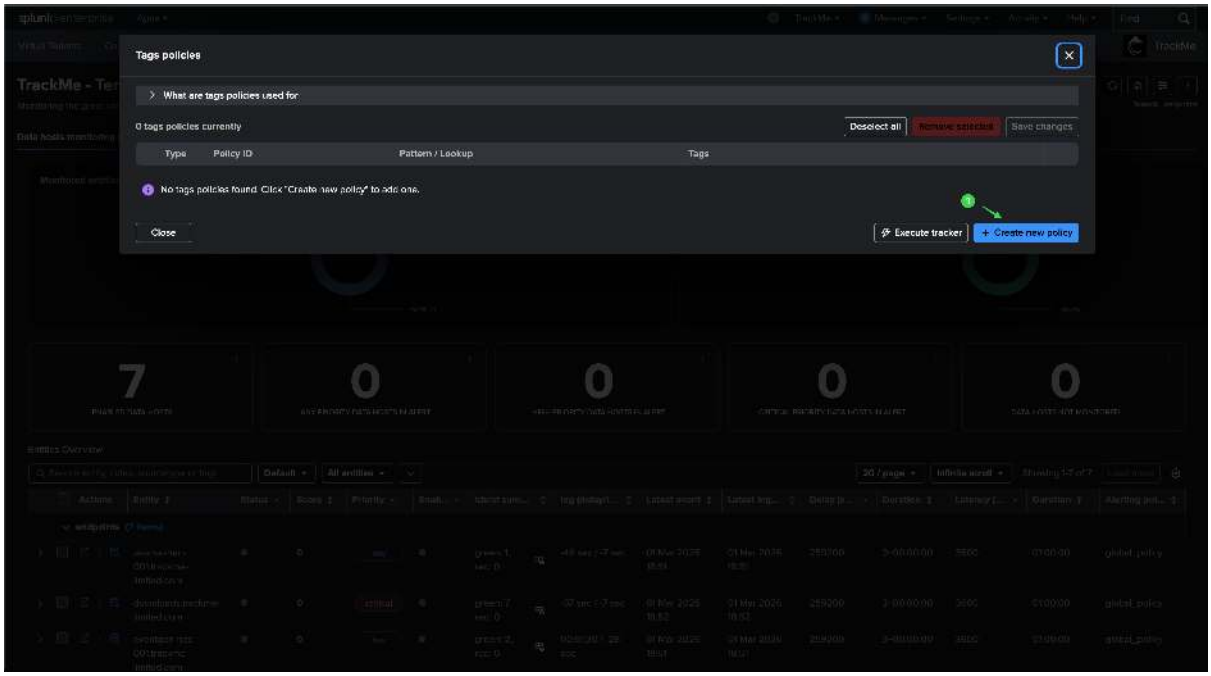


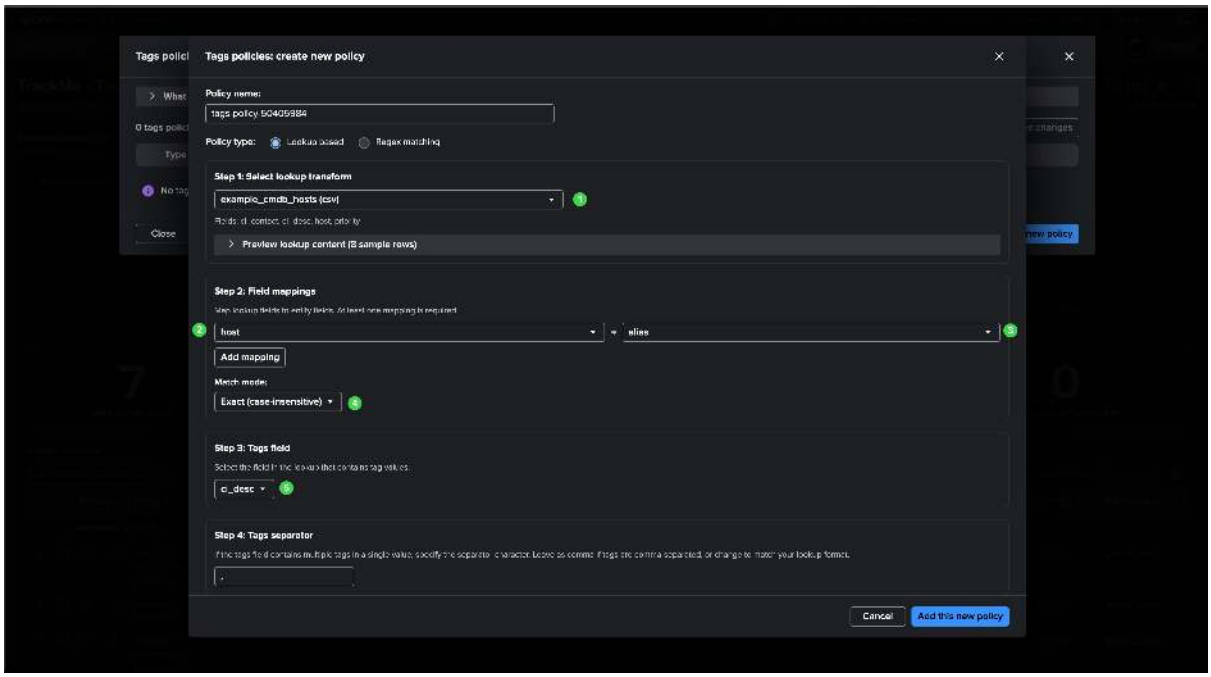


DHM - Step 2: Create a tags policy

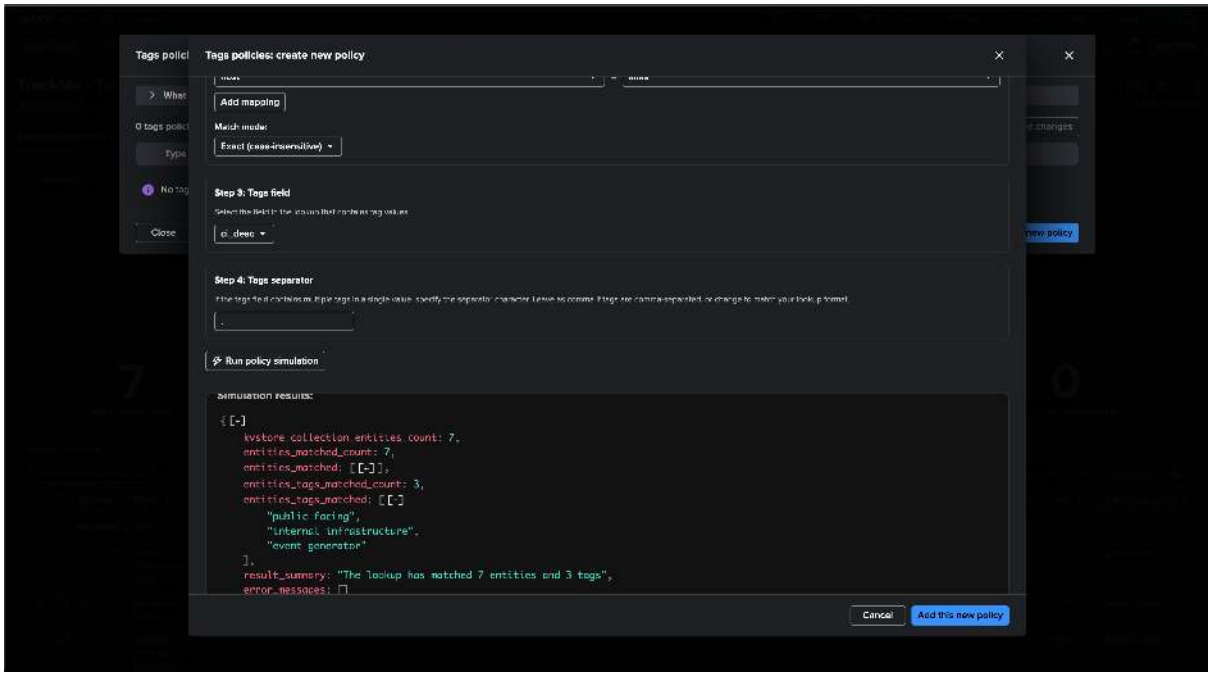
Create a lookup-based tags policy using the same lookup transform:

- Field mapping: `host` → `alias`, with **Exact** match mode
- Tags field: `ci_desc` — in this example, we leverage the CMDB description column as the source of tags (e.g., "Public facing", "Internal infrastructure", "Event generator")
- Tags separator: `,` (comma)

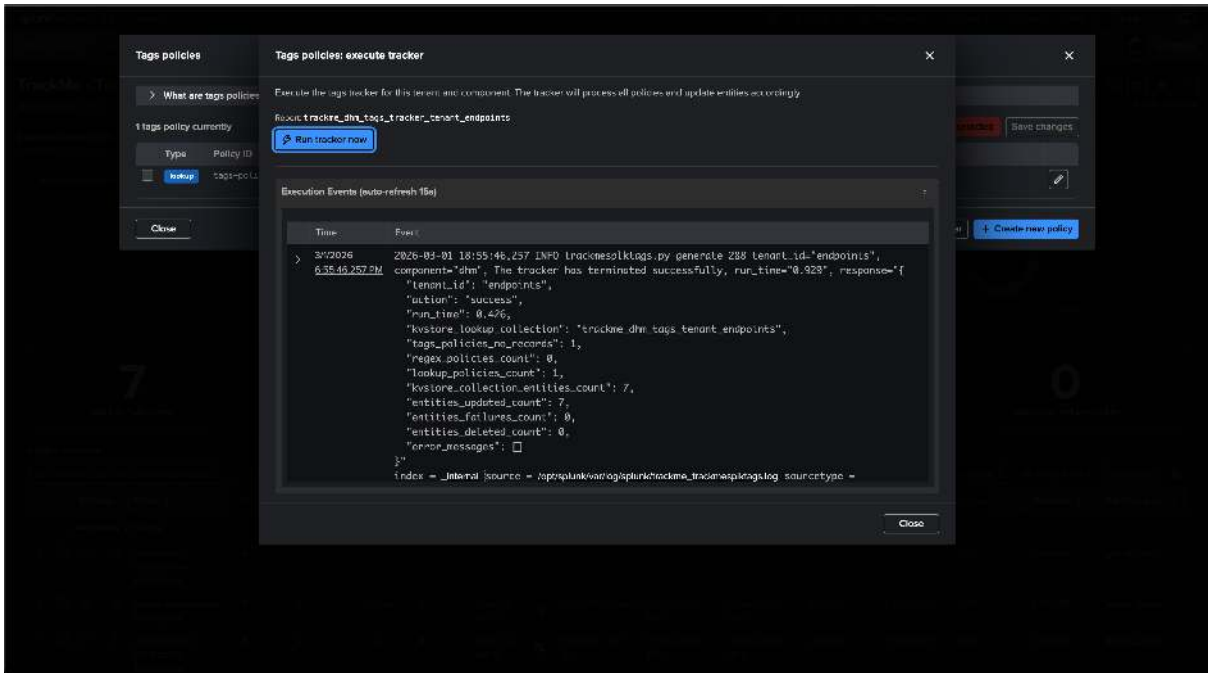




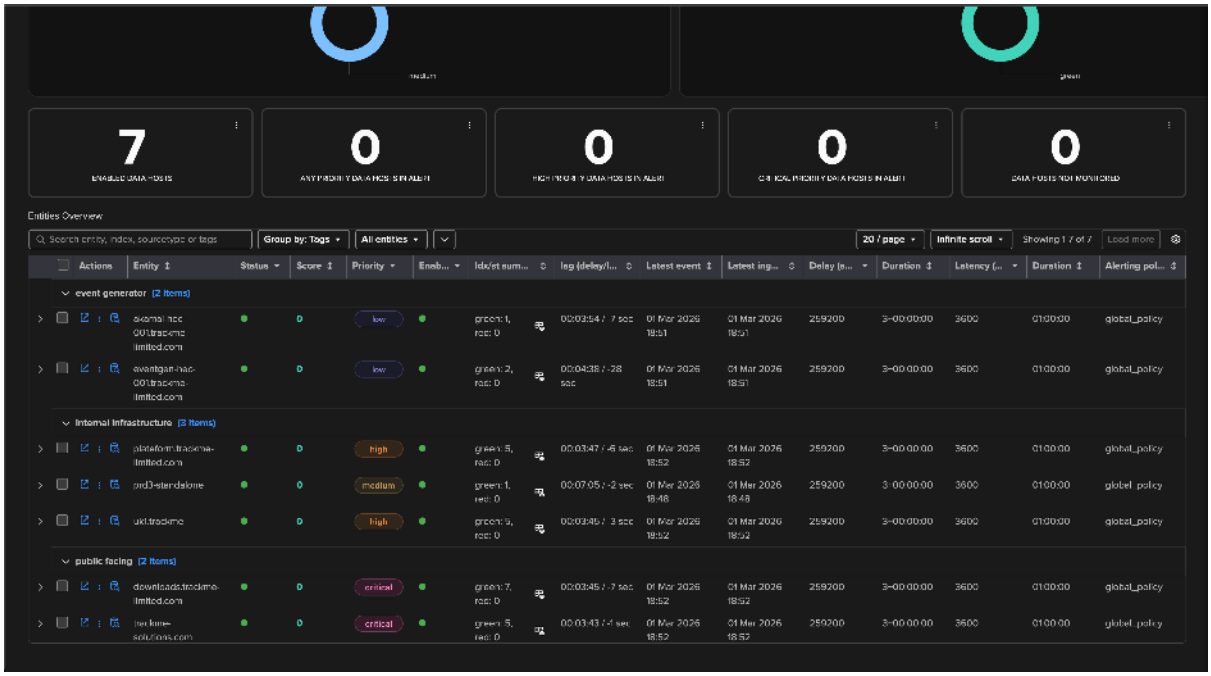
Run the simulation — 7 entities matched, 3 distinct tags discovered (Public facing, Internal infrastructure, Event generator):

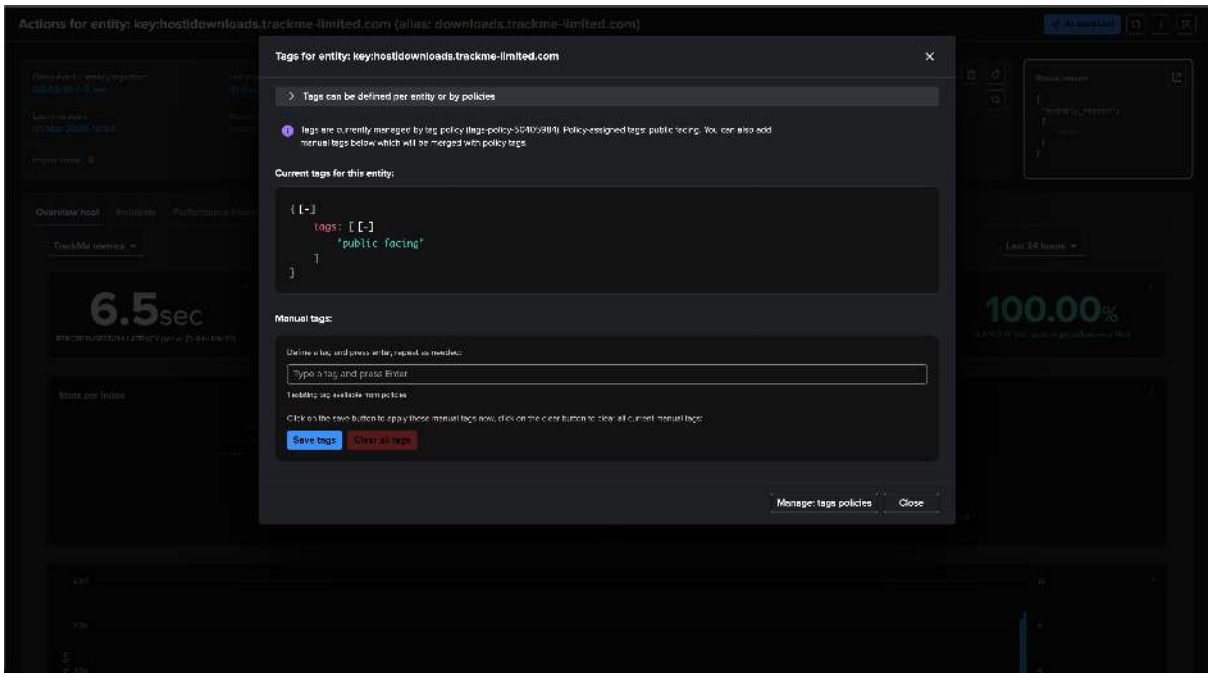


Execute the tracker to apply the tag assignments:



Result: Entities are now tagged and can be grouped by tags in the Tenant Home. The entity tags dialog confirms the tag assignment by the policy:

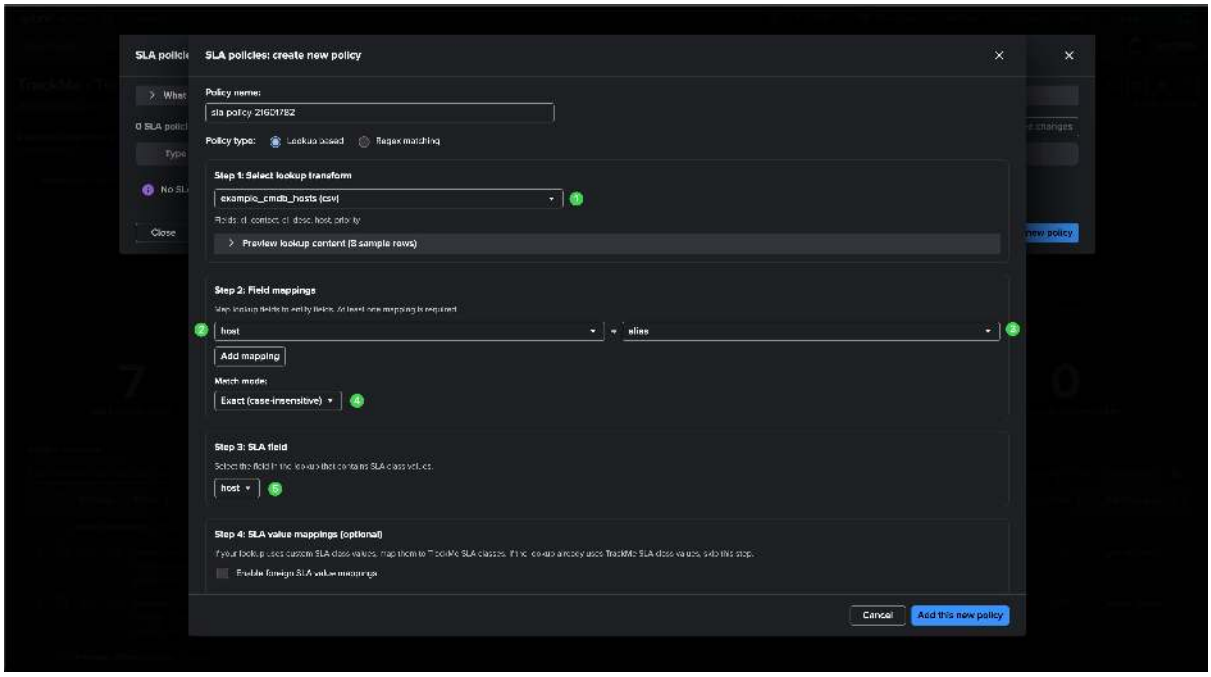




DHM - Step 3: Create an SLA policy

Create a lookup-based SLA policy using the same lookup transform:

- Field mapping: `host` → `alias`, with **Exact** match mode
- SLA field: `priority` — as in the DSM example, we reuse the priority column and translate values via mappings
- Enable **SLA value mappings**: `low` → `platinum`, `medium` → `platinum`, `high` → `silver`, `critical` → `gold`



SLA policies: create new policy
Policy name:
sla policy 21601782
Policy type:

Add this new policy

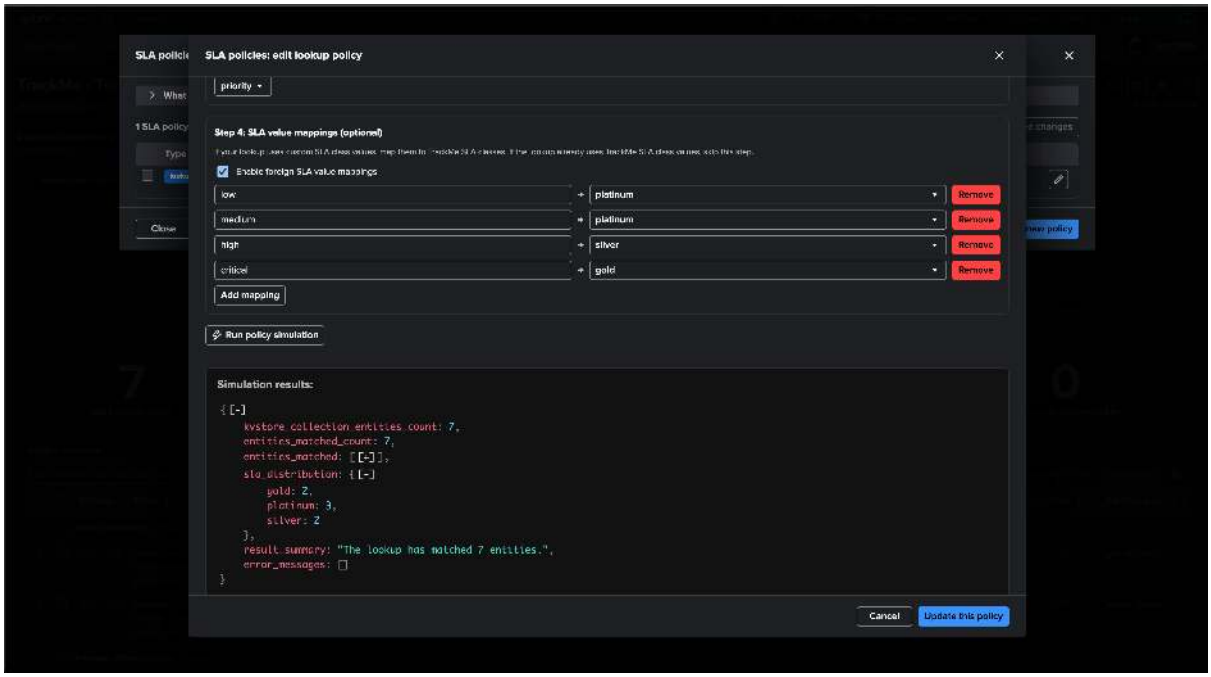
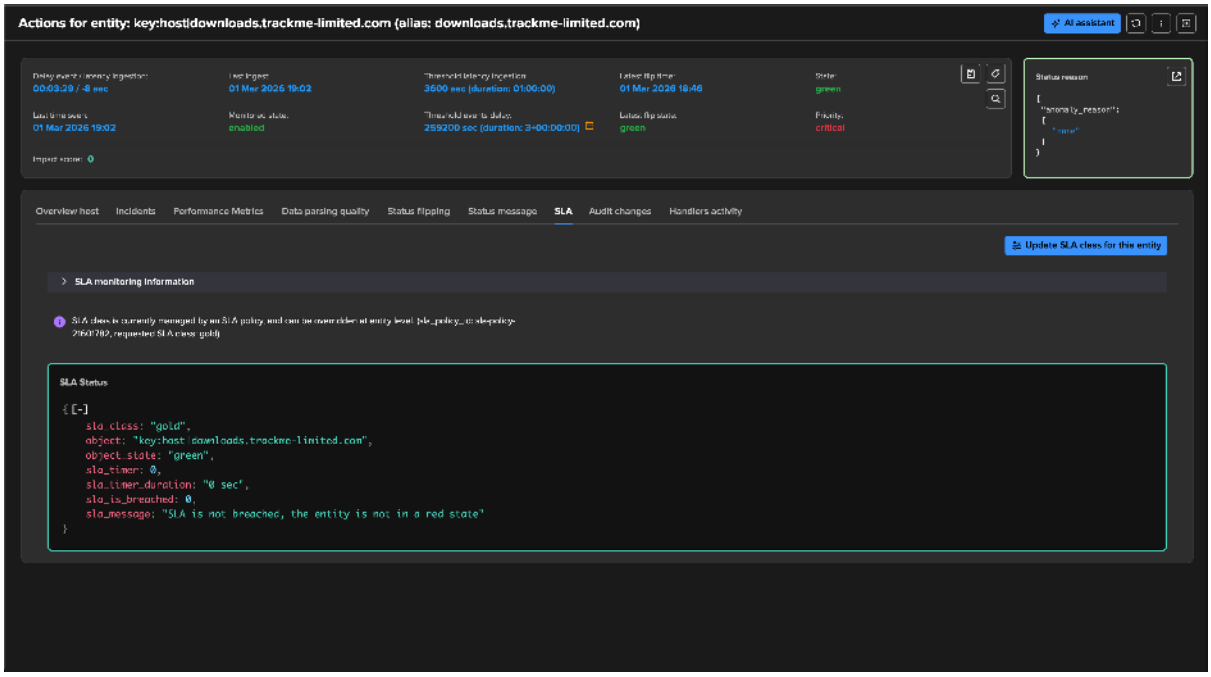
Run the simulation — 7 entities matched with SLA distribution (gold: 2, platinum: 3, silver: 2):



Result: Opening an entity's SLA tab confirms the SLA class assignment. In this example, `downloads.trackme-limited.com` is assigned the `gold` SLA class (critical priority mapped to gold):



Summary and best practices

Key takeaways

- **Single source of truth:** Maintain one lookup file per scope (e.g., one for indexes, one for hosts) and let TrackMe derive priority, tags, and SLA from it.
- **Wildcard matching:** Use wildcard match mode with patterns like `prd*_*_linux` to match complex naming conventions without enumerating every possible entity.
- **Value mappings:** When your lookup doesn't use TrackMe's native values (e.g., custom priority levels or no dedicated SLA column), use value mappings to translate on the fly.
- **Simulate before applying:** Always run a simulation before adding a policy to verify the match count and value distribution.
- **Execute trackers:** After creating or modifying policies, execute the relevant tracker to apply changes immediately. Trackers also run on schedule, so any future lookup updates will be picked up automatically.
- **Tags separator:** When a single lookup cell contains multiple tags (e.g., `eventgen,os`), configure the tags separator so TrackMe splits them into individual tags.
- **Conflict resolution: If multiple policies match the same entity, TrackMe applies the following resolution rules:**
  - **Priority:** Highest priority level wins across all policies
  - **Tags:** Tags are merged (union) across all matching policies
  - **SLA:** Highest-rank SLA class wins across all policies

QUICK START - Cross-tenant domain views with Virtual Groups

Aggregate entities from multiple tenants into unified domain views — without any new monitoring infrastructure

- This quickstart guides you through the design and implementation of **Virtual Groups** in TrackMe — a powerful approach to creating cross-tenant, read-only aggregation views that appear alongside your regular

tenant cards in the Virtual Tenants grid.

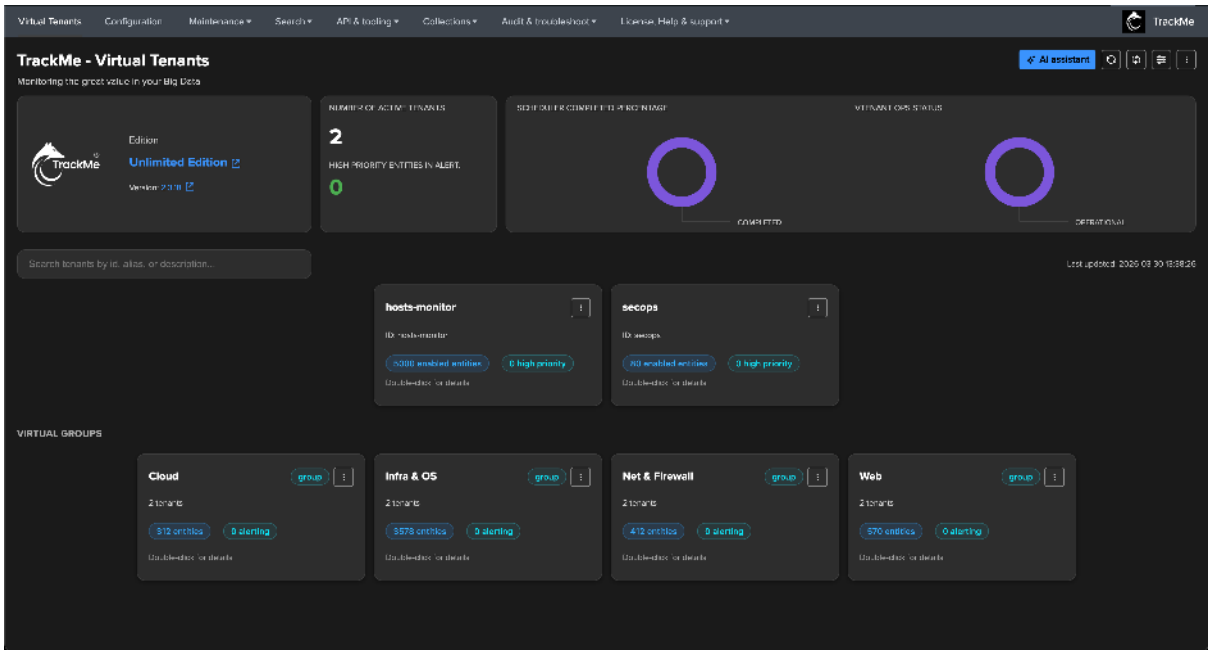
- The key idea: **tags policies** distribute your entities across logical domains (cloud, infra, network…), and **Virtual Groups** surface exactly those domains as first-class cards — spanning multiple tenants at once.
- This quickstart is built around a concrete example with **two tenants** and **~10,000 entities**, culminating in **four Virtual Group cards** each scoped to a distinct business domain.
- **Prerequisites:** An existing TrackMe deployment with at least one Virtual Tenant, discovered entities, and a lookup file (CSV or KVstore) containing knowledge about your environment.

Hint

For detailed reference documentation on tags policies, refer to *Accessing, defining and managing tags policies*.

The goal: what we are building

Before diving into the steps, here is what the end result looks like. Two tenants — `hosts-monitor` (Data Host Monitoring) and `secops` (Data Source Monitoring) — hold roughly 10,000 entities between them. After this quickstart, the Virtual Tenants grid will show **four Virtual Group cards**, each aggregating entities from both tenants, scoped to a specific business domain:



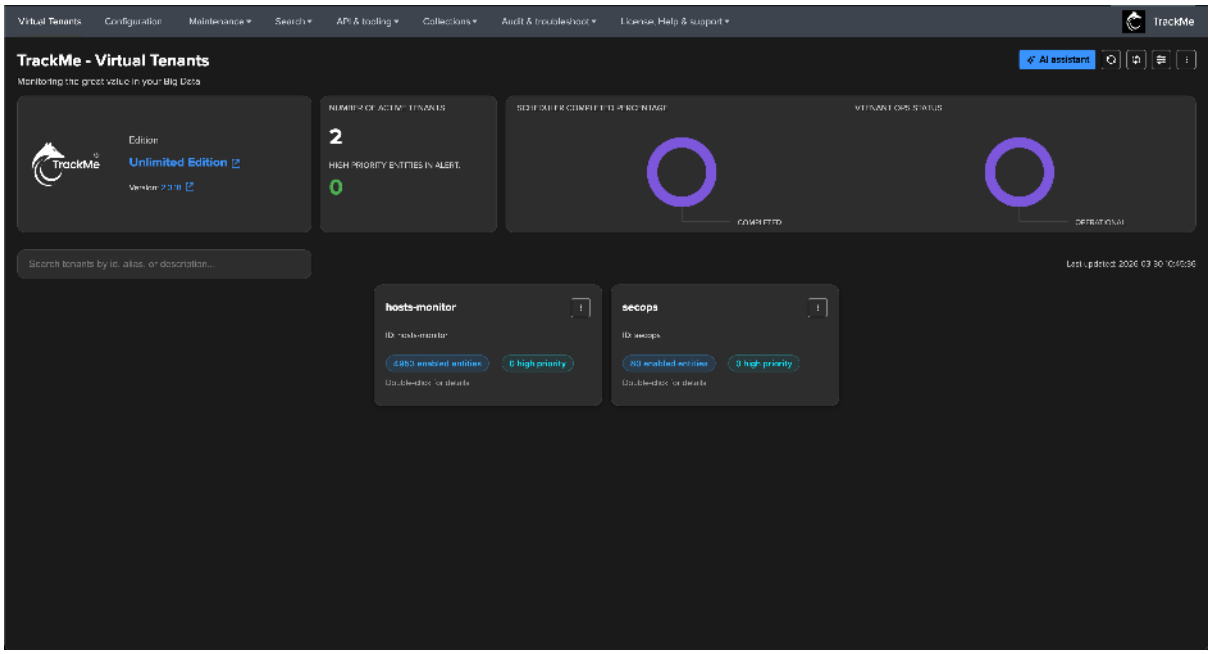
Each group card shows:

- The **number of tenants** contributing entities to the group
- The **total entity count** (aggregated across all tenants and components in scope)
- The **number of alerting entities** (red/orange state)
- A context menu to open the group overview, refresh, edit, or delete

The design relies on a single, elegant building block: **tags**. Every entity is tagged with its business domain by a lookup-based tags policy. Virtual Groups then use a free-form filter expression (`tags="cloud"`, `tags="infra" OR tags="os"`, etc.) to pick up exactly the right entities — automatically, from any tenant.

Our scenario

We start with two tenants in the Virtual Tenants grid, no Virtual Groups yet:



- **hosts-monitor** — Data Host Monitoring (DHM) tenant. Monitors ~5,000 data hosts.
- **secops** — Data Source Monitoring (DSM) tenant. Monitors ~5,000 data source entities.

Both tenants share the same domain taxonomy: each entity belongs to one or more of these domains — `cloud`, `infra`, `os`, `net`, `firewall`, `syslog`, `web`, `identity`. This knowledge lives in a single lookup file: `example_cmdb_indexes.csv`, which maps index patterns (for DSM) and host patterns (for DHM) to tags.

The plan:

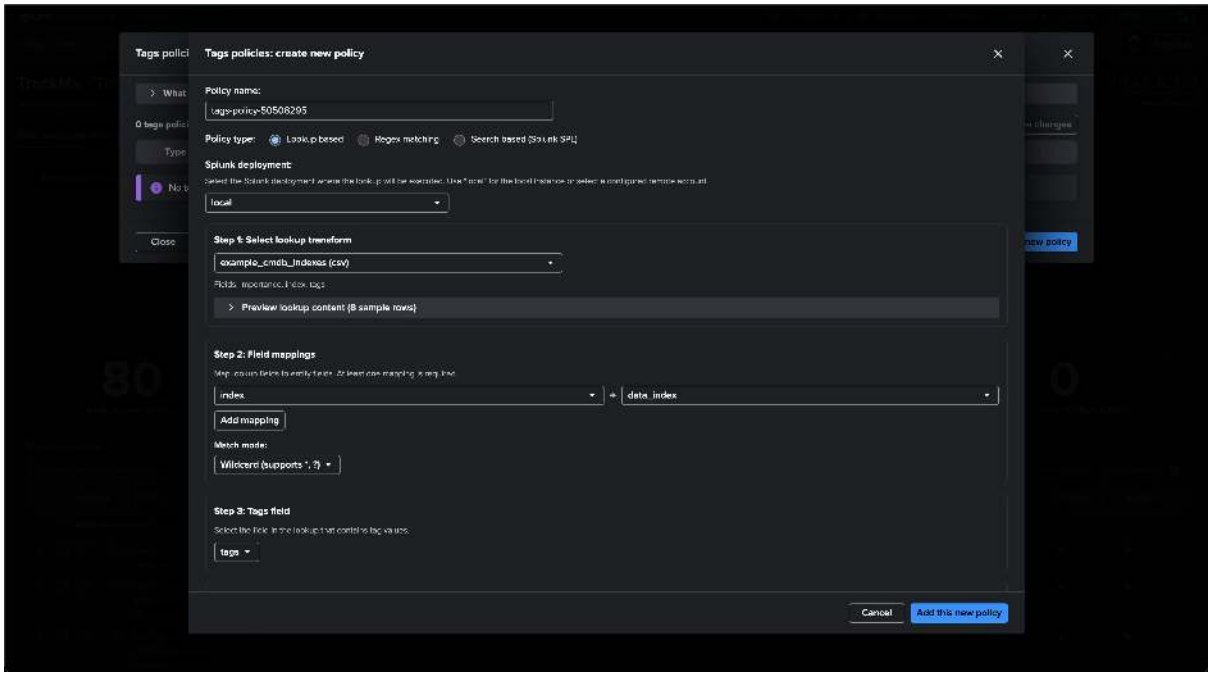
1. Create a **lookup-based tags policy** on `hosts-monitor` (DHM) to tag all data hosts
2. Create a **lookup-based tags policy** on `secops` (DSM) to tag all data sources
3. Create one **Virtual Group** per domain, referencing both tenants

Step 1 — Tag entities in hosts-monitor (DHM)

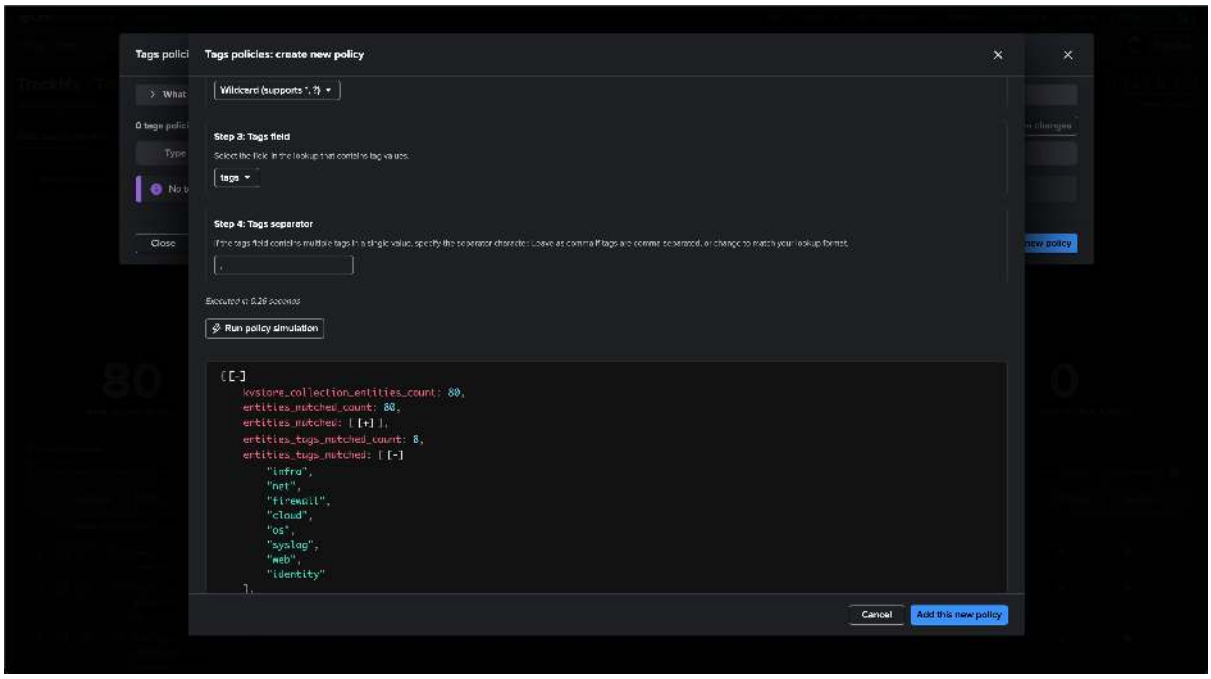
From the `hosts-monitor` Tenant Home, open **Actions → Manage tags policies** and create a new **Lookup based** policy.

Configure the policy wizard:

- **Step 1:** Select the lookup transform `example_cmdb_indexes (csv)`
- **Step 2:** Field mapping — map lookup field `index` to entity field `data_index`, match mode **Wildcard**
- **Step 3:** Tags field — select `tags`



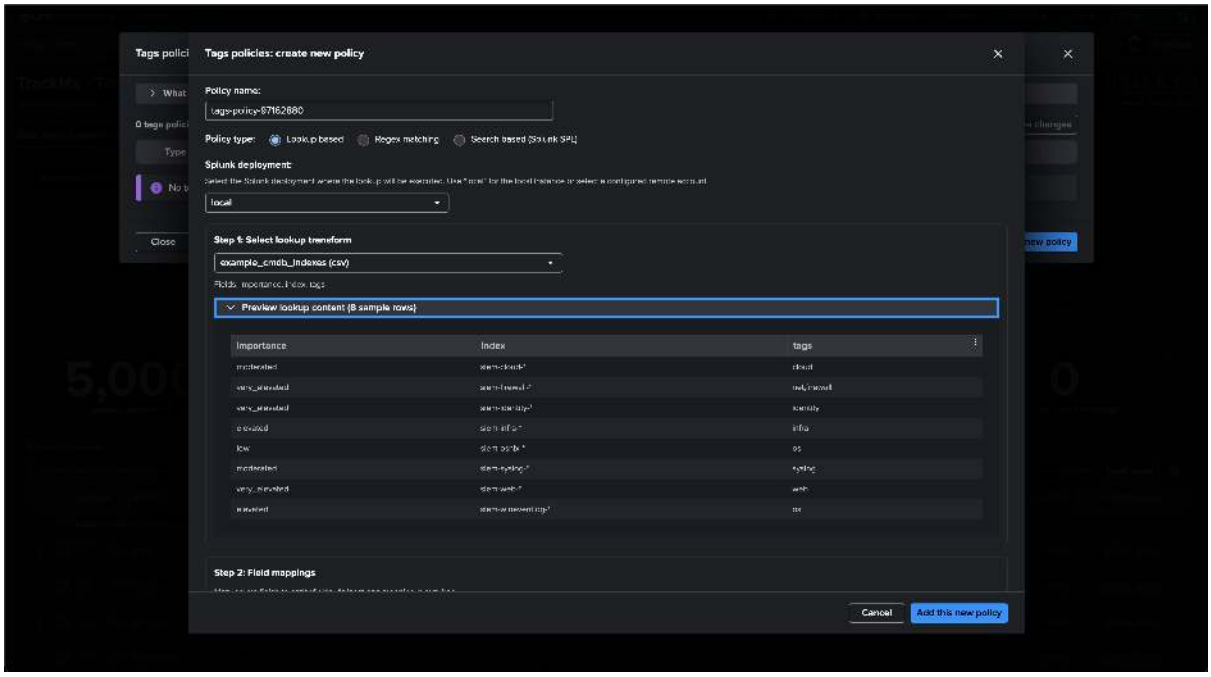
Run the **policy simulation** before saving. The simulation scans the entire entity collection and previews which entities would be matched and what tags would be assigned. For `hosts-monitor`, 80 entities are matched and 8 distinct tags are discovered (`infra`, `net`, `firewall`, `cloud`, `os`, `syslog`, `web`, `identity`):

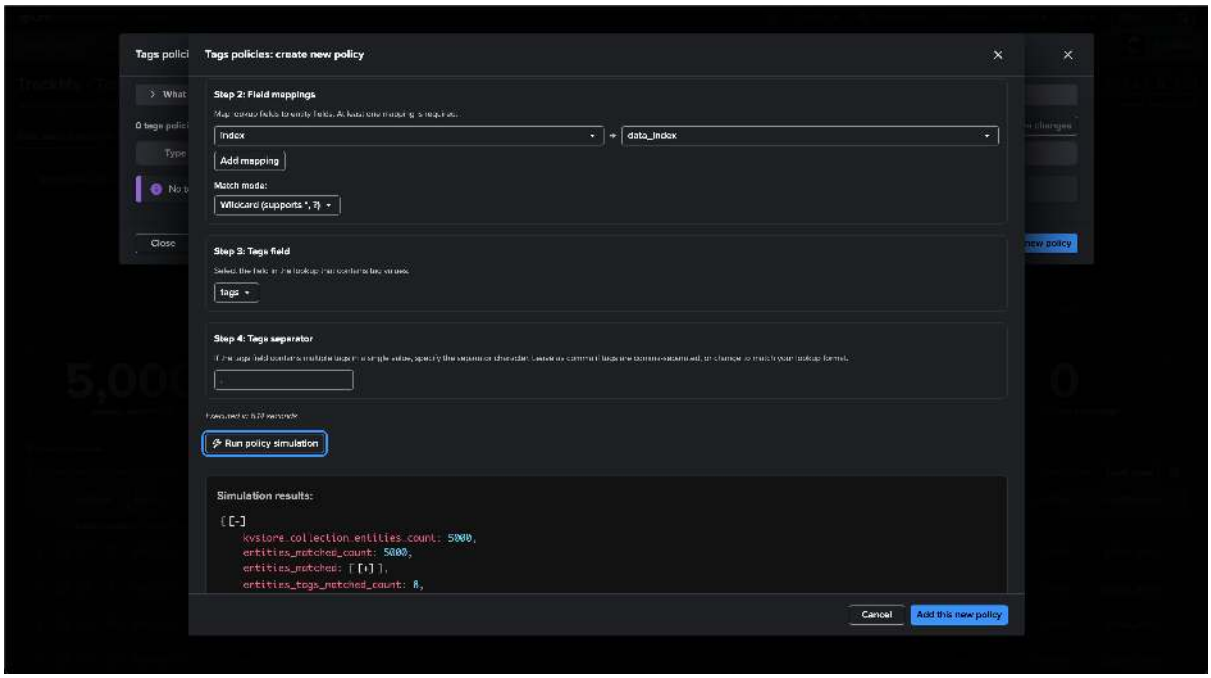


Click **Add this new policy**, then **Execute tracker** to apply the tag assignments immediately.

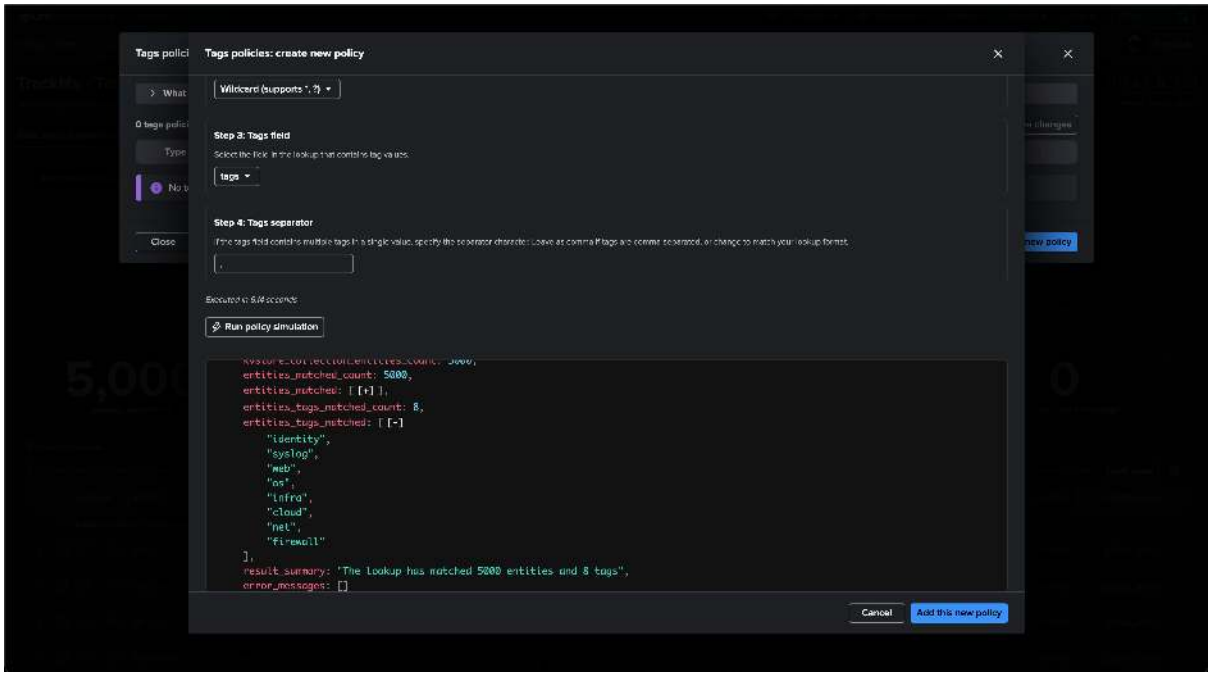
Step 2 — Tag entities in secops (DSM)

Repeat the same process on the `secops` tenant. The same lookup `example_cmdb_indexes (csv)` is used — the lookup preview confirms the mapping of index patterns to tags:





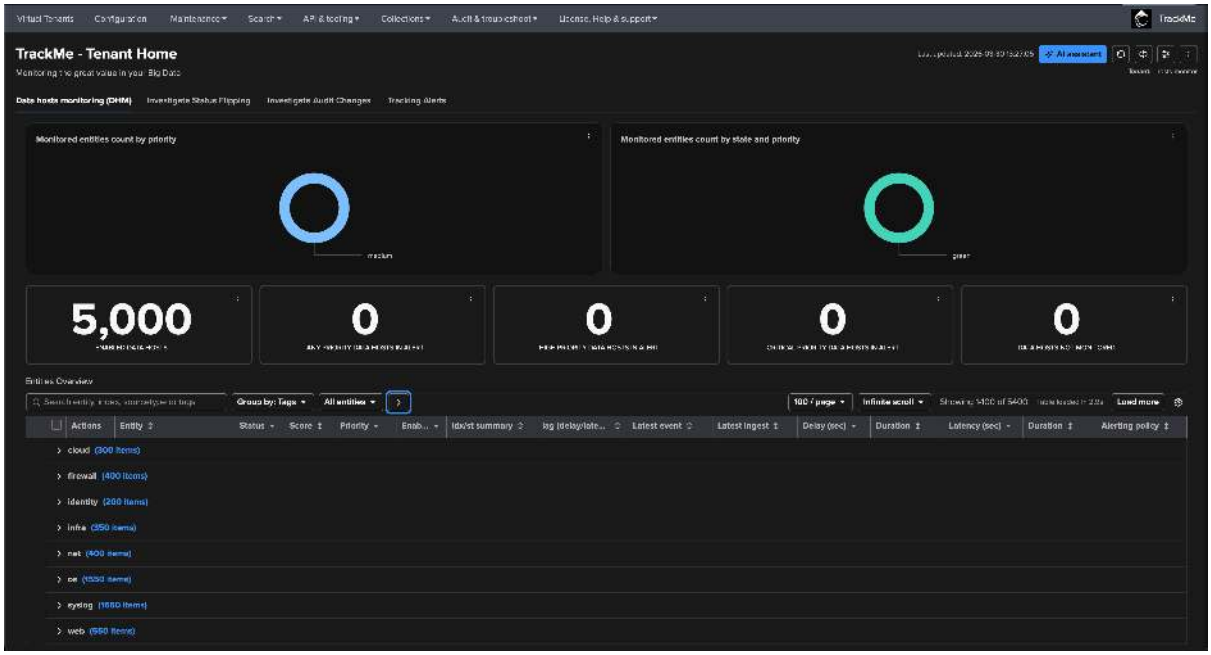
With 5,000 data sources in scope, the simulation confirms all entities are matched and 8 distinct tags are discovered. The result summary at the bottom of the simulation output confirms the coverage:



Execute the tracker. All data sources in `secops` are now tagged with their business domain.

Result: entities distributed across domains

With both tags policies applied, every entity across both tenants is now tagged. The Tenant Home **Group by Tags** view makes this immediately visible — entities are cleanly distributed across 8 domain buckets:



This is the foundation Virtual Groups build upon. The tags are the single source of truth — Virtual Groups simply reference them.

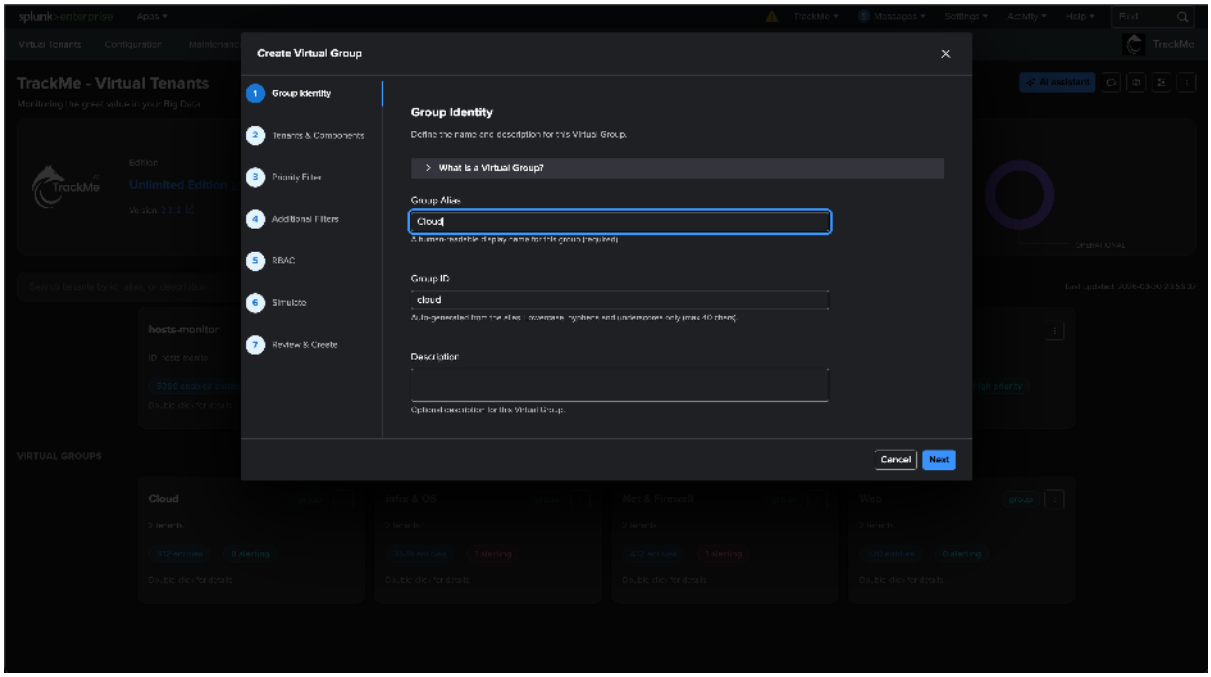
Step 3 — Create Virtual Groups

Now we create one Virtual Group per domain. Each group spans both tenants and both components (DHM + DSM), filtered by the relevant tag(s).

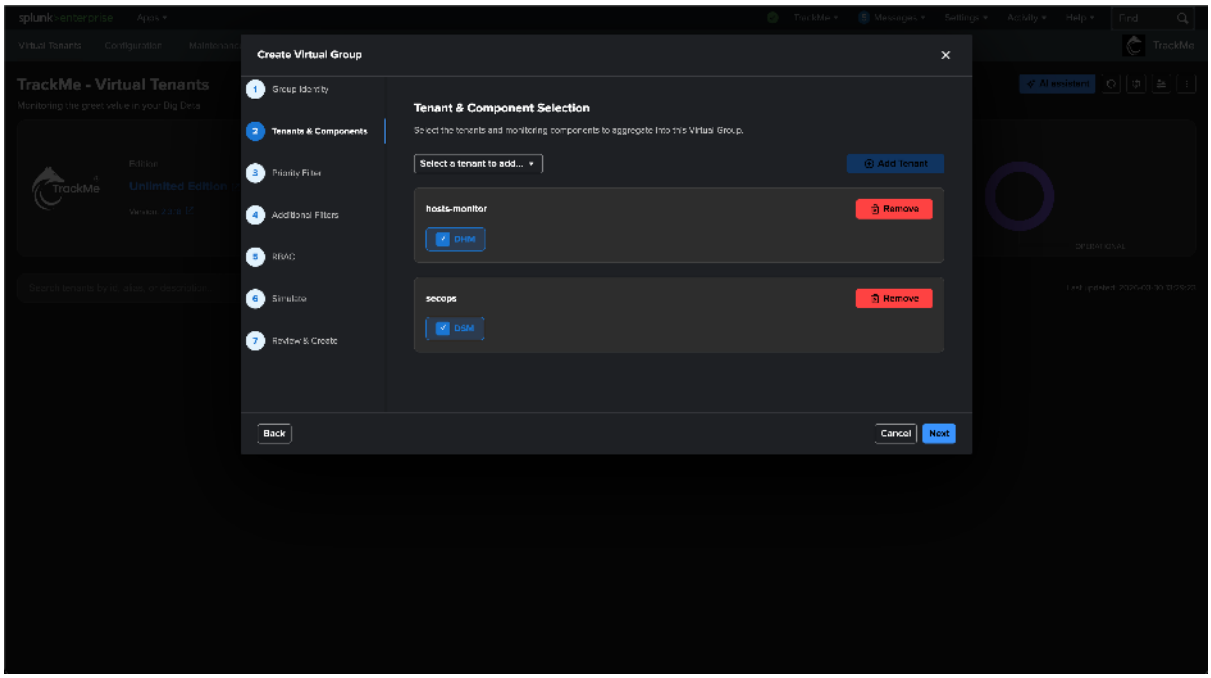
Creating the "Cloud" group

Open the **Administration** menu (top-right) and select **Create a virtual group**. The wizard opens.

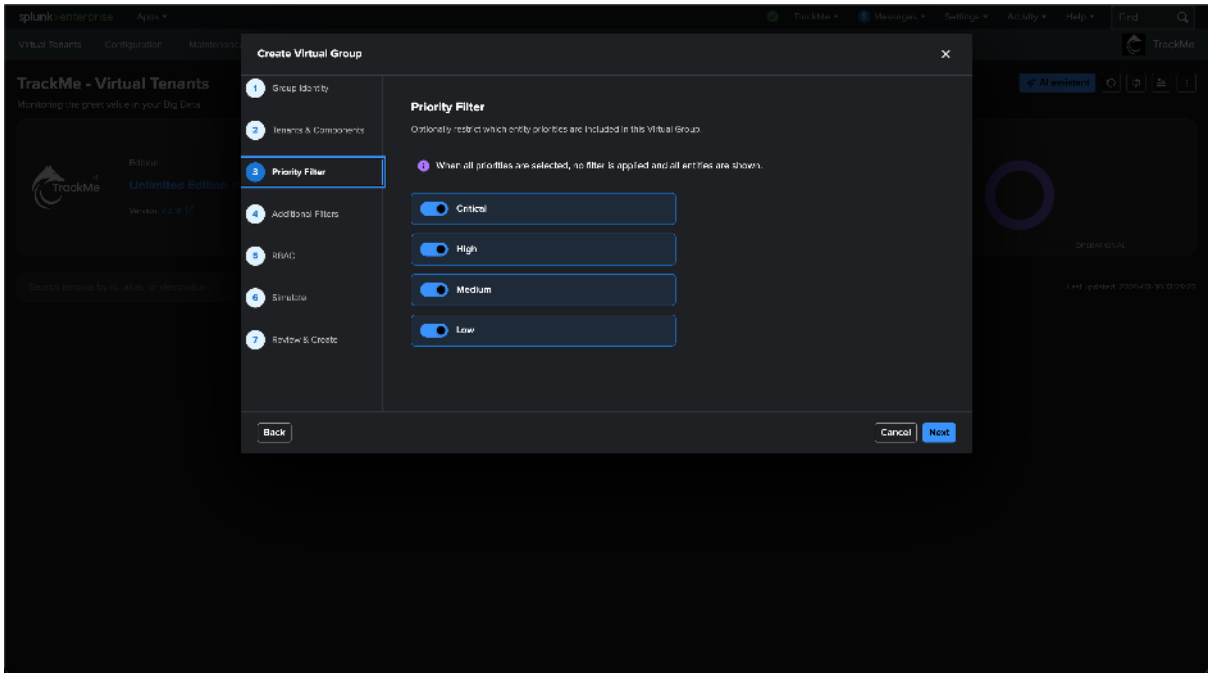
Step 1 — Group Identity: Give the group a human-readable alias and an auto-generated ID:



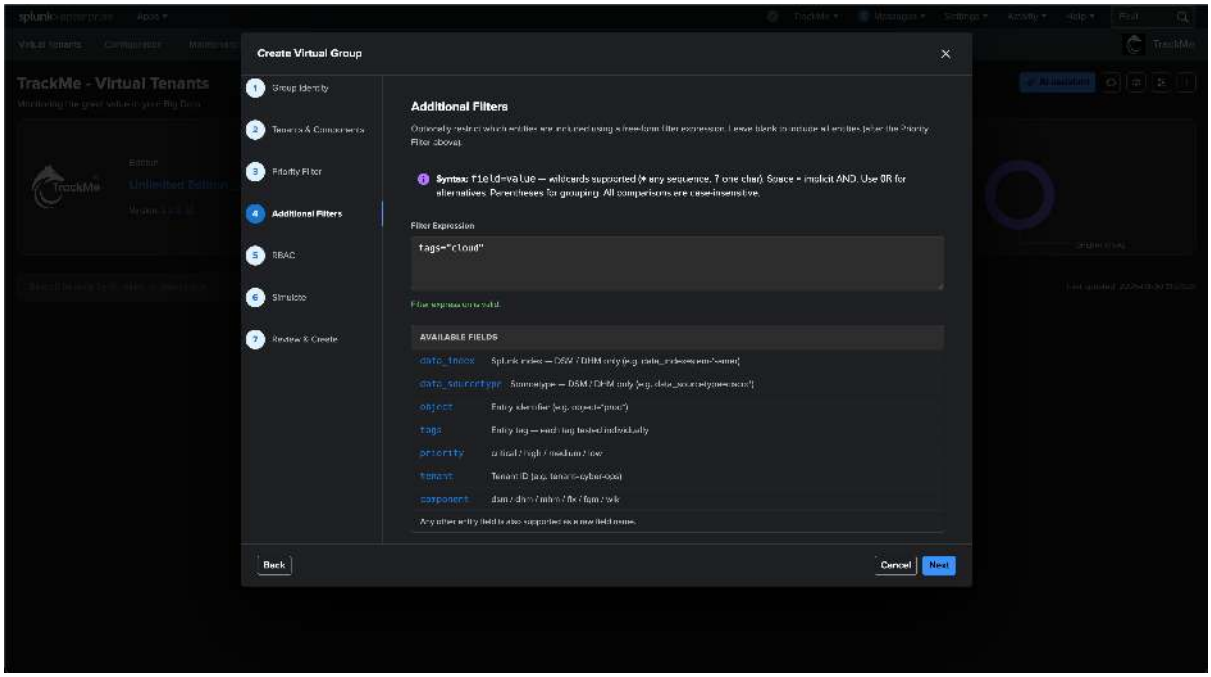
Step 2 — Tenants & Components: Add both tenants to the scope. For each tenant, select the relevant monitoring components. Here we include DHM from `hosts-monitor` and DSM from `secops`:



Step 3 — Priority Filter: Optionally restrict the group to entities of specific priority levels. Leaving all priorities enabled means all entities matching the domain filter are included — the most common choice for a full domain view:



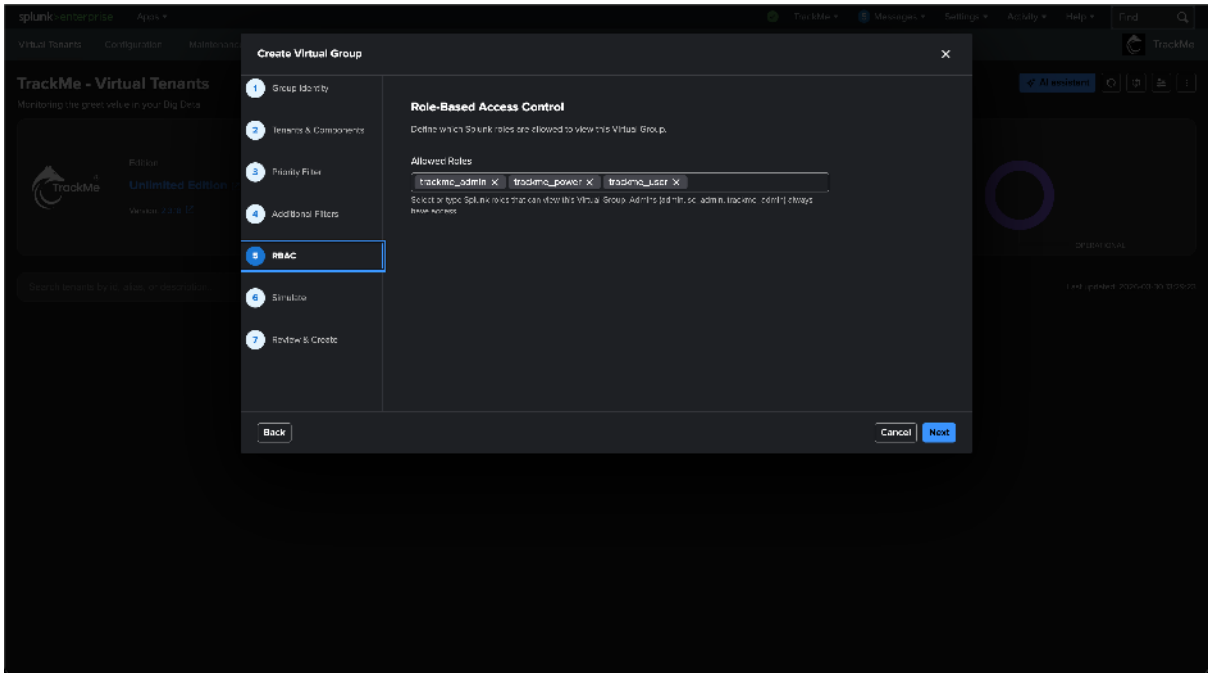
Step 4 — Additional Filters: This is where the domain scoping happens. Enter a free-form filter expression using entity fields. For the `Cloud` group, the expression is simply `tags="cloud"`:



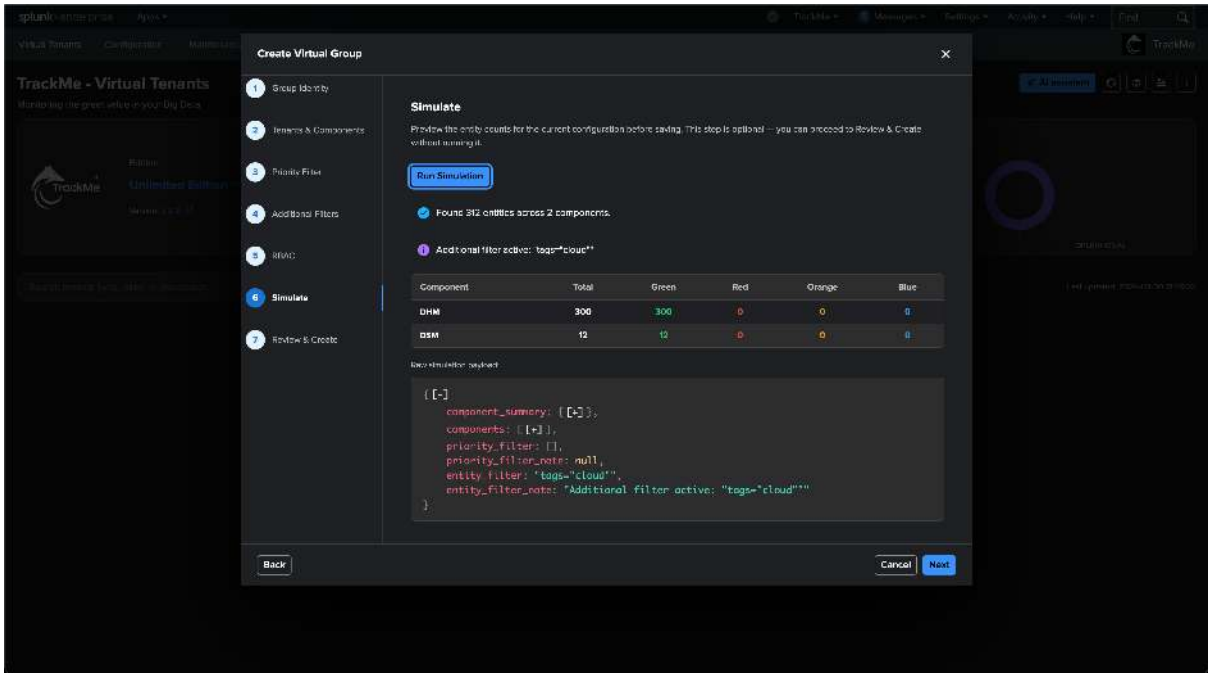
Hint

The filter syntax supports wildcards (`*`, `?`), logical operators (`AND`, `OR`), and parentheses for grouping. Comparisons are case-insensitive. Any entity field is supported — `tags`, `data_index`, `alias`, `priority`, `component`, and more. Leave the field blank to include all entities (after applying the Priority Filter above).

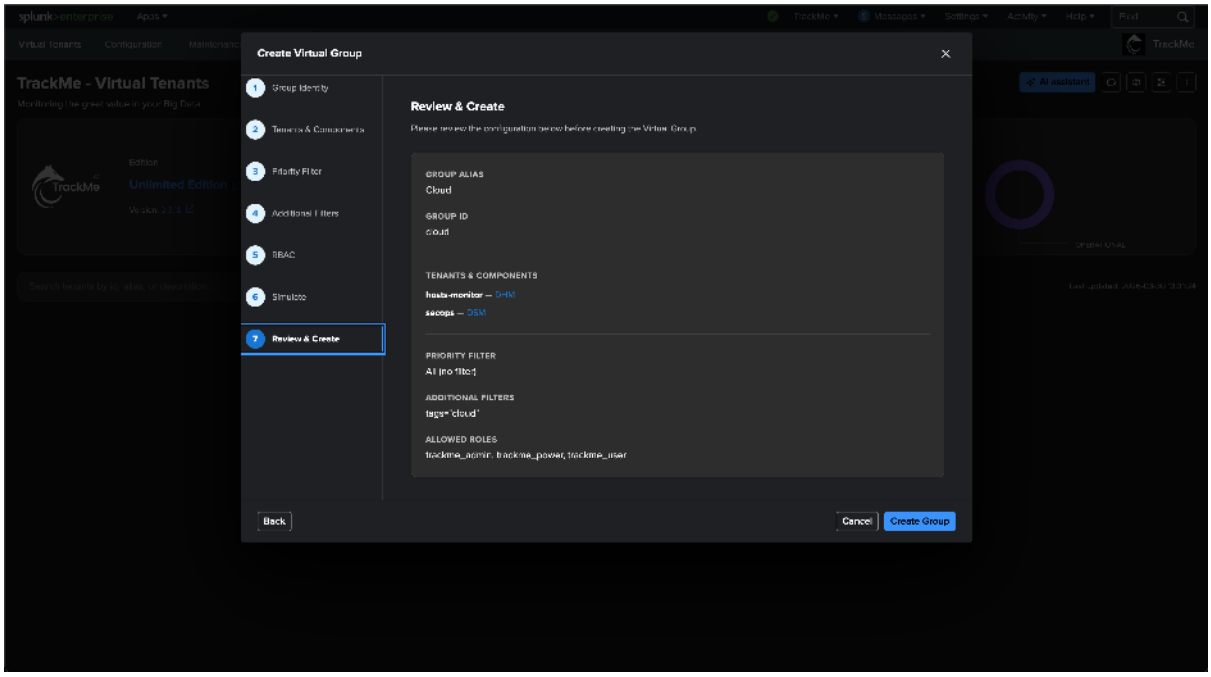
Step 5 — RBAC: Define which Splunk roles can see this Virtual Group. By default, all three TrackMe roles are pre-populated. You can remove roles to restrict visibility to specific teams:



Step 6 — Simulate: Before creating the group, run a simulation to preview how many entities will be included across each component. For the `Cloud` group, 312 entities are found across 2 components (DHM and DSM), confirming the filter is correct:



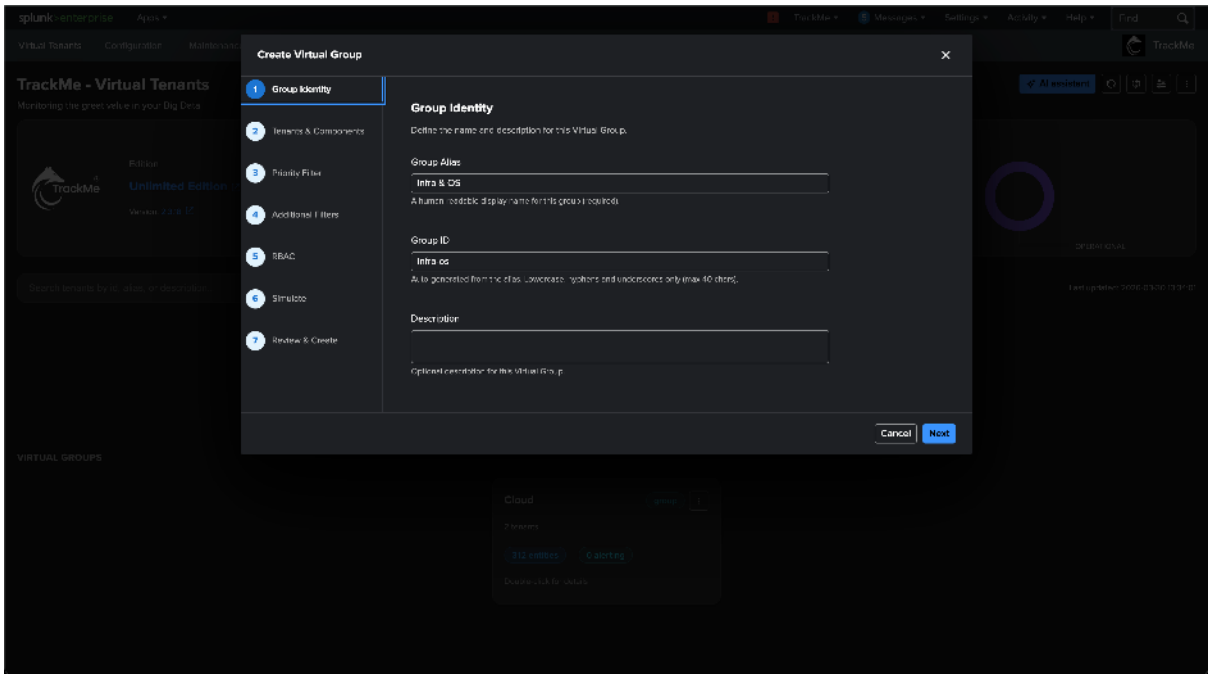
Step 7 — Review & Create: A final summary confirms all settings before creation. Click **Create Group**:

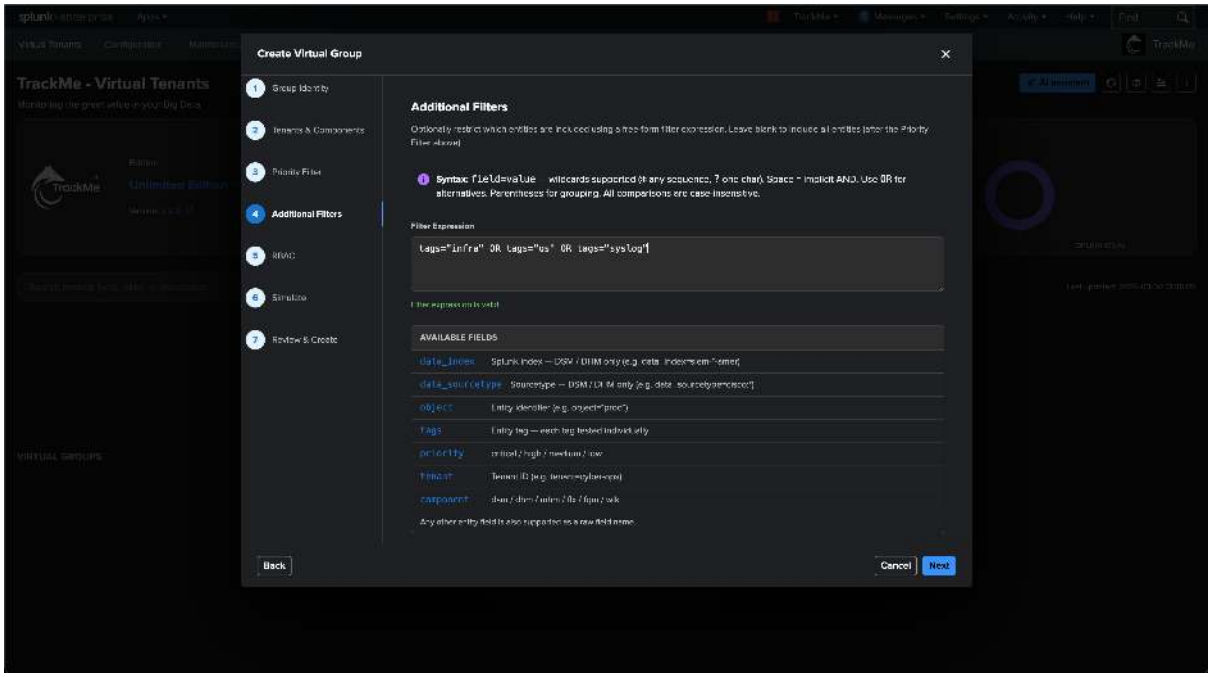


Creating the remaining groups

Repeat the wizard for each remaining domain. The only things that change between groups are the **alias** and the **filter expression**.

For example, the `Infra & OS` group aggregates three related domains into one view — useful when `infra`, `os`, and `syslog` are managed by the same team and benefit from a consolidated perspective:

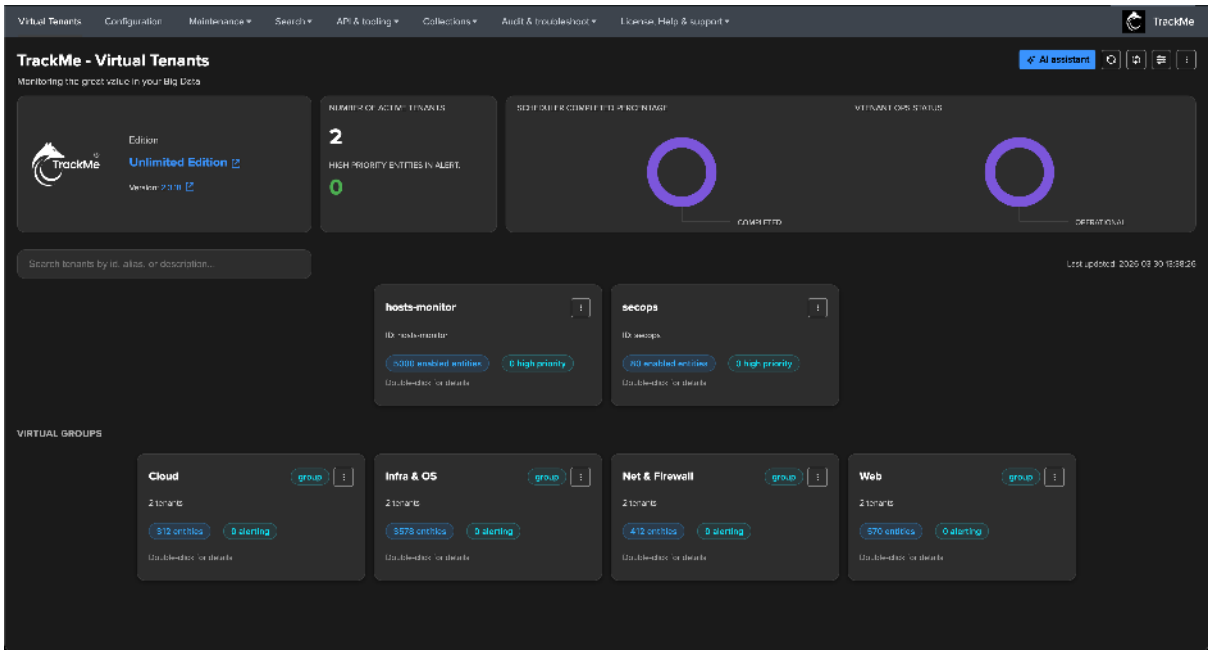




The `Net & Firewall` and `Web` groups follow the same pattern with their respective tag expressions (`tags="net" OR tags="firewall"` and `tags="web"`).

Step 4 — The final result

With all four groups created, the Virtual Tenants grid now shows a dedicated **Virtual Groups** section beneath the tenant cards. Each group card displays the aggregated entity count and alert status at a glance:

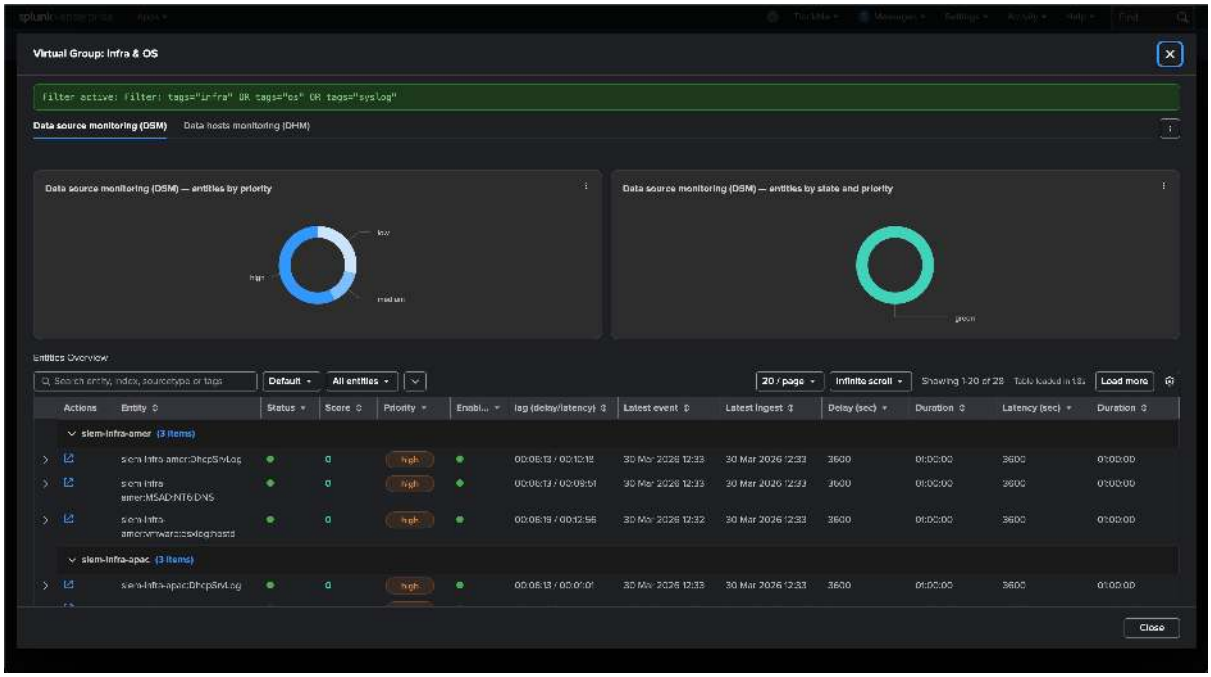


All four groups are live, sourcing their data from both tenants simultaneously. The cards update automatically alongside the rest of the Virtual Tenants grid — no manual refresh required.

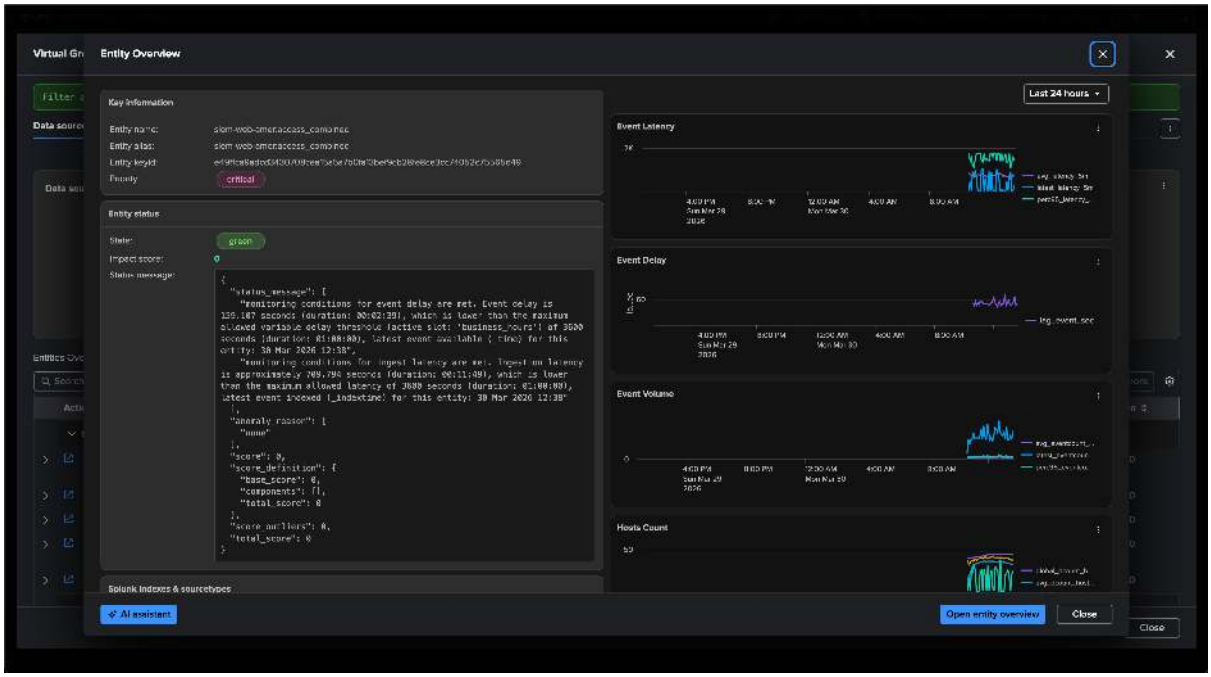
Exploring a Virtual Group

Double-click any Virtual Group card (or click **Open** in its context menu) to open the **Virtual Group Overview**. The overview provides a tabbed, per-component breakdown of all aggregated entities.

The active filter expression is shown at the top so it is always clear which entities are in scope. Charts give an immediate sense of the health distribution (by priority and by state) for each component, followed by the full entity table:

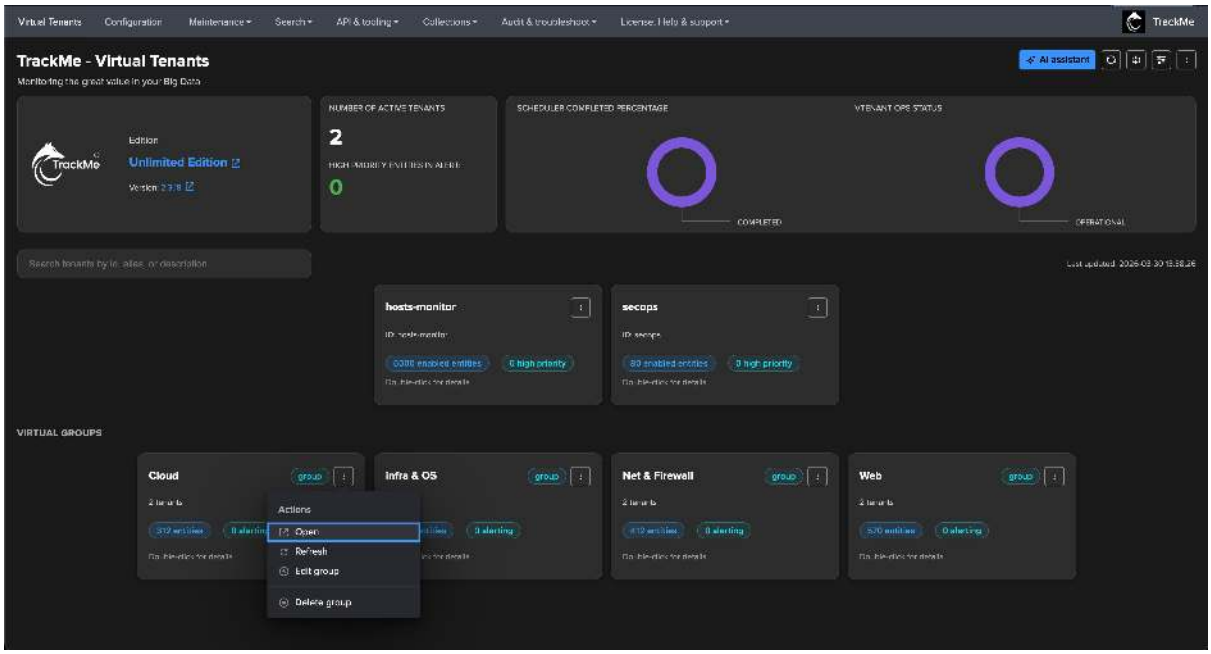


From the entity table, clicking on any entity opens its full **Entity Overview** — the same deep-dive view available from a regular Tenant Home, with event latency, delay, volume and hourly count charts, key information panel, and AI assistant access:



Managing Virtual Groups

Each Virtual Group card has a context menu (right-click or the ⋮ icon) with four actions:



- **Open** — opens the Virtual Group Overview modal
- **Refresh** — triggers an immediate re-fetch of entity counts for this group
- **Edit group** — reopens the creation wizard pre-populated with the current configuration (admin only)
- **Delete group** — removes the Virtual Group definition (admin only); no entity data is deleted

Summary and best practices

Key takeaways

- **Tags are the foundation.** Virtual Groups do not move or copy entities — they reference them by tag. Invest in a clean, consistent tagging strategy and your groups will always stay up to date automatically.
- **One lookup, many groups.** A single lookup-based tags policy per tenant can feed any number of Virtual Groups. Add a new domain? Add a row to the lookup, run the tracker, create a new group — done.
- **Compose domains freely.** The filter expression supports full boolean logic (`AND`, `OR`, parentheses, wildcards). You can combine multiple tags to represent composite domains (e.g., `Infra & OS`), add priority constraints, or filter by any entity field.
- **Cross-tenant by design.** A single Virtual Group can span any number of tenants and any combination of monitoring components (DSM, DHM, MHM, VOL, FLX, FQM, WLK). This is its core value: one view, many sources.
- **Read-only aggregation.** Virtual Groups do not participate in alerting, scoring, or the decision maker. They are pure visibility constructs — no monitoring side-effects.
- **Simulate before creating.** The Simulate step in the wizard lets you verify entity counts before committing. Use it to catch typos in filter expressions and confirm that both components contribute the expected entities.
- **RBAC per group.** Different groups can have different visibility rules. Use this to surface domain-specific views only to the teams that need them, without exposing the full tenant scope.
- **Priority filter for focused views.** When a domain contains thousands of entities, consider creating a

companion group with `Priority Filter = Critical + High` only — giving on-call teams a laser-focused alert view alongside the full domain view.

2.2 Use-case demos

Worked demonstrations of TrackMe in action — feeds monitoring, 360° services monitoring, fields quality (CIM and non-CIM), and Flex Objects.

2.2.1 Use Case Demo: This is All About Feeds

Hint

About impact score since TrackMe v2.3.5

- Since this release, TrackMe implements an impact score system to determine the status of an entity based on the KPIs, thresholds and anomalies.
- Impact score based analysis provides deep flexibility and control.
- The impact score is influenced by anomalies weights, such as a delay breach, as well as score events that can be generated by analysts (declaring false positives, manual score influence, etc.) or the system itself. (outliers detection for instance)

Use Case Demo: This is All About Feeds

- This white paper provides an overview of Splunk feeds tracking with TrackMe.
- It covers the key concepts and features around tracking data sources and hosts availability and indexing performance.
- Feeds tracking is a key feature of TrackMe, representing the root use case of TrackMe, and in many cases, the first reason why customers use TrackMe.
- This use case demo documentation explains and demonstrates the key features of TrackMe feeds tracking.

High Level Overview

At the source of TrackMe concepts stands the idea of tracking data sources and hosts availability and indexing performance.

The key features can be summarized as follows:

- `Discovery`: Discover and organize data sources automatically based on meaningful key metadata.
- `Persistence`: Persist entities and their key information over iterations, using various features from Splunk KVstore collections to events and metrics indexing.
- `Availability`: Track entities availability over time based on `delay` thresholds, to detect when a given entity has stopped forwarding events to Splunk.
- `Performance`: Track entities indexing performance over time based on `latency` thresholds, to detect when a given entity is suffering from indexing performance issues.
- `Quality`: Provide out-of-the-box and automated capabilities to detect meaningful lack of quality in the entities data.
- `Metrics`: Generate and store metrics in a high-performance way, using Splunk metric store capabilities.
- `Knowledge`: Accumulate knowledge over time to improve investigations and decision-making.

- `Machine Learning`: Implement meaningful and automated Machine Learning models to detect volume variations and potential anomalies on entities.
- `Flexibility`: Provide flexible and powerful capabilities to cover from basic tracking use cases to the most complex ones.
- `Alerting`: Provide out-of-the-box powerful and advanced alerting capabilities, from state-aware alerting to rich email deliveries, state-aware actions, and more.
- `Scalability`: Scale at any level, from few terabytes environments to hundreds of terabytes environments.
- `User Experience`: Provide a rich, easy, and fast user experience, with user interfaces and APIs that provide fast answers and browsing capabilities with TrackMe entities.

This use demo documentation covers four common and most valuable feeds related use cases:

- `Feed Interruption Detection`
- `Feed Indexing Performance Issues Detection`
- `Feed Volume Variation Detection`
- `Feed Quality Issues Detection`
- `Feed Hosts Distinct Count Anomaly Detection`

Many more use cases can be implemented with TrackMe, and through our Flex Trackers components, you can create custom monitoring solutions tailored to your specific needs.

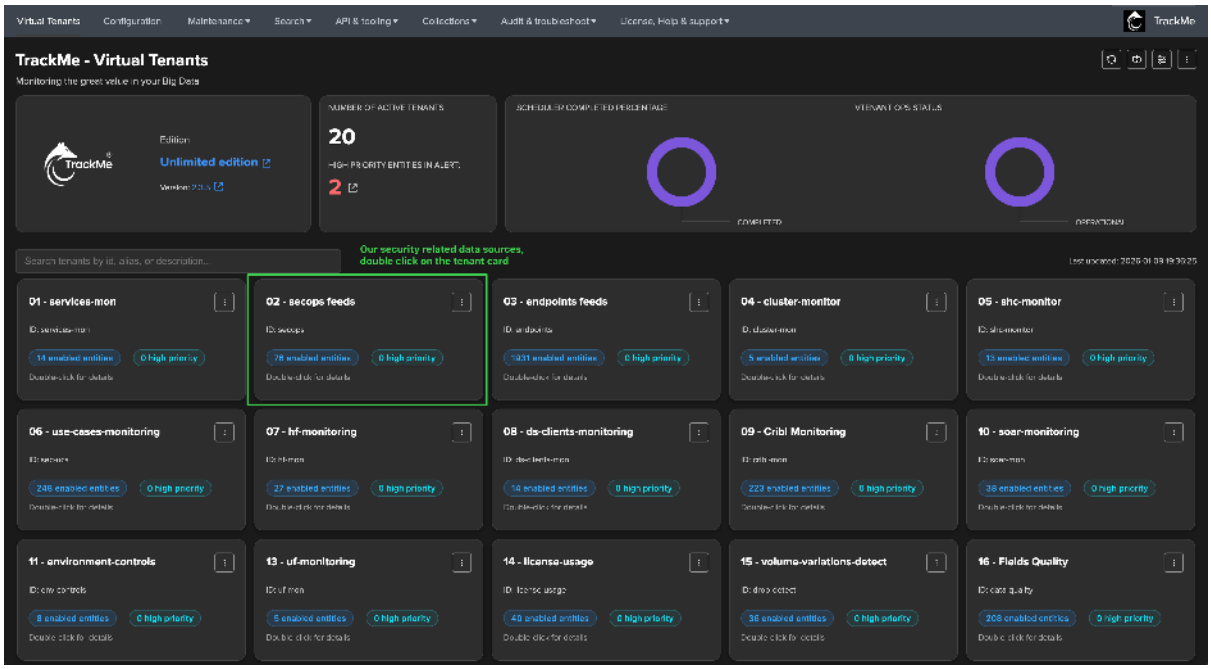
Feeds Tracking with TrackMe Data Sources Monitoring (splk-dsm)

The Data Sources Monitoring TrackMe component (splk-dsm) is the key component to track data sources availability and indexing performance.

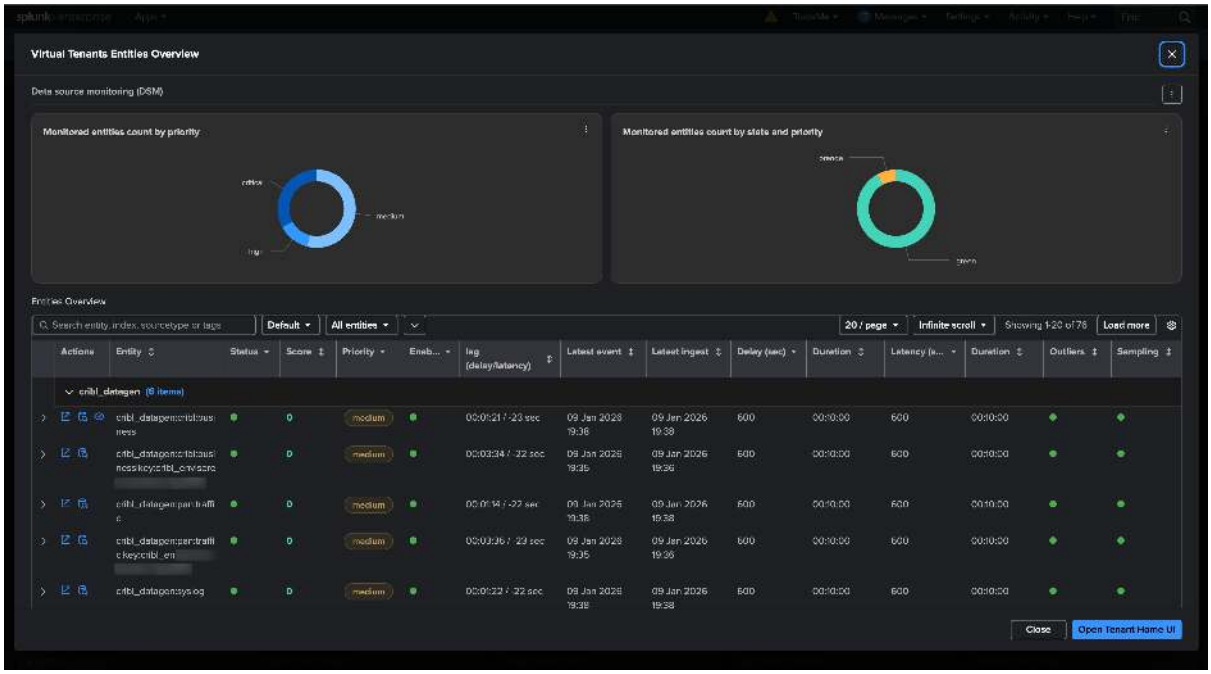
In its simplest form, it is tracking feeds, creating and organising entities based on `indexes` and `sourcetypes` metadata.

The Virtual Tenants UI

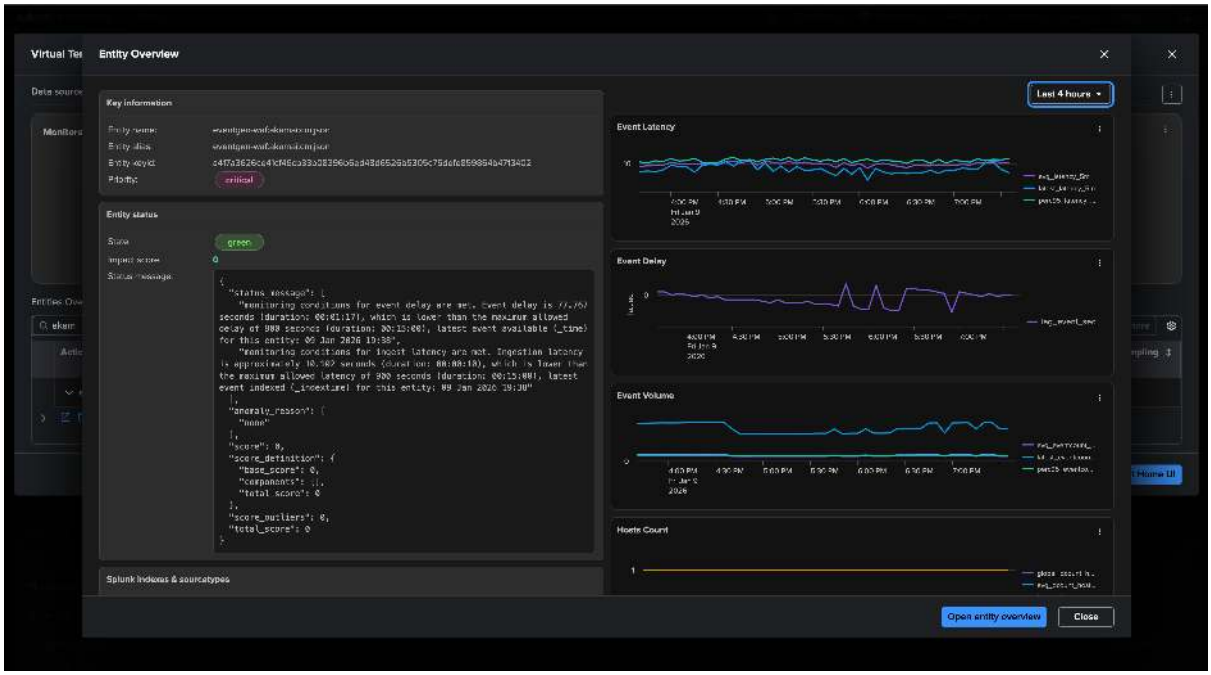
Virtual Tenants allow customers to segment use cases based on their needs, from geographically oriented use cases to use cases based on data sensitivity or perimeters:



Virtual Tenant Entities Overview:

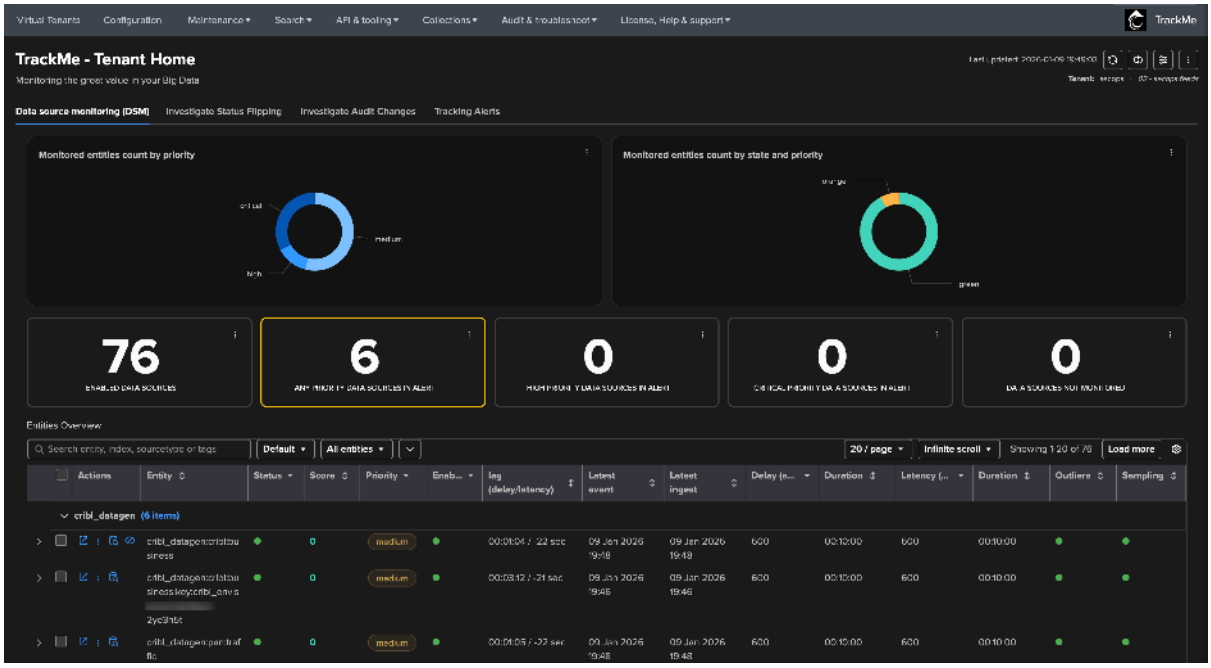


Expand or click on the name of an entity access the entity overview screen:

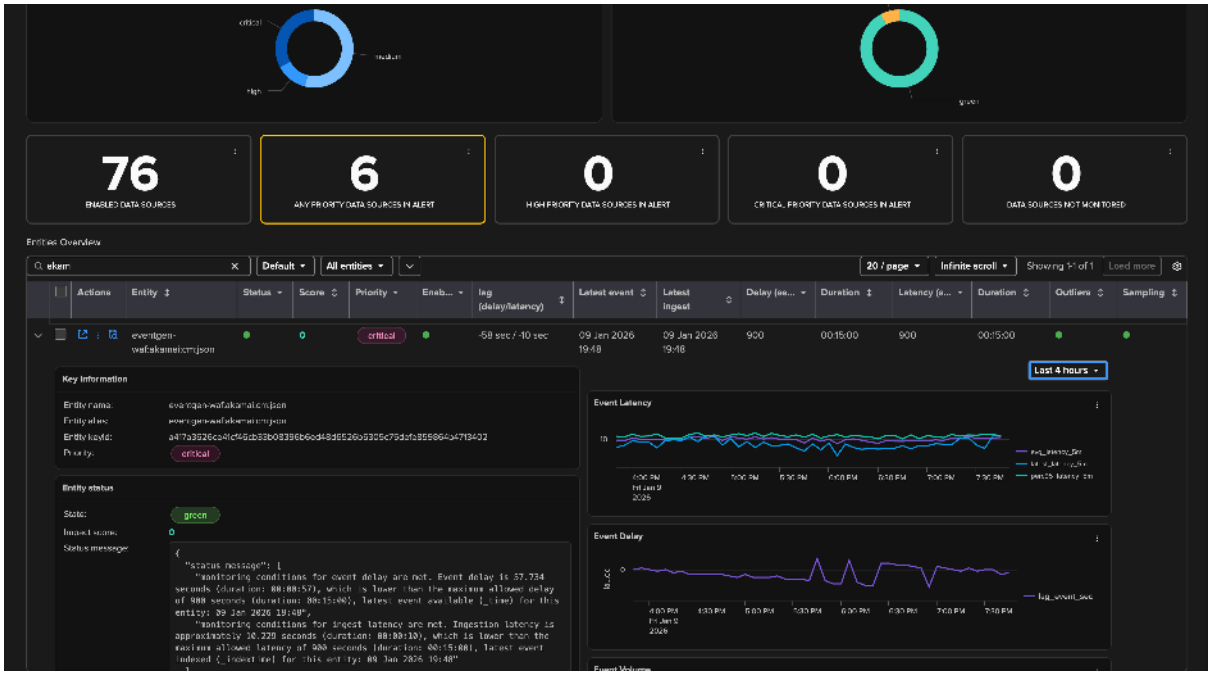


The Tenants Home UI

The Home UI is the main user interface to manage your TrackMe entities:

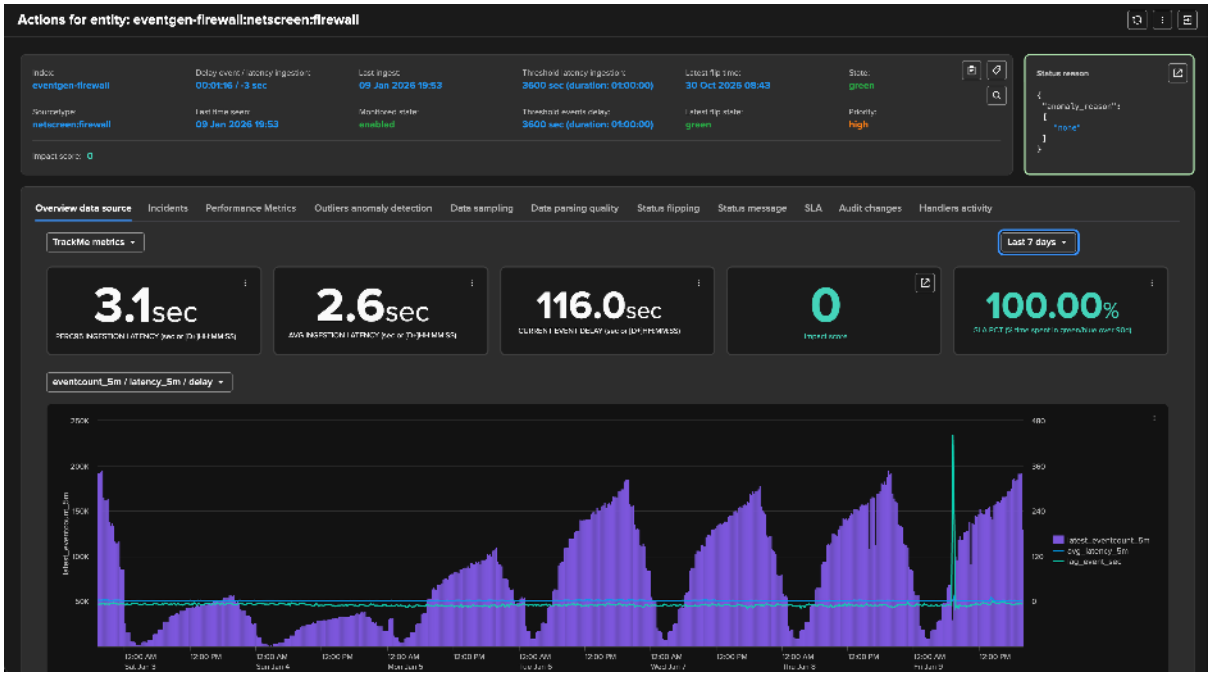


You can similarly access the entity overview by expanding or clicking on the name of an entity in the Tenants Home UI:



To Access to the status of a given entity, representing a Splunk feed (by default through its index and sourcetype metadata), click on the left hande side icon:

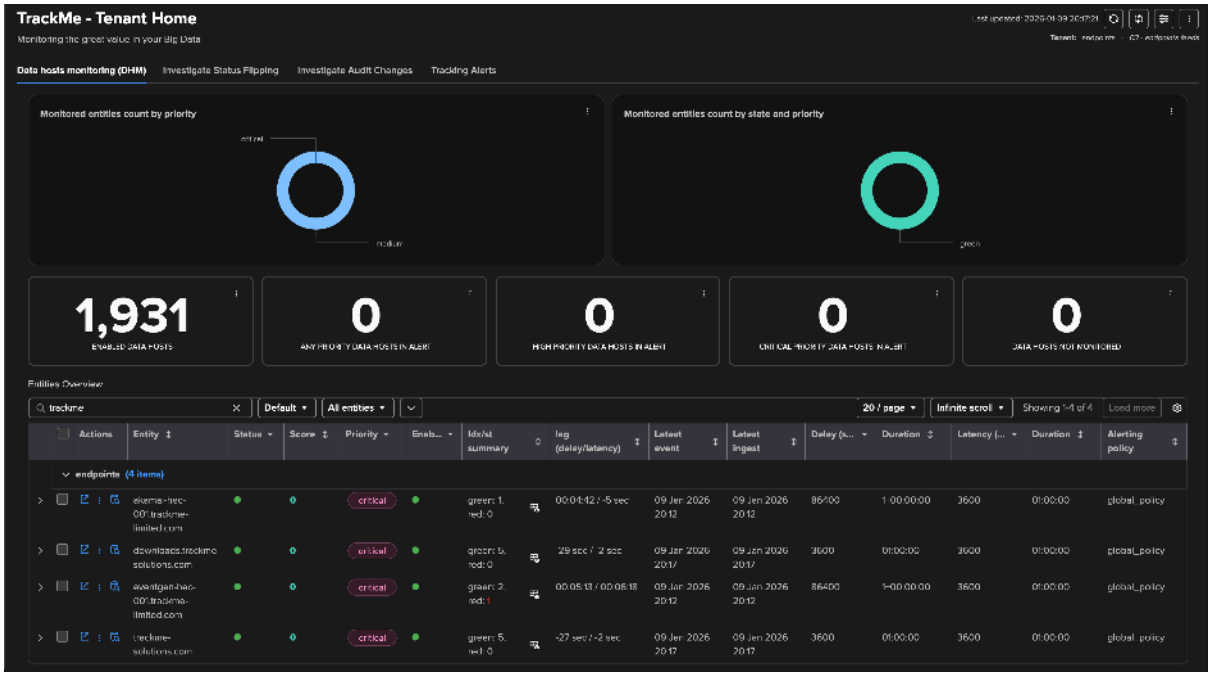
The entity details page provides a rich set of information about the entity, including its status, availability, indexing performance, metrics, knowledge, machine learning, flexibility, alerting, scalability, user experience, and more:

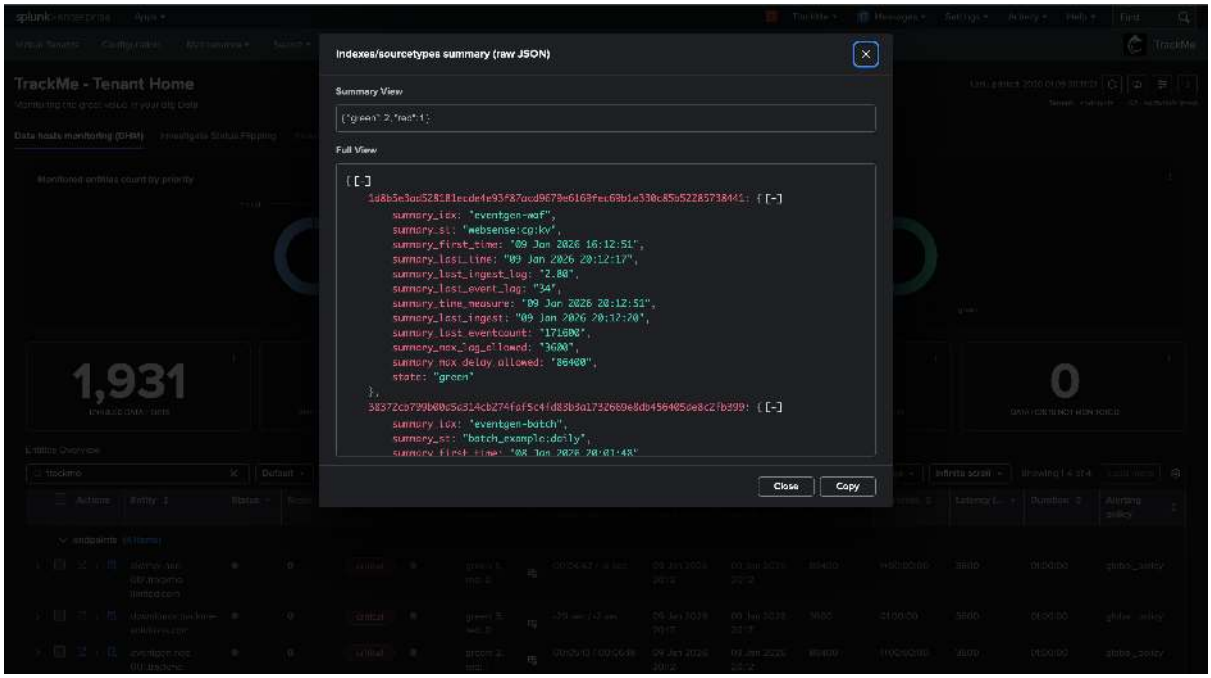


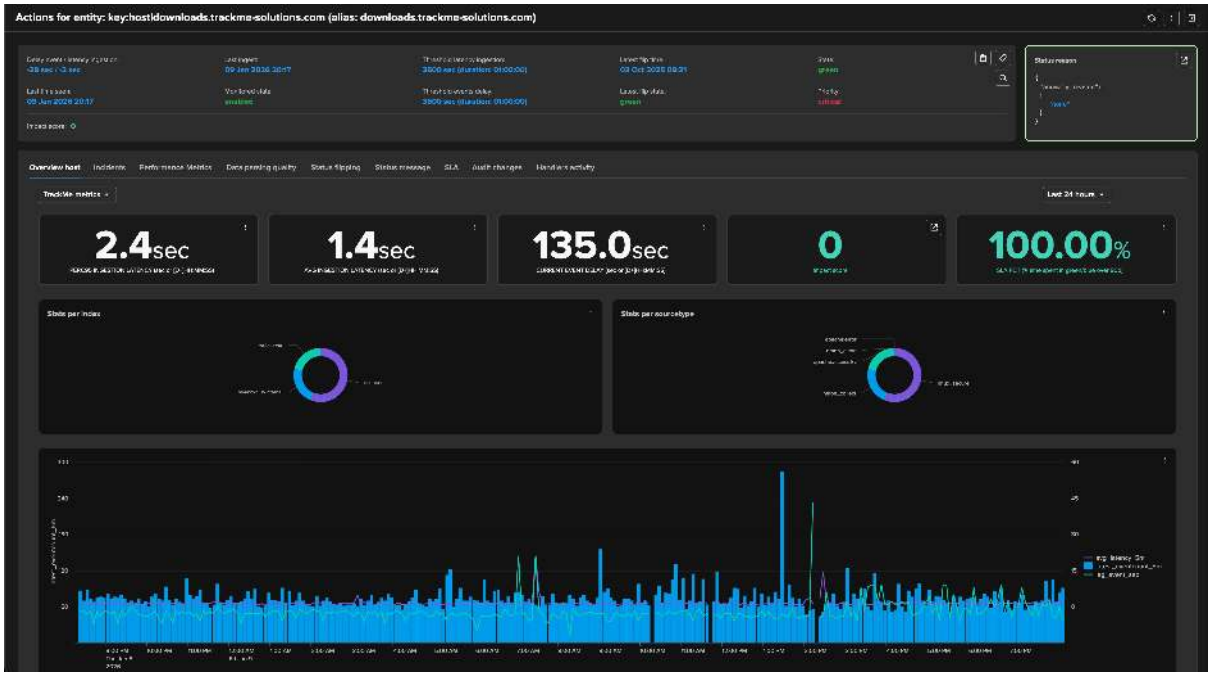
Hosts Tracking with TrackMe Hosts Sources Monitoring (splk-dhm)

The second main components for feeds tracking is the Hosts Sources Monitoring TrackMe component (splk-dhm).

It acts similarly to the Data Sources Monitoring TrackMe component (splk-dsm), at the difference that it is tracking data from host events producer perspective, which means sourcetypes associates with a given host depending on the tracker scope of data:







Primary Feeds Key Performance Indicators (KPIs)

Hint

About impact score since TrackMe v2.3.5

- Since this release, TrackMe implements an impact score system to determine the status of an entity based on the KPIs, thresholds and anomalies.
- Impact score based analysis provides deep flexibility and control.
- For feeds tracking and primary delay and latency KPIs, the default behaviour sets a delay breach anomaly as a major factor weight, and latency as a secondary factor weight.
- This means that by default, a feed affected by latency issues only appears in a warning state, while a feed

affected by delay issues appears in a alerting state.

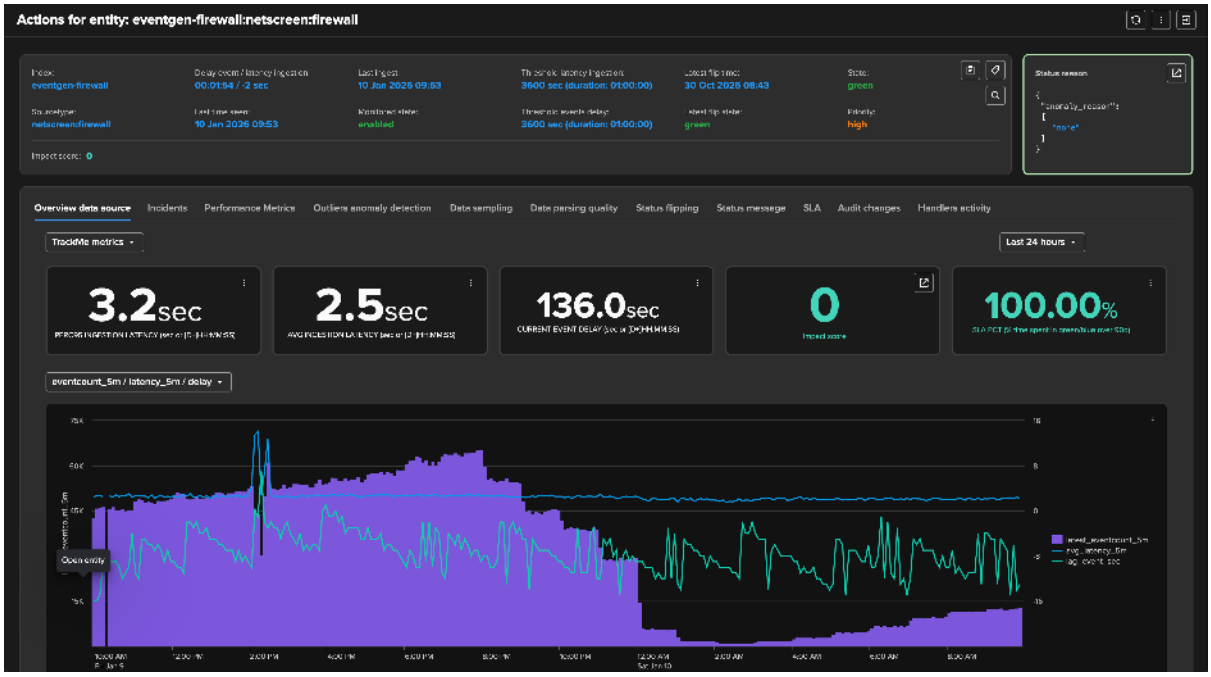
TrackMe is all about Key Performance Indicators (KPIs) and high performing metrics, this means that whatever the use case, we turn data into metrics then act against these.

In all components, you will find a tab called `Performance Metrics` which lists available metrics for the given entity.

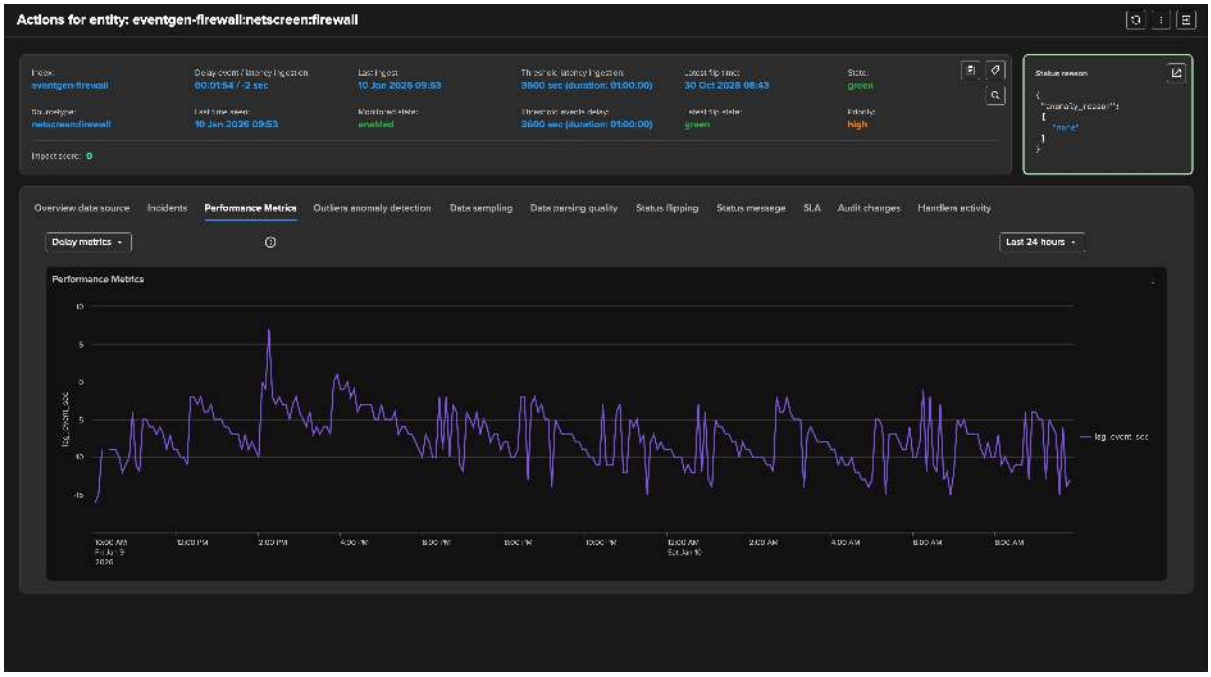
For Data Sources and Hosts, the primary KPIs are:

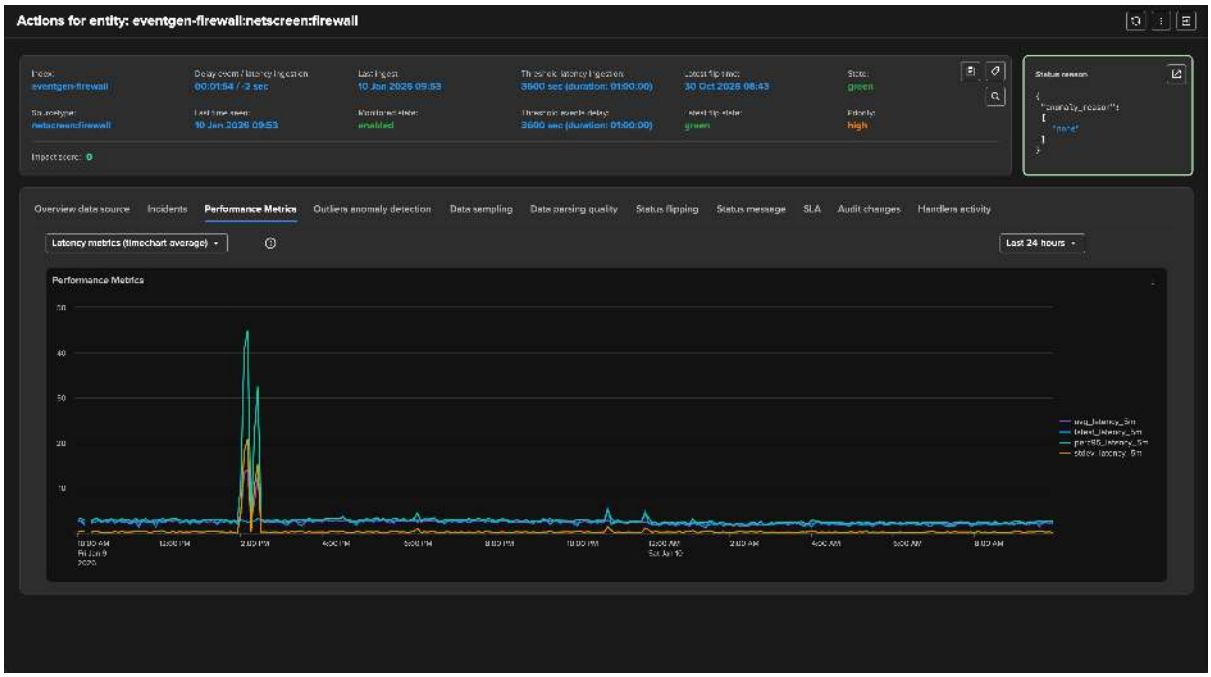
- `Latency`: The performance at the indexing level from the Splunk perspective, as the difference between the indexed time and the event time.
- `Delay`: How late the data is, calculated as the difference between now when the tracker is executed, and the very last event time.

The Entity overview shows both KPIs in the main view:

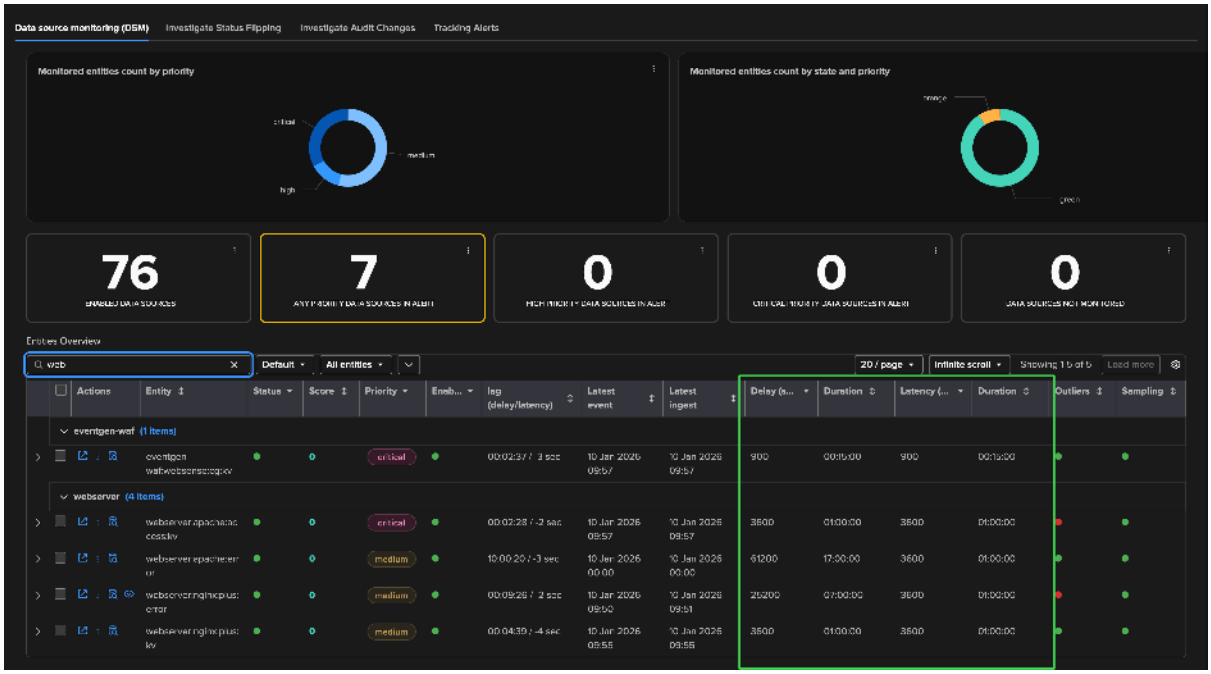


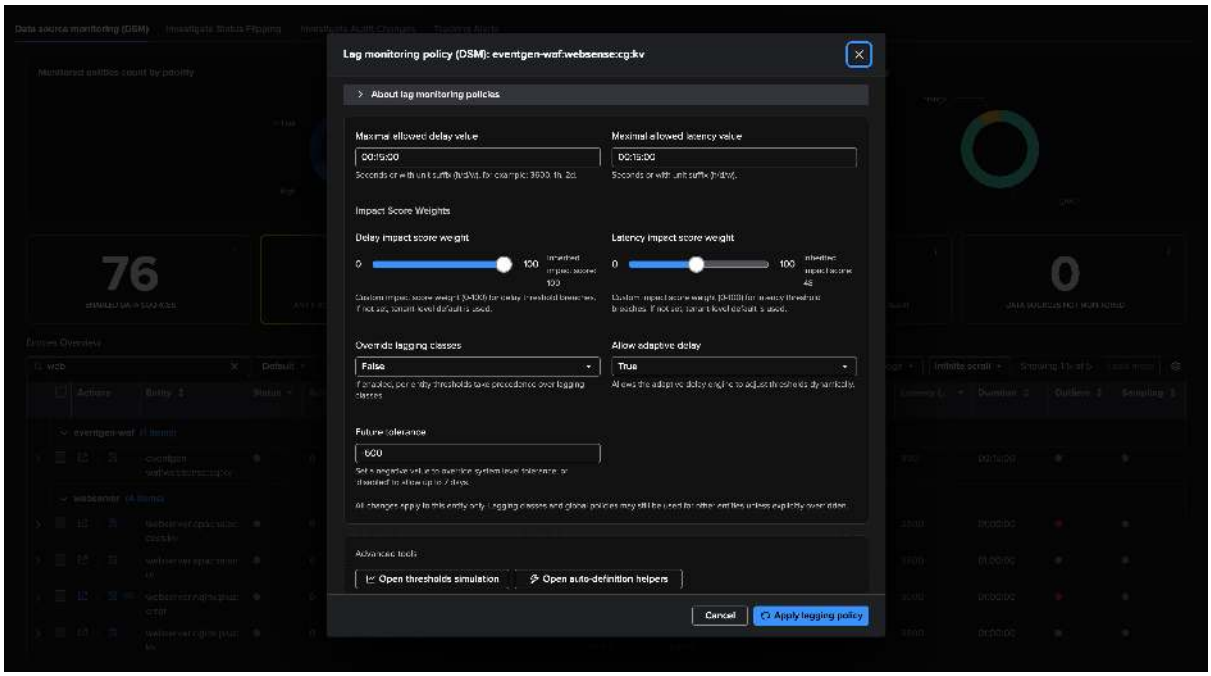
You can review in details metrics in the "Performance metrics" tab:





TrackMe applies configurable thresholds to influence the impact score calculation:





Use Case: Feed Interruption Detection

A first essential use case you want to cover when it comes to feeds availability monitoring is the detection of feed interruptions. In many use cases, you might expect the data to be flowing into Splunk in real-time or semi-real-time, though this isn't necessarily the case, and you need to have the capabilities to handle this on a case-by-case basis.

To cover this use case, TrackMe tracks the very latest event available on a per-entity basis, that is the event from the timestamp point of view (field _time). We calculate the difference between now, when the tracker is executed, and the last event, which gives you an indicator in seconds.

If this indicator breaches the threshold:

- The impact score is increased by 100 points by default, which raises the entity status to alert.
- The anomaly reason is set to `delay_threshold_breached` for entities using the static delay policy, or `variable_delay_threshold_breached` for entities using the variable delay policy (since TrackMe v2.3.12).

The workflow can be summarized as follows:

- The delay key performance indicator breaches the configured threshold value for this entity.
- TrackMe identifies the issue and raises the impact score by the associated weight, 100 by default. (anomalies score weight can be configured at the level of the tenant and overriden per entity)
- If the impact score is greater or equal to 100, the entity status is set red. (alerting state)
- TrackMe generates a flipping event which marks the entity state transition.
- If a TrackMe alert is configured, the alert fires and TrackMe runs associated actions. (email notification, incident creation, automated acknowledgement, etc.)

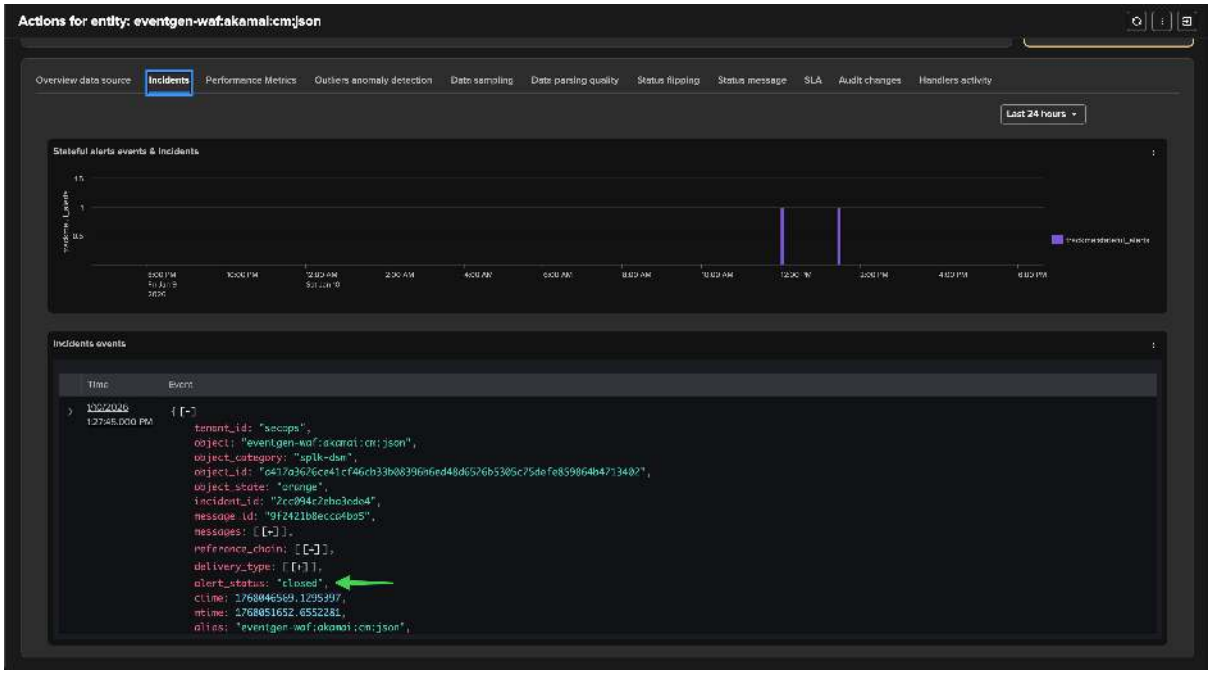
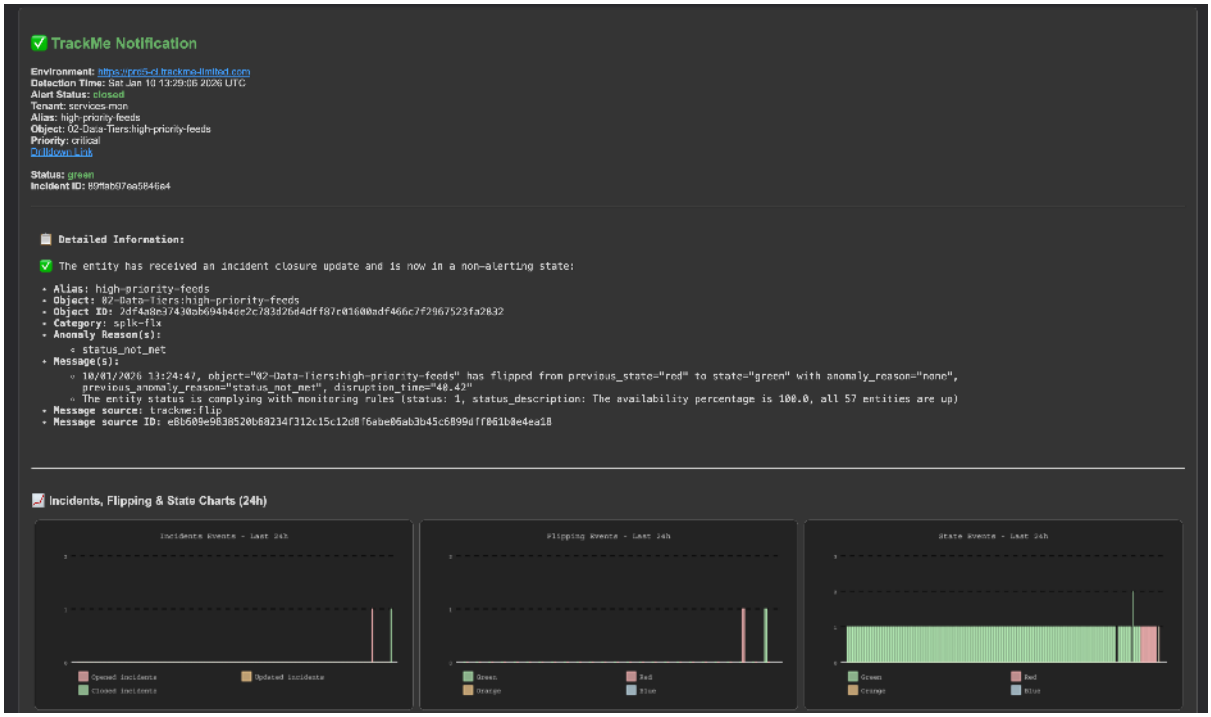
The alert is resolved and a closure notification is generated and sent:





About Adaptive and Variable Delay Thresholding

In addition with the threshold concept above, TrackMe provides two advanced delay threshold management approaches:

Adaptive Delay Thresholding (Machine Learning)

TrackMe leverages Machine Learning to adapt the delay threshold based on the knowledge accumulated over time on a per entity basis, and depending on the conditions.

This is called "Adaptive Delay Thresholding" and is widely documented here: *DSM — Data Source Monitoring*.

This feature is very valuable to reduce the administration costs by automatically defining the best suitable values according to the entity behaviour, it can increase and decrease thresholds in function of the events and statuses.

Variable Delay Thresholding (since TrackMe v2.3.12)

Variable delay thresholds allow the delay threshold for an entity to change dynamically based on the day of the week and the hour of the day. This allows defining tighter thresholds during business hours and more relaxed thresholds during quiet periods such as nights and weekends.

This feature is widely documented here: *Variable delay*.

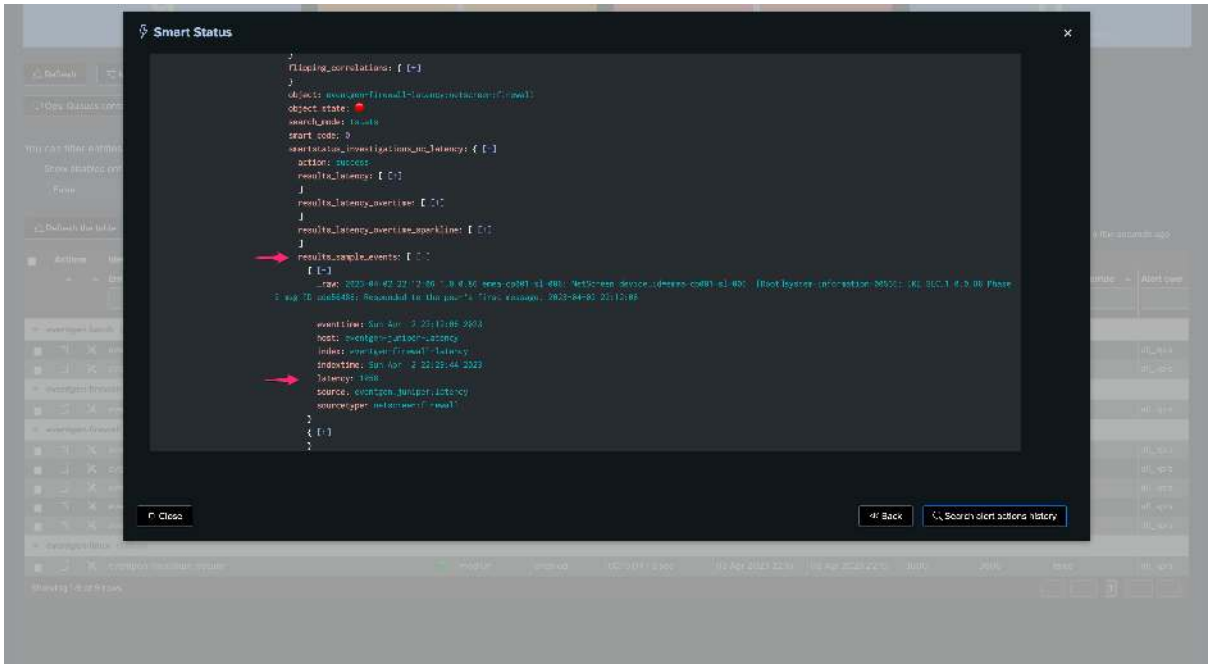
Adaptive delay and Variable delay are mutually exclusive

An entity can use either adaptive delay (static policy with ML-driven threshold adjustments) or variable delay (time-aware threshold slots), but not both simultaneously.

Use Case: Feed Indexing Performance Issues Detection

Understanding Latency in Splunk

Latency is a critical metric that measures the time gap between when an event is generated and when it becomes available in Splunk. Think of it as the "travel time" for your data:



Why Latency Matters

When latency issues occur, they can cause significant problems:

- **Search Inconsistency**: Searches run at different times may return different results
- **Delayed Insights**: Critical information arrives later than expected
- **Resource Impact**: Can indicate underlying system problems

Common Causes of Latency

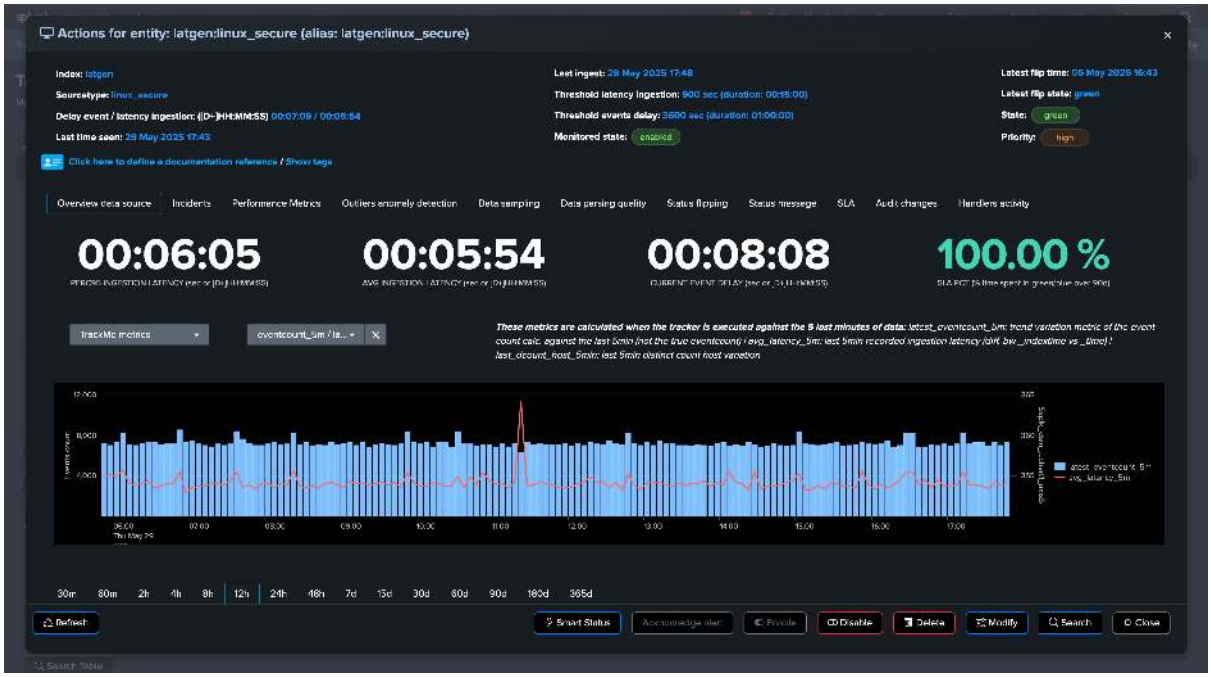
Latency issues can stem from various sources:

- Queue congestion
- Resource constraints
- Network bottlenecks
- System overload
- Configuration issues

How TrackMe Detects Latency Issues

TrackMe monitors latency by comparing the indexed time against the event time. When latency exceeds your configured threshold, TrackMe triggers an anomaly with `anomaly_reason="latency_threshold_breached"`.

Let's consider the following entity, currently the latency is very low and the entity is considered as healthy:



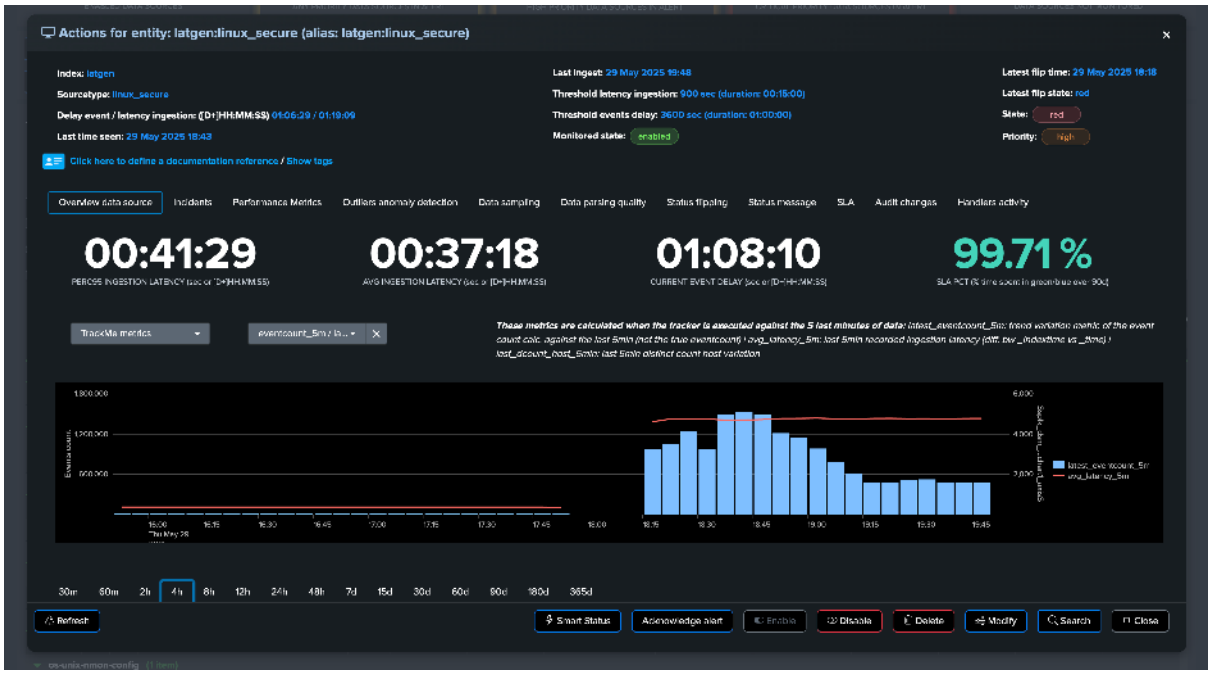
Suddenly, the entity starts experiencing latency issues. We begin receiving events with a significant time gap between their generation and indexing:

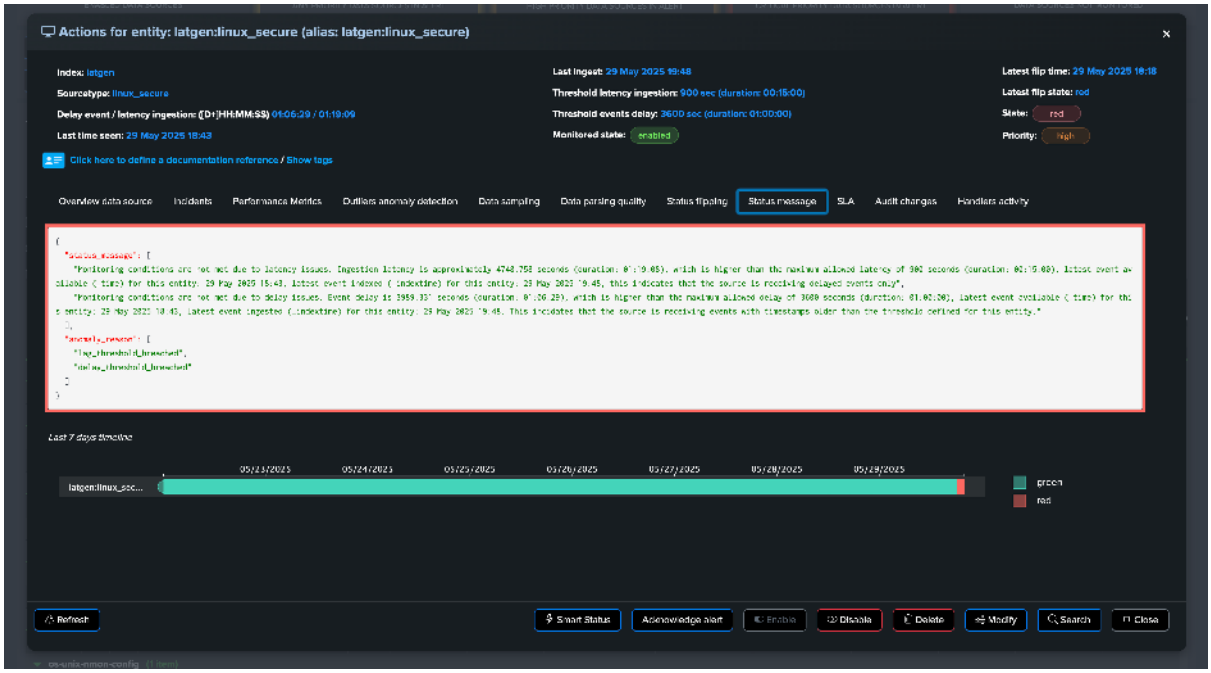
Some additional comments about latency:

- It is likely that latency will also affect the delay, but this is not necessarily the case.
- You can well be receiving a mix of real-time or quasi-real-time events, while at the same time receiving events made available with a large latency.
- This can be the case for a variety of reasons, from data feeds catching up situations to simply having collectors

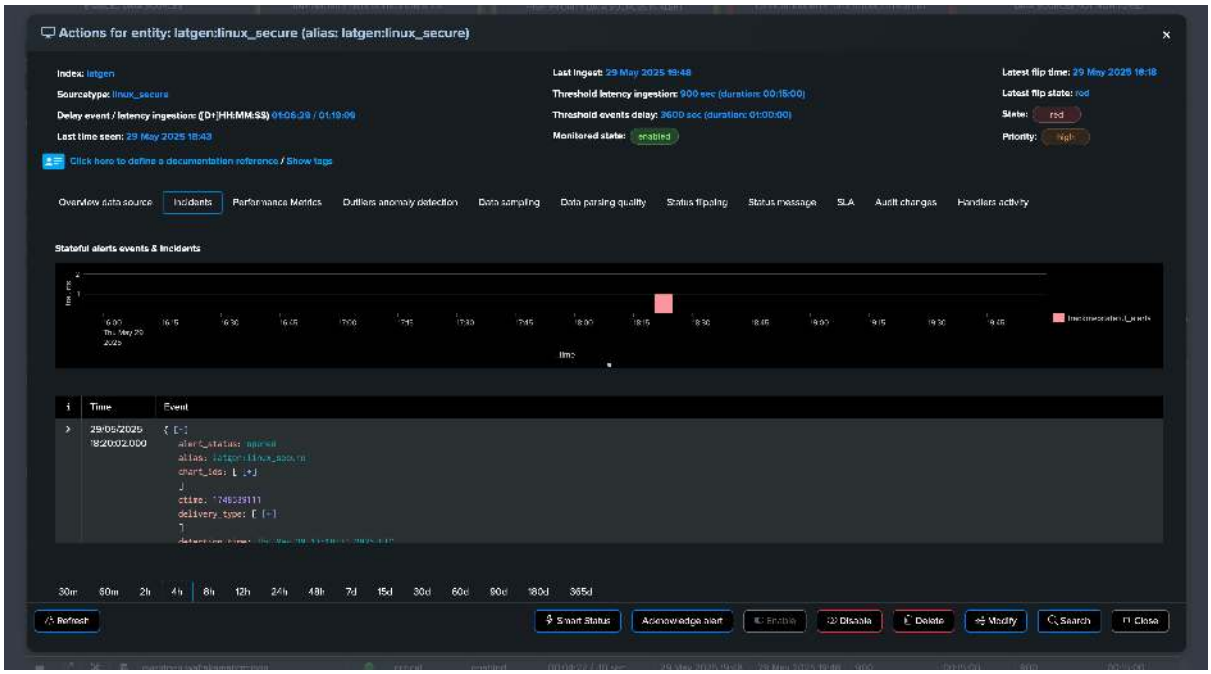
suffering from performance issues while others sending to the same context do not.

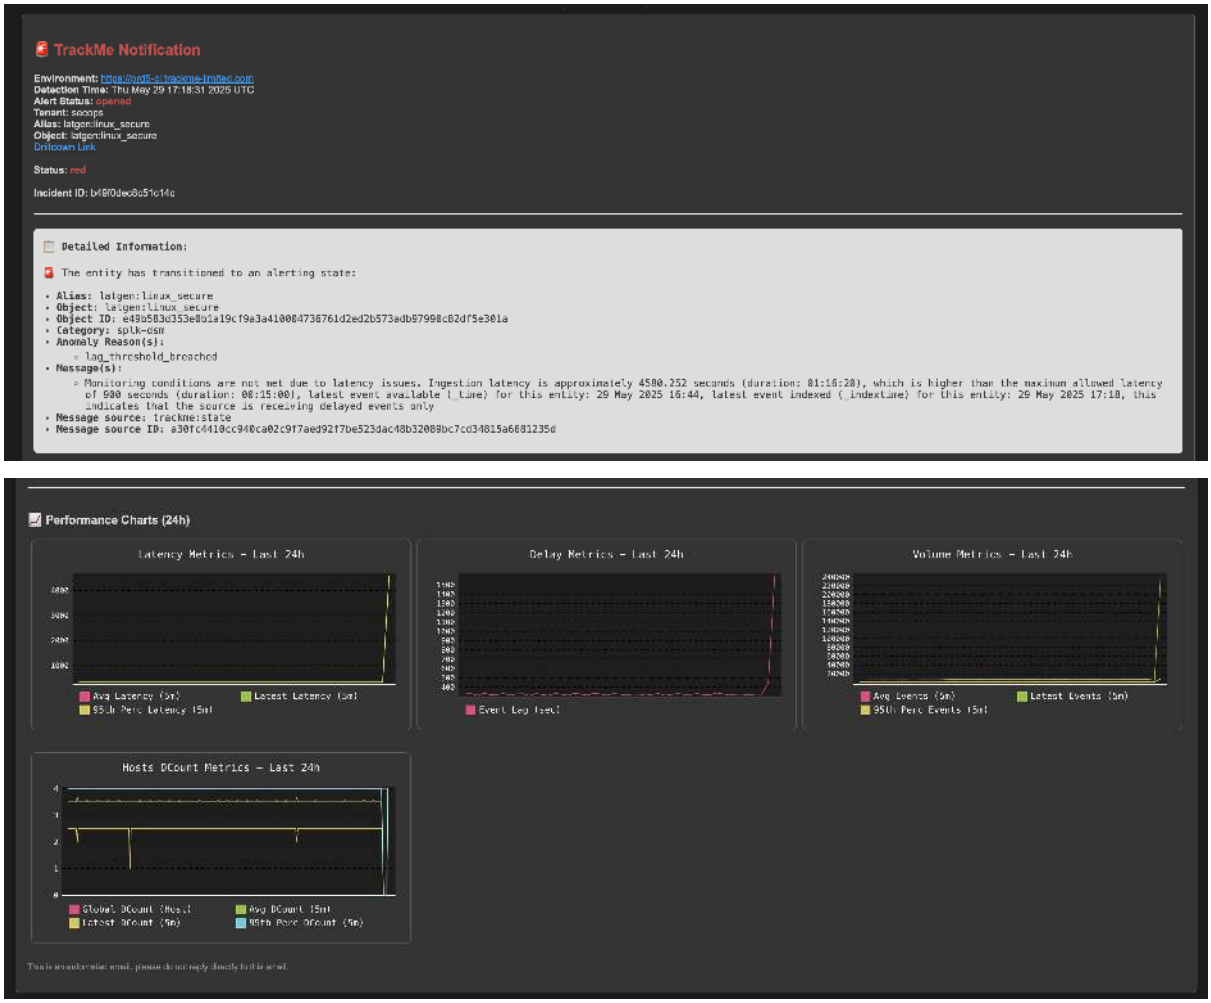
The situation escalates as the entity experiences high latency combined with a dramatic increase in event volume:





TrackMe immediately responds by opening an incident and sending a notification:





After the issue is resolved, the entity returns to a healthy state and the incident is automatically closed:

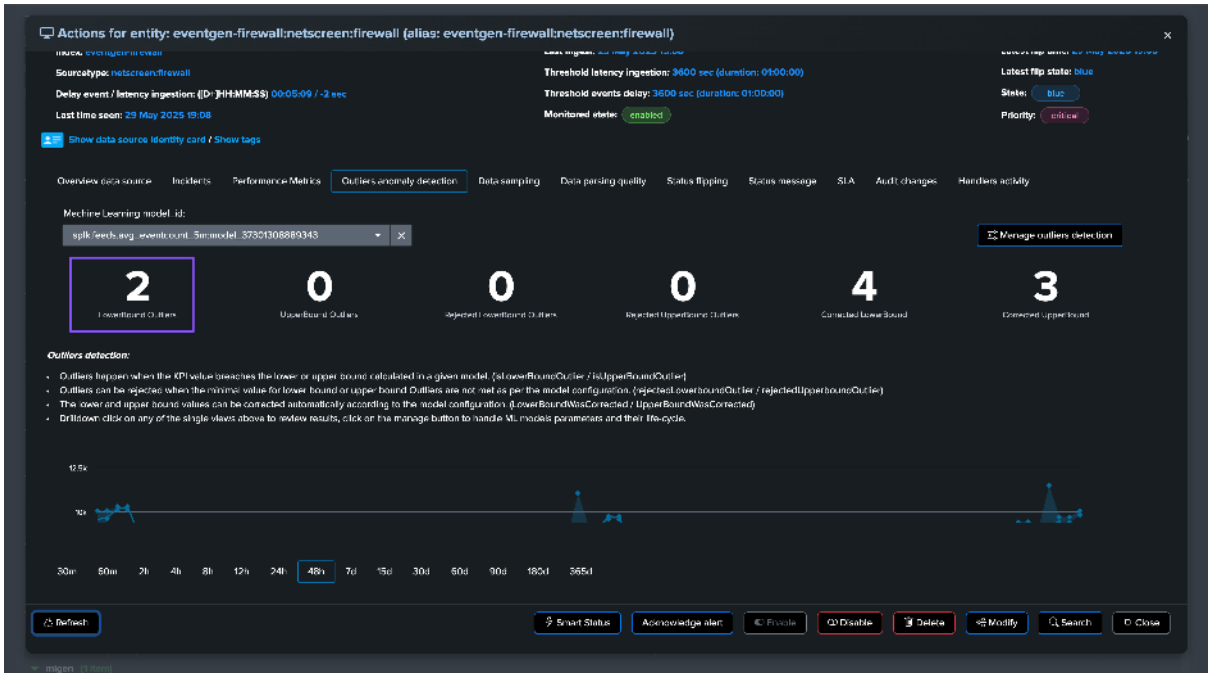
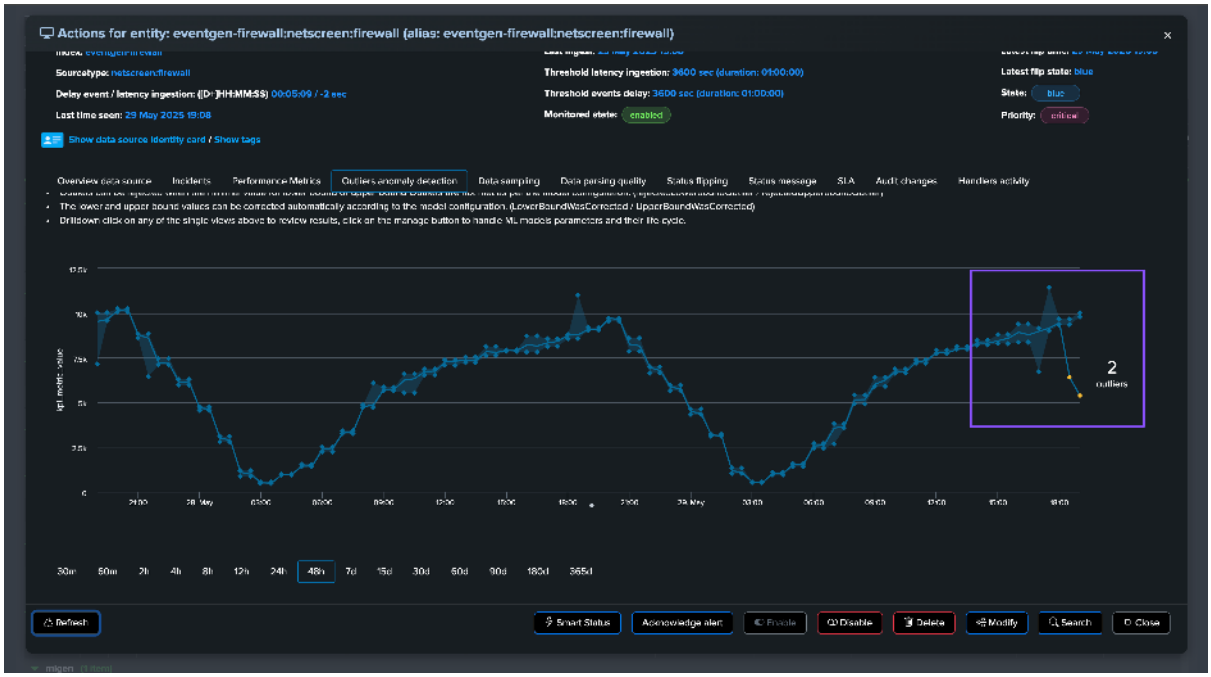
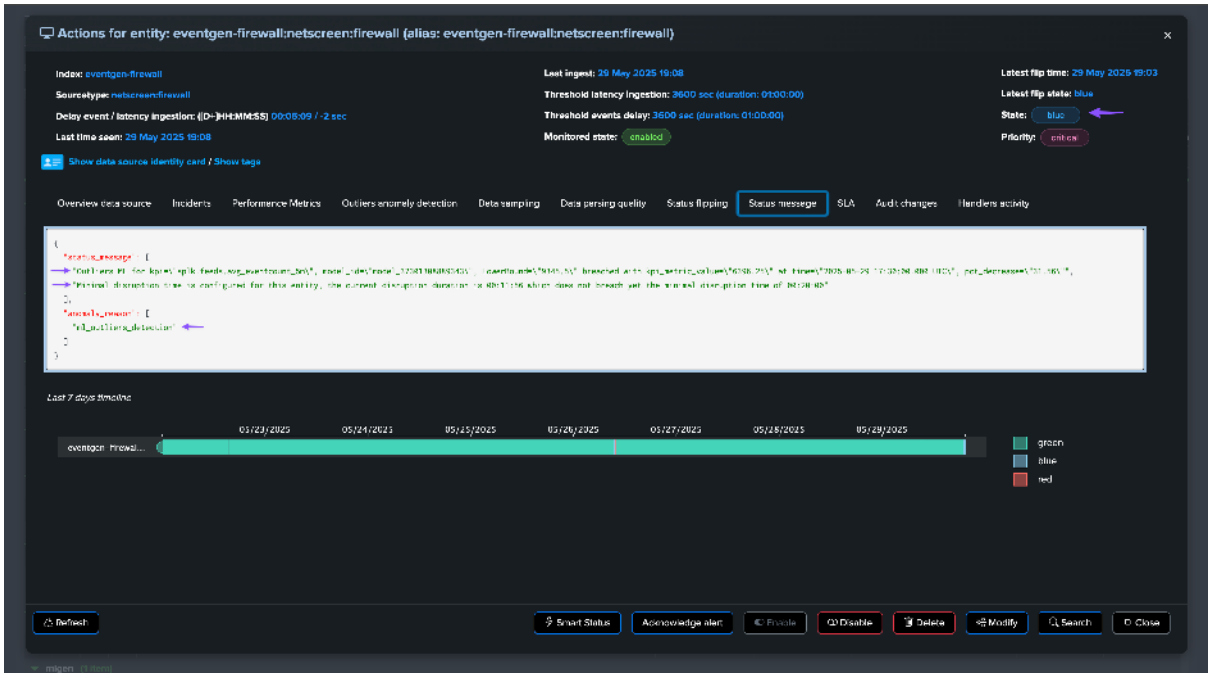
At some point, we start to see issues, we are still receiving events, but in a proportion that is not expected and indicates a potential issue:

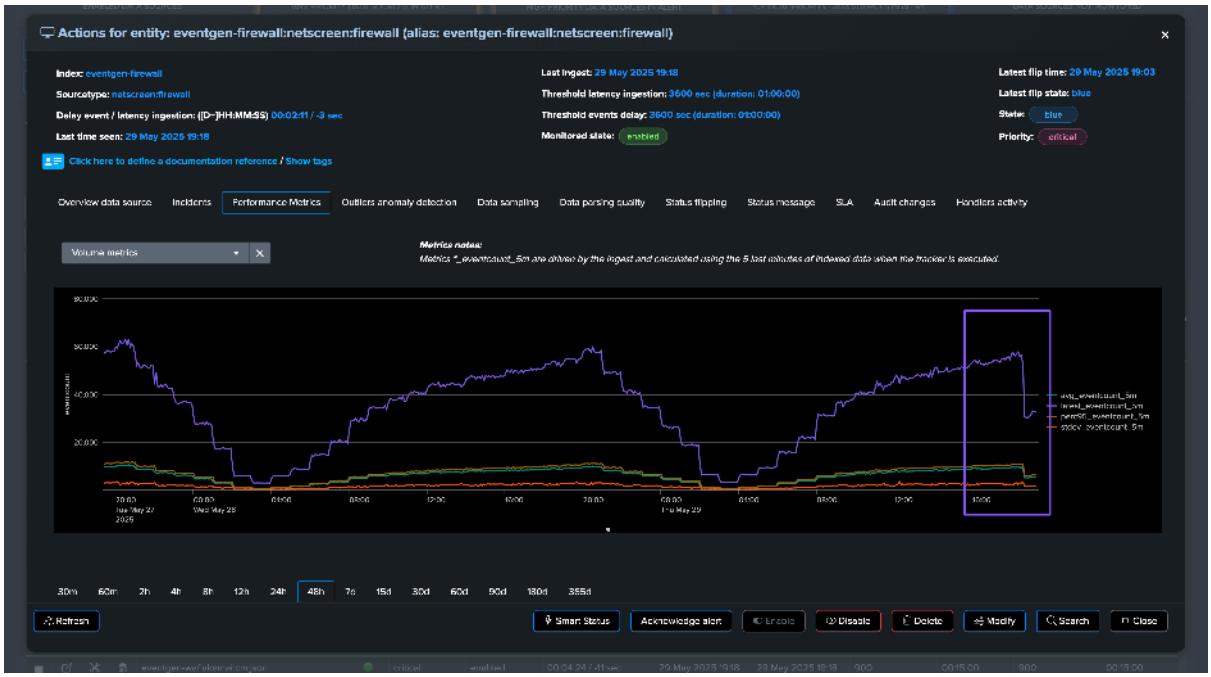




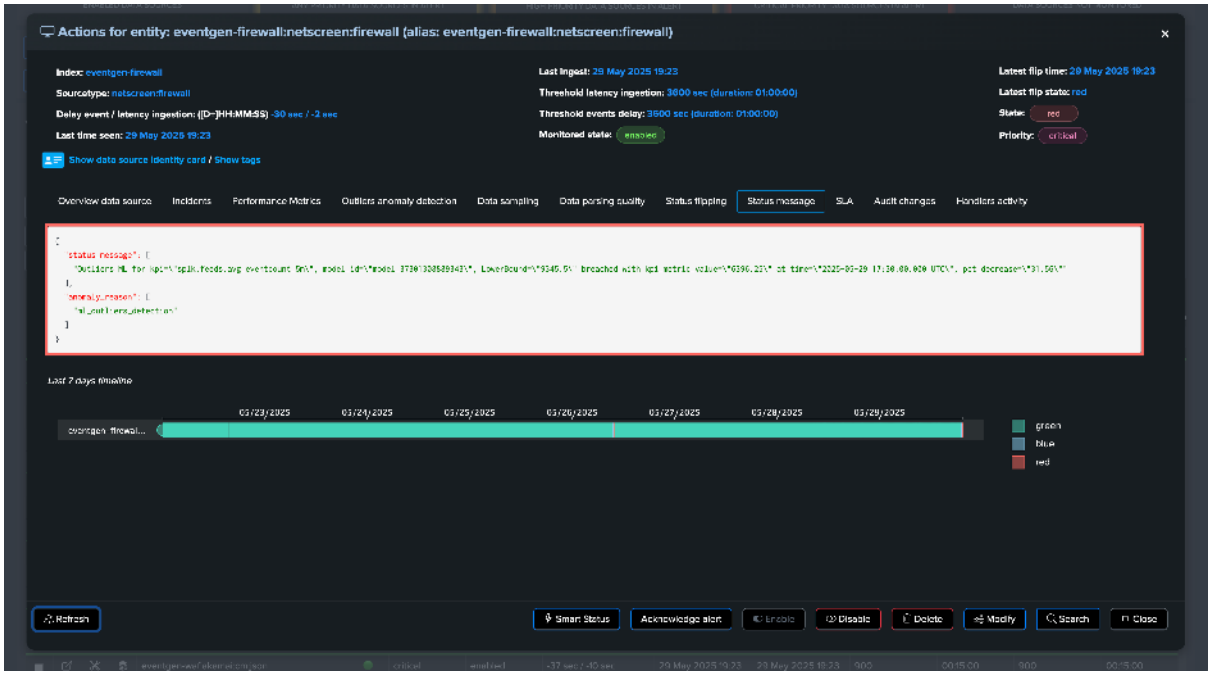
As this entity had a disruption queue configured, once the duration is breached, the entity transitioned to red and is now officially in alert:



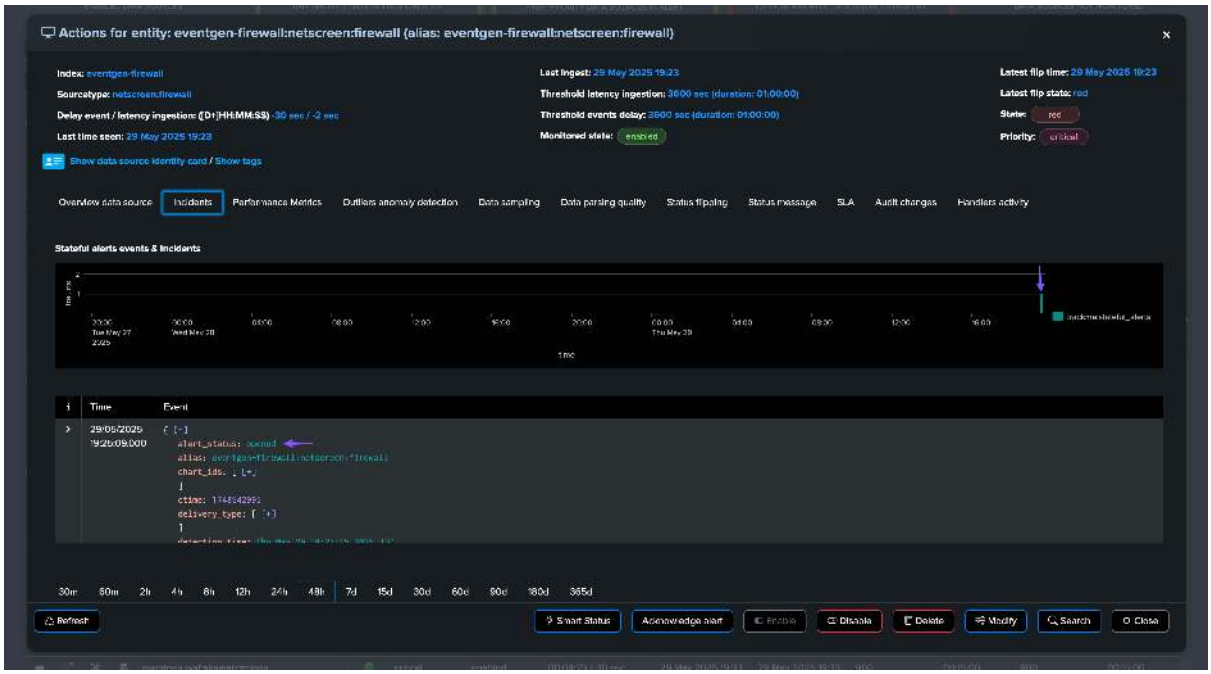
A significant amount of events is still making it to Splunk, without looking at this from the lens of Machine Learning and accumulated knowledge, we would have a hard time understanding that an abnormally low volume is happening.

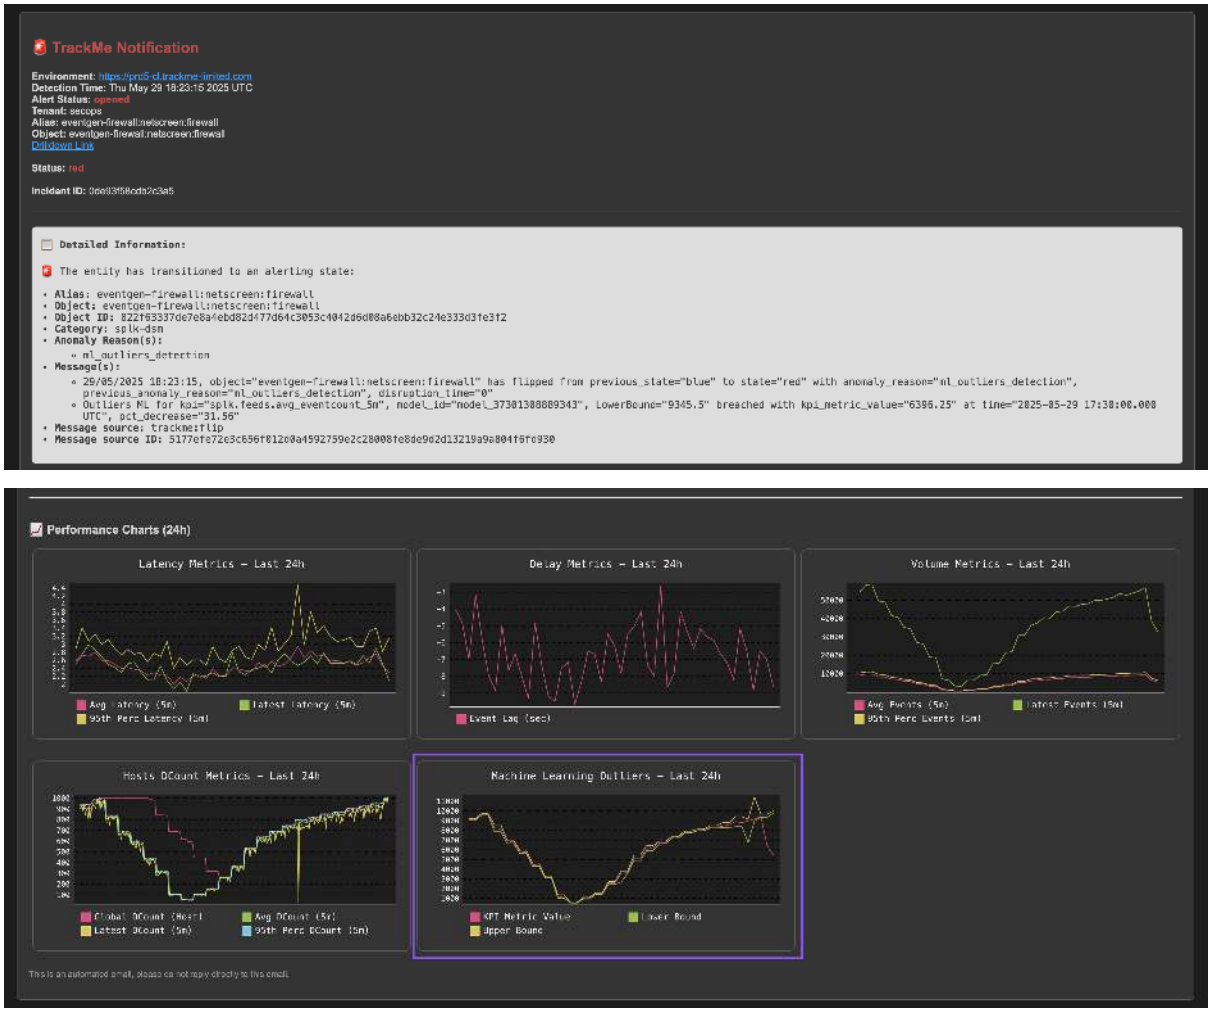


Once the disruption duration is over, the entity is now in alert:

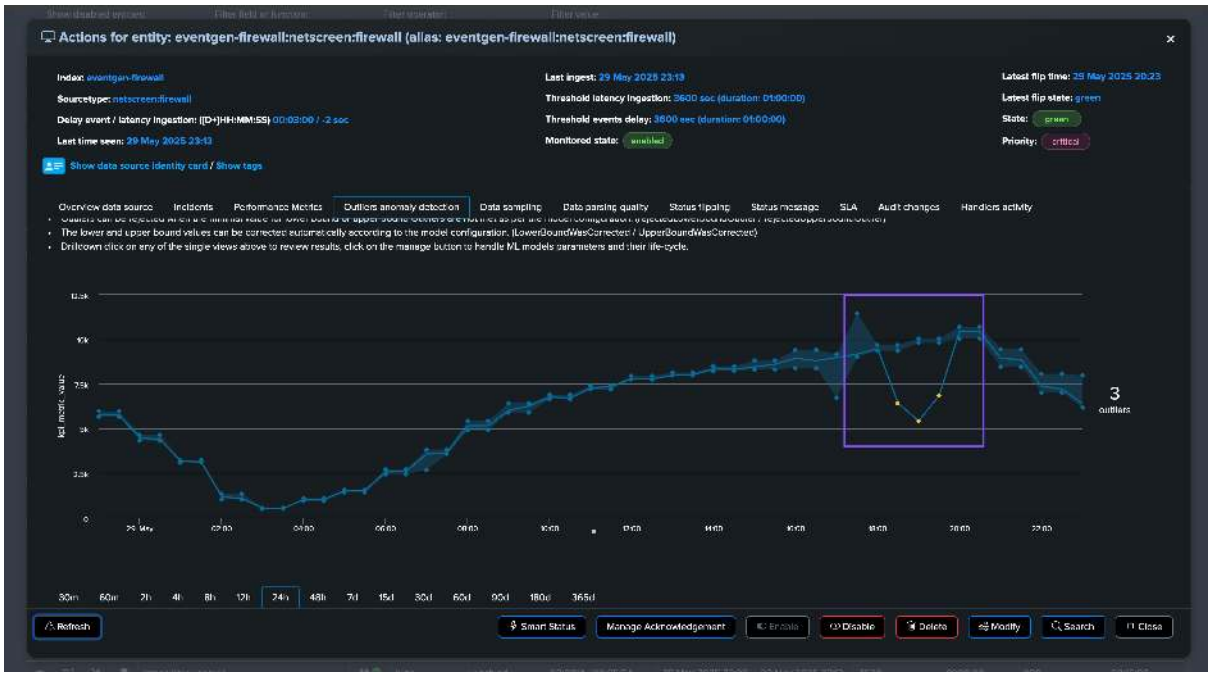


An incident is opened and a notification is sent:

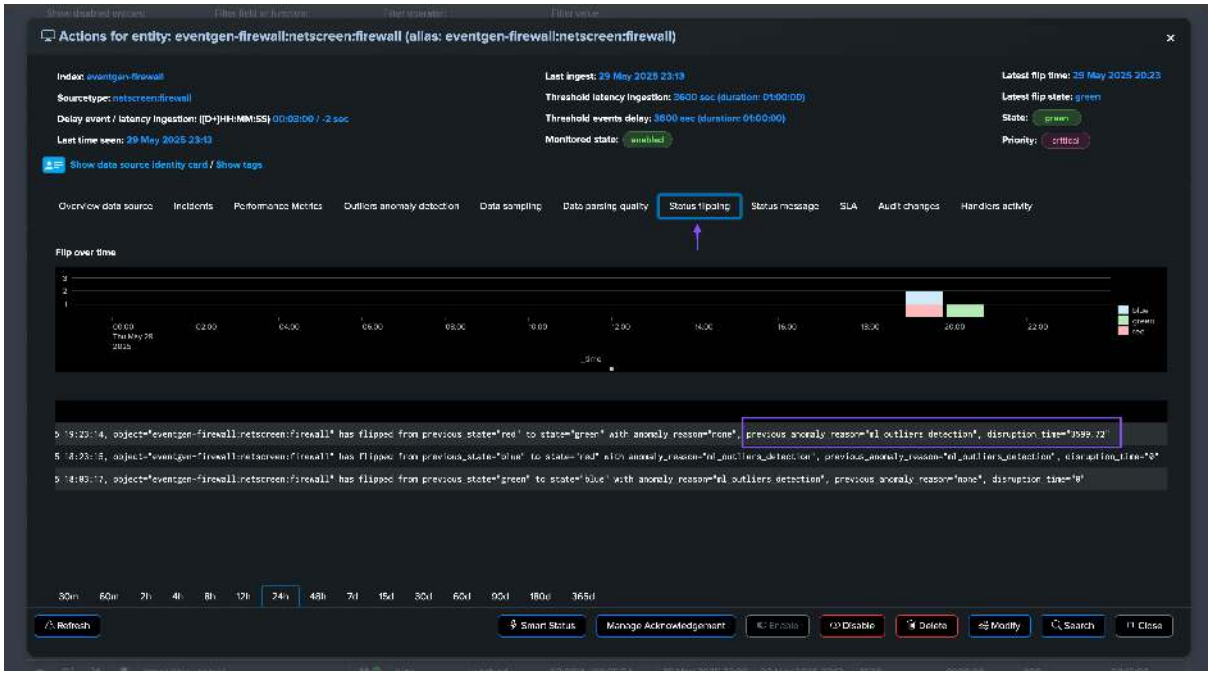


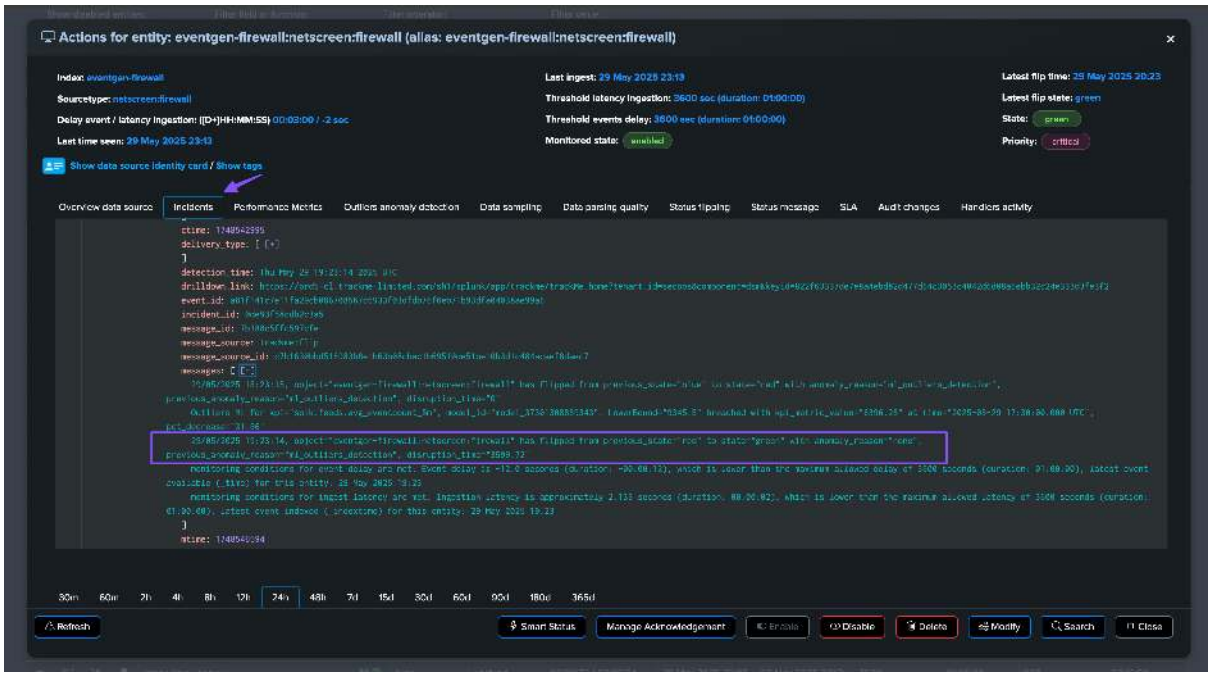


Once the issue is resolved, the entity will return to green after the Outliers anomaly condition is resolved and TrackMe has processed the ML rendering for this entity: (this can take some time depending on your settings and scale)



The incident is closed and a closure notification is sent:





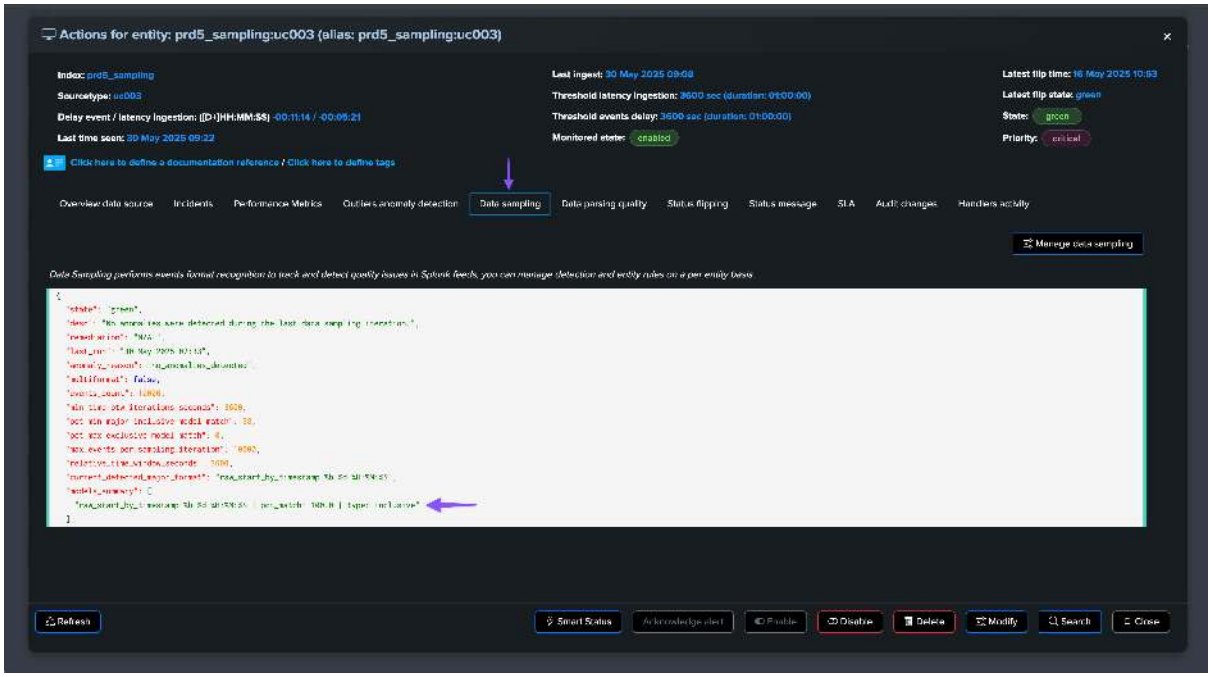
Use Case: Quality Issues Detection (Event Format Recognition)

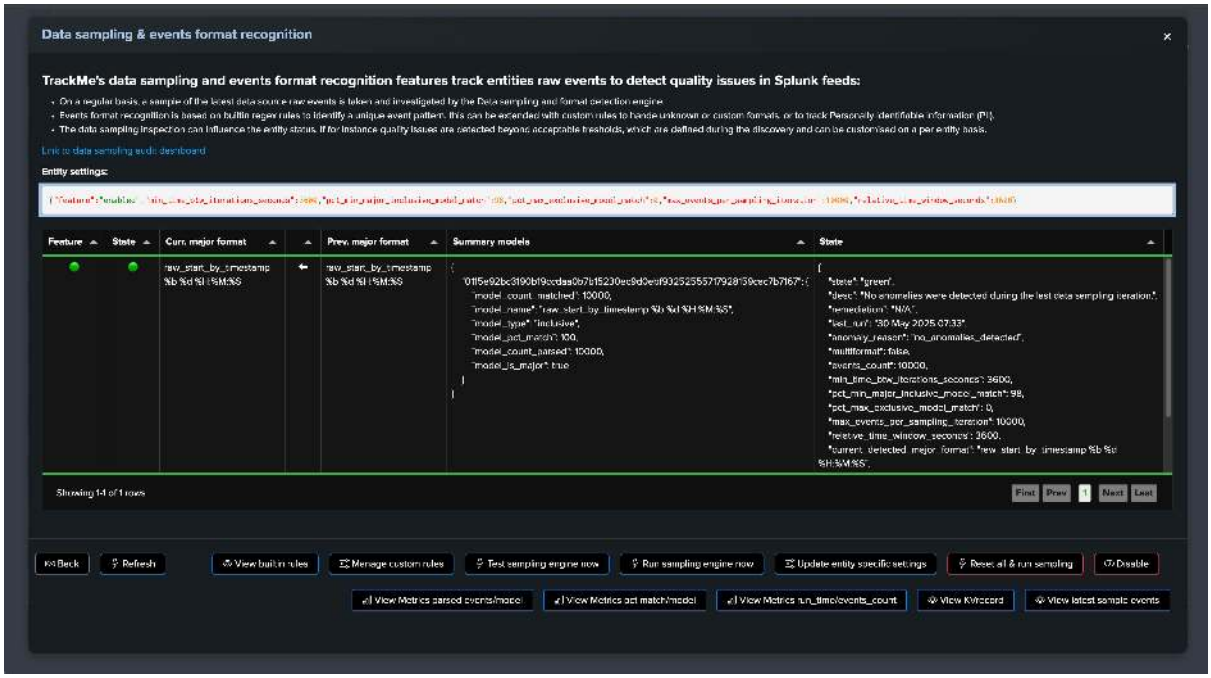
In Data Source monitoring (splk-dsm), TrackMe performs automated event format recognition using the events format recognition engine.

During this process, we will pick samples of events regularly, 10k events by default, which will be processed through the engine to detect the format of events, classified by types.

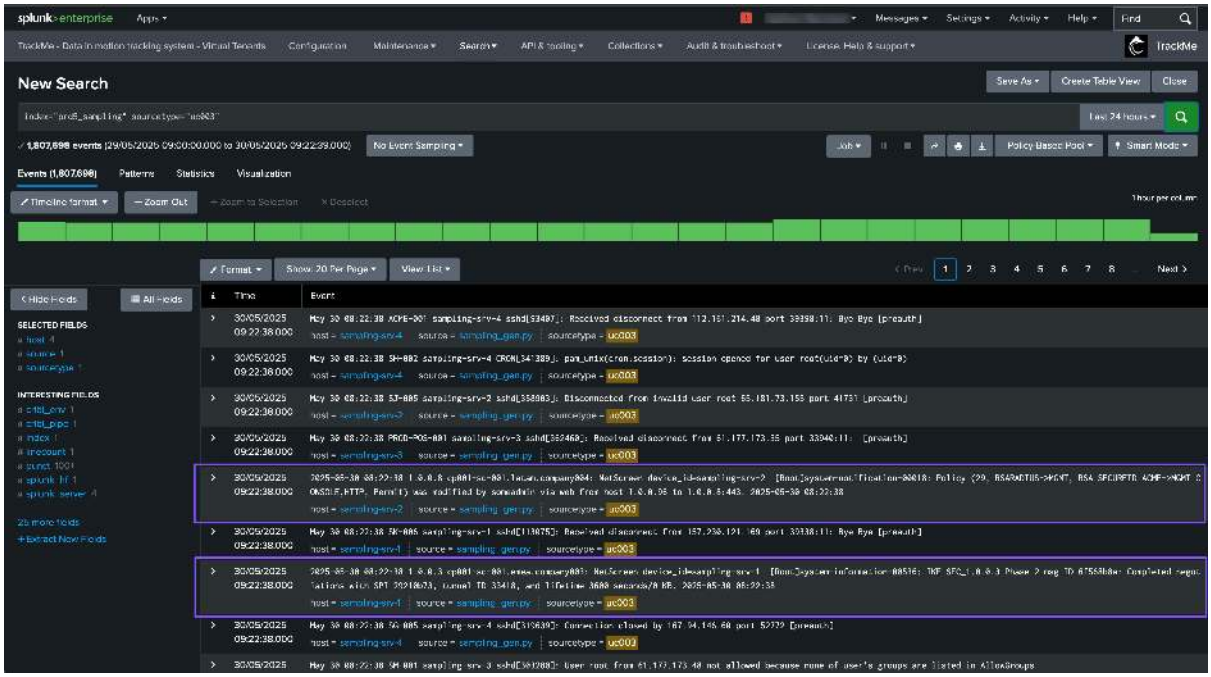
By default, TrackMe would alert against a lack of quality if it detects that the main format goes below 98% of the events being correctly classified.

Let's consider the following entity, the data sampling engine detected a single format and the entity is considered as healthy:



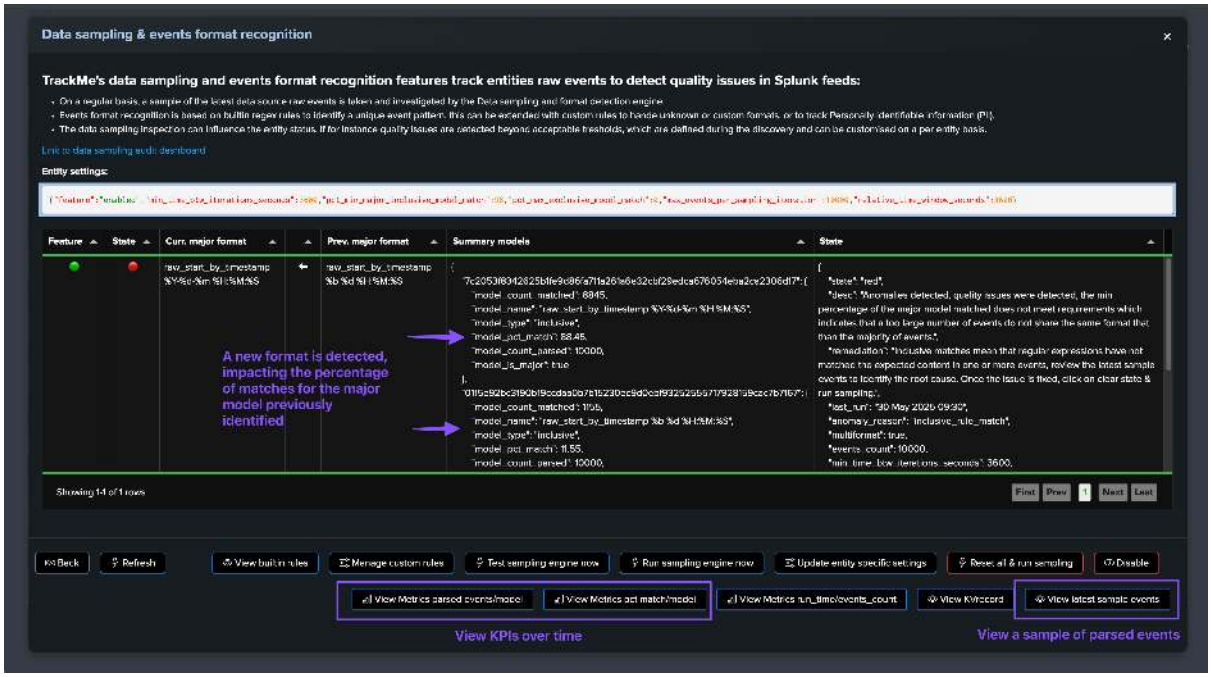


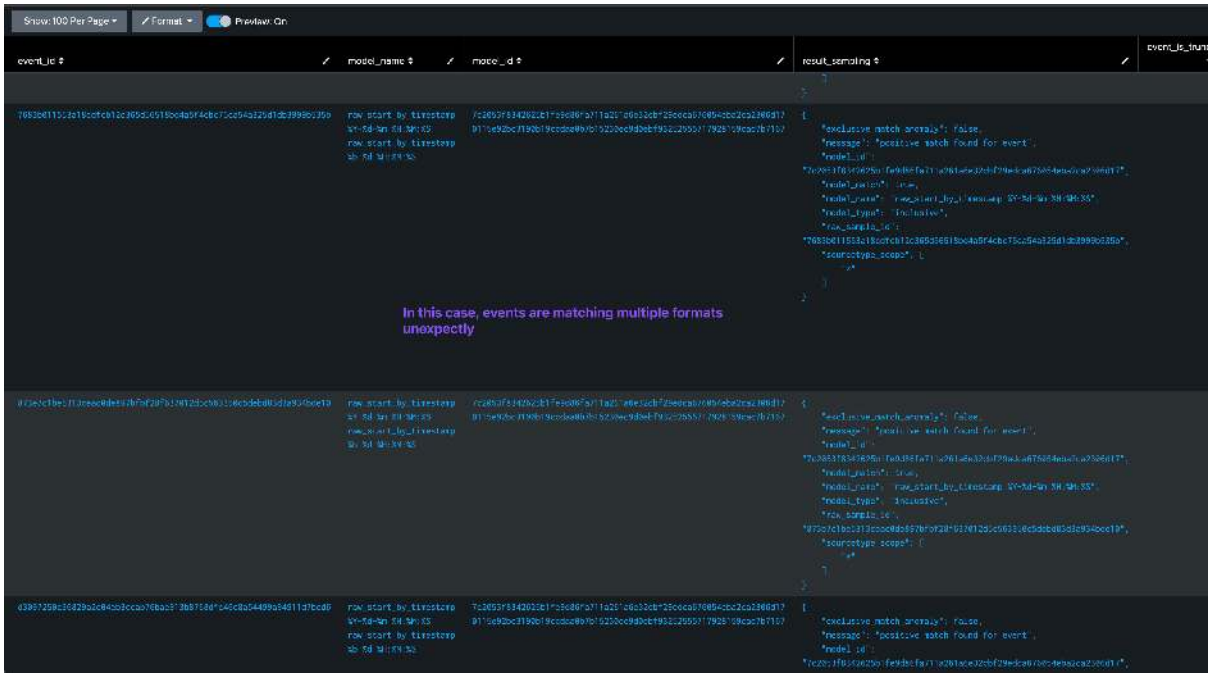
At some point, new sources are being on-boarded within the same sourcetype, however, mistakenly the expected format is not configured properly and events are making it with a different and non-expected structure:



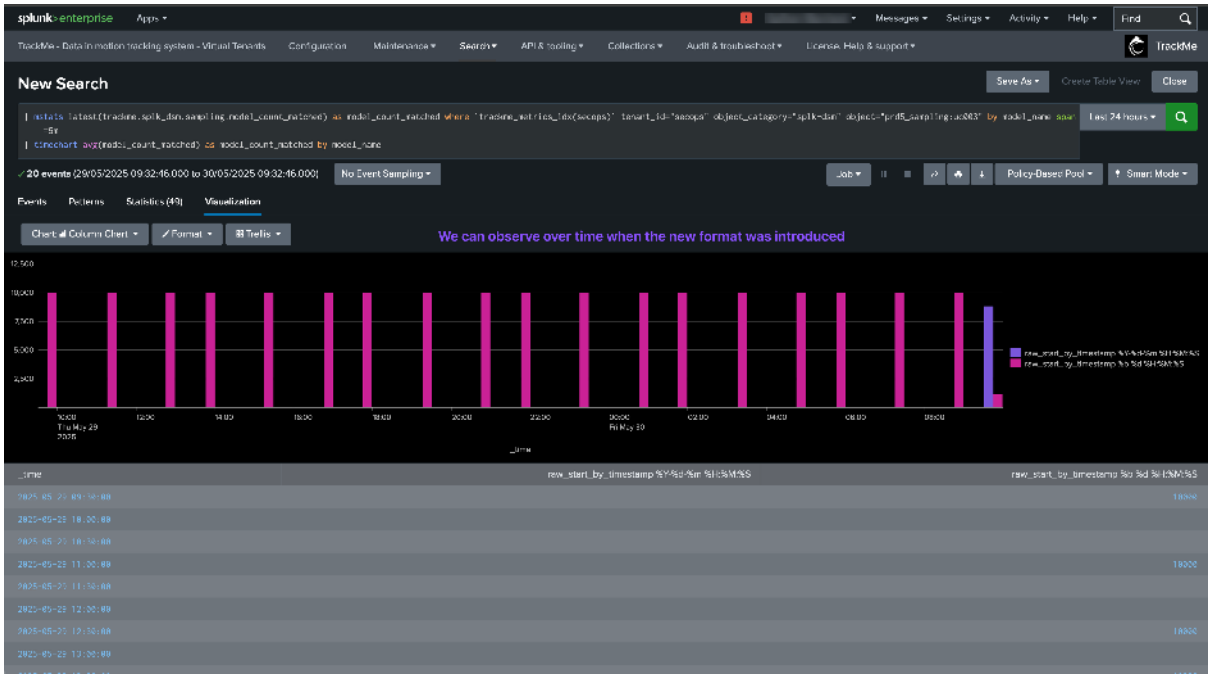
This may or may not be a strong issue, but in most use cases, receiving different types of events within the same sourcetype is not expected and leads to failures at the index time level, for instance, the timestamp extraction, or at search time with failures to extract fields for unstructured events.

The data sampling engine will detect that the format has changed and that the main format previously detected is not matching the required percentage of events, and that new event formats were introduced, leading to an alert for quality issues:

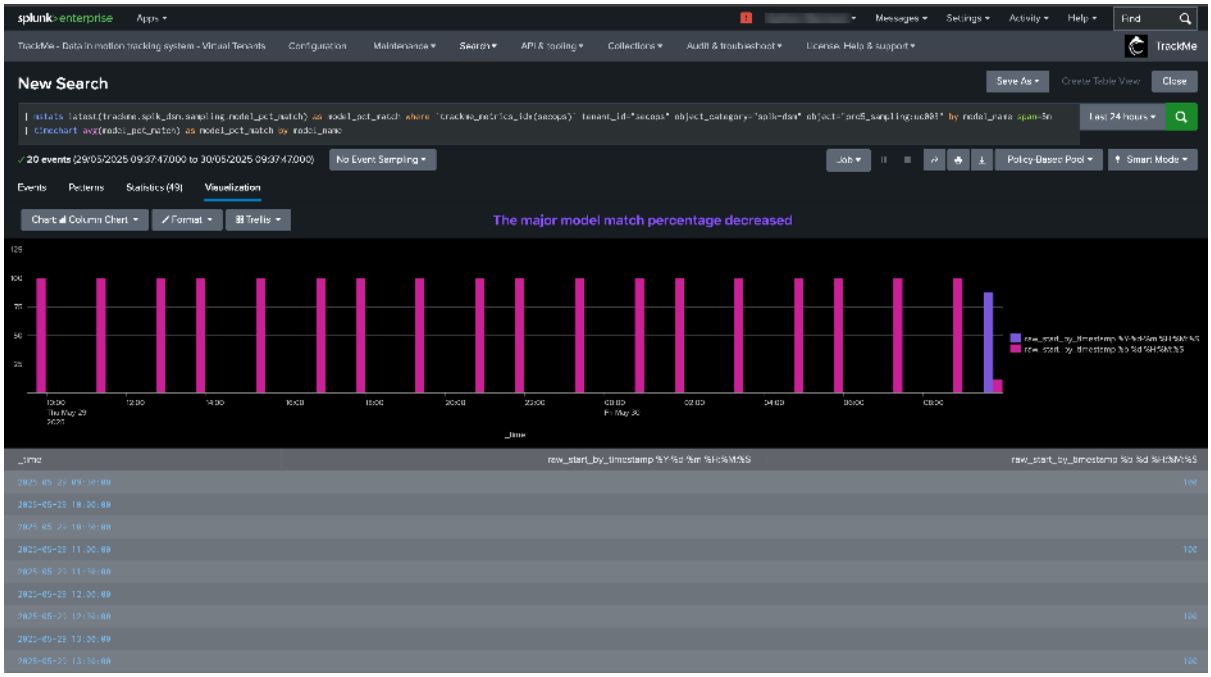




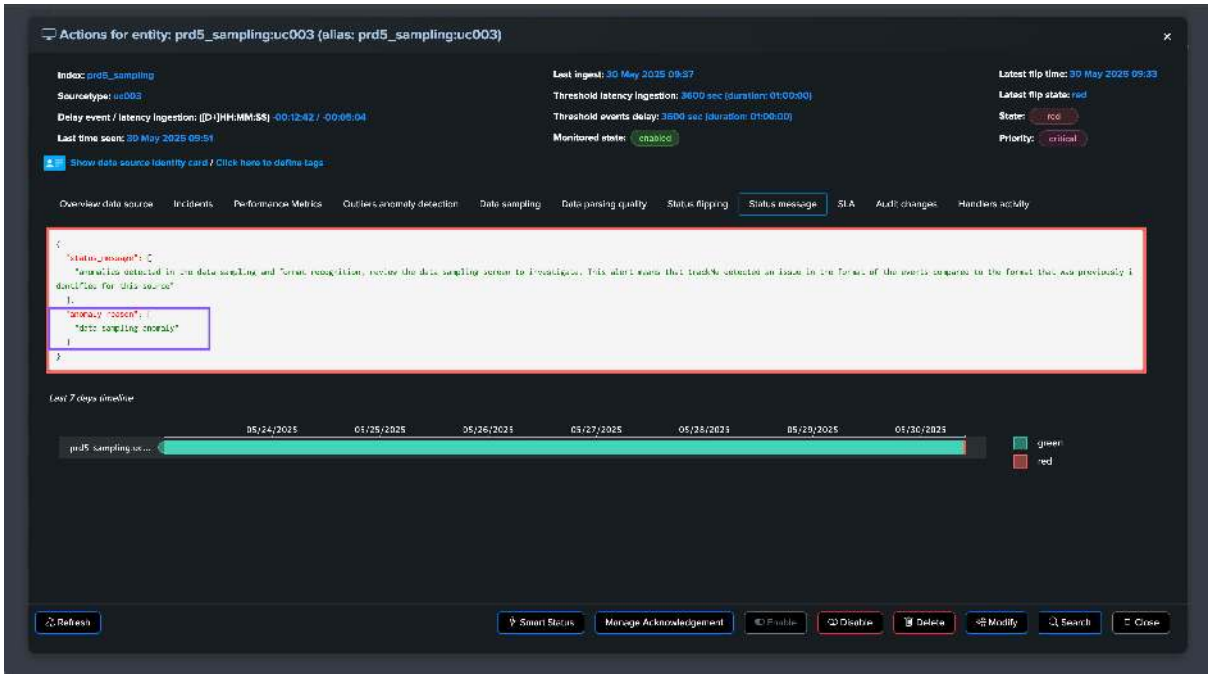
In this case, events are matching multiple formats unexpectly

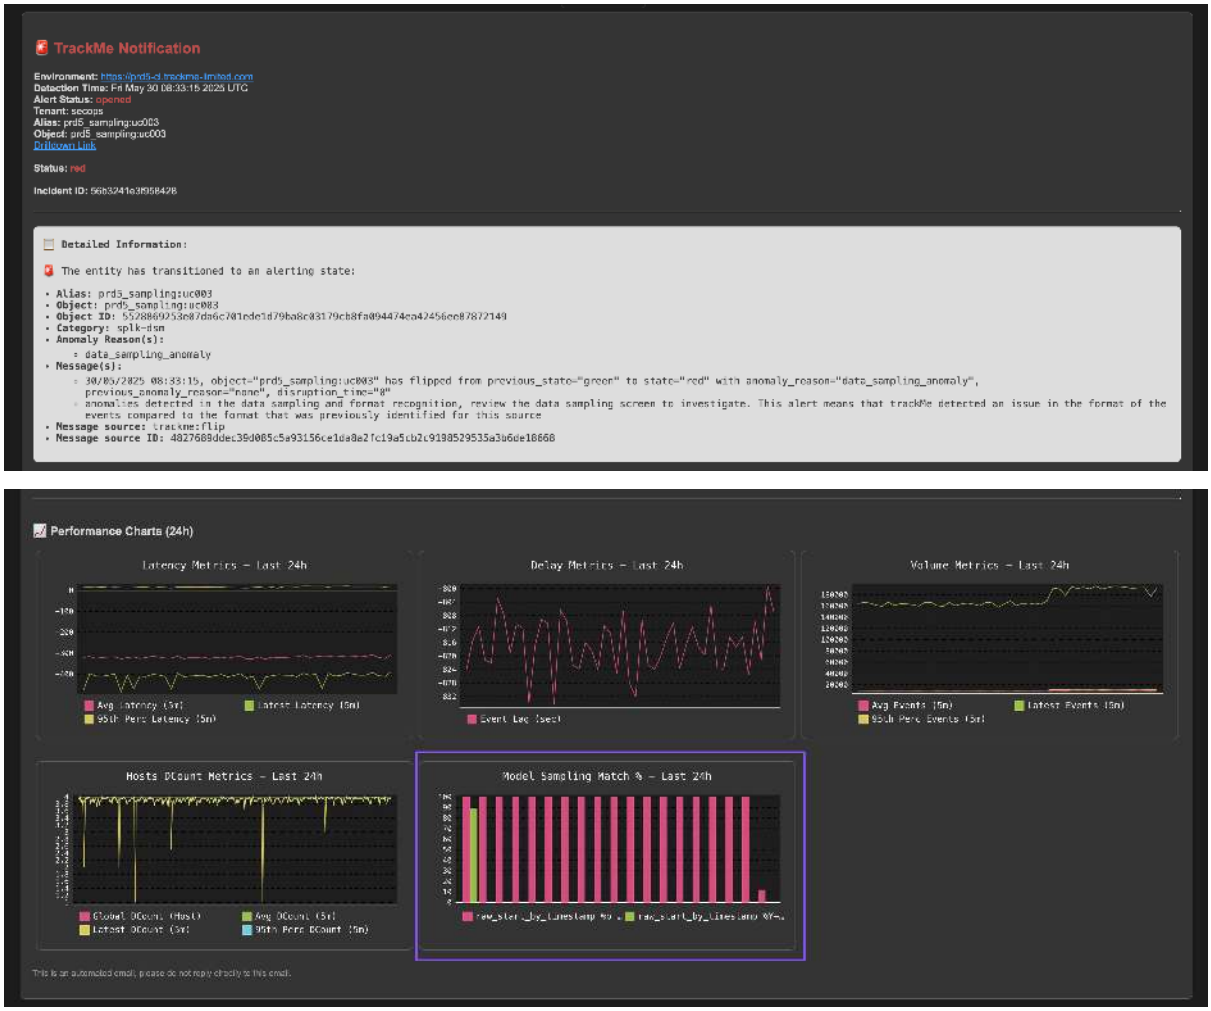


New Search
We can observe over time when the new format was introduced

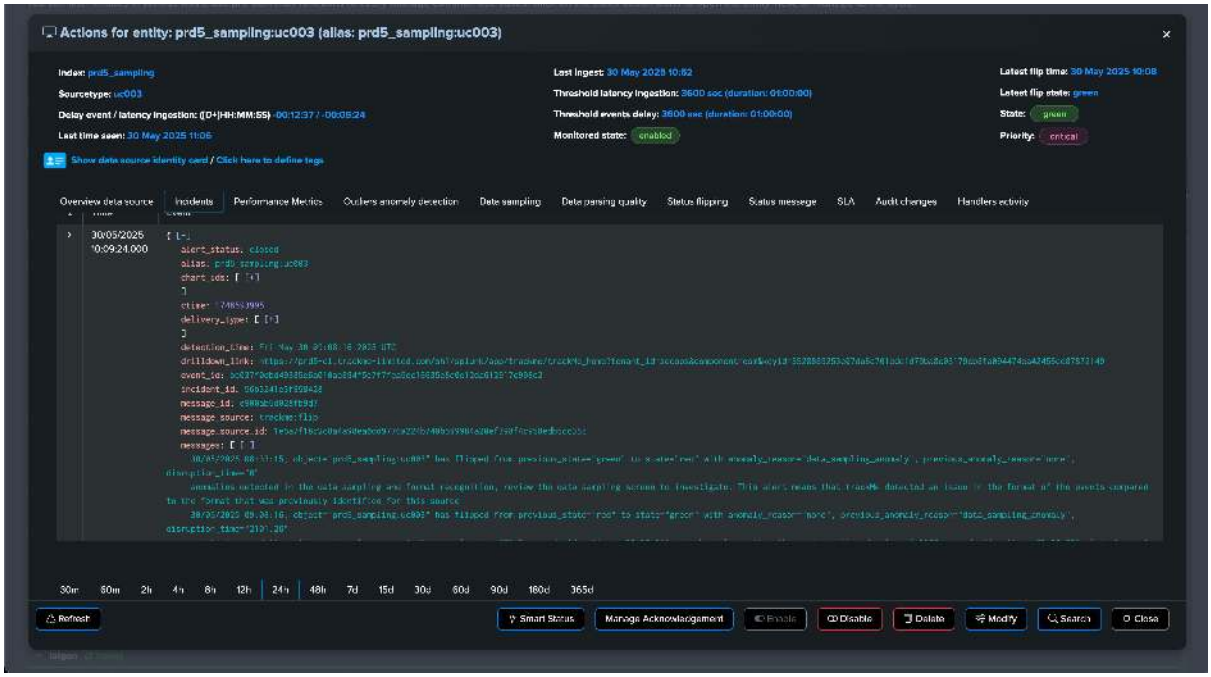


The quality issue detected influences the entity status, and an anomaly_reason="data_sampling_anomaly" is generated:





Once the root cause is identified and the issue is fixed, after some time the entity will return to green when the expected format is correctly detected again:



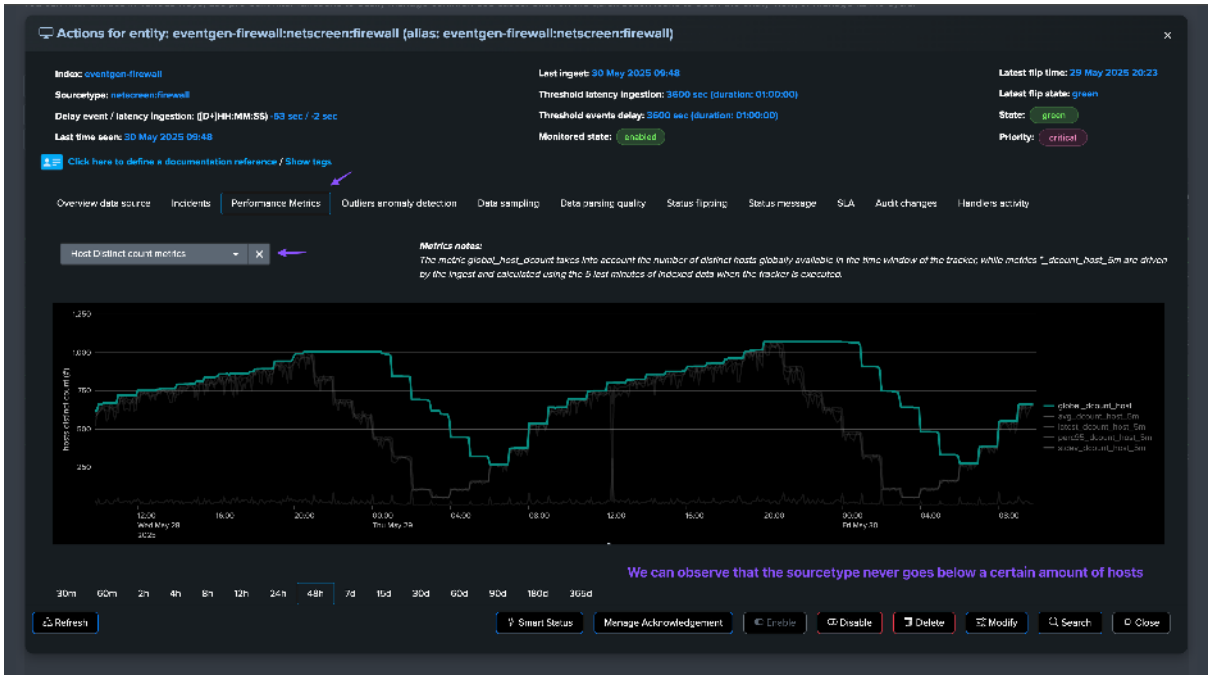
Use Case: Hosts Distinct Count Anomaly

Another use case is to detect anomalies in your feeds based on the amount of distinct hosts making it to Splunk.

This is a valuable use case especially at large scale that allows easily detecting issues, such as the potential loss of intermediate collectors or the potential loss of a major source.

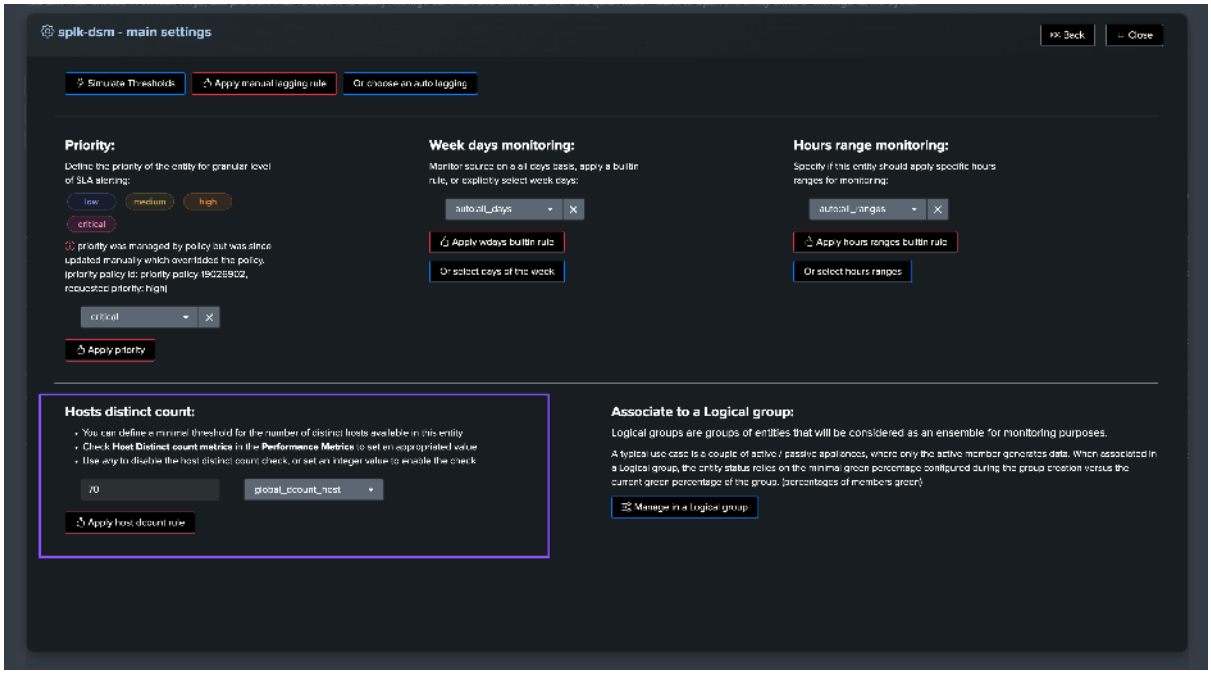
This activity can be performed using a static threshold against one of the distinct hosts metrics, as well as for more advanced use cases using Machine Learning Outliers detection.

The following example demonstrates the use of a static threshold to detect anomalies in the distinct hosts count, we can observe with the following entity that a certain amount of hosts are systematically available:

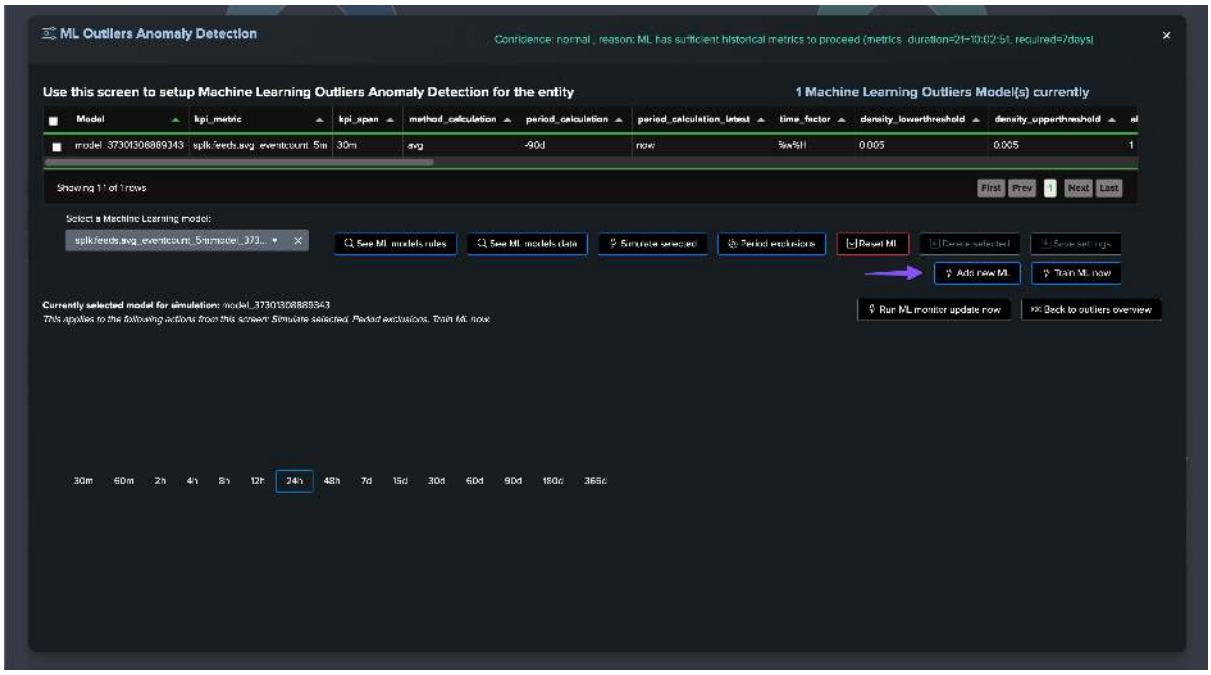


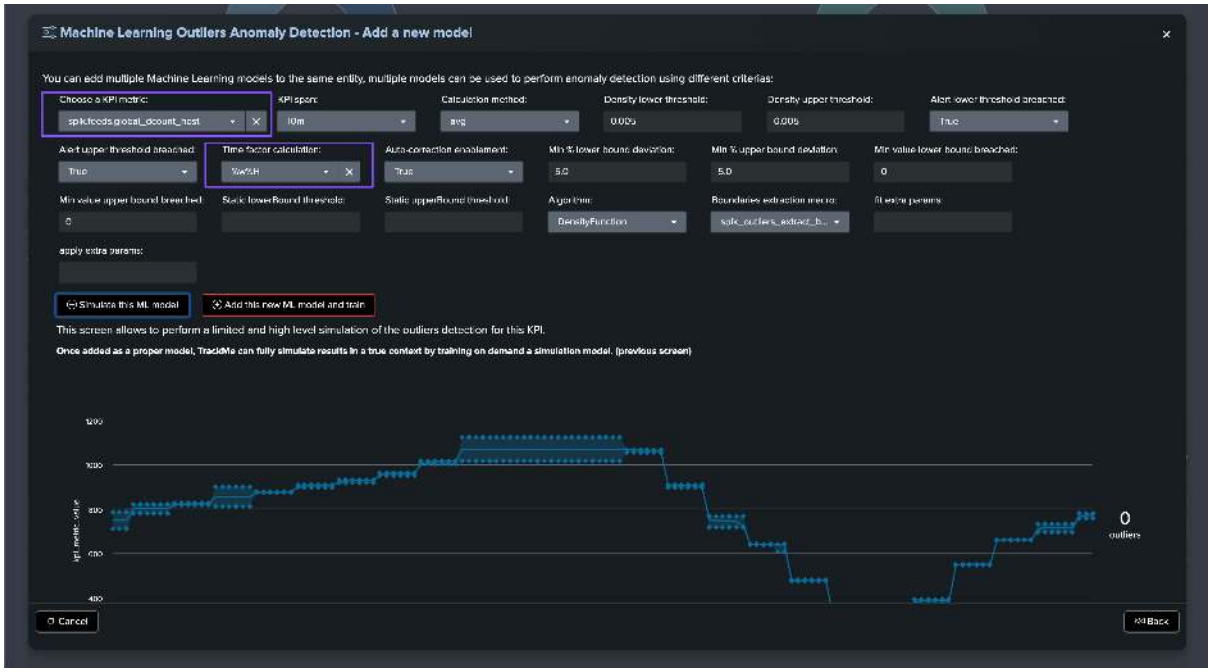
The big picture must be considered:

Based on this observation, we can configure a static minimal threshold for this entity, if the amount of distinct hosts goes below this threshold, the entity will be considered as in alert:



An alternative method or used in conjunction with the static threshold, is to use Machine Learning Outliers detection to detect anomalies in the distinct hosts count while taking into account time patterns:





Machine Learning Outliers Anomaly Detection - Add a new model
You can add multiple Machine Learning models to the same entity, multiple models can be used to perform anomaly detection using different criterias:
Choose a KPI metric:
KPI span:
Calculation method:
Density lower threshold:
Density upper threshold:
Alert lower threshold breached:
Alert upper threshold breached:
Time factor calculation:
Auto-correction enablement:
Min % lower bound deviation:
Min % upper bound deviation:
Min value lower bound breached:
Min value upper bound breached:
Static lowerBound threshold:
Static upperBound threshold:
Algorithm:
Boundaries extraction macro:
fit extra params:
apply extra params:
Simulate this ML model
Add this new ML model and train
This screen allows to perform a limited and high level simulation of the outliers detection for this KPI.
Once added as a proper model, TrackMe can fully simulate results in a true context by training on demand a simulation model. (previous screen)

If at some point, the amount of distinct hosts goes below the threshold, the entity will be considered as in anomaly, and an incident will be opened:

Notes:

- The "global" distinct count KPI measures the number of unique hosts across the entire tracker period. Due to this global aggregation, there may be a delay in detecting anomalies as the system needs to accumulate enough data to establish a clear pattern.
- A decrease in the number of distinct hosts often correlates with a decrease in event volume. In such cases, TrackMe's Machine Learning Outliers detection may trigger alerts for both volume-based and distinct hosts models simultaneously, providing multiple indicators of the same underlying issue.

For the purposes of this demo, we have set both the static threshold and Machine Learning Outliers detection. After some time, both detection methods trigger:

2.2.2 Use Case Demo: 360 Services Monitoring with TrackMe

Use Case Demo: 360 Services Monitoring with TrackMe

- This use case demo demonstrates how TrackMe can be used to perform a **360 degree monitoring** of the different services that are commonly composing Splunk environments, with addition of third parties notably Cribl Logstream.
- **The purpose of this demo is to show step by step how to design and implement TrackMe concepts and features, notably:**
  - `Data Tiers:` Monitoring high priority Splunk Feeds availability and performance using TrackMe component `splk-dsm`.
  - `Data Tiers:` Monitoring high priority endpoints availability (Think about Active Directory domain controllers, Checkpoint firewalls, etc.) using TrackMe component `splk-dsm`.
  - `Data Tiers:` Monitoring abnormal volume variations in Splunk indexes and Splunk license usage using TrackMe component `splk-flx`. (Since TrackMe 2.4.18 the `splk-vol` component covers per-index licensed volume out of the box — see *VOL — Volume Outliers*.)
  - `Splunk Tiers:` Monitoring key aspects and metrics of Splunk Indexers Cluster using TrackMe component `splk-flx`.
  - `Splunk Tiers:` Monitoring key aspects and metrics of Splunk Search Head Cluster or Search Heads using TrackMe component `splk-flx`.
  - `Splunk Tiers:` Monitoring key aspects of Splunk Heavy Forwarder tiers using TrackMe component `splk-flx`.
  - `Splunk Tiers:` Monitoring Splunk deployment servers and clients using TrackMe component `splk-flx`.
  - `Use Cases & Controls:` Monitoring Splunk core & Splunk Enterprise Security use cases using TrackMe Workload component `splk-wlk`.
  - `Use Cases & Controls:` Monitoring various environments control points using TrackMe component `splk-flx`.
  - `Cribl Logstream:` Monitoring Cribl Logstream availability and performance using TrackMe component `splk-flx`.
  - `Splunk SOAR tier:` Monitoring Splunk SOAR platforms using TrackMe component `splk-flx`.
- Some of the components leveraged in this demo are restricted features available in TrackMe Enterprise Edition & Unlimited Edition.
- **This demo documentation is currently a work in progress** and will be updated in the future to reflect the latest features and capabilities of TrackMe.

2.2.3 Use Case Demo: Fields Quality (CIM and non-CIM)

Hint

New component: Fields Quality (splk-fqm) - since TrackMe 2.1.22!

- **TrackMe 2.1.22** introduced a new component called **Fields Quality (splk-fqm)** which is designed to perform continuous fields quality assessment on Splunk data.
- This component implements the concepts described in this white paper, built into TrackMe, with flexibility, scalability and automated wizards.
- This white paper was updated to focus on the new component and its capabilities, with associated sections available in the annexes.
- **TrackMe version 2.1.23** provided several important improvements to the Fields Quality component.
- **TrackMe version 2.1.24** introduced full support for non-CIM data contexts in the Fields Quality component.
- **TrackMe version 2.1.26** slightly enhanced the performance of simulation and execution phases, and provided full support for custom break by definitions for both CIM and non CIM contexts.
- **TrackMe version 2.1.27** provided the capability to create additional monitor only collect jobs through the wizard, allowing to re-use existing quality samples events for different aggregations purposes, such as aggregating per datamodel in a different tenant than the original tenant performing the collect and pre-processing.

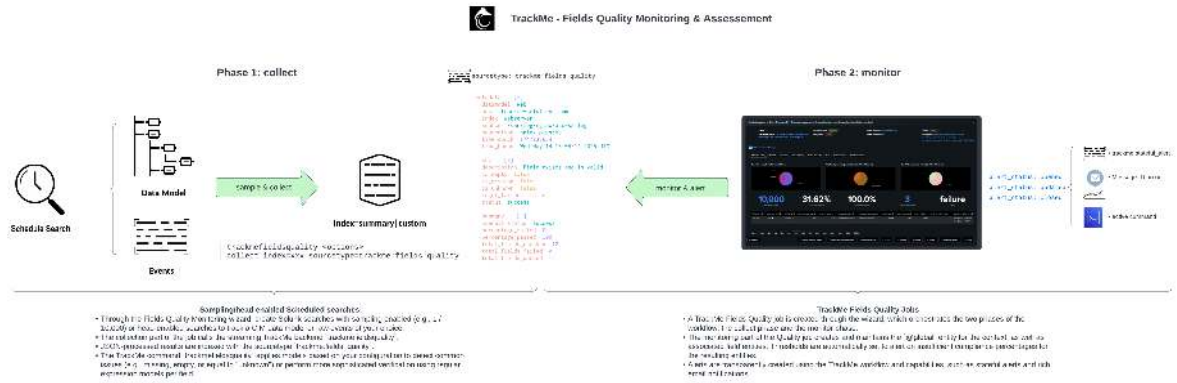
Use Case Demo: Fields Quality

- This white paper describes a new concept for performing continuous fields quality assessment on Splunk data.
- This leverages different scalable Splunk techniques and TrackMe components to perform this task.
- Fields quality assessment is a crucial aspect of Splunk monitoring, as it helps ensure that the data is accurate and consistent and ready to serve use cases.
- By implementing this, you will be able to build a solid, robust, and scalable solution to monitor the quality of fields parsing for your various sourcetypes in Splunk, as well as receive automated alerts when fields quality issues are detected.
- These concepts are applicable to both Splunk Common Information Model (CIM) and non-CIM data.

- This work was made possible through the support and deep collaboration of several major fellow TrackMe customers. Thank you!

High level workflow and diagram

The following diagram shows the high-level workflow for fields quality assessment:



From a high-level perspective, the workflow is as follows:

In the Fields Quality component, you create collect jobs which consist of two phases

Phase 1: collect

- Through the Collect job creation wizard, you define a new `collect` job which is tied to a data context (a Splunk search constraint) associated with a data dictionary.
- The data dictionary can be generated by TrackMe according to the CIM data model, or you can set the collect job to use a previously generated data dictionary. (Dictionaries can be shared between collect jobs)
- Once validated and executed, the collect job starts collecting and processing event samples, stored in a summary index and associated with a source value unique per collect job.

Phase 2: monitor

- In the collect job, a second set of `monitor` trackers are created, which are set to be executed automatically 10 minutes after the collect job is executed.
- The `monitor` job parses and processes the JSON events generated by the collect job, and discovers and maintains TrackMe entities associated with the collect job.

Hint

Common Information Model (CIM) context versus raw events context

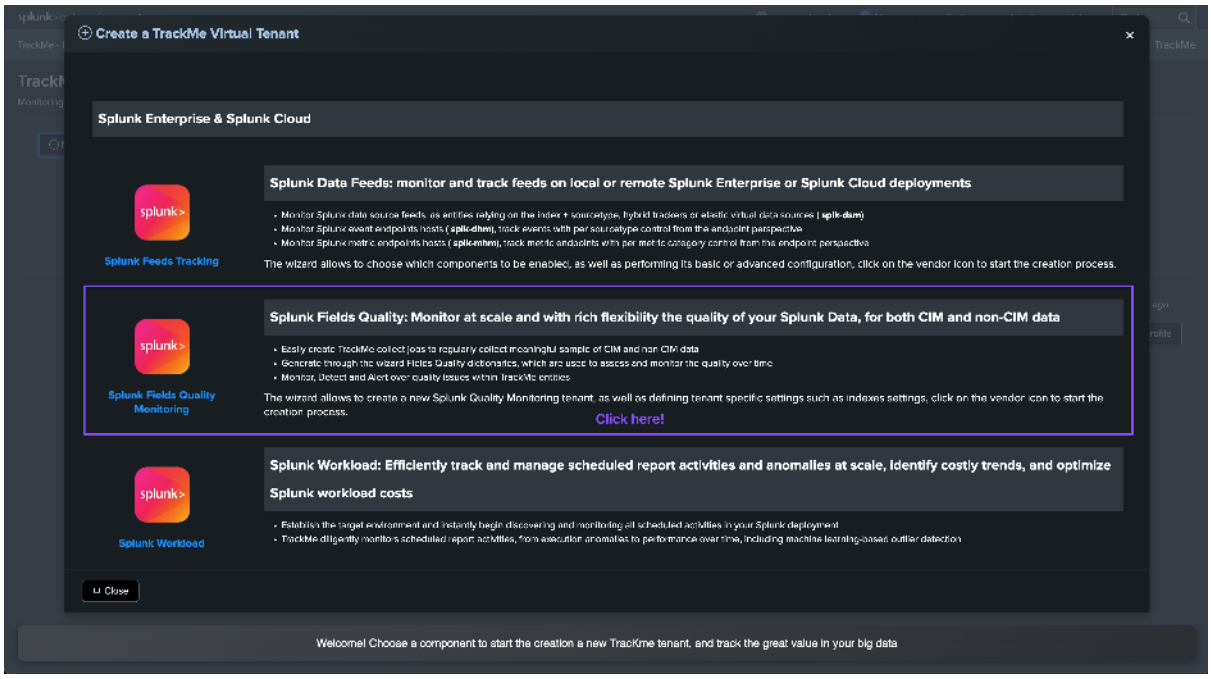
- These concepts apply equally to both the Common Information Model and any raw events in Splunk.
- CIM parsing quality is generally a critical topic when use cases heavily rely on CIM, but there can be many use cases where you need to ensure the parsing quality outside of a CIM context.
- These concepts are applicable to both CIM and non-CIM data, and you can simply use the same approach for both.

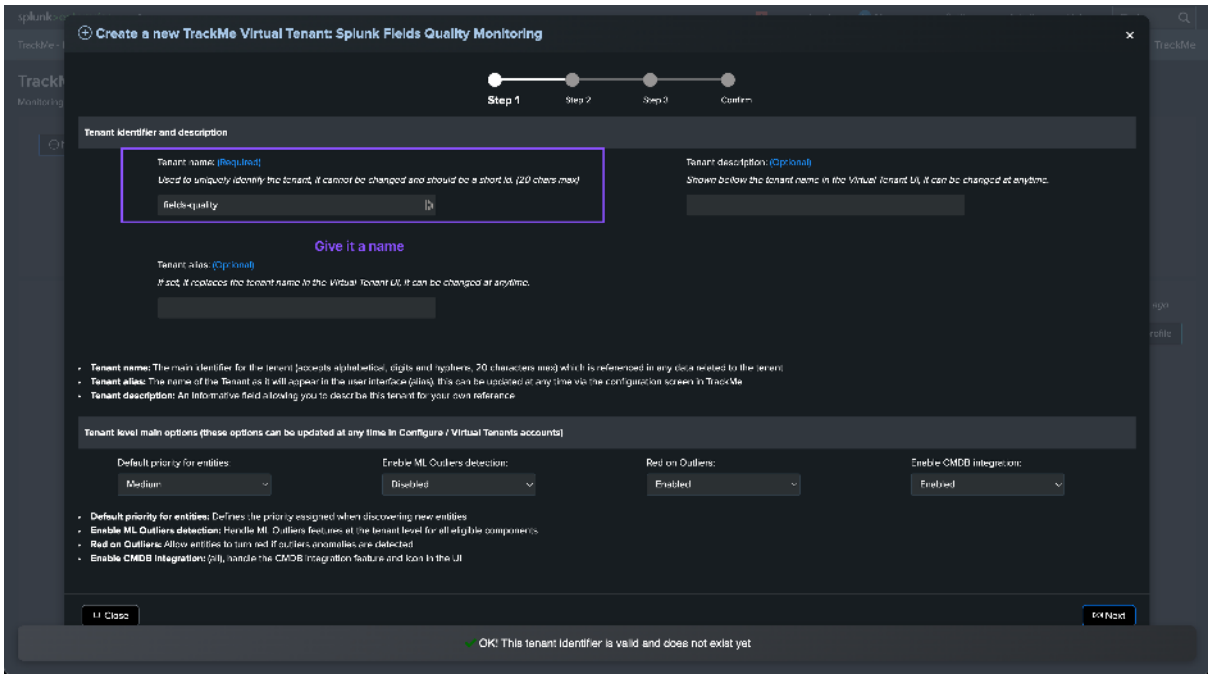
Preparing a Virtual Tenant for the Fields Quality component

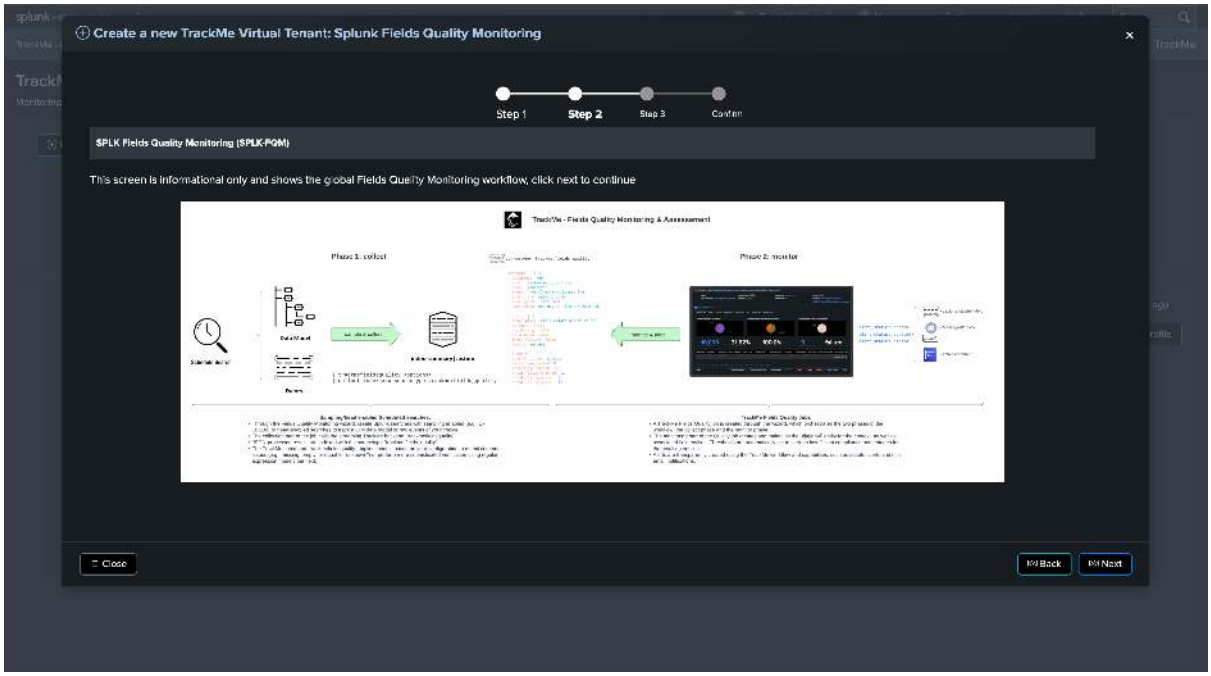
You can either create a fresh new Virtual Tenant in a couple of clicks, or add the component to an existing Virtual Tenant.

Creating a new Virtual Tenant

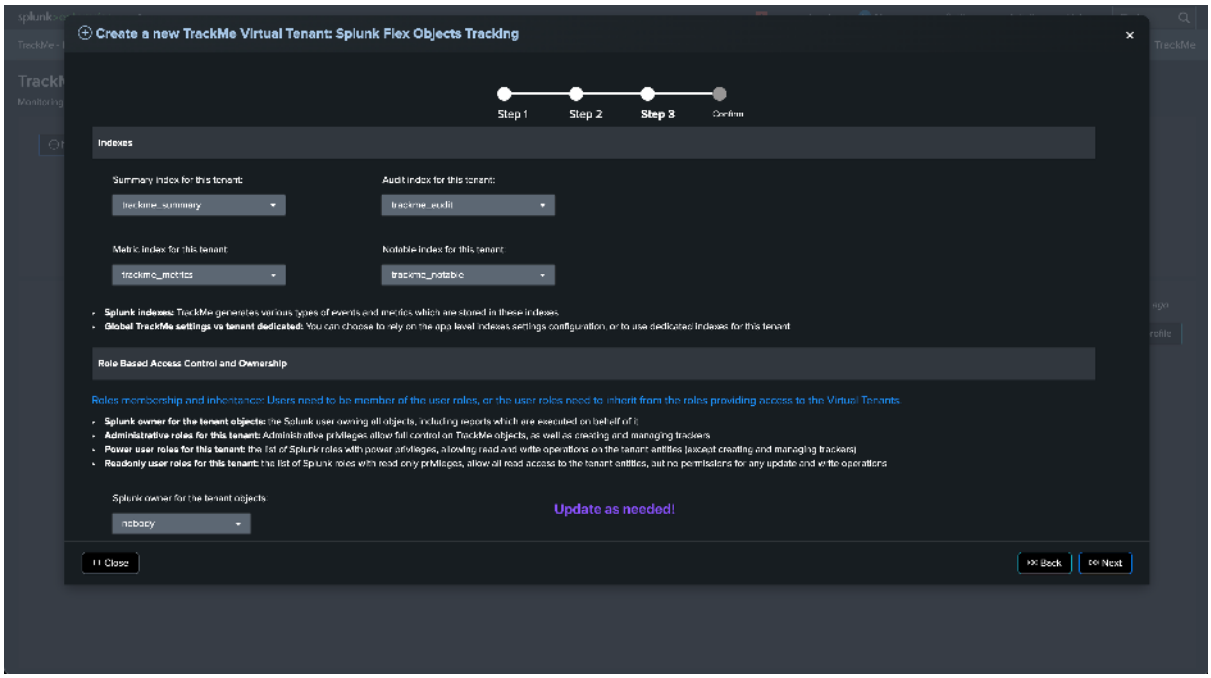
To create a new Virtual Tenant, you can follow these steps:



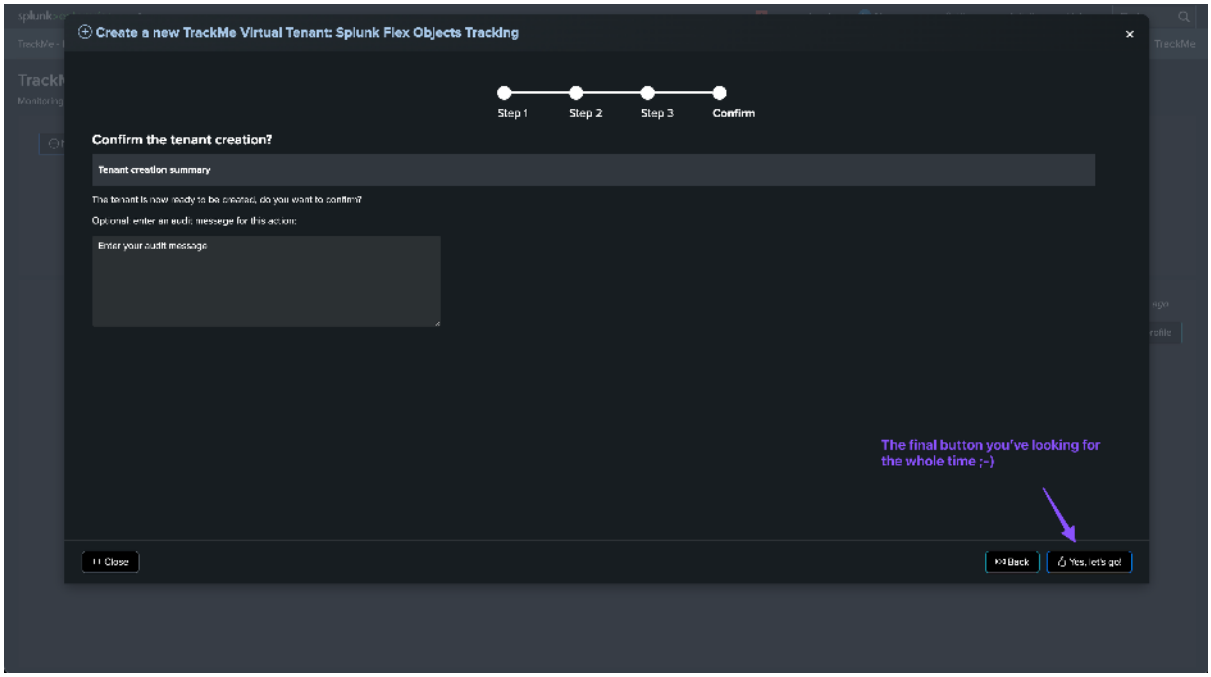




Create a new TrackMe Virtual Tenant: Splunk Fields Quality Monitoring
Step 1
Step 2
Step 3
Confirm
SPLK Fields Quality Monitoring (SPLK-FQM)
This screen is informational only and shows the global Fields Quality Monitoring workflow, click next to continue
Close
Back
Next

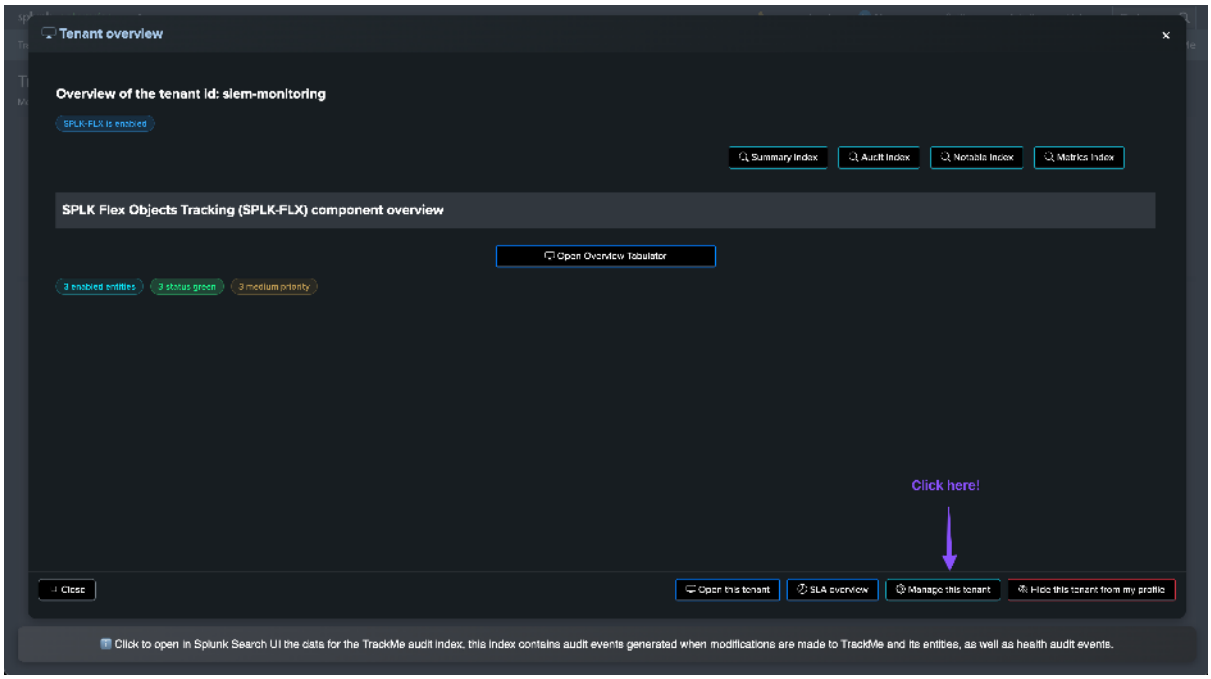


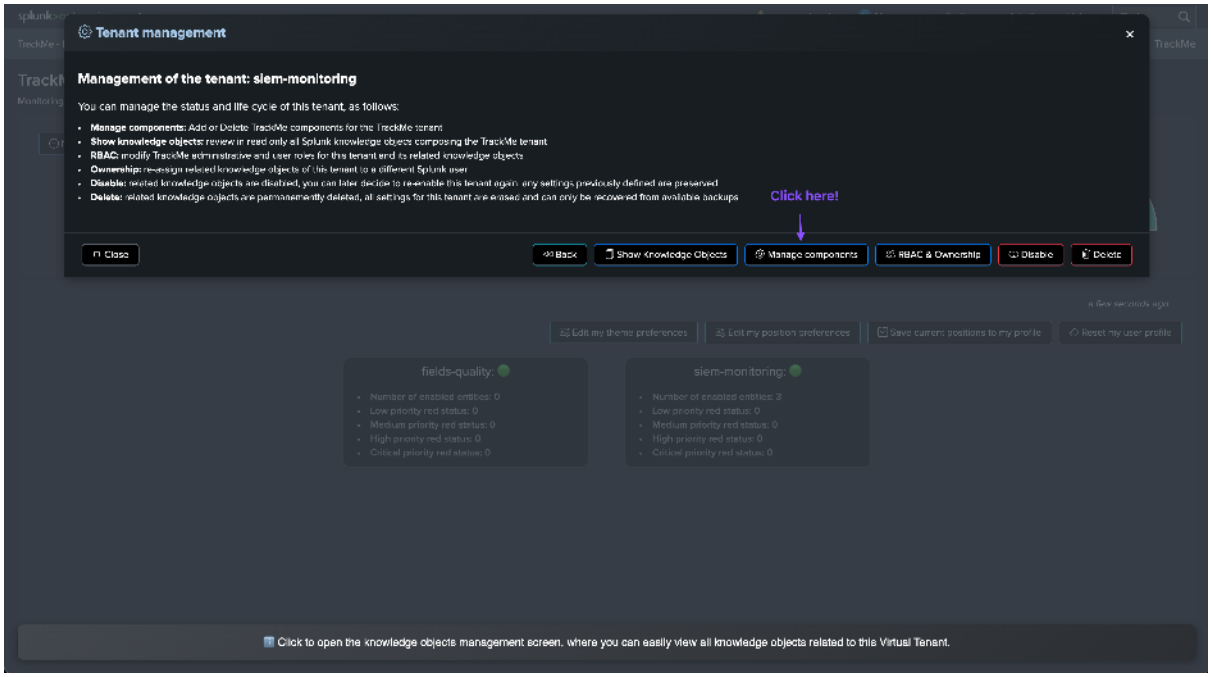
Create a new TrackMe Virtual Tenant: Splunk Flex Objects Tracking
Step 1
Step 2
Step 3
Confirm
Indexes
Summary index for this tenant:
Audit index for this tenant:
Metric index for this tenant:
Notable index for this tenant:
Role Based Access Control and Ownership
Update as needed!
Close
Back
Next



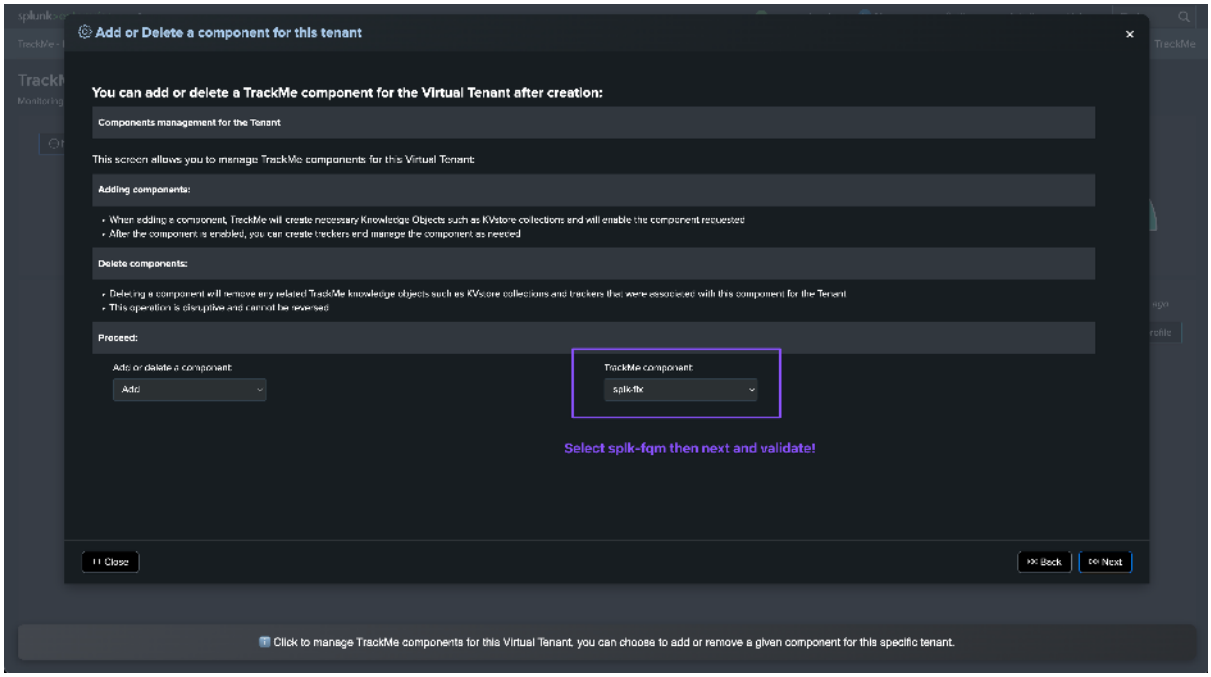
Adding the Fields Quality component to an existing Virtual Tenant

You can also add the Fields Quality component to an existing Virtual Tenant:

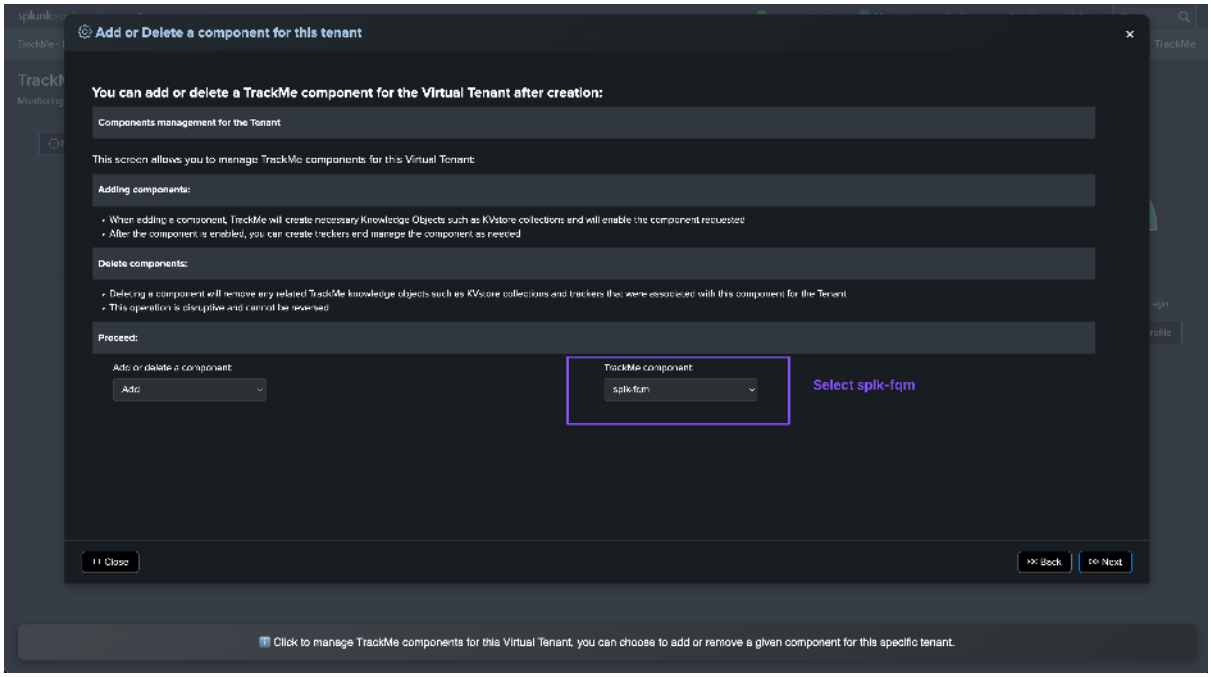




Tenant management
Management of the tenant: siem-monitoring
You can manage the status and life cycle of this tenant, as follows:
Manage components: Add or Delete TrackMe components for this TrackMe tenant
Show knowledge objects: review in read only all Splunk knowledge objects composing the TrackMe tenant
RBAC: modify TrackMe administrative and user roles for this tenant and its related knowledge objects
Ownership: re-assign related knowledge objects of this tenant to a different Splunk user
Disable: related knowledge objects are disabled, you can later decide to re-enable this tenant again: any settings previously defined are preserved
Delete: related knowledge objects are permanently deleted, all settings for this tenant are erased and can only be recovered from available backups
Click here!
Close
Back
Show Knowledge Objects
Manage components
RBAC & Ownership
Disable
Delete
Edit my theme preferences
Edit my position preferences
Save current positions to my profile
Reset my user profile
fields-quality:
siem-monitoring:
Click to open the knowledge objects management screen, where you can easily view all knowledge objects related to this Virtual Tenant.



Add or Delete a component for this tenant
You can add or delete a TrackMe component for the Virtual Tenant after creation:
Components management for the Tenant
This screen allows you to manage TrackMe components for this Virtual Tenant:
Adding components:
When adding a component, TrackMe will create necessary Knowledge Objects such as KVstore collections and will enable the component requested
After the component is enabled, you can create trackers and manage the component as needed
Delete components:
Deleting a component will remove any related TrackMe knowledge objects such as KVstore collections and trackers that were associated with this component for the Tenant
This operation is disruptive and cannot be reversed
Proceed:
Add or delete a component:
Add
TrackMe component:
splk-fix
Select splk-fqm then next and validate!
Close
Back
Next
Click to manage TrackMe components for this Virtual Tenant, you can choose to add or remove a given component for this specific tenant.



Creating your first collect job

Hint

About CIM and non CIM data contexts:

- Since TrackMe 2.1.24, the Fields Quality component supports both CIM and non-CIM data contexts.
- The main difference between creating a collect job for non CIM contexts relies on the creation of the data dictionary in the wizard and in the same time than the collect job creation.
- For non CIM contexts, you need to define the fields to be monitored by declaring the fields of interests in the data dictionary.
- On the other hand and for CIM contexts, TrackMe can generate a new data dictionary for you and based on the selected CIM data model.

Once we have a Virtual Tenant with the Fields Quality component enabled, we can create our first collect job.

To start the wizard, click on `Manage: trackers & dictionaries` then choose an action button:

`Create a new Quality job (for CIM, generate or use existing dictionary):`

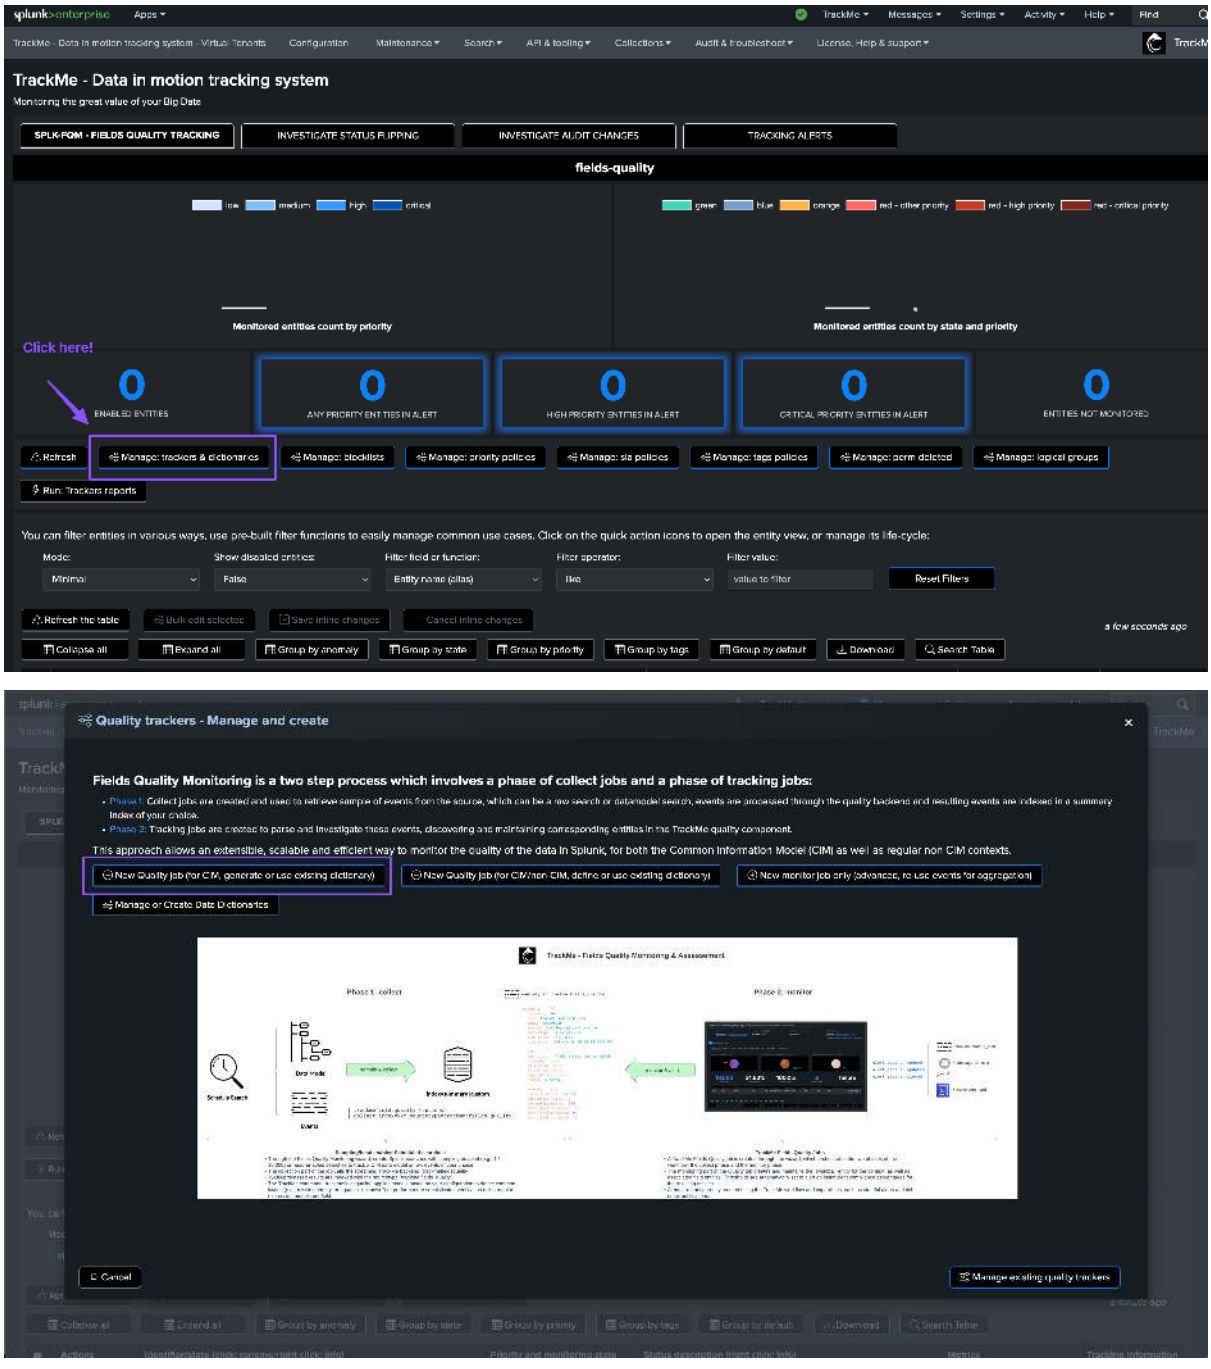
- This wizard allows creating a new collect job from scratch, and which targets a Common Information Model (CIM) only context.
- The wizard can generate the data dictionary for you, based on the selected CIM data model, and some of your preferences.
- You can also select an existing data dictionary to be used for the collect job, if any.

`Create a new Quality job (for CIM or non CIM, define or use existing dictionary):`

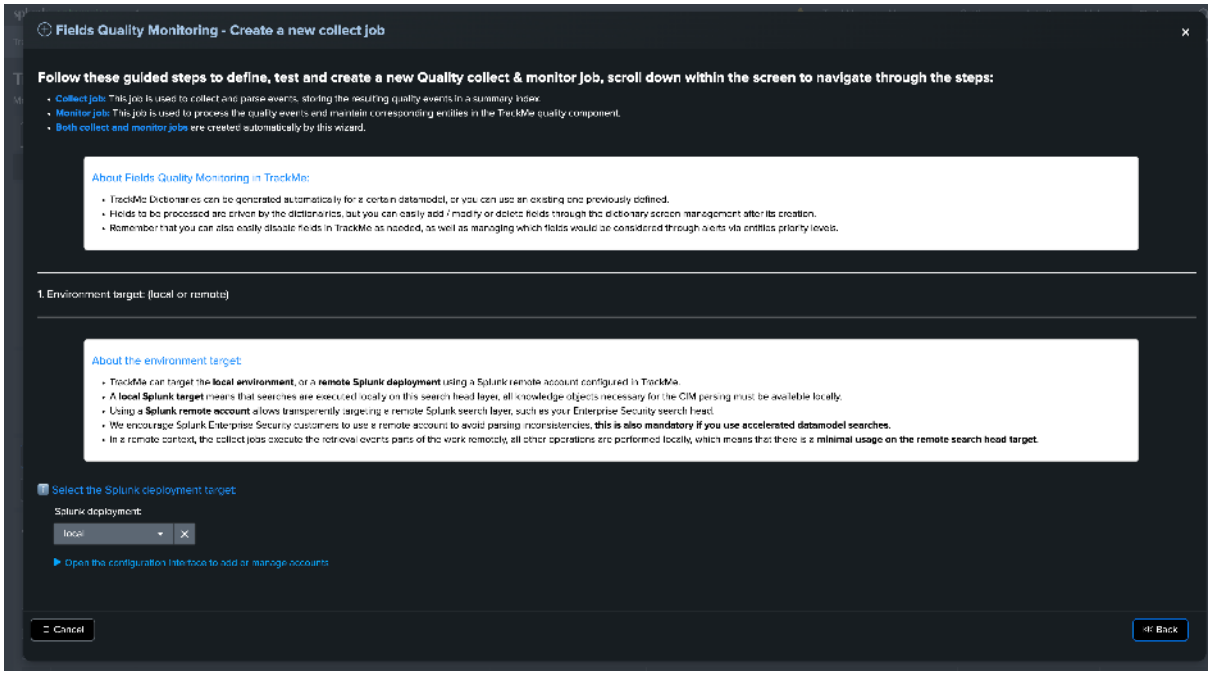
- This wizard allows creating a new collect job for both CIM and non CIM contexts, the main difference being the way the data dictionary is defined.
- You can either choose to create and define the data dictionary within the wizard, or use an existing data dictionary.
- It is intended primarly to be used for non CIM contexts, or contexts where you want to have full control over the data dictionary definition at the stage of the collect job creation.

`New monitor job only (advanced, re-use events for aggregation):`

- This is an advanced option, intented to allow creating a monitor only collect job, and re-use the events generated by a previous collect job for different aggregation purposes.
- It can be used for instance to track fields quality for existing collectors, but in a different way, such as aggregating at the level of the datamodel rather than datamode/index/sourcetype, without re-collecting and pre-processing the same sources, nor affecting the source tenant way of aggregating and processing the quality entities.
- To use this feature, you first need an existing configured collect job and you should have identified your use case, and particularly the aggregation definition. (break by definition)



Wizard welcoming screen



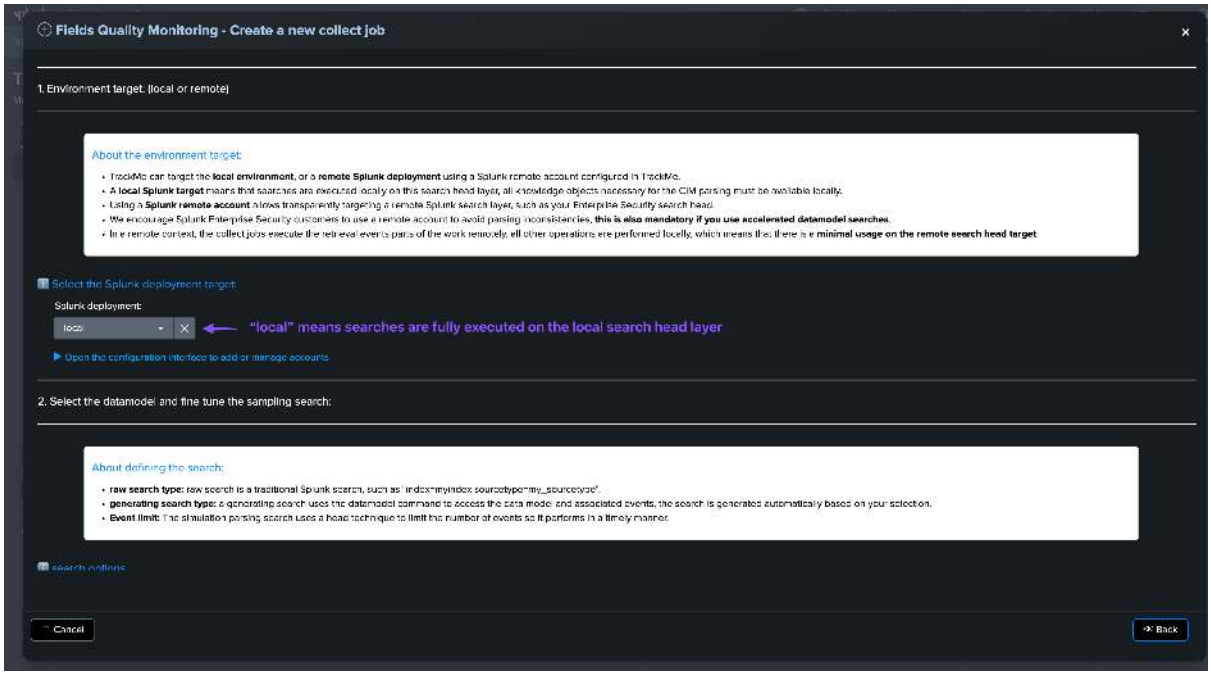
Environment target selection

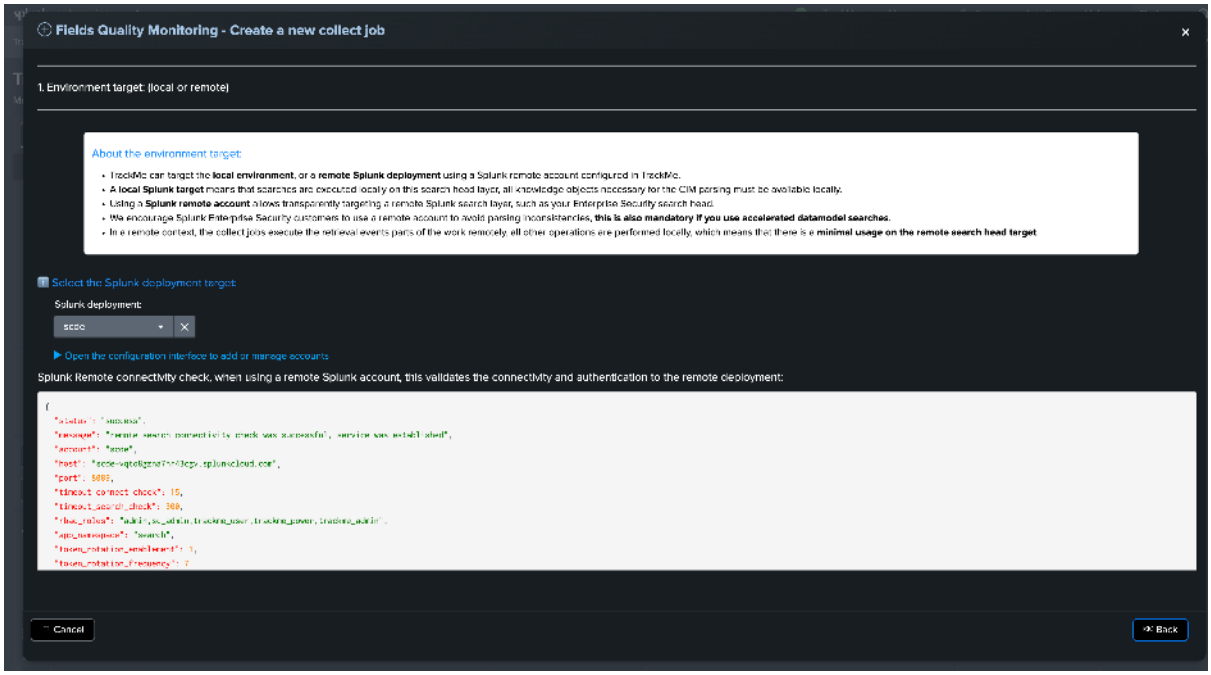
The first step is to select whether the environment target is the local search head or a remote search head:

Hint

About the environment target:

- TrackMe can target the local environment, or a remote Splunk deployment using a Splunk remote account configured in TrackMe.
- A local Splunk target means that searches are executed locally on this search head layer. All knowledge objects necessary for the CIM parsing must be available locally.
- Using a Splunk remote account allows transparently targeting a remote Splunk search layer, such as your Enterprise Security search head.
- We encourage Splunk Enterprise Security customers to use a remote account to avoid parsing inconsistencies. This is also mandatory if you use accelerated datamodel searches.
- In a remote context, the collect jobs execute the retrieval events parts of the work remotely. All other operations are performed locally, which means there is minimal usage on the remote search head target.





Datamodel and root search definition

Hint

About CIM and non CIM data contexts:

- The datamodel selection applies to CIM contexts only.
- When creating a collect job for non CIM contexts, you simply need to define the root search constraint.

The next step is to define the type of the search to be executed, the datamodel selection and finally the root search constraints:

About defining the search:

- Raw search type: A raw search is a traditional Splunk search, such as "index=myindex sourcetype=my_sourcetype".
- Generating search type: A generating search uses the datamodel command to access the data model and associated events. The search is generated automatically based on your selection.
- Event limit: The simulation parsing search uses a head technique to limit the number of events so it performs in a timely manner.

Hint

About your design strategy:

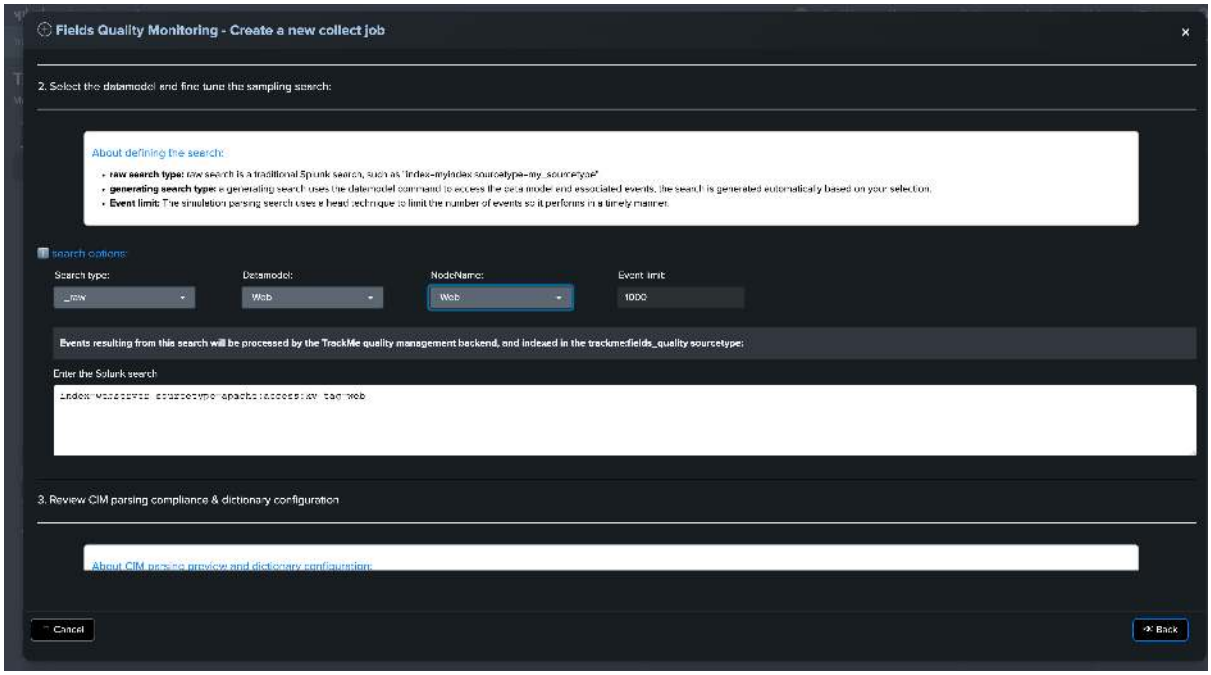
- The best strategy is the one that matches your preferences, custom context and objectives.
- A single collect job can technically handle multiple indexes, sourcetypes, and so forth, BUT it is tied to a specific datamodel and data dictionary.
- Therefore, at minimum you want to segregate your collect jobs per datamodel and sourcetype. (or context feeds, for instance one collect job for WinEvent logs, one for Linux secure logs, etc.)
- To ensure a good level of sampling, you can also be as granular as needed, for instance one collect job per datamodel/index/sourcetype. (or context feed)

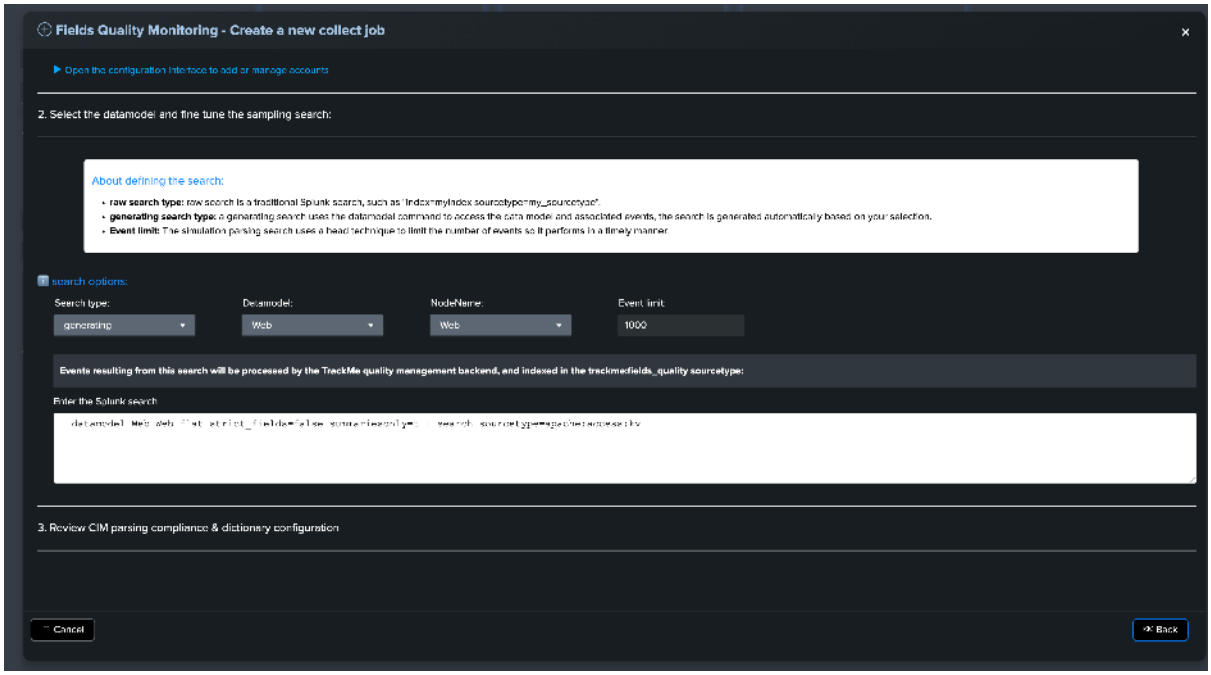
Hint

About search performance, costs, raw versus generating searches:

- Overall, the collect jobs are very efficient and inexpensive.
- TrackMe implements two techniques: the `head` technique and the `sampling` technique to produce fast and performant collect phase searches.
- The monitor phase is dependent on the associated collect job events produced and is also very efficient.
- Note that when selecting a generating search, TrackMe generates the base root search automatically, according to the selected datamodel.
- Finally, generating searches are direct consumers of the datamodel and therefore more restricted in context, while raw searches offer all levels of flexibility in terms of filters.

Examples of both approaches:





Example of a raw search definition targeting the Web datamodel context:

```
index=webserver sourcetype=apache:access:kv tag=web
```

Example of a generating search definition targeting the Web datamodel context:

```
| datamodel Web Web flat strict_fields=false summariesonly=t | search␣
↪sourcetype=apache:access:kv
```

We generally recommend having at minimum one collect job per datamodel/sourcetype.

Data dictionary generation or selection (for CIM context)

About CIM parsing preview and dictionary configuration:

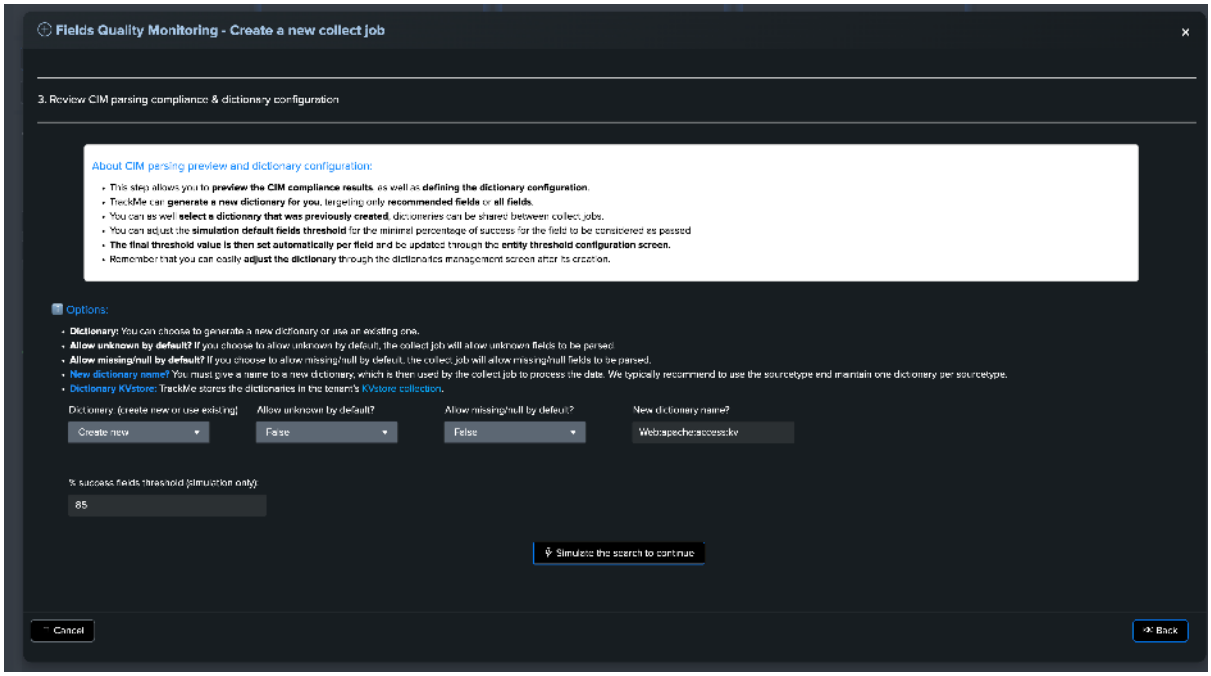
- This step allows you to preview the CIM compliance results, as well as define the dictionary configuration.
- TrackMe can generate a new dictionary for you, targeting only recommended fields or all fields.
- You can also select a dictionary that was previously created. Dictionaries can be shared between collect jobs.
- You can adjust the simulation default fields threshold for the minimal percentage of success for the field to be considered as passed.
- The final threshold value is then set automatically per field and can be updated through the entity threshold configuration screen.
- Remember that you can easily adjust the dictionary through the dictionaries management screen after its creation.

Hint

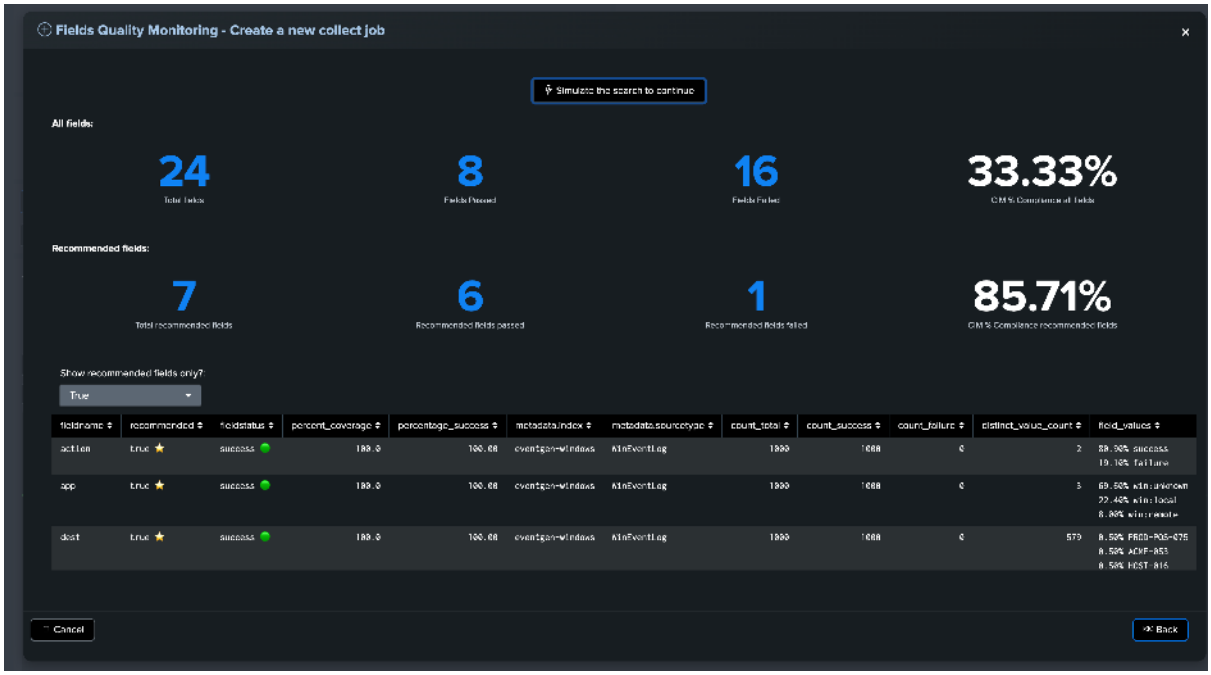
Naming the data dictionary:

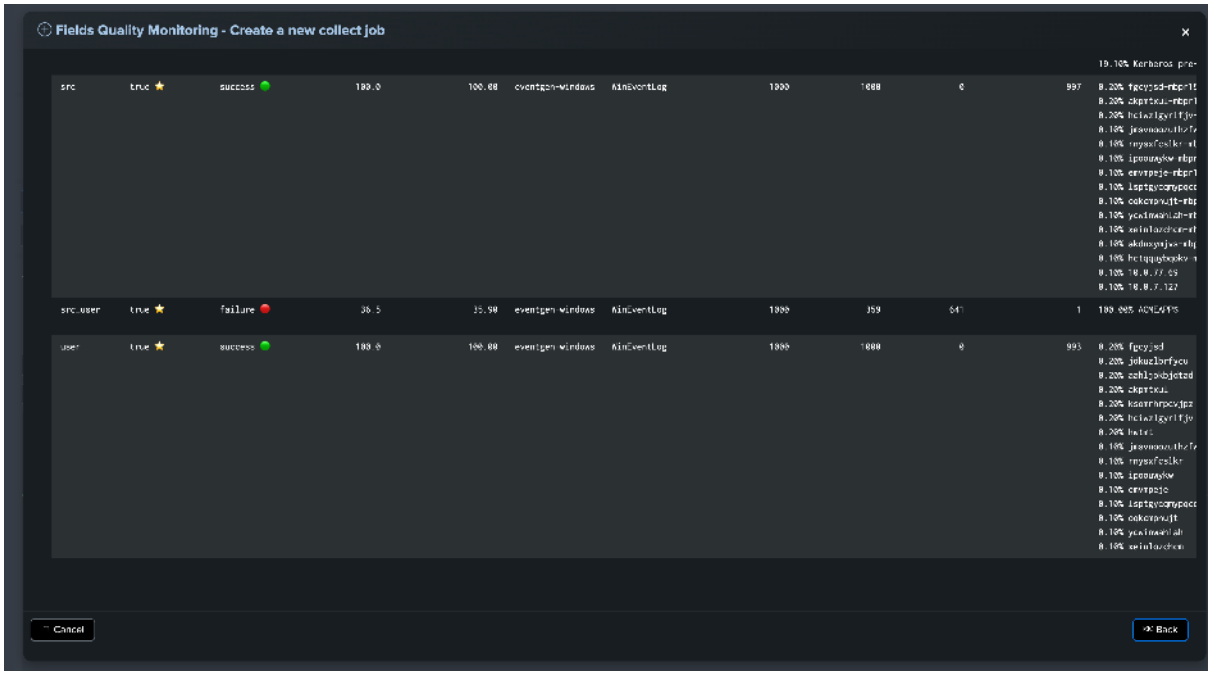
- The data dictionary name is defined in this step input field.
- We recommend having a meaningful naming convention, such as `<datammodel>:<sourcetype>`
- Remember that dictionaries can be shared between collect jobs.
- In our example, we name our new dictionary `Web:apache:access:kv`

Generate a new dictionary, or select an existing one, and adjust default behavior and thresholds:



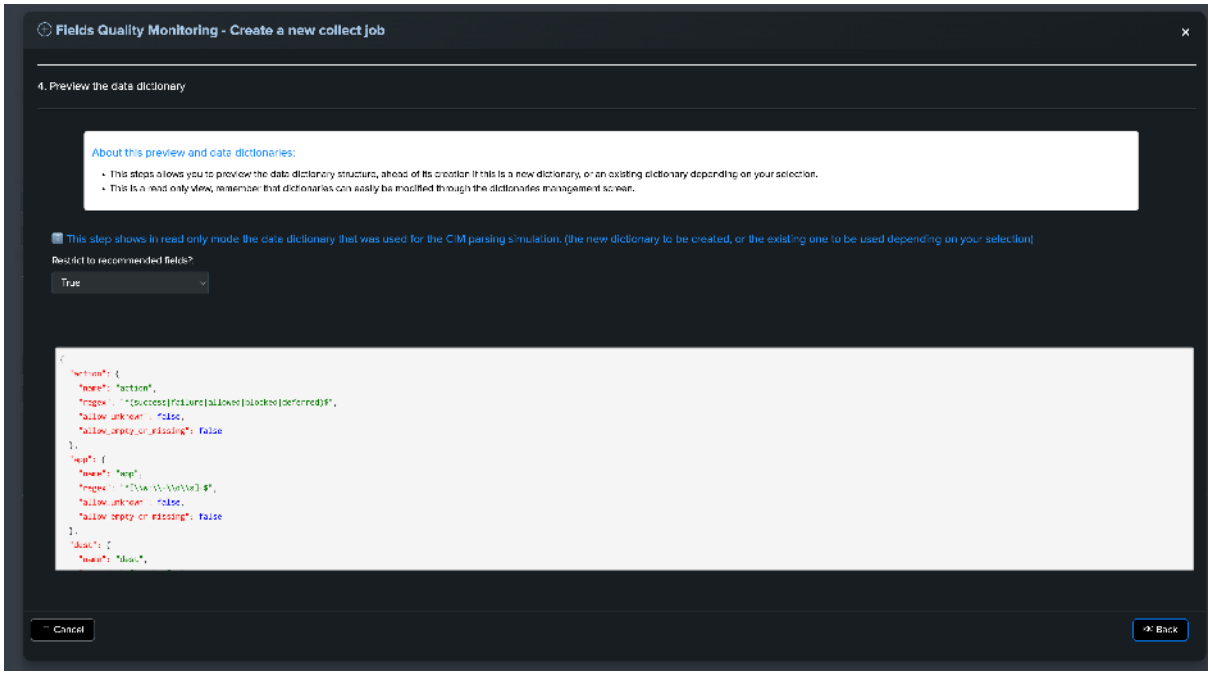
Finally, execute the sampling search to preview the CIM compliance results, which shows key information about the expected results:





Previewing the data dictionary (CIM context only)

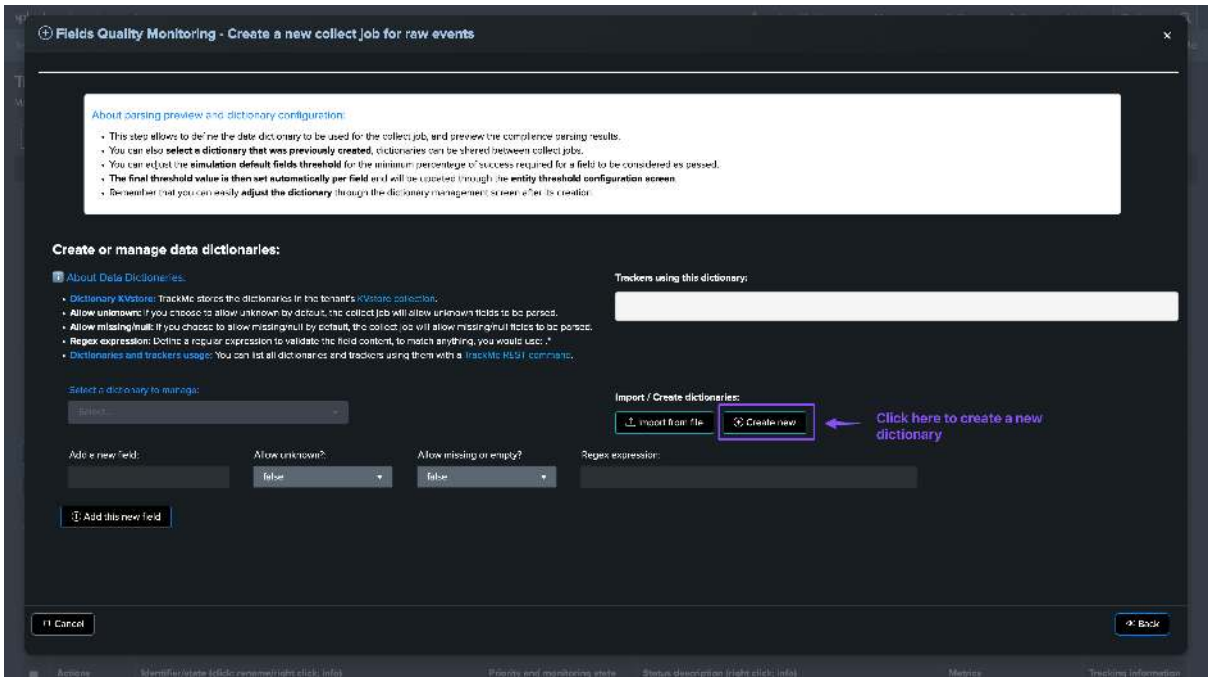
This part of the wizard is informational only and shows a preview of the structure of the data dictionary:

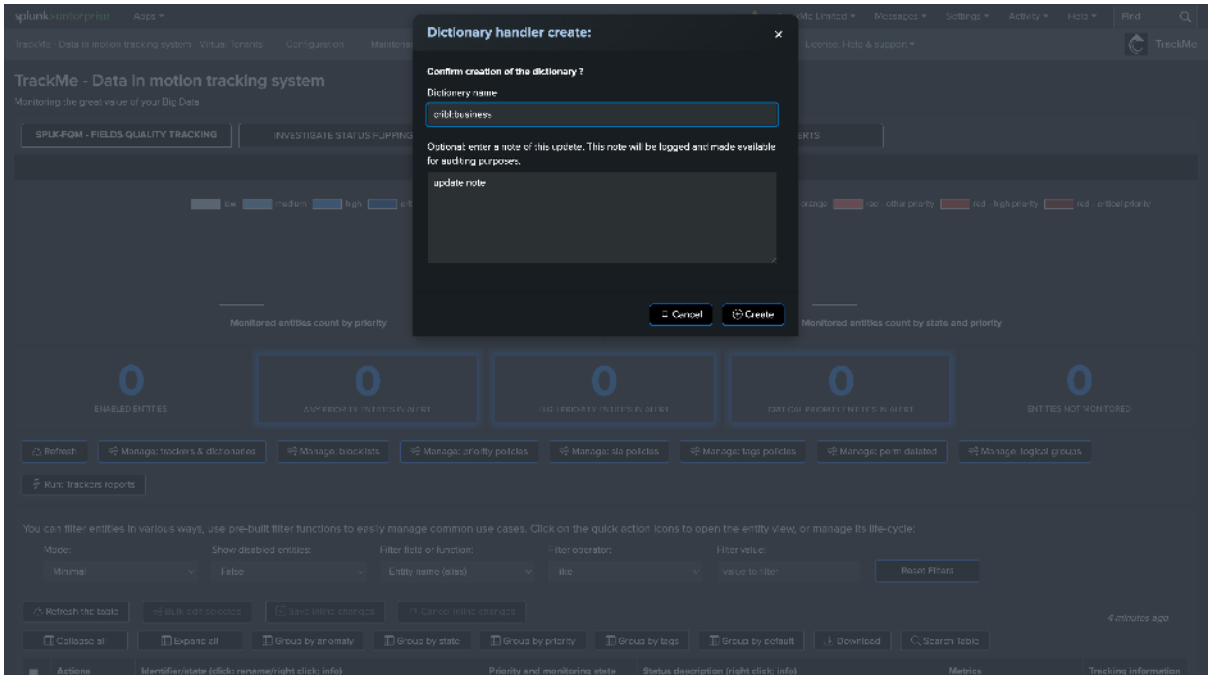


Data dictionary generation or selection (for non CIM context)

For non CIM contexts, you need to define the fields to be monitored by declaring the fields of interests in the data dictionary.

The data dictionary definition step can be performed before the collect job creation via the `Manage: dictionaries` screen, or during the collect job creation wizard.





Dictionary handler create:
Confirm creation of the dictionary ?
Dictionary name:
cribl:business
Optional: enter a note of this update. This note will be logged and made available for auditing purposes.

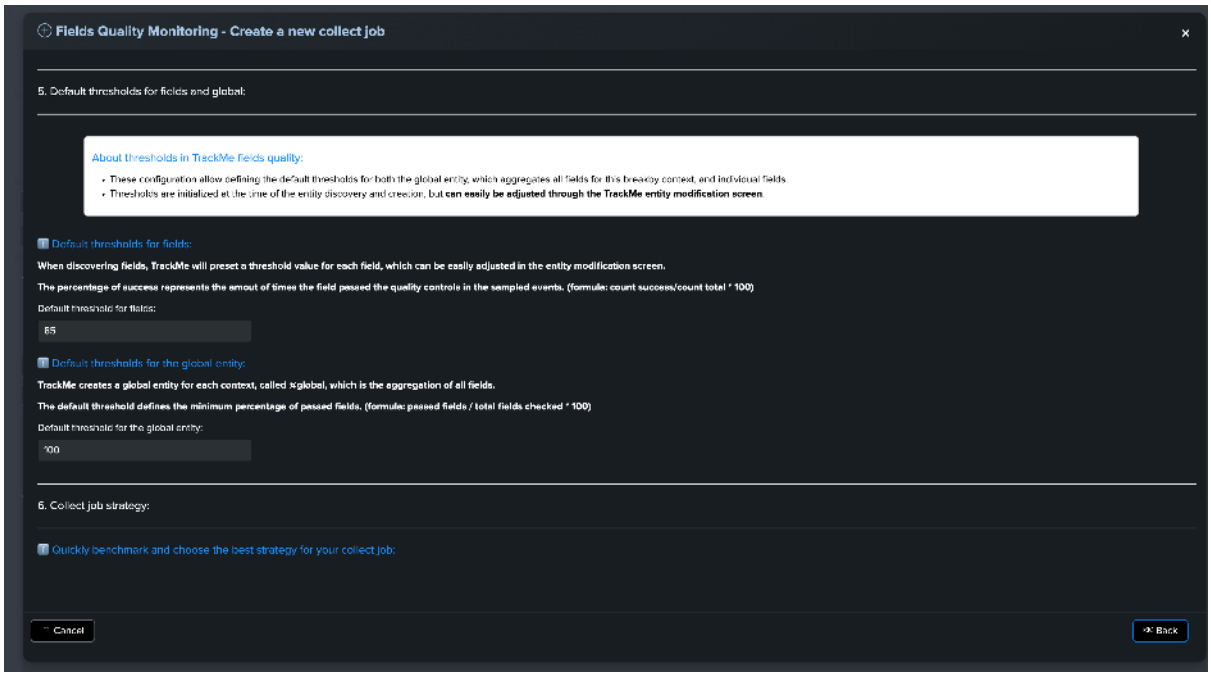
Default thresholds for fields and global

About thresholds in TrackMe fields quality:

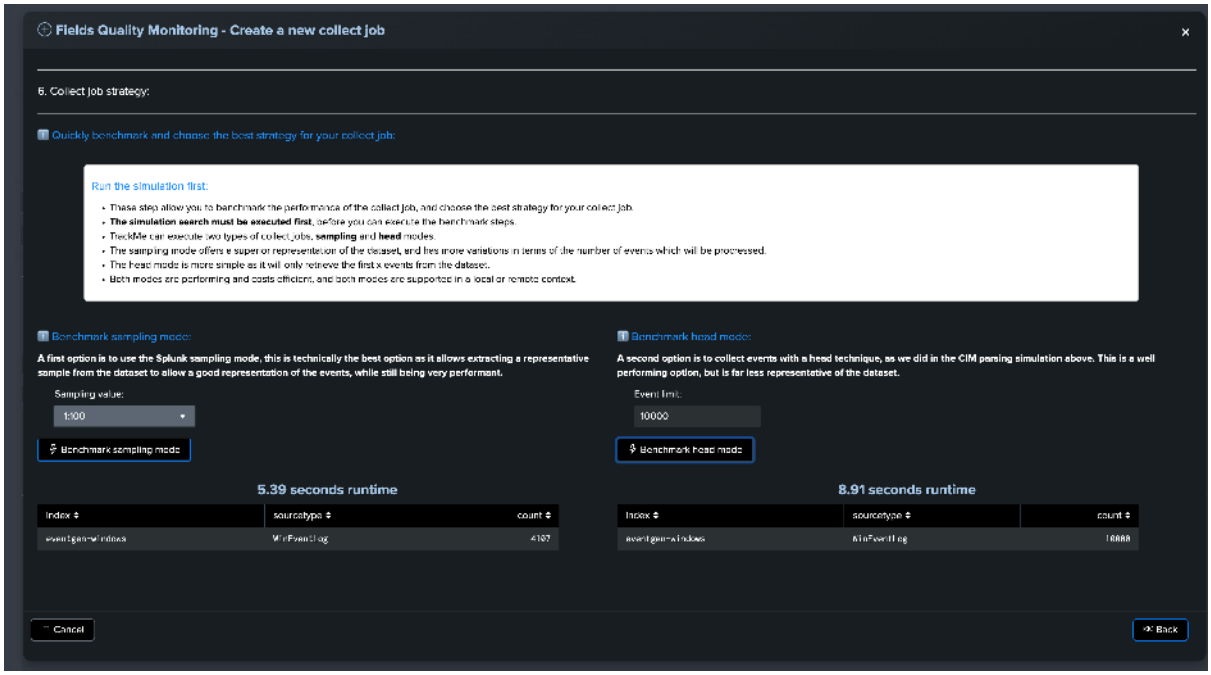
- These configurations allow you to define the default thresholds for both the global entity, which aggregates all fields for this breakby context, and individual fields.
- Thresholds are initialized at the time of entity discovery and creation, but can easily be adjusted through the TrackMe entity modification screen.



Benchmark the collect job strategy

About the collect job strategy benchmark:

- These steps allow you to benchmark the performance of the collect job and choose the best strategy for your collect job.
- The simulation search must be executed first, before you can execute the benchmark steps.
- TrackMe can execute two types of collect jobs: sampling and head modes.
- The sampling mode offers a superior representation of the dataset and has more variations in terms of the number of events that will be processed.
- The head mode is simpler as it will only retrieve the first x events from the dataset.
- Both modes are performant and cost-efficient, and both modes are supported in a local or remote context.



Collect job main settings

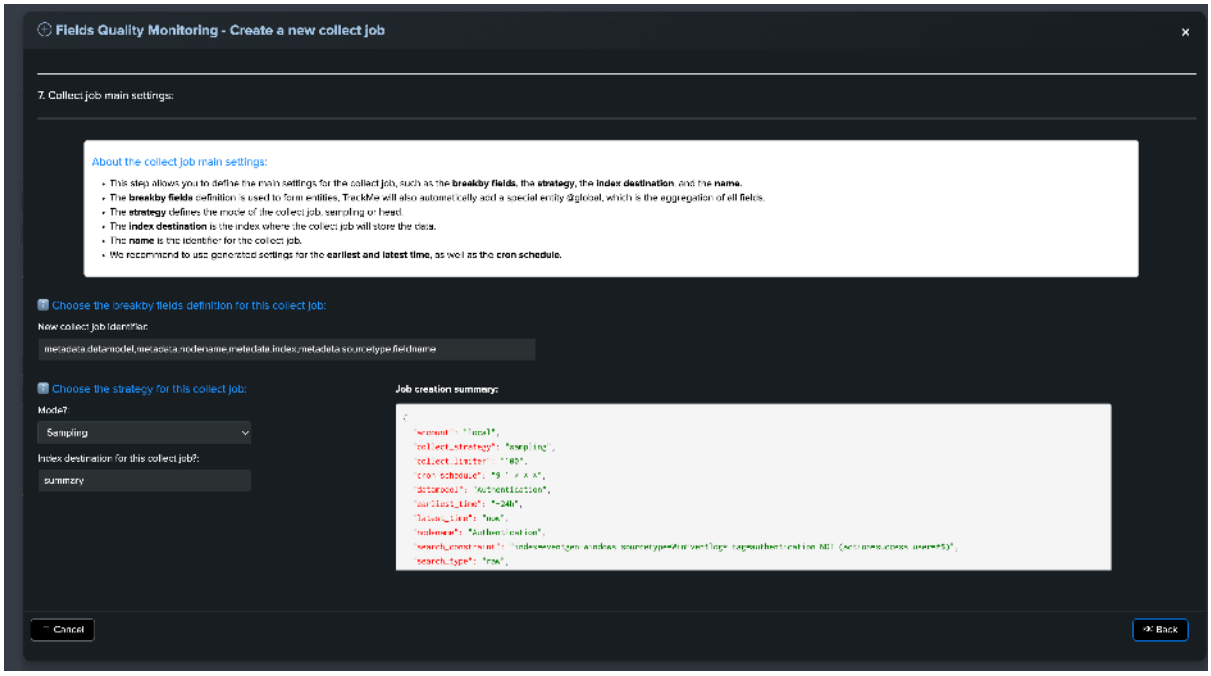
About the collect job main settings:

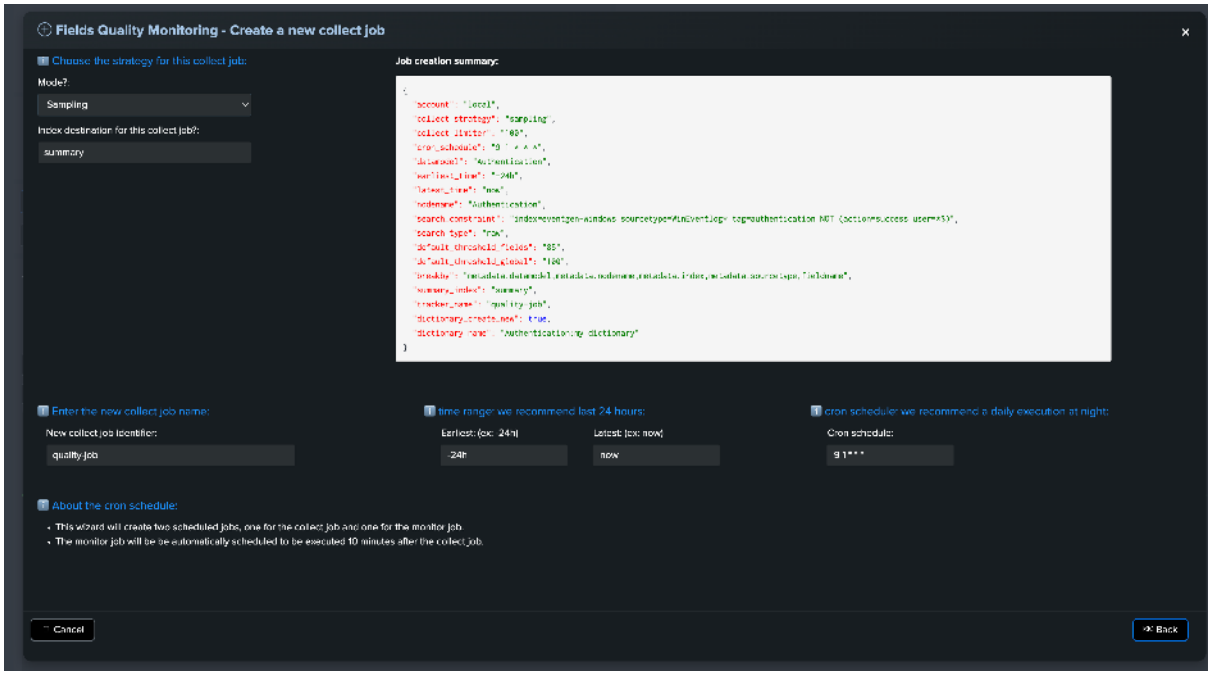
- This step allows you to define the main settings for the collect job, such as the breakby fields, strategy, index destination, and name.
- The breakby fields definition is used to form entities. TrackMe will also automatically add a special entity @global, which is the aggregation of all fields.
- The strategy defines the mode of the collect job: sampling or head.
- The index destination is the index where the collect job will store the data.
- The name is the identifier for the collect job.
- We recommend using generated settings for the earliest and latest time, as well as the cron schedule.

Hint

About the cron schedule:

- This wizard will create two scheduled jobs, one for the collect job and one for the monitor job.
- The monitor job will be automatically scheduled to be executed 10 minutes after the collect job.

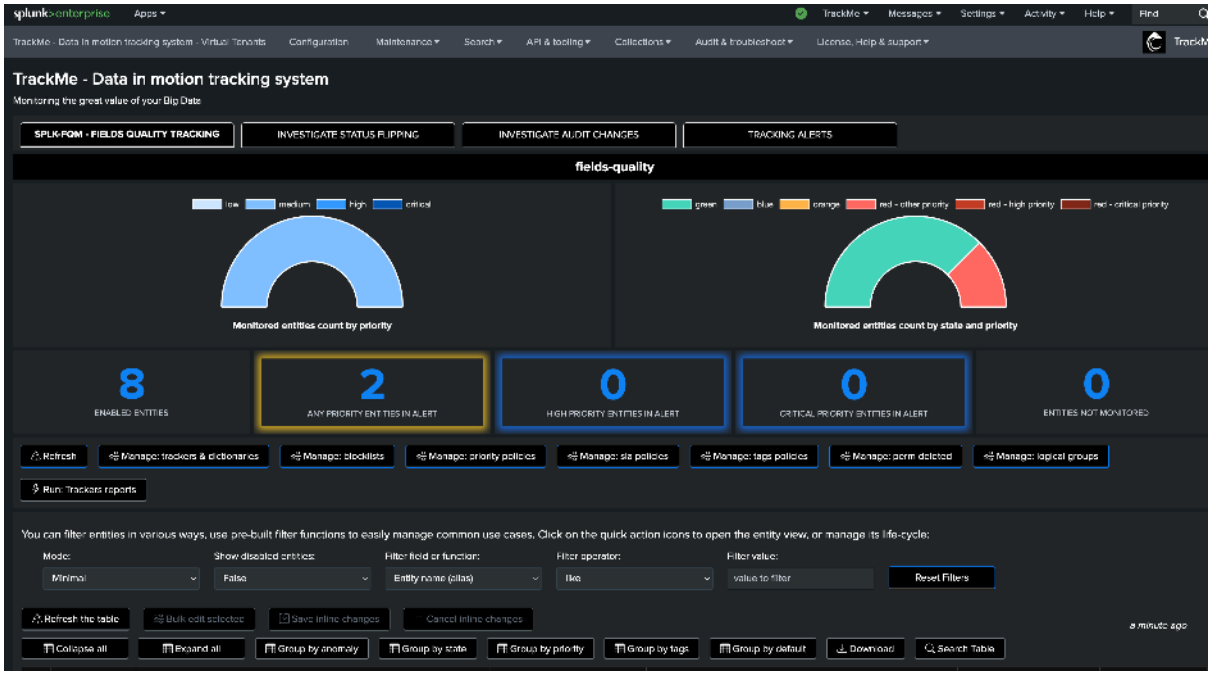


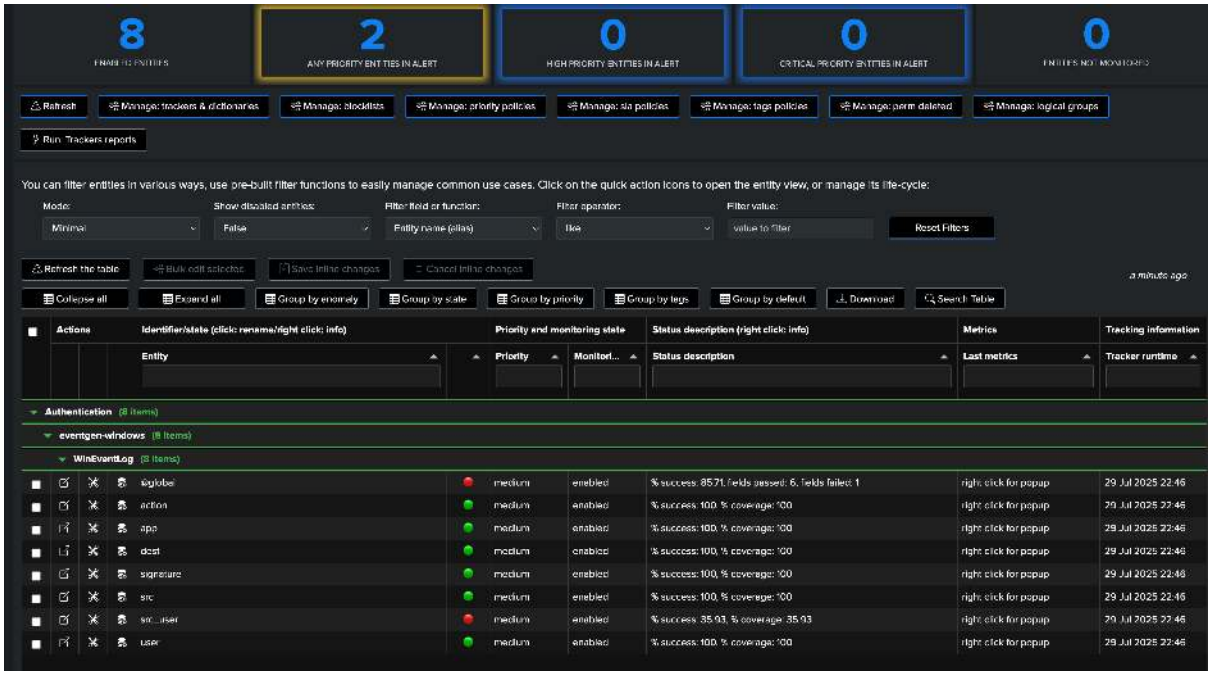


Validate the collect job creation

Finally! Hit the magic button and let TrackMe do the job.

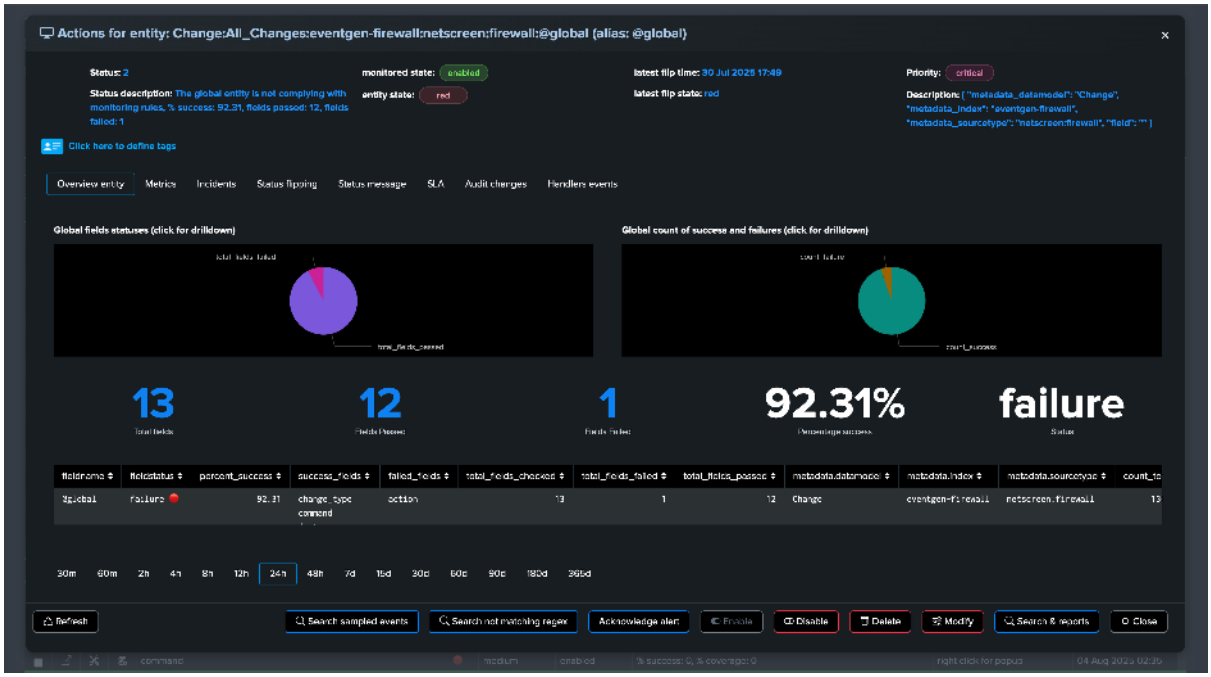
Once created, you can immediately execute the `collect` phase of the job, **then** the `monitor` phase to start seeing entities in TrackMe:





Fields Quality: @global entity

The @global entity is the aggregation of all fields for this breakby context. The UI provides full context and visualization of the entity:



Actions for entity: Change:All_Changes:eventgen-firewall:netscreen:firewall:@global (alias: @global)

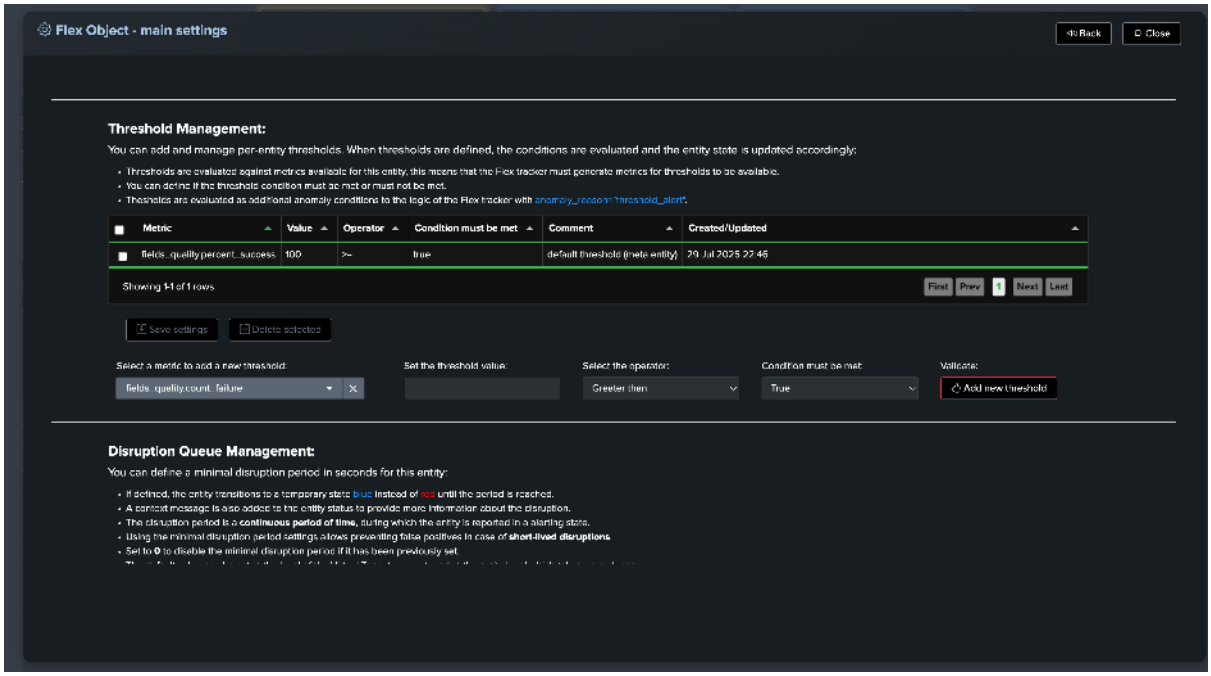
Updating the @global entity and fields entities thresholds

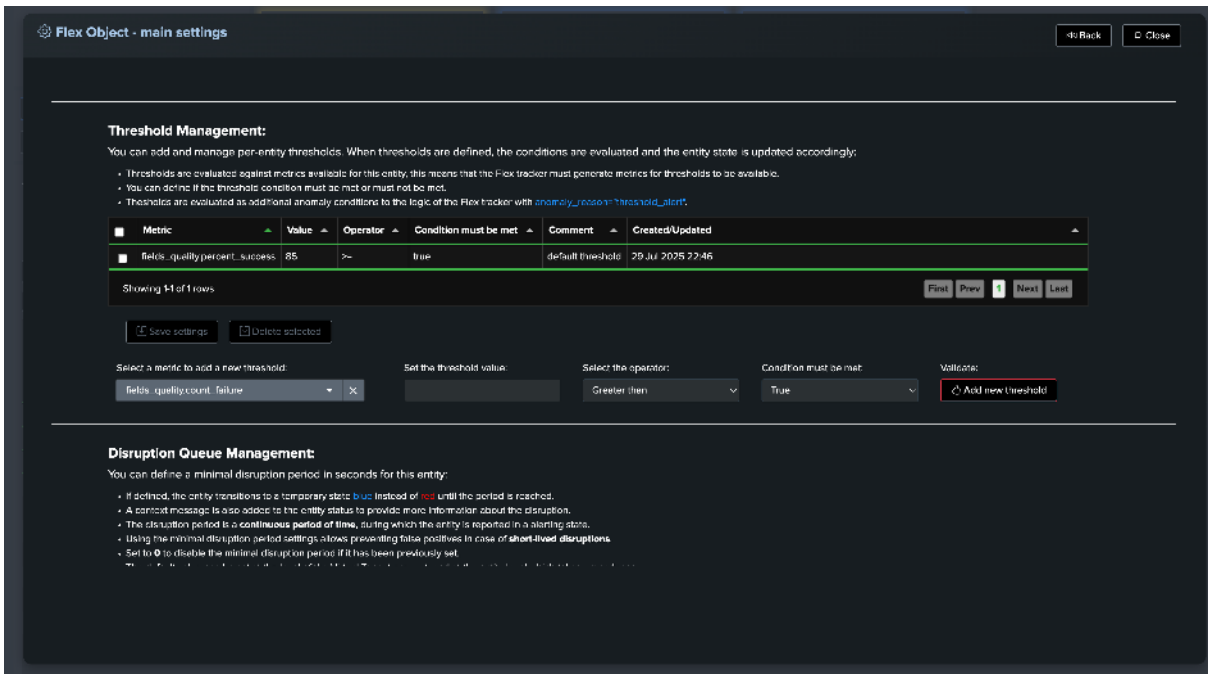
The @global entity and fields entities thresholds can be updated through the entity modification screen:

Hint

About updating fields entities thresholds:

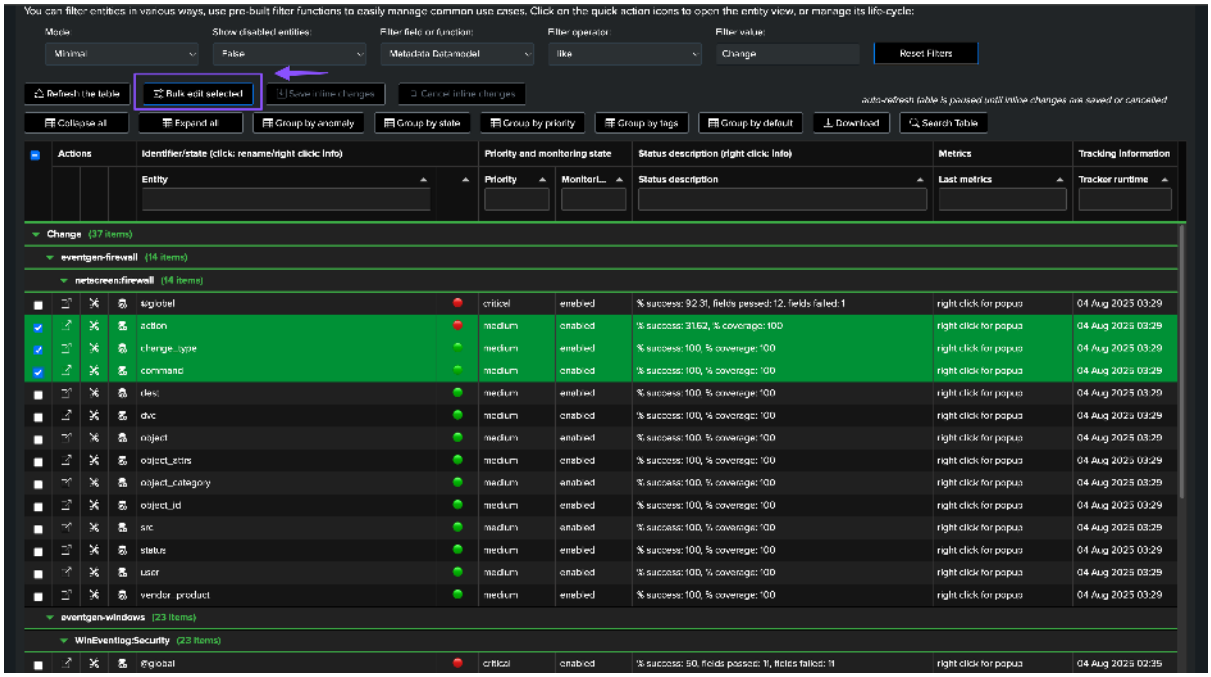
- Updating a threshold for a field is immediately reflected in the field entity view.
- However, for the @global entity to reflect the new field status, the `monitor` phase of the collect job must be executed.

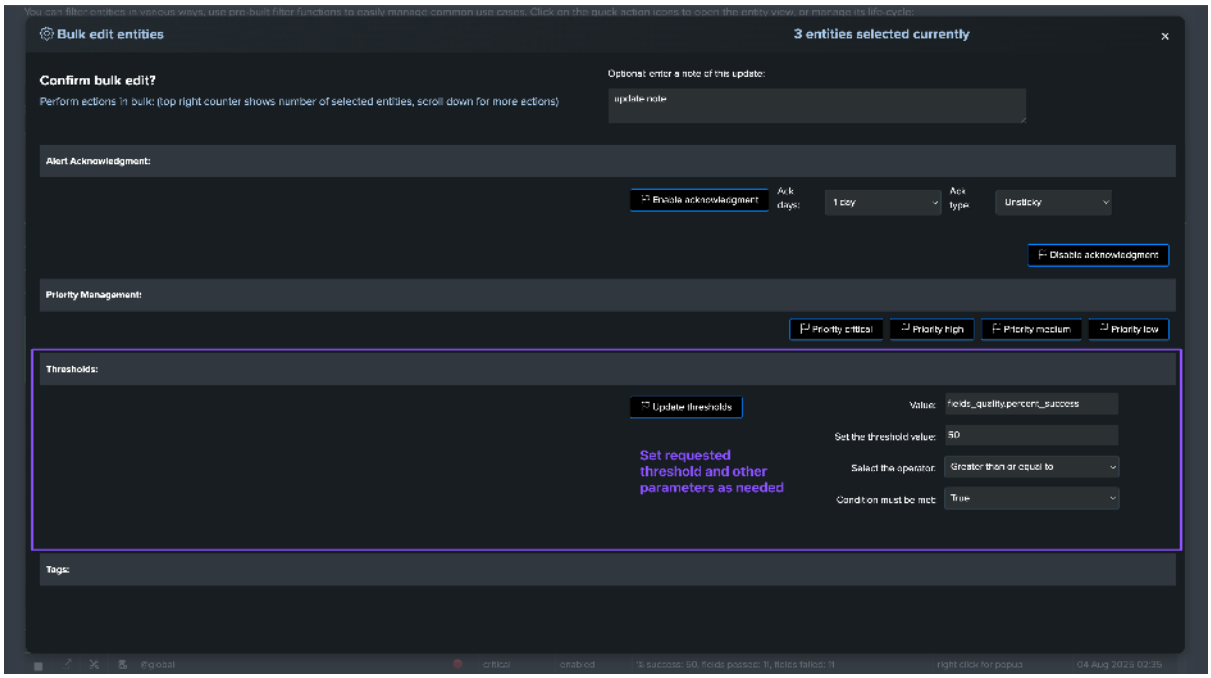




Updating thresholds in bulk after the entities discovery

You can update the thresholds in bulk after the entities discovery, by selecting the entities to be updated and then performing a bulk update through the bulk edit screen:





Disabling fields entities

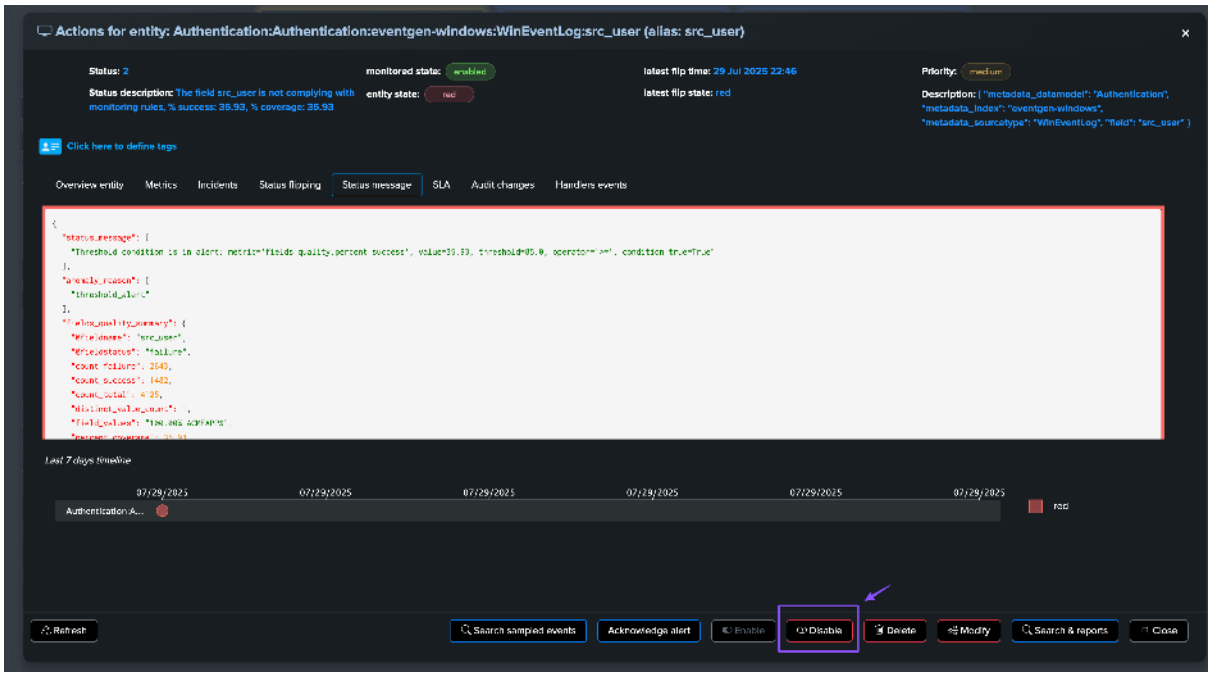
You can use the normal TrackMe workflow to disable a field entity that you wouldn't want to consider anymore:

Hint

About disabling a field entity and how it is reflected in the @global entity view:

- Disabling a field entity is immediately taken into account for the entity itself.
- This means that if, for instance, you have created an alert that covers field entities, a disabled field entity will never be considered.
- As well, the UI will not show by default entities that are disabled.

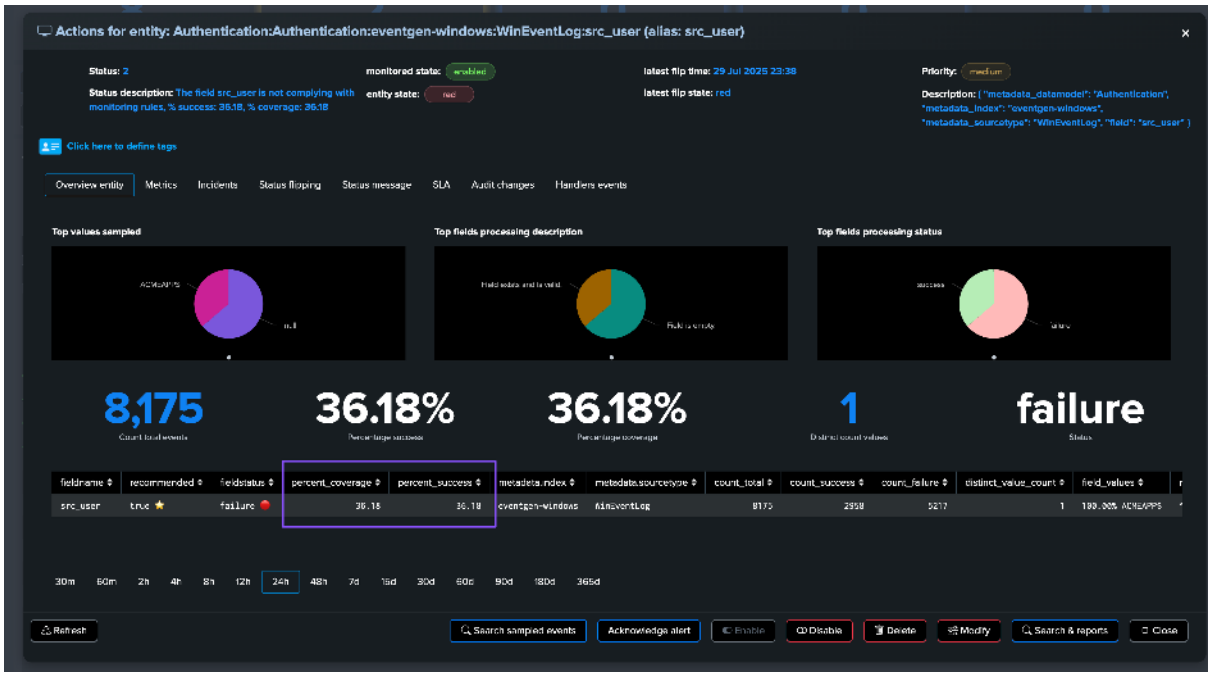
- **However**, the @global entity will still aggregate the disabled fields until the `monitor` phase of the collect job is executed.

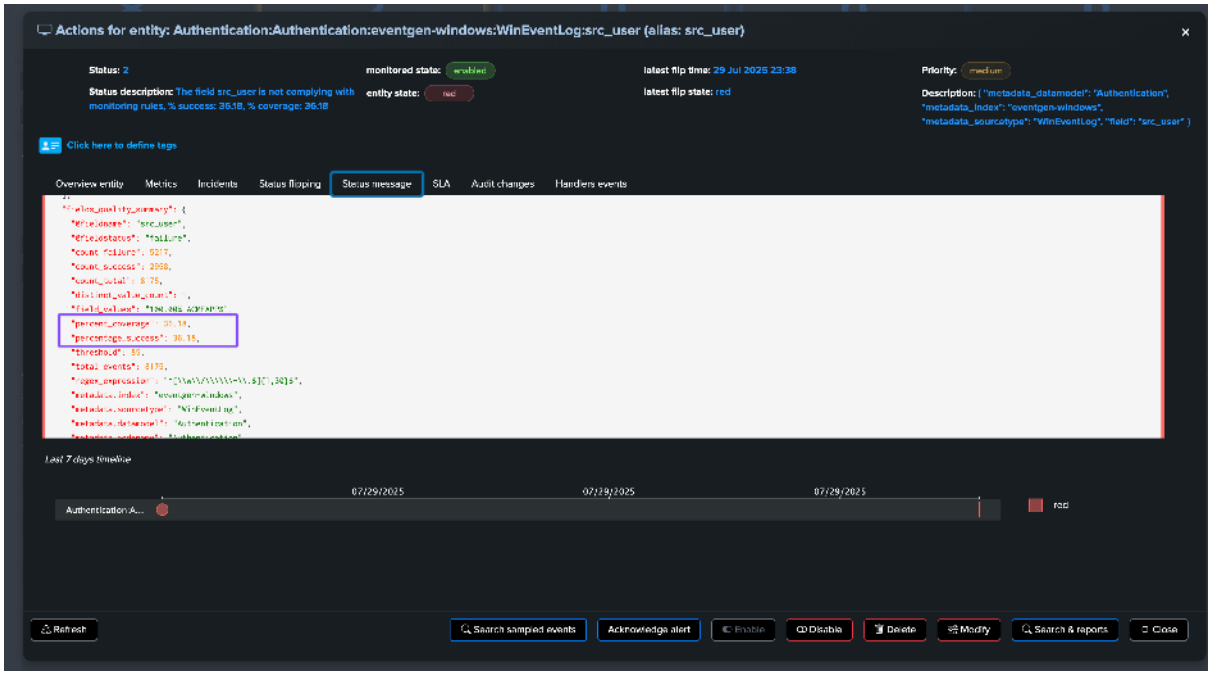


About fields percentage of success and percentage of coverage

For fields entities, TrackMe reports two key metrics:

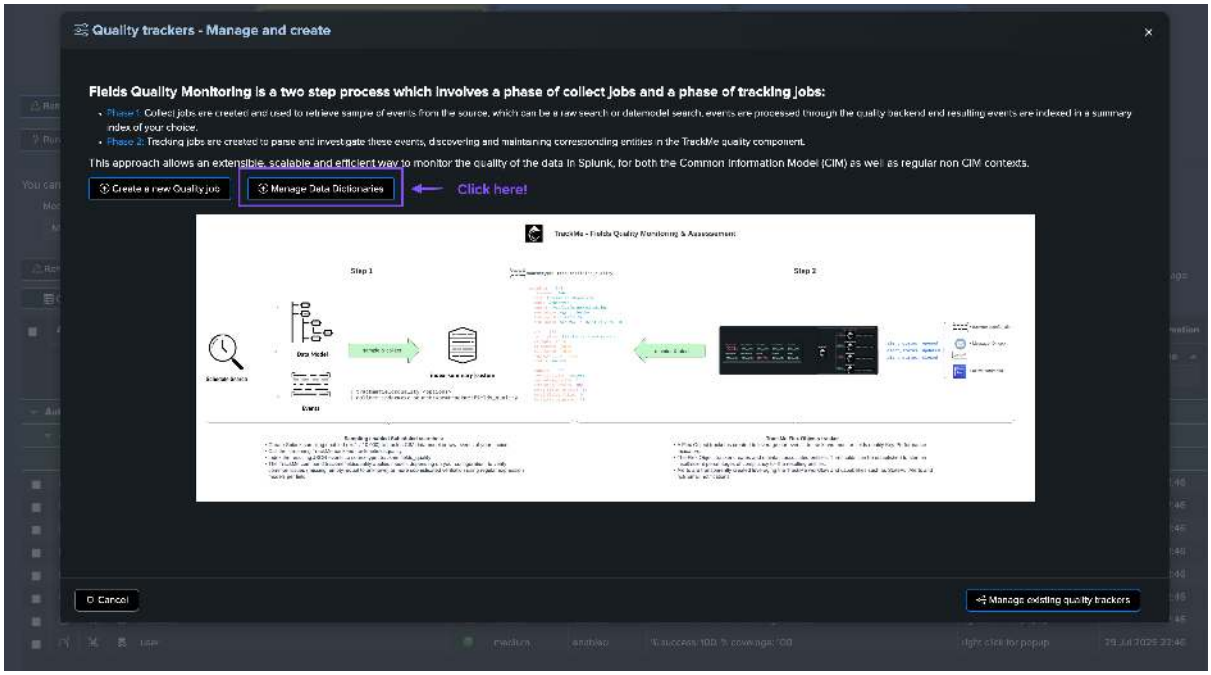
- The percentage of success, which is the percentage of times a field has passed the quality checks according to the dictionary definition: is the field empty, missing or null, unknown, or has the regular expression matched.
- The percentage of coverage, which is simply the percentage of times the field was part of the dataset and not empty or null.

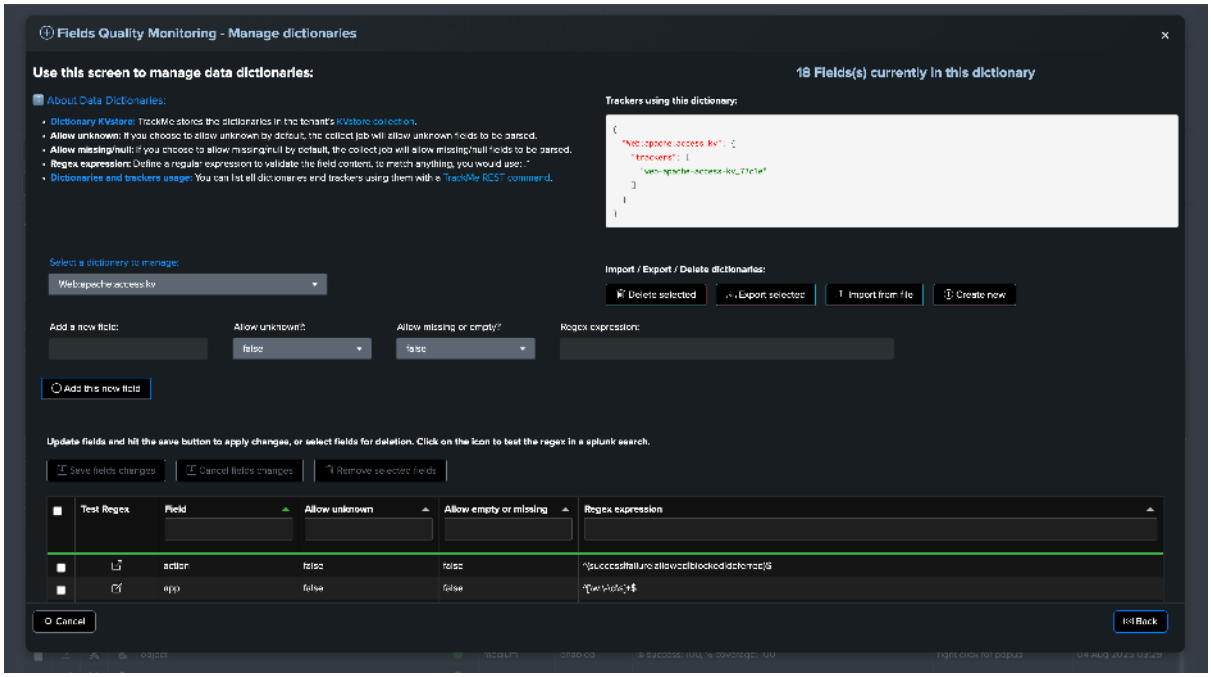




Managing Data Dictionaries

You can manage the data dictionaries through the dictionaries management interface:





About the data dictionary management:

- Dictionary KVstore: TrackMe stores the dictionaries in the tenant's KVstore collection.
- Allow unknown: If you choose to allow unknown by default, the collect job will allow unknown fields to be parsed.
- Allow missing/null: If you choose to allow missing/null by default, the collect job will allow missing/null fields to be parsed.
- Regex expression: Define a regular expression to validate the field content. To match anything, you would use: .*
- Dictionaries and trackers usage: You can list all dictionaries and trackers using them with a TrackMe REST command.

Hint

Actions that can be performed on a data dictionary:

- Delete selected dictionary
- Export selected dictionary
- Import selected dictionary
- Adding a new field and specifying allow unknown, allow missing/null, regex expression
- Updating existing fields definition and their parameters
- Testing a regular expression against the field dataset

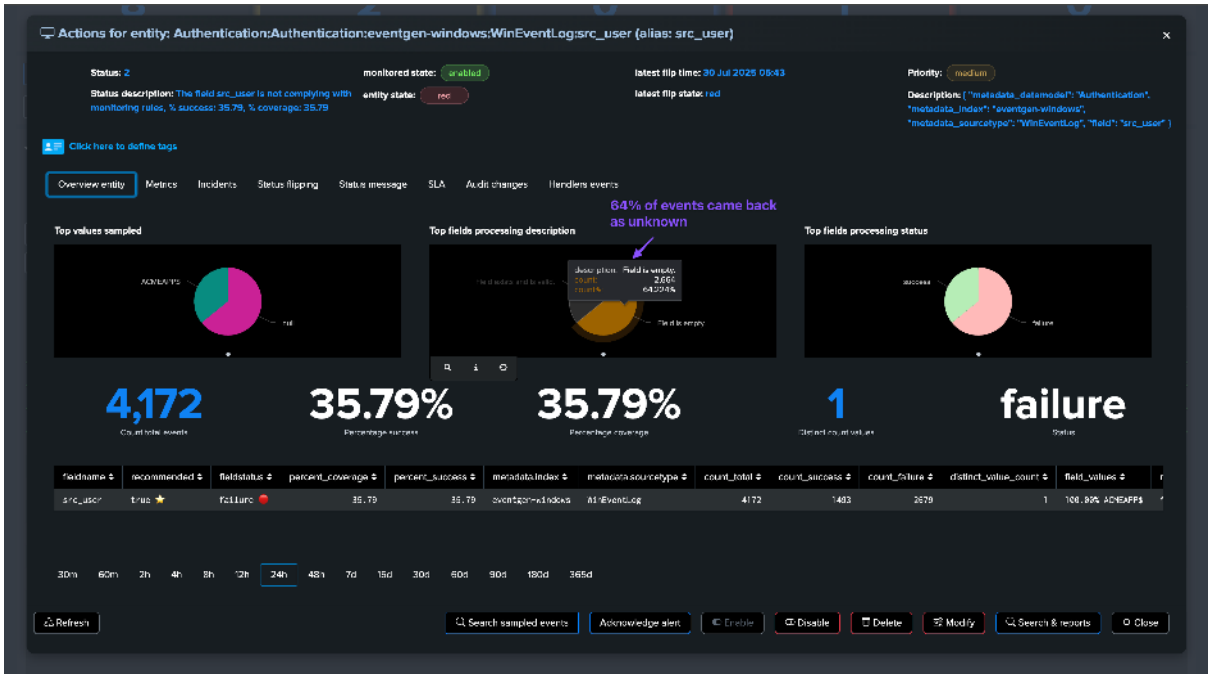
Modifying fields entities compliance rules in the data dictionary

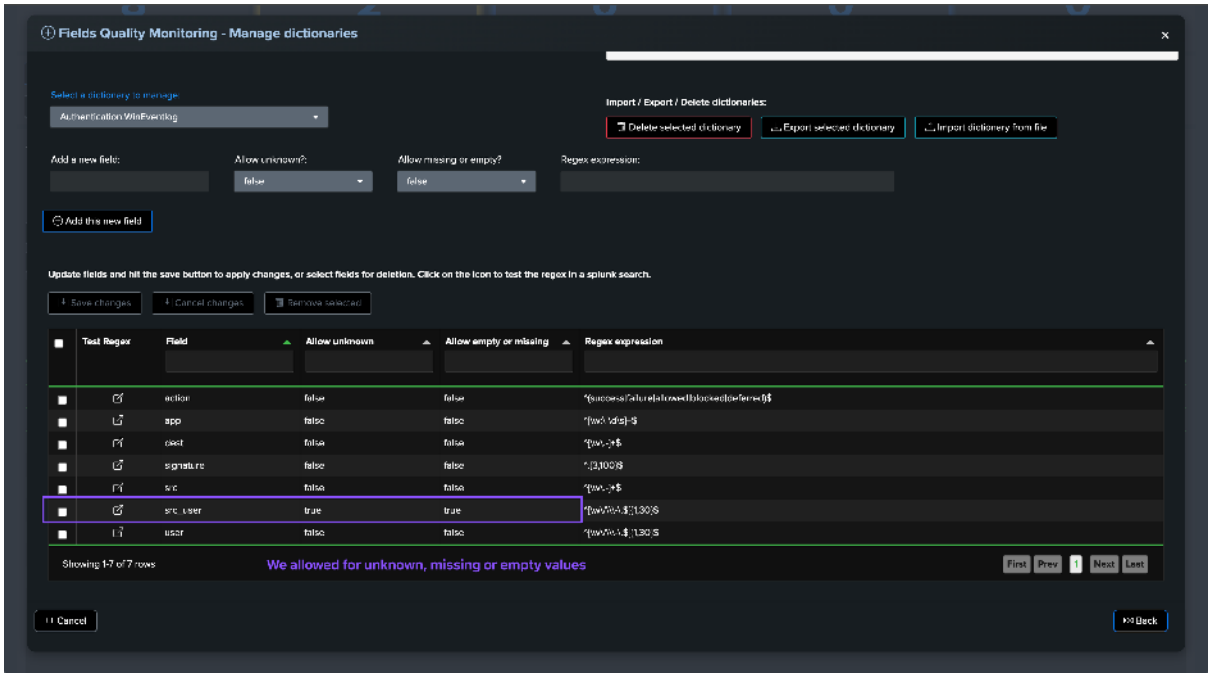
When modifying rules for compliance in the data dictionary, such as:

- **Allowing the field to be unknown:** `allow_unknown: True` or `False`
- **Allowing the field to be missing/null:** `allow_missing_null: True` or `False`

- **Regular expression:** `regex`: a regular expression to validate the field content

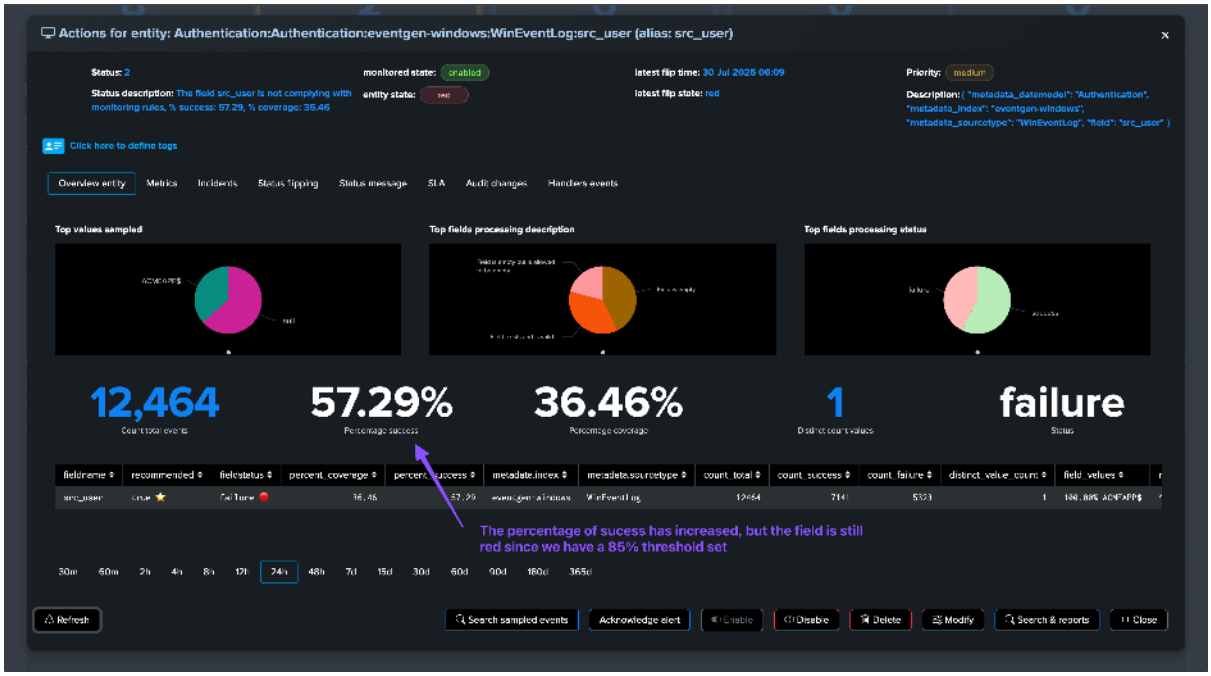
You have to keep in mind that the percentage of success will be updated according to the events processed and time. If, for instance, we have a field that is initially failing with a condition due to unknown values, and we just modified the data dictionary to allow unknown values:

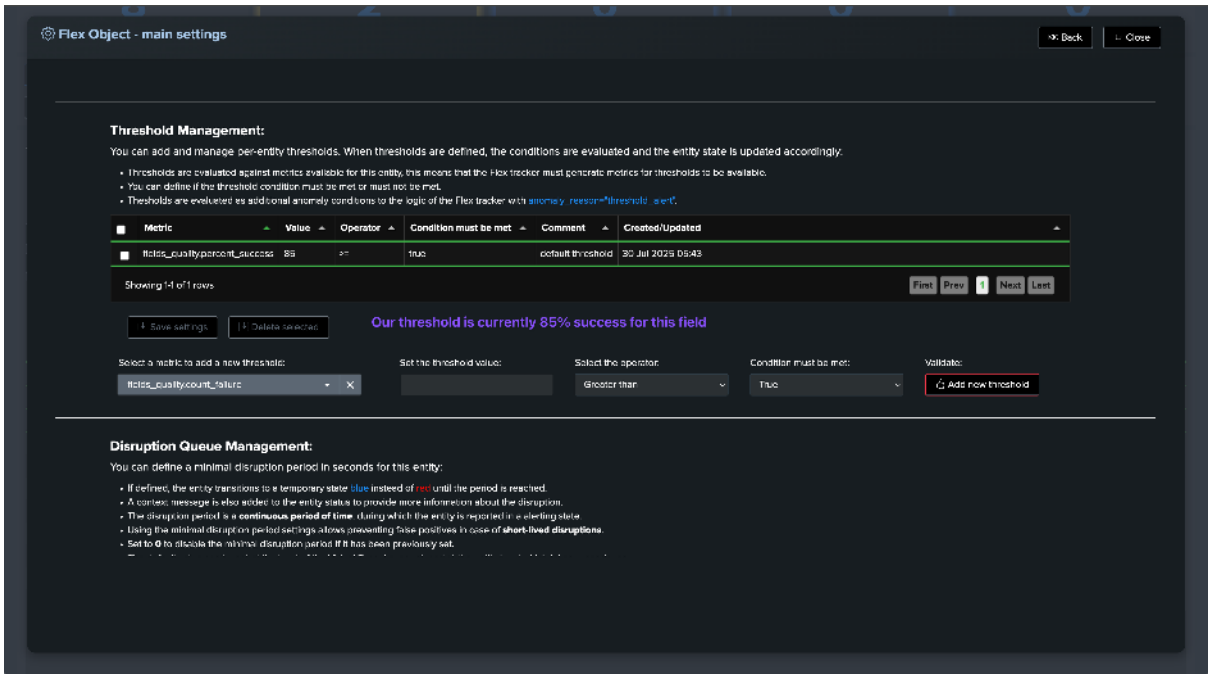




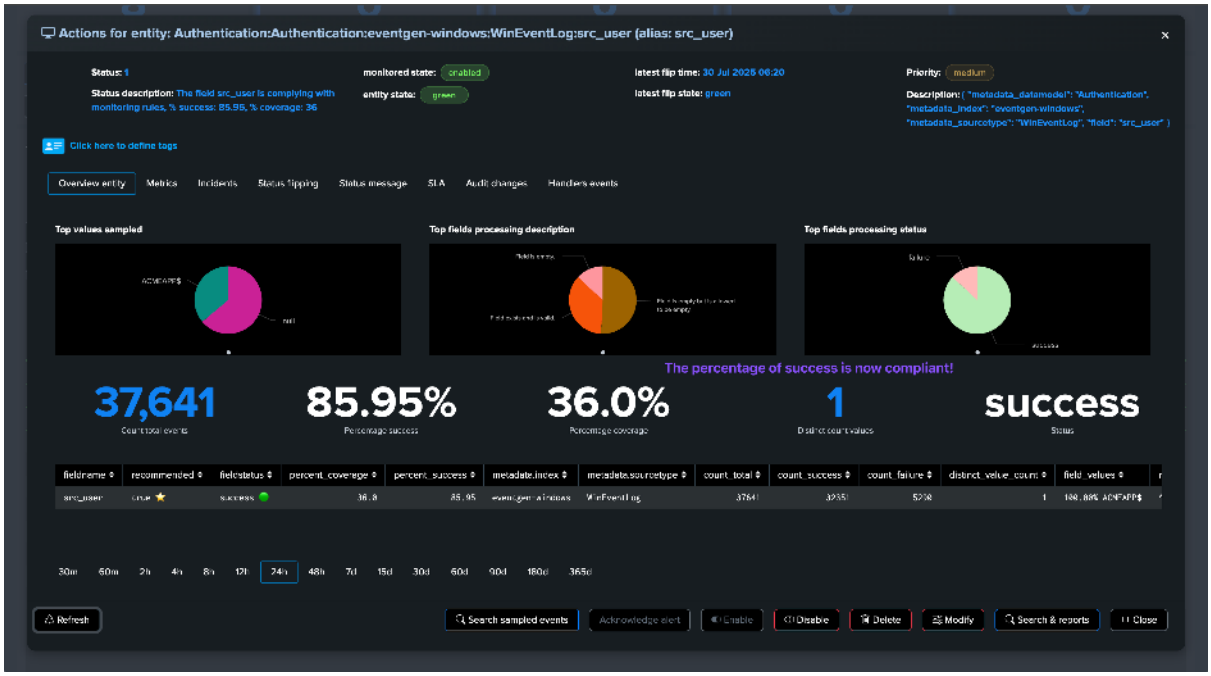
The percentage of success will not grow until we have a new execution of the `collect` and `monitor` phases of the collect job.

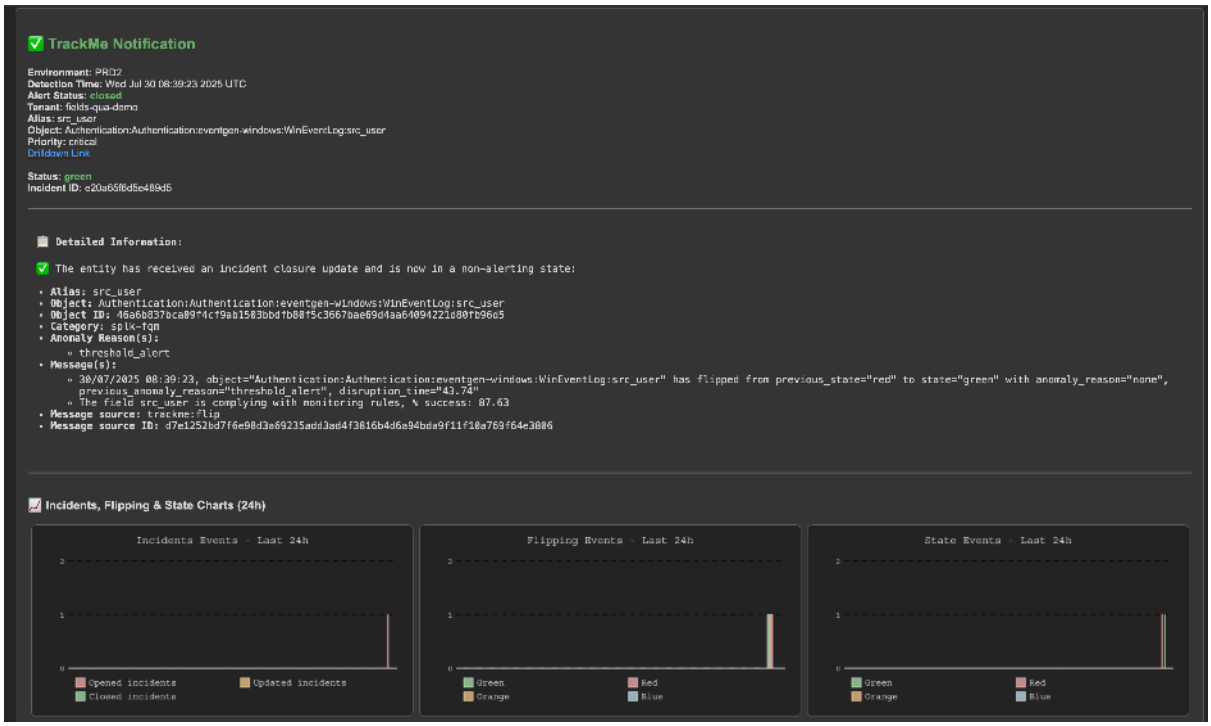
Therefore, depending on the initial percentage of failures and conditions, it may take several iterations before we reach a stable percentage of success and the field is considered as passing the compliance checks:





Once conditions are met, or if we lower the requested percentage of success for that field, the field will transition to green and is now compliant according to our requirements:





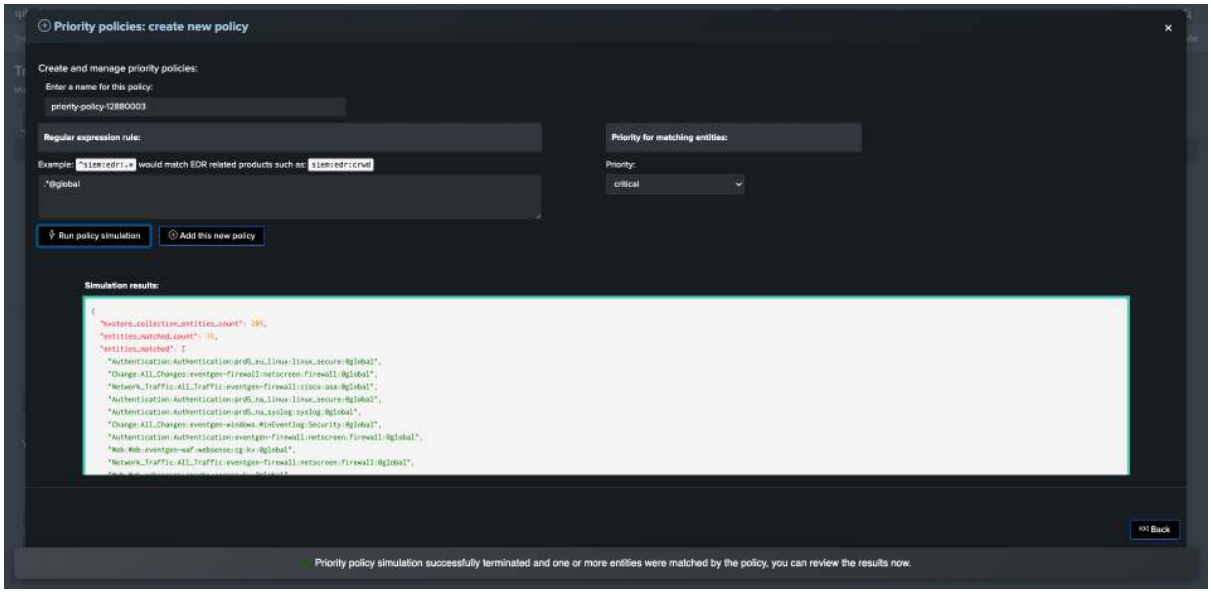
Creating a priority policy for global entities

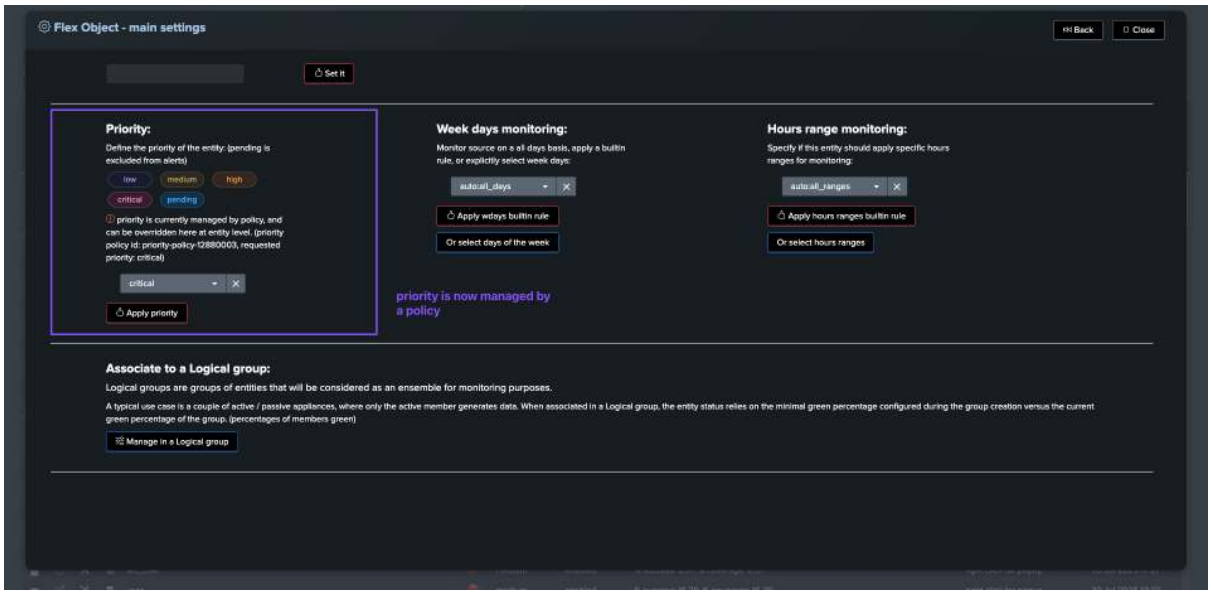
TrackMe provides a feature called priority policies, which allows to automatically handle the priority level for entities matching a regular expression.

We can easily leverage this feature to automatically set the priority for our `@global` entity, so that if wanted, we can enable email notifications for all global entities only:

Expression used in the following example:

```
.*@global
```





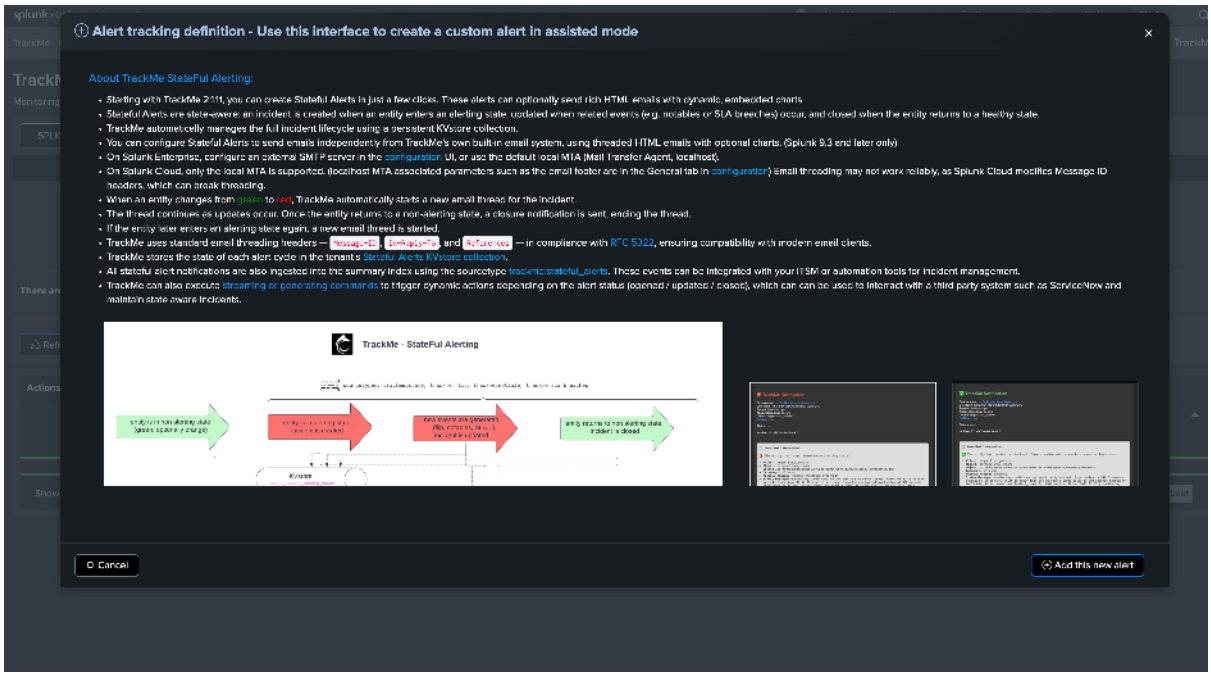
Alerting on fields quality issues, and generating emails or other types of notifications

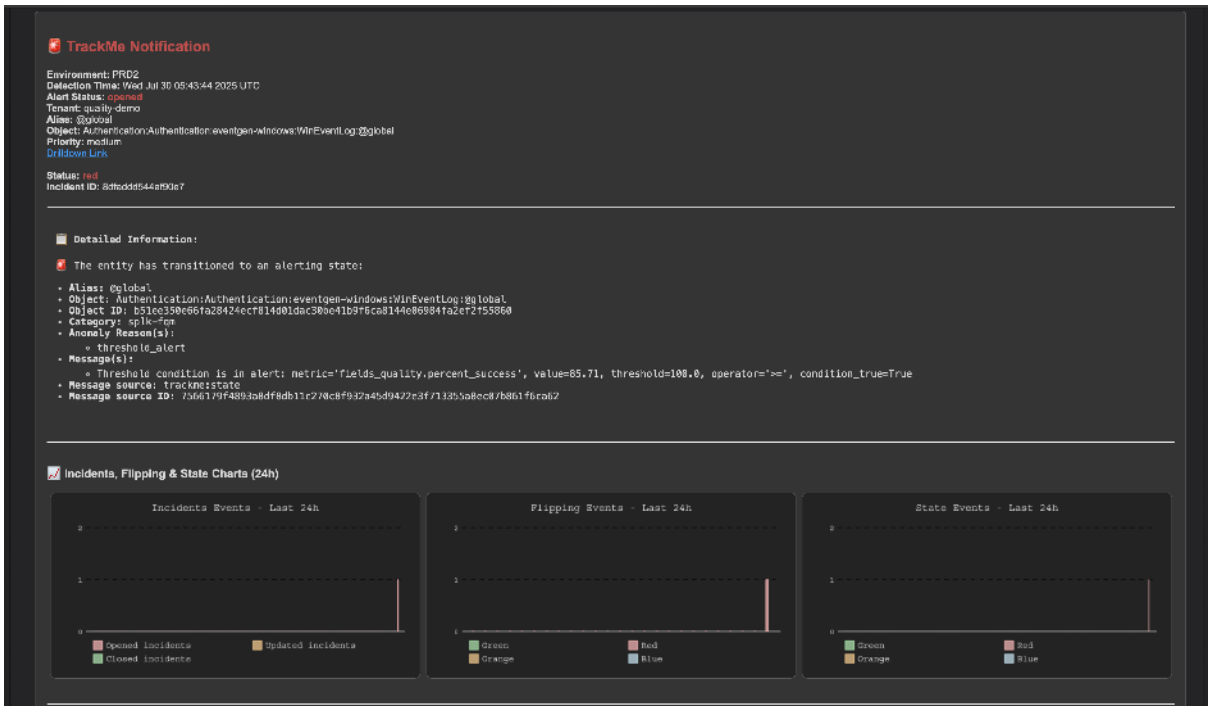
Alerting on fields quality issues works exactly in TrackMe as for any other component, using our extensive and flexible alerting concepts, such as the Stateful alerts in TrackMe.

Hint

About alerting only against the @global entity, and/or fields entities:

- This choice is entirely up to you. You can choose to do both, any kind of combination is possible.
- A recommended approach would be to rely on the priority level. You could simply set the @global entity priority to `high` or `critical` and set up your alert to trigger on these levels.
- If you need at some point to alert on certain fields, simply increase the priority level of the field entities you want to alert on.





Annex: usage and options for the command trackmefieldsquality

The command `trackmefieldsquality` is used in the collect phase to parse and validate the fields compliancy, this is a powerful and flexible Python backend that provides various options.

The command accepts the following parameters:

argument	description	default	example or valid values
`fields_to_check_list`	The list of fields to verify, provided as a comma-separated list	None	"action,app,bytes,url"
`fields_to_check_fiel`	Name of the field containing the list of fields to check (comma-separated)	None	"fields_list"
`fields_to_check_dict`	JSON string containing a dictionary of fields to check with optional regex patterns	None	'{"field1": {"name": "field1", "regex": "^[A-Z]+$"}, "field2": {"name": "field2"}}'
`fields_to_check_dict`	Path to a JSON file containing a dictionary of fields to check with optional regex patterns	None	"/opt/splunk/etc/apps/myapp/mydir/web_data
`fields_to_check_dict`	Name of the field containing a JSON string with a dictionary of fields to check	None	fields_dict
`fields_to_check_sear`	The search command to use to generate the dictionary of fields to check	None	"| trackmefieldsquality-gendict datamodel=Web show_only_recommended_fields=True"
`include_field_values`	Boolean option to include field values in the JSON summary	False	True/False
`pretty_print_json`	Boolean option to pretty print the JSON summary	True	True/False
`output_mode`	The mode to output the results (json or raw)	json	json
`metadata_fields`	CSV list of metadata fields to include in the metadata section of the JSON	index,sourcetype,host,source	"datamodel"
`summary_fieldname`	Defines the name of the summary field	summary	"summary"
`metadata_fieldname`	Defines the name of the metadata field added to the summary JSON	metadata	"metadata"

The first 6 options are **mutually exclusive**, only one of these options can be used at a time:

- `fields_to_check_list`
- `fields_to_check_fieldname`
- `fields_to_check_dict`
- `fields_to_check_dict_path`
- `fields_to_check_dict_fieldname`
- `fields_to_check_search_command`

These options exist so that we can cover all use cases, this provides all levels of flexibility to use different Splunk techniques such as subsearches or simply storing the list of fields or models, dynamic generation in SPL, etc.

Let's take an example over each of these options:

Argument: fields_to_check_list

This is the most simple use case:

- Provide the list of fields to be checked as a comma-separated list
- For each field, we will check the following: - Missing - Empty - Null - Equal to unknown

If the field passes all these checks, it is declared as valid with a status of `success`, and `failure` otherwise.

The command will store with the JSON object a section for the field, which includes `flags` for each check, with a boolean value True or False:

- `is_missing`
- `is_empty`
- `is_unknown`
- `regex_failure`

In addition, the command will account the field and its status in the `summary` section of the JSON object:

- `overall_status`: the overall status of the field checks, either `success` or `failure`
- `total_fields_checked`: the total number of fields checked
- `total_fields_failed`: the total number of fields that failed
- `total_fields_passed`: the total number of fields that passed
- `percentage_failed`: the percentage of fields that failed
- `percentage_passed`: the percentage of fields that passed

Note: this argument does NOT process a regular expression to check for the content, therefore the `regex_failure` flag will always be `False`. (see next options for this)

Argument: fields_to_check_fieldname

This does exactly the same as `fields_to_check_list`, but instead of providing the list of fields to check as a comma-separated list, we provide the name of a field that contains the list of fields to check.

You would therefore call the command as follows:

Example:

```
| eval fields_list="action,app,bytes,url"
| trackmefieldsquality fields_to_check_fieldname="fields_list"
```

The point of having this option is that could for instance use a Splunk subsearch to generate the list of fields dynamically, for instance by accessing a lookup table where you store the fields depending on your criteria, or any other solution of your choice.

Hint

Providing a JSON dictionary model

- The next 3 options allow to provide a JSON dictionary model that models the fields to check, as well as optional parameters for each field.
- Especially, you can define a regular expression with the field `regex` to be apply against the value, allowing to valid the content of the field according to any needs.

- You can also define the field `allow_unknown` to be `True` or `False`, which can be used to disable the check for the field `is_unknown`.

Argument: fields_to_check_dict

This option is more sophisticated and allows to define a dictionnary that models the fields to check, and as well as an option regular expression to be apply against the value.

For instance, the following distionnary would verify the fields `bytes` including the fact that this should be a numerical value using a regular expression, the field `action` that for instance would accept only `success` or `failure`, and finally the field `http_referrer` where we would only perform the basic checks without verifying that its value matches certain criteria.

```
| trackmefieldsquality fields_to_check_dict="{\"bytes\": {\"name\": \"bytes\", \
↪"regex\": \"^\\d*\"}, \"action\": {\"name\": \"action\", \"regex\": \"^
↪(success|failure)$\"}, \"http_referrer\": {\"name\": \"http_referrer\"}}"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True
```

In this case, if a regrex expression is provided, the `regex_failure` flag will be set to `True` if the value does not match the regular expression, and `False` otherwise, which accounts for status of the field in addition to the other checks.

Example of JSON output:

```
{
    "time": 1747261746,
    "bytes": {
        "status": "success",
        "description": "Field exists and is valid.",
        "is_missing": false,
        "is_empty": false,
        "is_unknown": false,
        "regex_failure": false,
        "value": "309"
    },
    "action": {
        "status": "failure",
        "description": "Field exists but value does not match the required␣
↪pattern.",
        "is_missing": false,
        "is_empty": false,
        "is_unknown": false,
        "regex_failure": true,
        "value": "Bad Request"
    },
    "http_referrer": {
        "status": "failure",
        "description": "Field is 'unknown'.",
        "is_missing": false,
        "is_empty": false,
        "is_unknown": true,
        "regex_failure": false,
        "value": "unknown"
    },
    "summary": {
        "overall_status": "failure",
        "total_fields_checked": 3,
```

(continues on next page)

(continued from previous page)

```
        "total_fields_failed": 2,
        "total_fields_passed": 1,
        "percentage_failed": 66.67,
        "percentage_passed": 33.33
    },
    "metadata": {
        "time_epoch": 1747261746,
        "time_human": "Wed May 14 22:29:06 2025 UTC",
        "index": "webserver",
        "sourcetype": "nginx:plus:kv",
        "host": "trackme-solutions.com",
        "source": "/var/log/nginx/access.log",
        "datamodel": "Web"
    },
    "event_id": "f5ed1437ee8486a3782ebaea846dad37c52d47b825d1913c1ae7d085ba01f943"
}
```

Hint

Escaping backslashes and special characters

- The tricky part is that you need to pay attention to the JSON provided as input to the command
- Especially, double quotes within the JSON string need to be escaped.
- The regular expression also needs to be escaped, for instance `^\\\d*` which would otherwise be `\d*` in normal circumstances.

Argument: fields_to_check_dict_fieldname

Similarly to `fields_to_check_fieldname`, this option allows to provide the name of a field that contains the dictionary of fields to check as in the previous example.

This allows to use a Splunk subsearch to generate the dictionary dynamically, for instance by accessing a lookup table where you store the fields depending on your criteria, or any other solution of your choice.

Example:

```
| eval fields_dict="{\"bytes\": {\"name\": \"bytes\", \"regex\": \"^\\\d*\"}, \
↪"action\": {\"name\": \"action\", \"regex\": \"^(success|failure)$\"}, \
↪"http_referrer\": {\"name\": \"http_referrer\"}}"
| trackmefieldsquality fields_to_check_dict_fieldname="fields_dict"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True
```

Argument: fields_to_check_search_command

This option allows to provide a search command that will be executed to generate the dictionary of fields to check dynamically. This is particularly useful when you want to generate the dictionary on-the-fly using commands like `trackmefieldsqualitygendict` or any other search command that produces the required JSON dictionary format.

The search command will be executed and its output will be used as the dictionary for fields quality assessment. This provides maximum flexibility for dynamic dictionary generation.

Example:

```
| trackmefieldsquality fields_to_check_search_command="|␣
↪trackmefieldsqualitygendict datamodel=Web show_only_recommended_fields=True"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True
```

Example with custom search command:

```
| trackmefieldsquality fields_to_check_search_command="| inputlookup␣
↪my_data_dict_lookup | where somefilter=\"somevalue\"" pretty_print_json=False␣
↪output_mode=json metadata_fields="datamodel" include_field_values=True
```

Argument: fields_to_check_dict_path

This option is similar to `fields_to_check_dict_fieldname`, but instead of providing the dictionary as a JSON string, we provide the path to a JSON file that contains the dictionary.

The file must exist on the file system of the Splunk instance, and the path must be provided as a string.

Our JSON file would look like this:

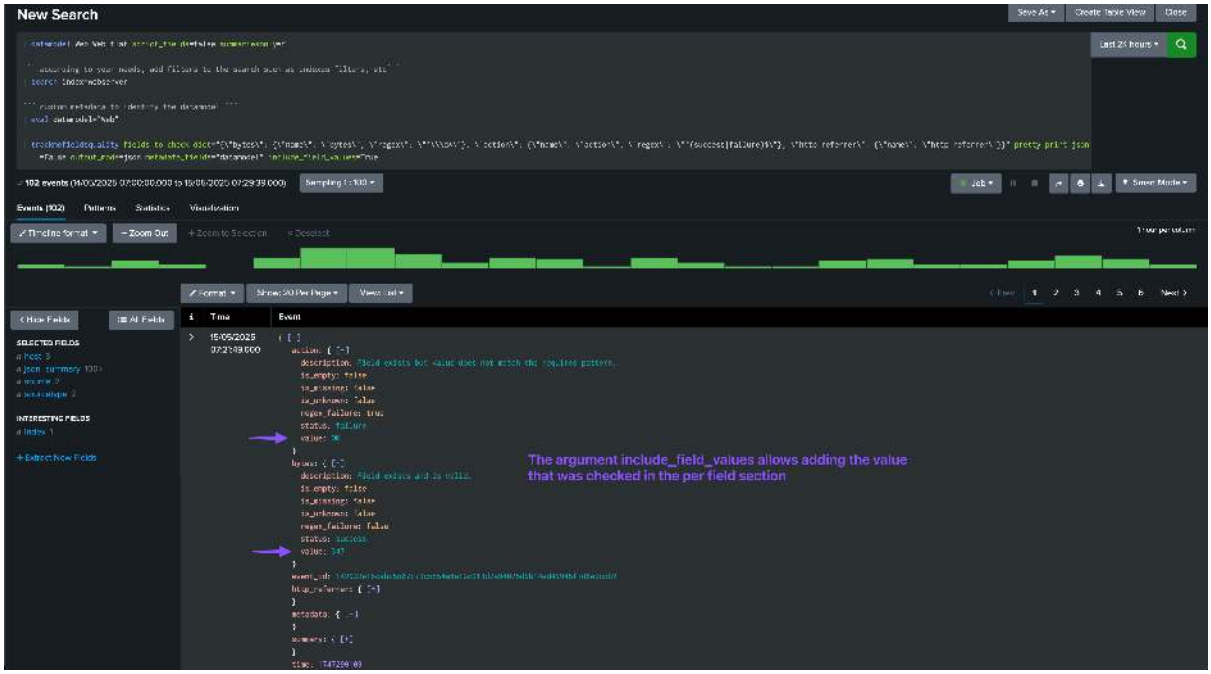
```
{
    "action": {
        "name": "action",
        "regex": "^(success|failure)$"
    },
    "bytes": {
        "name": "bytes",
        "regex": "^\\d*"
    },
    "http_referrer": {
        "name": "http_referrer"
    }
}
```

Example:

```
| trackmefieldsquality fields_to_check_dict_path="/
↪opt/splunk/etc/apps/myapp/mydir/web_datamodel.json" pretty_print_json=False␣
↪output_mode=json metadata_fields="datamodel" include_field_values=True
```

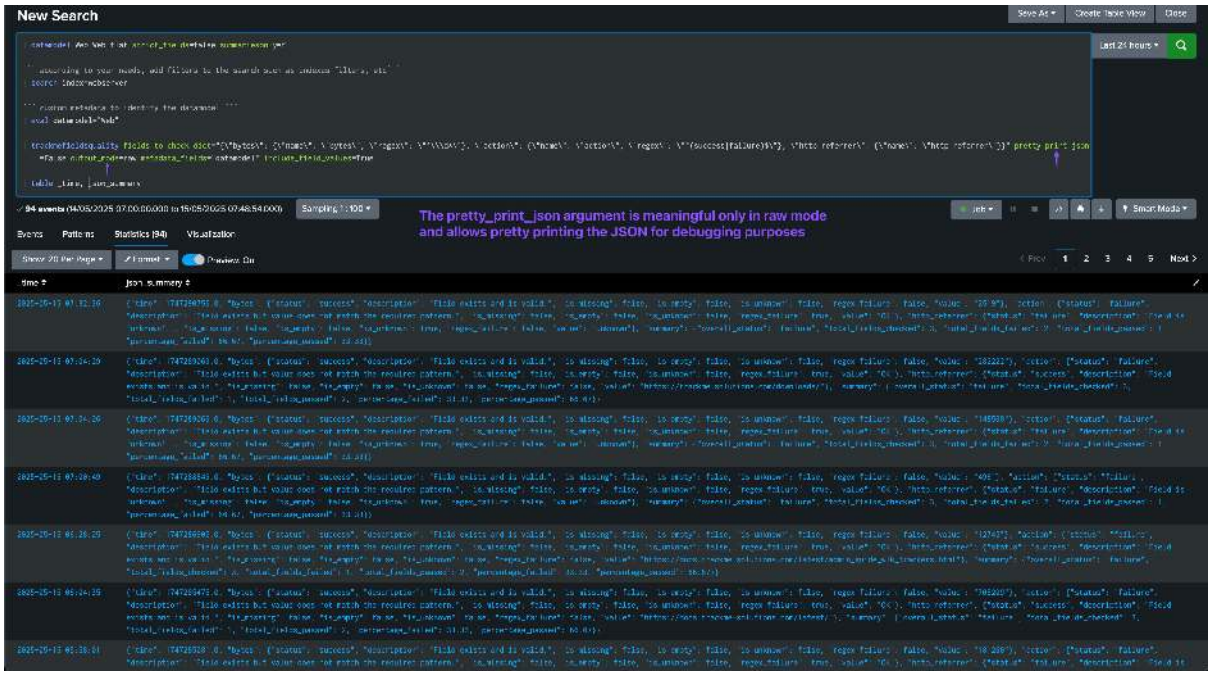
Argument: include_field_values

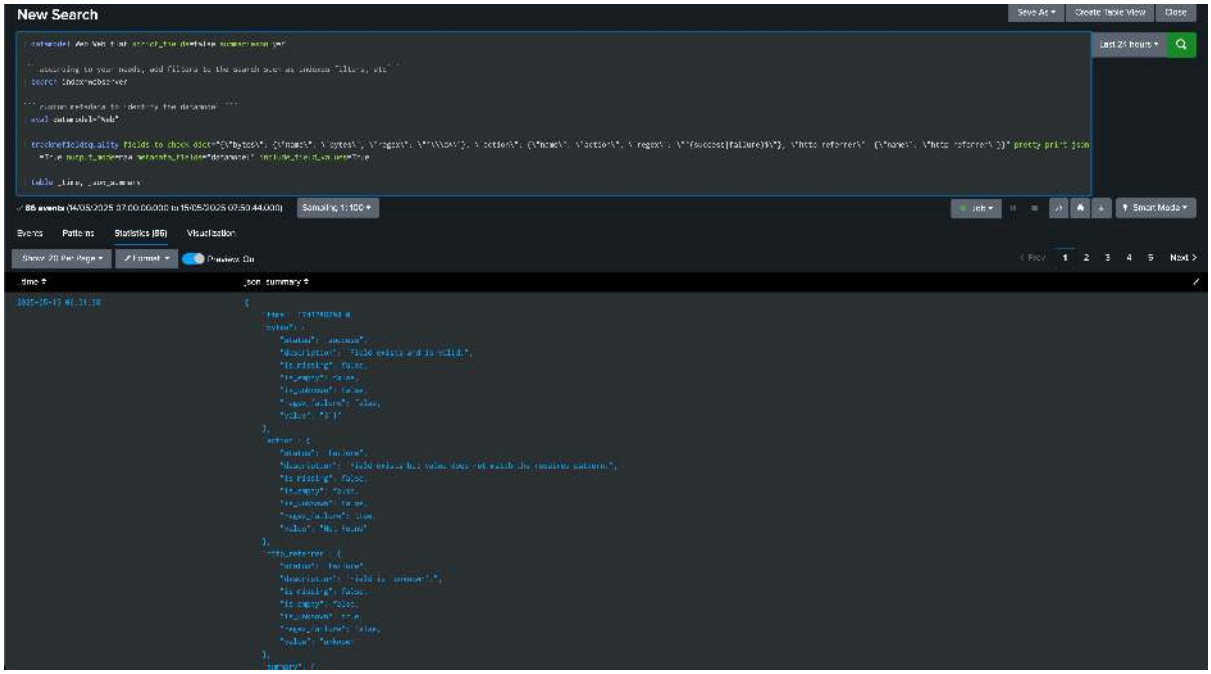
This option allows to include the field values in the JSON output, which can useful for analytics and reporting purposes.



Argument: pretty_print_json

This option allows to pretty print the JSON output, which can be useful for debugging purposes.





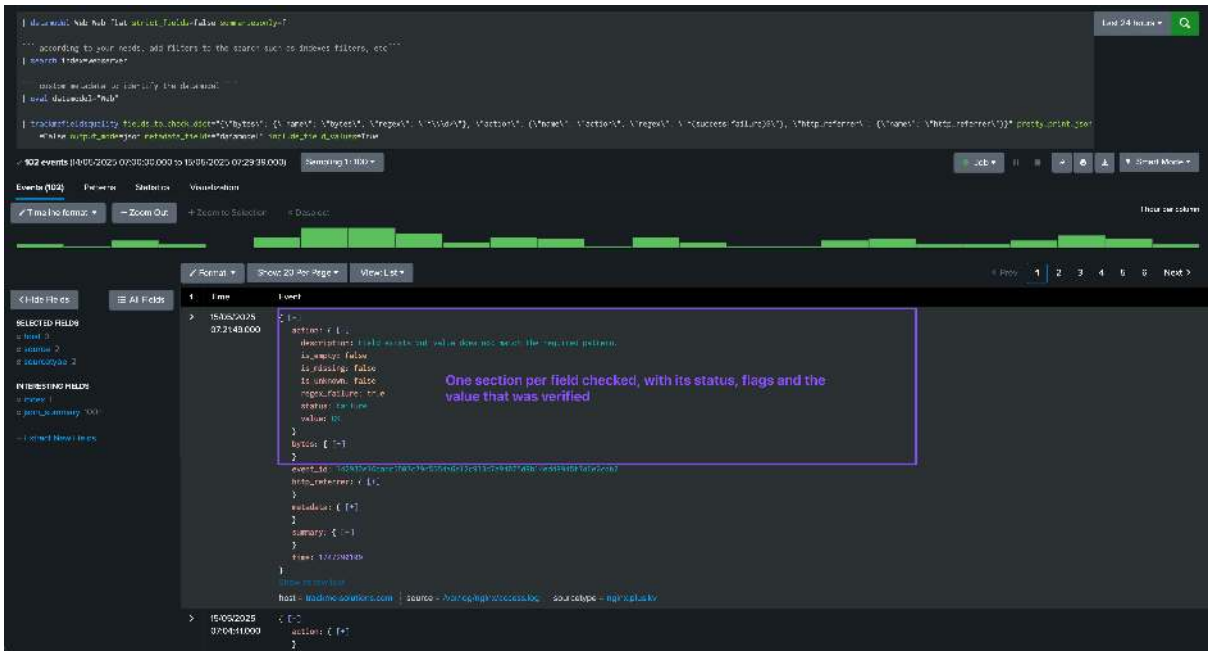
Argument: output_mode

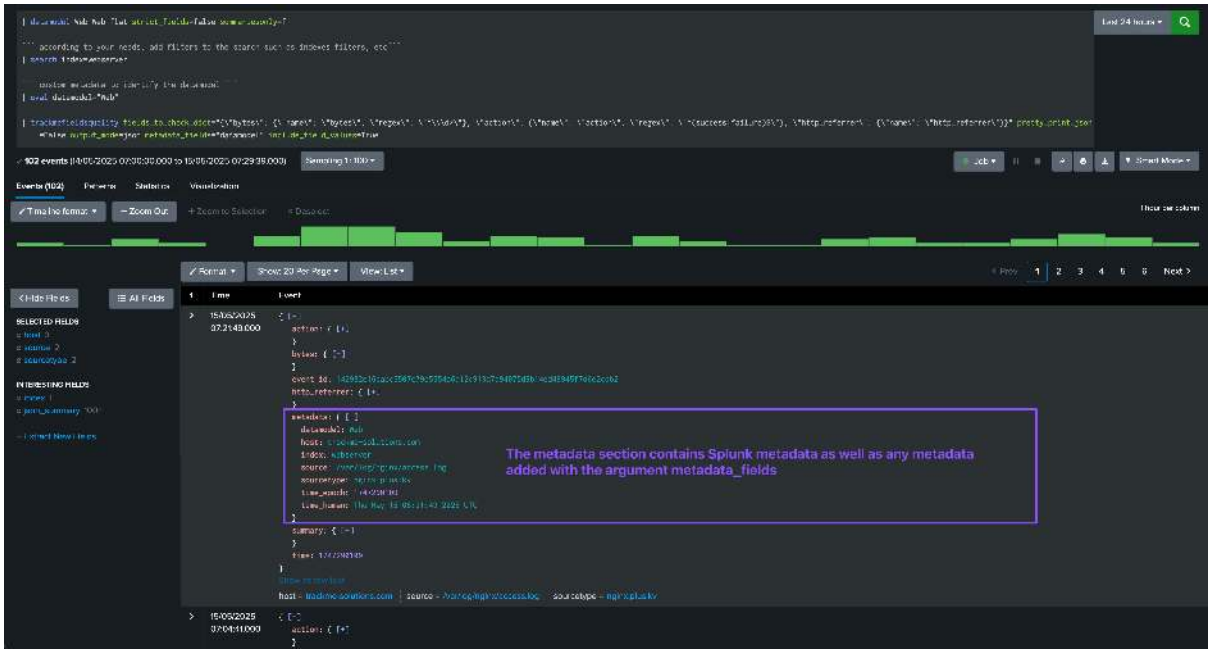
This option allows to specify the output mode, which can be `json` or `raw`.

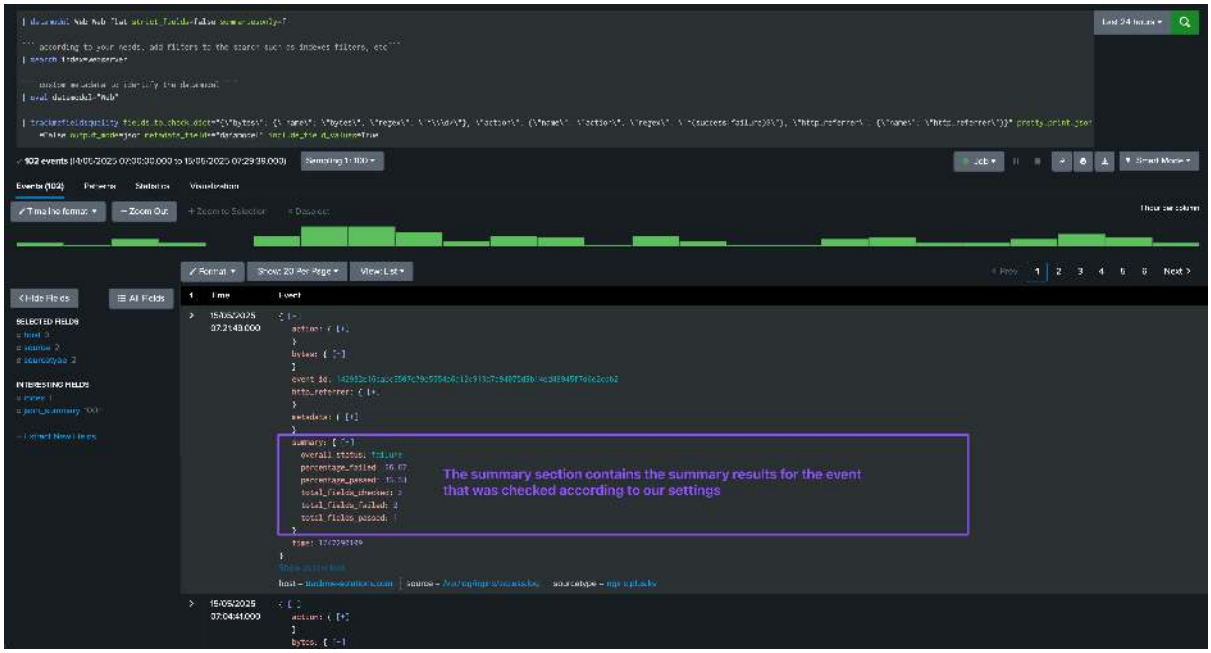
We recommend using the `json` mode for most use cases, especially this document is focused on the JSON output which is leveraged and indexed using the TrackMe sourcetype `trackme:fields_quality`.

output_mode=json

In JSON mode, the command verifies the fields and generates a JSON object per event:

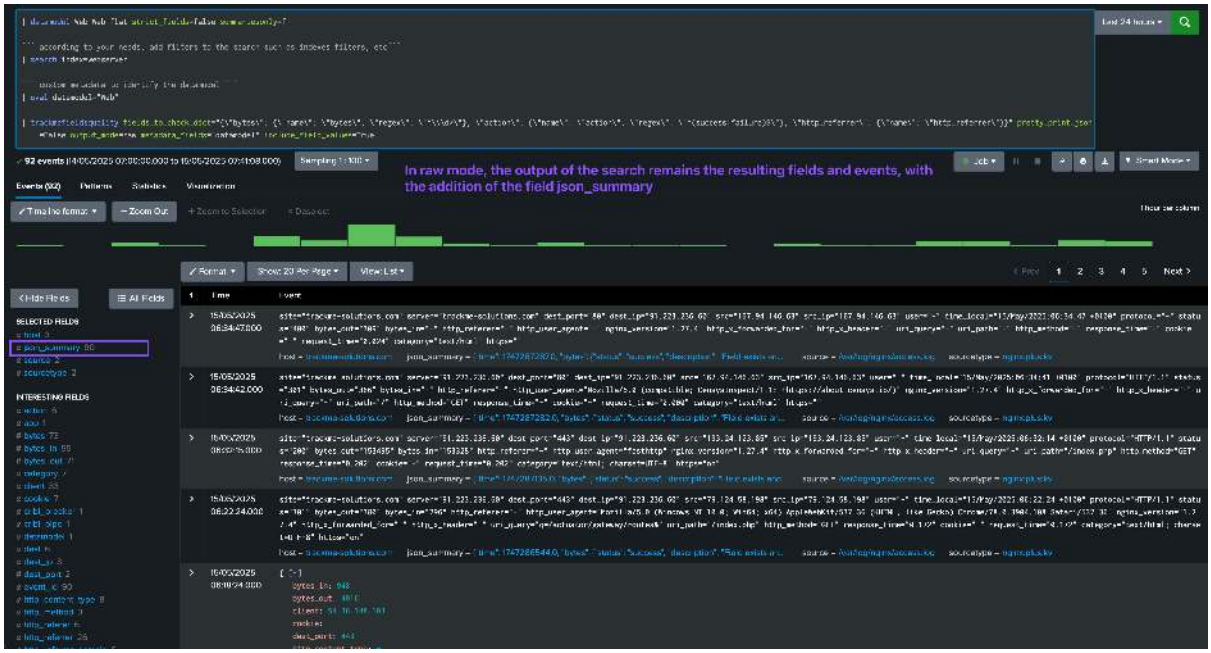


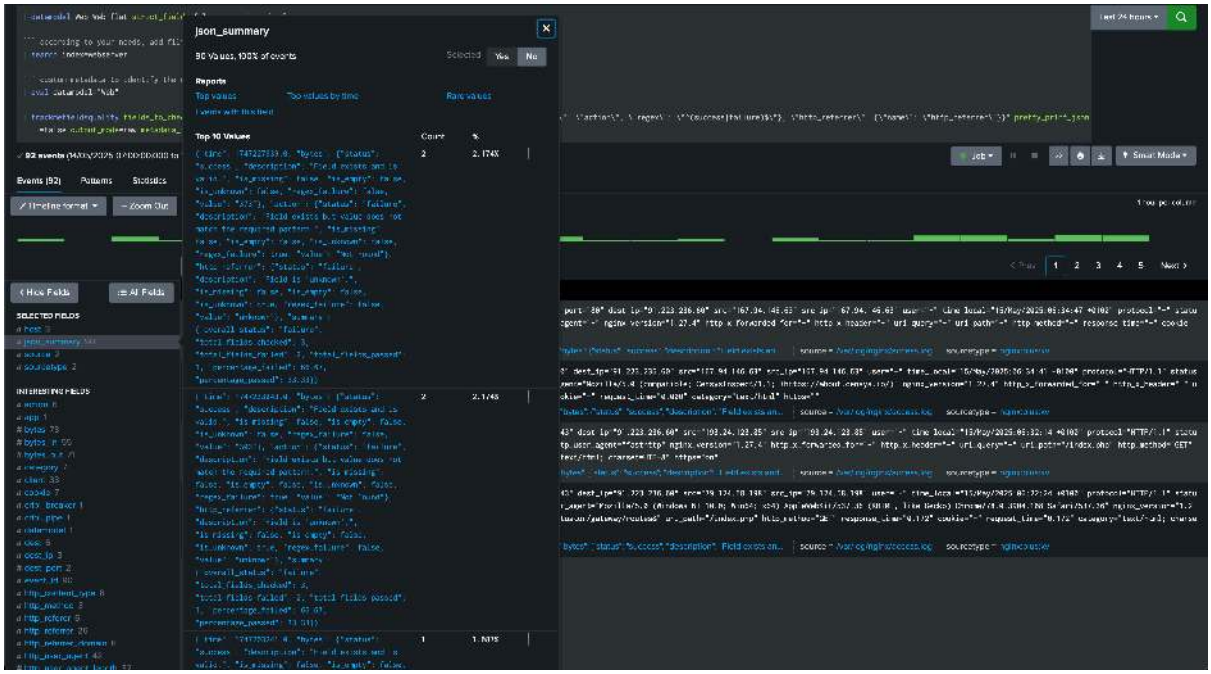




output_mode=raw

In raw mode, the command generates the events as they are, and adds a field called `json_summary` which contains our JSON object:





Argument: metadata_fields

This option allows to specify the metadata fields as a comma-separated list of fieldsto include in the JSON output.

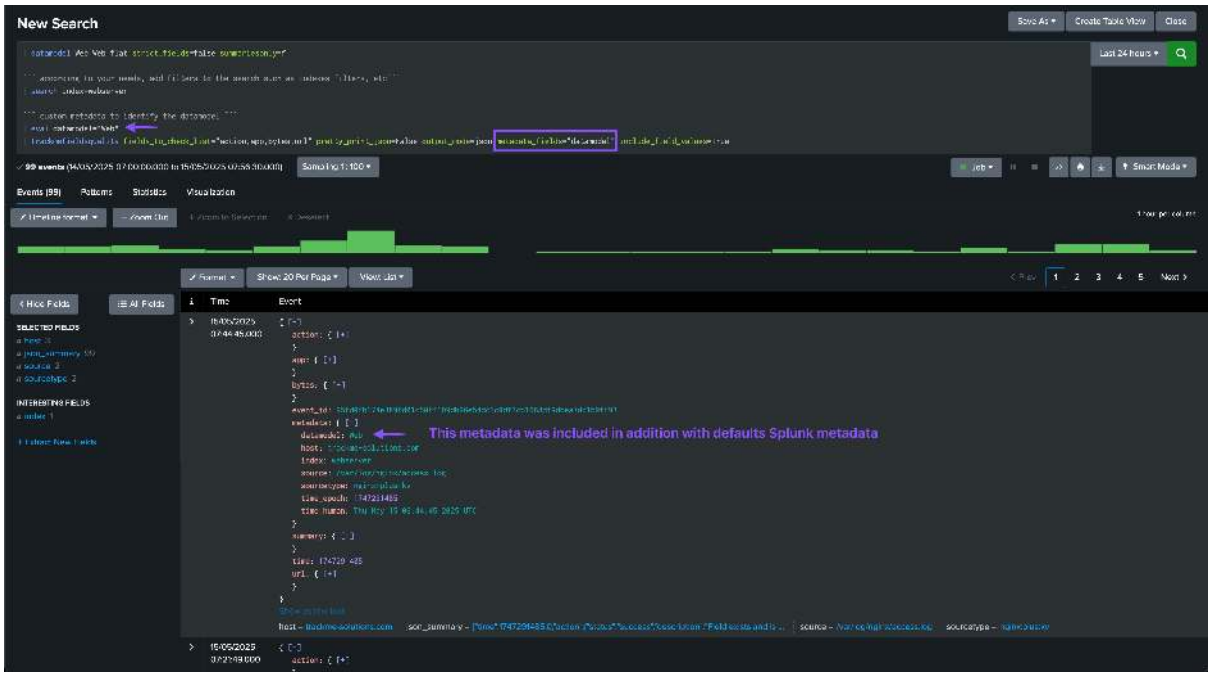
The metadata fields always include the following:

- `index`: the index of the event
- `sourcetype`: the sourcetype of the event
- `host`: the host of the event
- `source`: the source of the event

By defining the `metadata_fields` parameter, you can add additional fields to the JSON output, for instance the `datamodel` field which in our implementation is used to identify the data model of the event.

In our example, we are defining a field called `datamodel` using an eval which will be added to the JSON output:

```
| eval datamodel="Web"
| trackmefieldsquality fields_to_check_list="action,app,bytes,url"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True
```

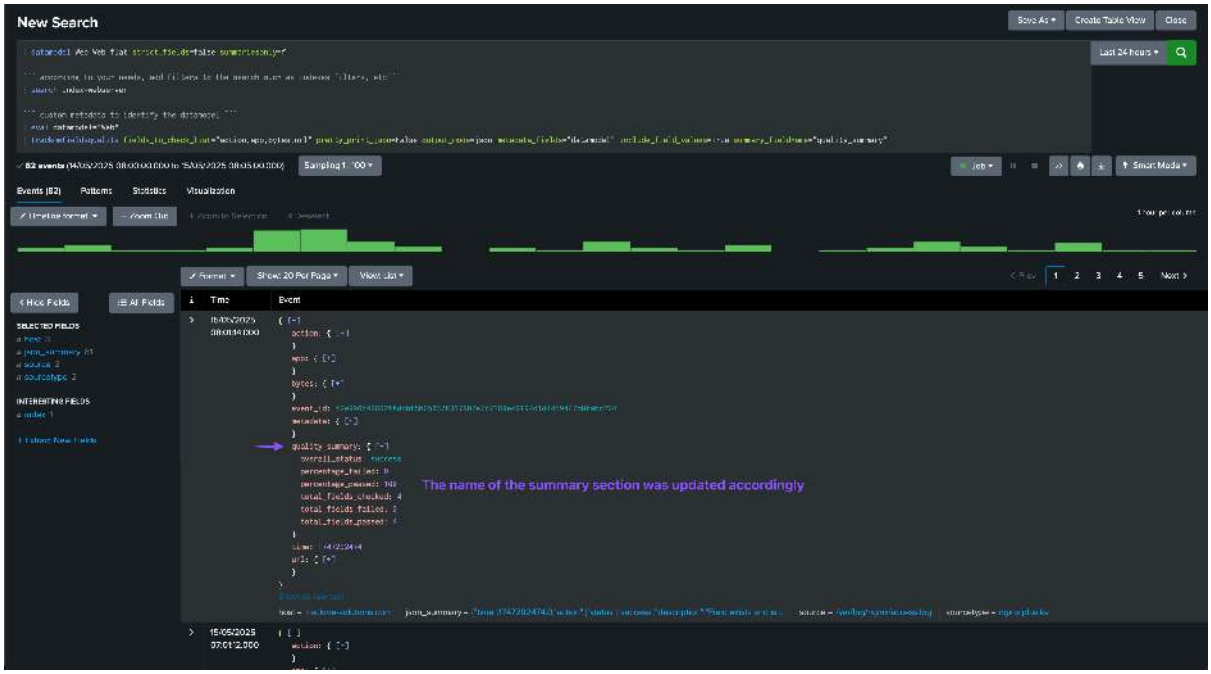


Argument: summary_fieldname

This option allows to specify the name of the summary field in the JSON output, this defaults to `summary` but can be customised if needed, for instance if there is a conflict with a field from the data model or events.

In this example, instead of `summary`, we use `quality_summary`:

```
| trackmefieldsquality fields_to_check_list="action,app,bytes,url"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True summary_fieldname="quality_summary"
```

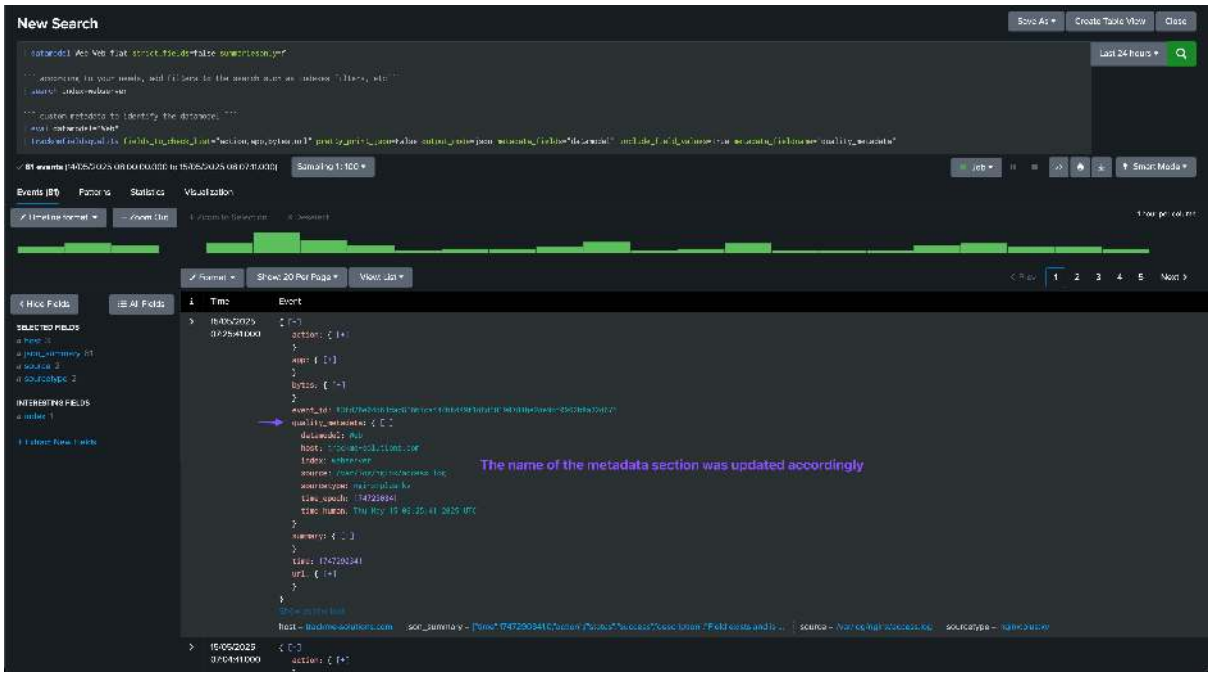


Argument: metadata_fieldname

This option allows to specify the name of the metadata field in the JSON output, this defaults to `metadata` but can be customised if needed, for instance if there is a conflict with a field from the data model or events.

In this example, instead of `metadata`, we use `quality_metadata`:

```
| trackmefieldsquality fields_to_check_list="action,app,bytes,url"␣
↪pretty_print_json=False output_mode=json metadata_fields="datamodel"␣
↪include_field_values=True metadata_fieldname="quality_metadata"
```



Annex: usage and options for the command trackmefieldsqualitygendict

The command `trackmefieldsqualitygendict` is used to generate JSON dictionary models for CIM data models, which can then be used with the `trackmefieldsquality` command for fields quality assessment.

The command accepts the following parameters:

argument	description	default	example or valid values
`datamodel`	The name of the CIM data model to generate the dictionary for	None (required)	"Authentication", "Web", "Network_Traffic"
`show_only_recomm`	Boolean option to only include recommended fields from the data model	False	True/False
`allow_unknown`	Boolean option to allow unknown field values	False	True/False
`allow_empty_or_mis`	Boolean option to allow empty or missing field values	False	True/False

Usage:

```
| trackmefieldsqualitygendict datamodel=<datamodel name>␣
↪show_only_recommended_fields=<boolean> allow_unknown=<boolean>␣
↪allow_empty_or_missing=<boolean>
```

Examples:

Generate dictionary for Authentication data model with only recommended fields:

```
| trackmefieldsqualitygendict datamodel="Authentication"␣
↪show_only_recommended_fields=true
```

Generate dictionary for Web data model with all fields and allow unknown values:

```
| trackmefieldsqualitygendict datamodel="Web" show_only_recommended_fields=false␣
↪allow_unknown=true
```

Generate dictionary for Network_Traffic data model with only recommended fields and allow empty/missing values:

```
| trackmefieldsqualitygendict datamodel="Network_Traffic"␣
↪show_only_recommended_fields=true allow_empty_or_missing=true
```

Generate dictionary for Authentication data model with all options enabled:

```
| trackmefieldsqualitygendict datamodel="Authentication"␣
↪show_only_recommended_fields=true allow_unknown=true allow_empty_or_missing=true
```

Output:

The command generates a JSON dictionary that can be used with the `trackmefieldsquality` command. The output includes:

- Field names as keys
- Field configuration objects as values, including: - `name`: The field name - `regex`: Optional regular expression pattern for validation - `allow_unknown`: Boolean flag to allow "unknown" values (can be overridden by the command parameter) - `allow_empty_or_missing`: Boolean flag to allow empty or missing values (can be overridden by the command parameter)

Example output for Web data model:

```
{
    "action": {
        "name": "action",
        "regex": "^(success|failure|allowed|blocked|deferred)$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "app": {
        "name": "app",
        "regex": "^[\\w:\\-\\d\\s]+$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "dest": {
        "name": "dest",
        "regex": "^[\\w\\.-]+$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "signature": {
        "name": "signature",
        "regex": "^.{3,100}$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "src": {
        "name": "src",
        "regex": "^[\\w\\.-]+$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "src_user": {
        "name": "src_user",
        "regex": "^[\\w\/\\\\\\-\\.$]{1,30}$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    },
    "user": {
        "name": "user",
        "regex": "^[\\w\/\\\\\\-\\.$]{1,30}$",
        "allow_unknown": false,
        "allow_empty_or_missing": false
    }
}
```

Integration with fields quality workflow:

This command is typically used in the first phase of the fields quality workflow to generate the dictionary models that will be stored in lookup tables and used by the collect scheduled searches:

```
| trackmefieldsqualitygendict datamodel=Authentication␣
↪show_only_recommended_fields=True
| append [ | trackmefieldsqualitygendict datamodel=Web␣
↪show_only_recommended_fields=True ]
| append [ | trackmefieldsqualitygendict datamodel=Network_Traffic␣
↪show_only_recommended_fields=True ]
| table datamodel, json_dict
```

(continues on next page)

(continued from previous page)

```
| trackmeprettyjson fields=json_dict
| outputlookup cim_datamodels_dict.csv
```

The generated lookup table can then be used in the collect scheduled searches:

```
| lookup cim_datamodels_dict.csv datamodel OUTPUT json_dict as quality_dict
| trackmefieldsquality fields_to_check_dict_fieldname="quality_dict"␣
↪output_mode=json metadata_fields="datamodel,nodename" include_field_values=True
```

Annex: usage and options for the command trackmefieldsqualitygensummary

The command `trackmefieldsqualitygensummary` is used to generate a summary of the quality of fields in records that have been processed by the `trackmefieldsquality` command. This command is typically used in the monitoring phase to aggregate and summarize field quality data for reporting and analysis purposes.

The command accepts the following parameters:

argument	description	default	example or valid values
`maxvals`	Max number of distinct values to report in field_values	15	10, 20, 50
`fieldvalues_format`	Format of field_values, either list or csv	csv	list, csv
`groupby_metadata_fie`	Comma-separated list of metadata fields to group by in addition to fieldname	"" (empty)	"metadata.datamodel,metadata.nodename,metadata.

Usage:

```
| trackmefieldsqualitygensummary maxvals=<max number of distinct values to report>␣
↪fieldvalues_format=<format of field_values, either list or csv>␣
↪groupby_metadata_fields=<comma separated list of metadata fields to group by in␣
↪addition to fieldname>
```

Examples:

Generate summary with default settings:

```
| trackmefieldsqualitygensummary
```

Generate summary with custom maxvals and list format:

```
| trackmefieldsqualitygensummary maxvals=20 fieldvalues_format=list
```

Generate summary with grouping by metadata fields:

```
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields=
↪"metadata.datamodel,metadata.nodename,metadata.index,metadata.sourcetype"
```

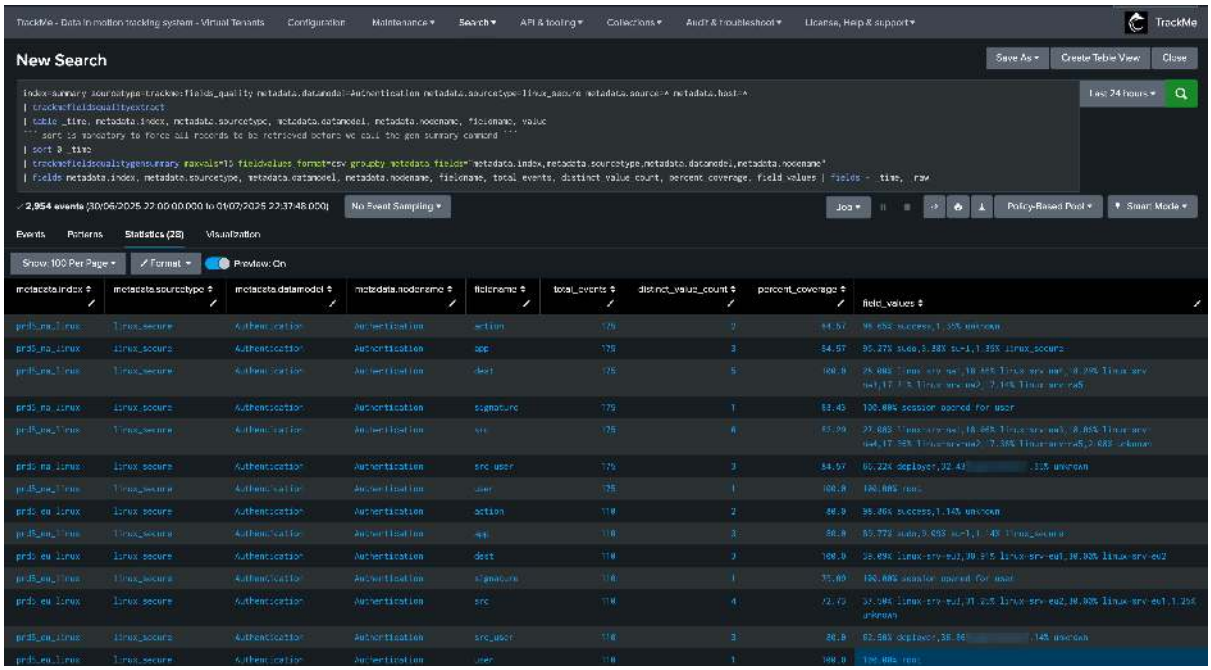
Output:

The command generates a summary that includes:

- **fieldname**: The name of the field being analyzed
- **total_events**: Total number of events processed for this field

- **distinct_value_count**: Number of distinct values found for this field
- **percent_coverage**: Percentage of events where this field has a value
- **field_values**: Summary of the most common values for this field (limited by maxvals)

Example output:



Example of field_values output:

The field_values column contains a summary of the most representative values for each field. For example:

- **CSV format**: "98.65% success,1.35% unknown"

Note: the list format renders the same information but as a proper list, which will appear in Splunk as a multi-value field.

Integration with fields quality workflow:

This command is typically used in the monitoring phase, specifically within the Flex Object tracker SPL logic to generate summaries of field quality data:

```
| search index=summary sourcetype=trackme:fields_quality metadata.sourcetype=*␣
↪metadata.source=* metadata.host=*
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel, metadata.
↪nodename, fieldname, value
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields=
↪"metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename"
```

The output from this command is then used to populate the `extra_attributes` field in the Flex Object tracker, providing detailed field quality information for each entity.

Argument: maxvals

This option controls the maximum number of distinct values to report in the field_values column. This is useful for limiting the output size while still providing meaningful insights into the most common values for each field.

Example:

```
| trackmefieldsqualitygensummary maxvals=10
```

This would limit the field_values output to show only the top 10 most common values for each field.

Argument: fieldvalues_format

This option controls the format of the field_values output. Two formats are supported:

- **csv**: Comma-separated values format (default)
- **list**: List format with percentages in parentheses

CSV format example: "98.65% success,1.35% unknown"

List format example: "success (98.65%), unknown (1.35%)"

Example:

```
| trackmefieldsqualitygensummary fieldvalues_format=list
```

Argument: groupby_metadata_fields

This option allows grouping the summary by additional metadata fields beyond the default fieldname grouping. This is particularly useful when you want to analyze field quality across different dimensions such as data models, nodes, indexes, or sourcetypes.

Example:

```
| trackmefieldsqualitygensummary groupby_metadata_fields=
↪"metadata.datamodel,metadata.nodename,metadata.index,metadata.sourcetype"
```

This would generate separate summaries for each combination of datamodel, nodename, index, and sourcetype, allowing for more granular analysis of field quality across different contexts.

Integration example in Flex Object tracker:

In the Flex Object tracker source code, this command is used to generate detailed field summaries that are stored in the entity's extra_attributes:

```
| join type=outer metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname [ search index=summary␣
↪sourcetype=trackme:fields_quality metadata.sourcetype=* metadata.source=*␣
↪metadata.host=*
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel, metadata.
↪nodename, fieldname, value
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields=
↪"metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename"
| fields metadata.index, metadata.sourcetype, metadata.datamodel, metadata.
↪nodename, fieldname, total_events, distinct_value_count, percent_coverage,␣
↪field_values, regex_expression | fields - _time, _raw
```

You can for example run this search to get the percentage of coverage for the field "action" in the datamodel Network_Traffic and nodename All_Traffic, for the sourcetype cisco:asa:

```
index=summary sourcetype=trackme:fields_quality metadata.datamodel=Network_Traffic␣
↪metadata.nodename=All_Traffic metadata.sourcetype=cisco:asa metadata.source=*␣
↪metadata.host=*
| table _time, _raw
```

(continues on next page)

(continued from previous page)

```
| trackmefieldsqualityextract

| table _time, metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, value, regex_expression
``` sort is mandatory to force all records to be retrieved before we call the gen␣
↪summary command ```
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields="metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename
| fields metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, total_events, distinct_value_count,␣
↪percent_coverage, field_values, regex_expression | fields - _time, _raw

| where fieldname="action"
```

This would be equivalent to run the following search:

```
index=summary sourcetype=trackme:fields_quality metadata.datamodel=Network_Traffic␣
↪metadata.nodename=All_Traffic metadata.sourcetype=cisco:asa metadata.source=*␣
↪metadata.host=* | head 100
| table _time, _raw
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel, metadata.
↪nodename, fieldname, value, is_empty, is_missing

| where fieldname="action"

| stats count, count(eval(is_empty=0 AND is_missing=0)) as count_covered,␣
↪count(eval(is_empty=1 OR is_missing=1)) as count_not_covered
| eval percentage_covered=count_covered/count*100
```

Annex: Per field table statistics

The following search example shows the statistics per field:

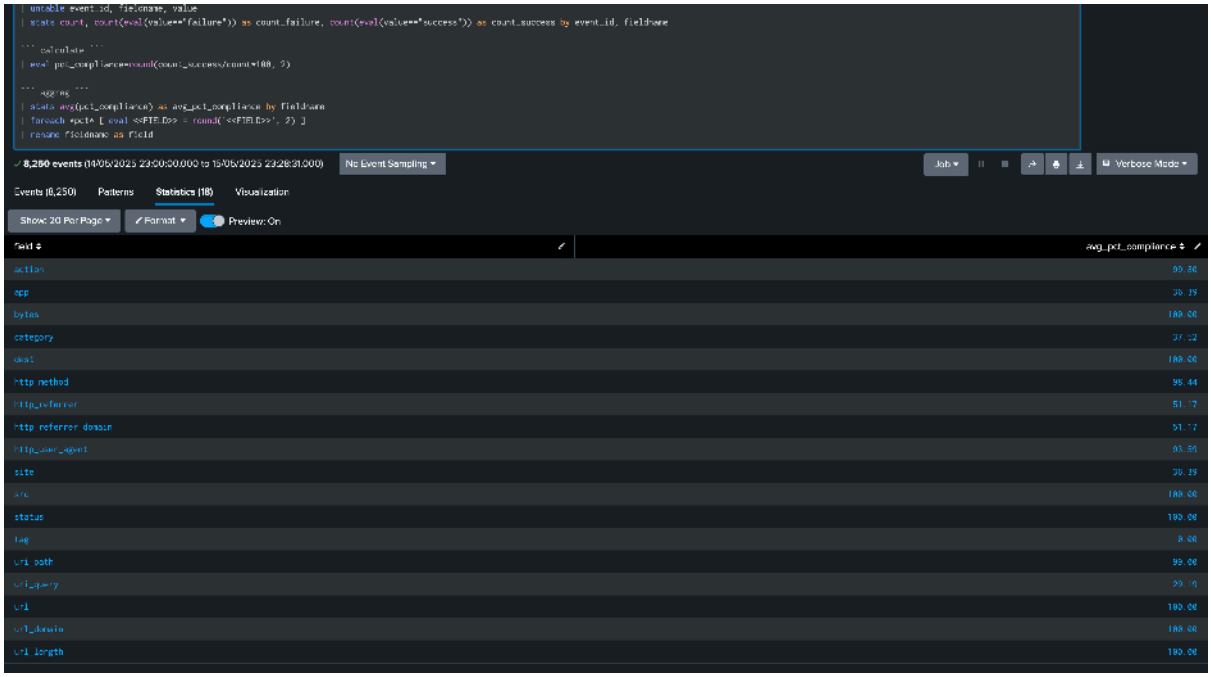
```
index=summary sourcetype=trackme:fields_quality
``` you can filter our metadata fields to focus on a specific sourcetype, index,␣
↪etc...```
| search metadata.datamodel="Web"

``` stats ```
| fields - summary.* metadata.*
| stats first(*status) as "*status" by event_id
| rename "*.status" as "*"

``` untable ```
| untable event_id, fieldname, value
| stats count, count(eval(value=="failure")) as count_failure,␣
↪count(eval(value=="success")) as count_success by event_id, fieldname

``` calculate ```
| eval pct_compliance=round(count_success/count*100, 2)

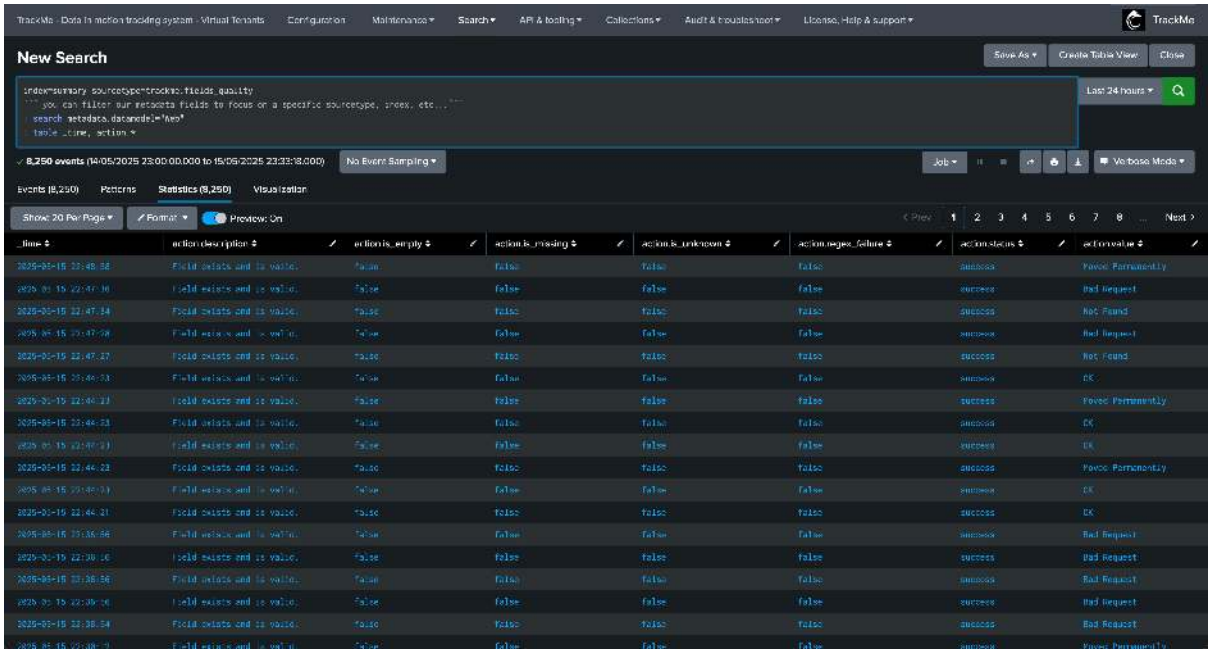
``` aggreg ```
| stats avg(pct_compliance) as avg_pct_compliance by fieldname
| foreach *pct* [ eval <<FIELD>> = round('<<FIELD>>', 2) ]
| rename fieldname as field
```



Annex: Looking after a specific field

The following search example shows the statistics per field:

```
index=summary sourcetype=trackme:fields_quality
``` you can filter our metadata fields to focus on a specific sourcetype, index,␣
↪etc...```
| search metadata.datamodel="Web"
| table _time, action.*
```



Annex: Flex Object tracker SPL logic

The following search example shows the Flex Object tracker SPL logic:
```

```
index=summary sourcetype=trackme:fields_quality metadata.sourcetype=*␣
↪metadata.source=* metadata.host=*
| table _time, _raw
| trackmefieldsqualityextract

| stats count as count_total, count(eval(status=="success")) as count_success,␣
↪count(eval(status=="failure")) as count_failure by fieldname, metadata.index,␣
↪metadata.sourcetype, metadata.datamodel, metadata.nodename
| eval percentage_success=round(count_success/count_total*100, 2)

``` set the threshold per field, this defines if the field is considered as passed␣
↪or failed globally, this threshold has to be part of the SPL logic ```
| eval threshold=99

``` flag field ```
| eval fieldstatus=if(percentage_success>=threshold, "success", "failure")

``` join field summary ```
| join type=outer metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname [ search index=summary␣
↪sourcetype=trackme:fields_quality metadata.sourcetype=* metadata.source=*␣
↪metadata.host=*
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, value, regex_expression
``` sort is mandatory to force all records to be retrieved before we call the gen␣
↪summary command ```
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields="metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename
| fields metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, total_events, distinct_value_count,␣
↪percent_coverage, field_values, regex_expression | fields - _time, _raw
]

``` generate the per field json for reporting purposes, we also rename fieldname␣
↪to @fieldname so it appears first in the JSON ```
| rename fieldname as @fieldname, fieldstatus as @fieldstatus
| tojson
| rename _raw as per_field_json

``` calculate ```
| stats values(eval(if('@fieldstatus'=="success", '@fieldname', null()))) as␣
↪list_fields_passed, values(eval(if('@fieldstatus'=="failure", '@fieldname',␣
↪null()))) as list_fields_failed, values(per_field_json) as per_field_json,␣
↪max(total_events) as total_events_parsed by metadata.index, metadata.sourcetype,␣
↪metadata.datamodel, metadata.nodename

``` format the per_field_json ```
| eval per_field_json = "[" . mvjoin(per_field_json, ", ") . "]"

``` build the list of fields that passed and failed ```
| eval all_fields = mvappend(list_fields_failed, list_fields_passed)
| eval all_fields = mvdedup(all_fields)
| eval final_state = mvmap(
all_fields,
if(
```

(continues on next page)

(continued from previous page)

```
mvfind(list_fields_failed, "^" . all_fields . "$") >= 0,
all_fields . "|failed",
all_fields . "|success"
)
)
| eval success_fields = mvfilter(match(final_state, "\|success$"))
| eval failed_fields = mvfilter(match(final_state, "\|failed$"))
| eval success_fields = mvmap(success_fields, mvindex(split(success_fields, "|"),␣
↪0))
| eval failed_fields  = mvmap(failed_fields,  mvindex(split(failed_fields, "|"),␣
↪0))
| fields - final_state
| eval success_fields=if(isnull(success_fields), "", success_fields),␣
↪failed_fields=if(isnull(failed_fields), "", failed_fields)
| fields - list_fields_passed, list_fields_failed

``` calculate ```
| eventstats dc(all_fields) as total_fields_checked, dc(success_fields) as␣
↪total_fields_passed, dc(failed_fields) as total_fields_failed by metadata.index,␣
↪metadata.sourcetype, metadata.datamodel, metadata.nodename
| eval percentage_passed=round(total_fields_passed/total_fields_checked*100, 2),␣
↪percentage_failed=round(total_fields_failed/total_fields_checked*100, 2)

``` rename ```
| rename metadata.* as "*"

``` save this as parts of extra attributes ```
| eval extra_attributes = "{" . "\"success_fields\": \"" . mvjoin(success_fields,
↪",") . "\", \"failed_fields\": \"" . mvjoin(failed_fields, ",") . "\", " . "\
↪"fields\":" . per_field_json . "}"
| fields - per_field_json

``` set principal metadata for the flex entity ```
| eval group = datamodel
| eval object = nodename . ":" . index . ":" . sourcetype, alias=index . ":" .␣
↪sourcetype
| eval object_description = "CIM Quality for DM: " . datamodel . ":" . nodename .
↪", index:" . index . ", sourcetype:" . sourcetype

``` gen metrics ```
| eval metrics = "{" .
"\"fields_quality.percentage_passed\": " . if(isnum(percentage_passed),␣
↪percentage_passed, 0) . ", " .
"\"fields_quality.percentage_failed\": " . if(isnum(percentage_failed),␣
↪percentage_failed, 0) . ", " .
"\"fields_quality.total_fields_checked\": " . if(isnum(total_fields_checked),␣
↪total_fields_checked, 0) . ", " .
"\"fields_quality.total_fields_failed\": " . if(isnum(total_fields_failed),␣
↪total_fields_failed, 0) . ", " .
"\"fields_quality.total_fields_passed\": " . if(isnum(total_fields_passed),␣
↪total_fields_passed, 0) . ", " .
"\"fields_quality.total_events_parsed\": " . if(isnum(total_events_parsed),␣
↪total_events_parsed, 0) . "}"

``` no outliers for now ```
| eval outliers_metrics="{}"
```

(continues on next page)

(continued from previous page)

```
``` basic status, thresholds can be defined on a per entity basis ```
| eval status=1
| eval status_description="DM Quality: " . metrics
| eval status_description_short="% passed: " . percentage_passed . ", checked: " .␣
↪total_fields_checked . ", passed: " . total_fields_passed . ", failed: " .␣
↪total_fields_failed

``` this sets a default threshold, which can then be overriden on a per entity␣
↪basis via the TrackMe UI ```
| eval default_threshold = "{'metric_name': 'fields_quality.percentage_passed',
↪'operator': '>=', 'value': 95, 'condition_true': 1}"

```alert if inactive for more than 2 days```
| eval max_sec_inactive=86400*2
```

Annex: Understanding & troubleshooting the percentage of success

The percentage of success is calculated by the main Flex tracker SPL logic, it represents the percentage of times the field is passing the quality check, a field is considered as passing the quality check if:

- `is_empty: false`
- `is_null: false`
- `is_unknown: false` (depending on if a dictionary is used and if in the dictionary and for this field, unknown is allowed or not)
- `regex_failure: false` (depending on if a dictionary is used and if there is a regex expression for this field)

```
index=summary sourcetype=trackme:fields_quality metadata.sourcetype=* metadata.
↪source=* metadata.host=*
| table _time, _raw
| trackmefieldsqualityextract

| stats count as count_total, count(eval(status=="success")) as count_success,␣
↪count(eval(status=="failure")) as count_failure by fieldname, metadata.index,␣
↪metadata.sourcetype, metadata.datamodel, metadata.nodename
| eval percentage_success=round(count_success/count_total*100, 2)
```

In this example, we are looking at the percentage of success for the field "action" in the datamodel Network_Traffic and nodename All_Traffic, for the sourcetype cisco:asa:

```
index=summary sourcetype=trackme:fields_quality metadata.datamodel=Network_Traffic␣
↪metadata.nodename=All_Traffic metadata.sourcetype=cisco:asa metadata.source=*␣
↪metadata.host=*
| table _time, _raw
| trackmefieldsqualityextract

| stats values(value) as values, values(regex_expression) as regex_expression,␣
↪count as count_total, count(eval(status=="success")) as count_success,␣
↪count(eval(status=="failure")) as count_failure by fieldname, metadata.index,␣
↪metadata.sourcetype, metadata.datamodel, metadata.nodename
| eval percentage_success=round(count_success/count_total*100, 2)

``` set the threshold per field, this defines if the field is considered as passed␣
↪or failed globally, this threshold has to be part of the SPL logic ```
```

(continues on next page)

(continued from previous page)

```
| eval threshold=99

``` flag field ```
| eval fieldstatus=if(percentage_success>=threshold, "success", "failure")

| where fieldname="action"
```

Annex: Understanding and troubleshooting the percentage of coverage and others summary information per field

The percentage of coverage is reported by the `trackmefieldsqualitygensummary` command, it represents the percentage of events where the field has a value, that is not null and not empty. (it is for instance present equally in the CIM Vladiator table)

In the Flex tracker, this is the join part:

```
search index=summary sourcetype=trackme:fields_quality metadata.sourcetype=*␣
↪metadata.source=* metadata.host=*
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, value, regex_expression
``` sort is mandatory to force all records to be retrieved before we call the gen␣
↪summary command ```
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields="metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename
| fields metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, total_events, distinct_value_count,␣
↪percent_coverage, field_values, regex_expression | fields - _time, _raw
```

You can for example run this search to get the percentage of coverage for the field "action" in the datamodel Network_Traffic and nodename All_Traffic, for the sourcetype cisco:asa:

```
index=summary sourcetype=trackme:fields_quality metadata.datamodel=Network_Traffic␣
↪metadata.nodename=All_Traffic metadata.sourcetype=cisco:asa metadata.source=*␣
↪metadata.host=*
| table _time, _raw
| trackmefieldsqualityextract

| table _time, metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, value, regex_expression
``` sort is mandatory to force all records to be retrieved before we call the gen␣
↪summary command ```
| sort 0 _time
| trackmefieldsqualitygensummary maxvals=15 fieldvalues_format=csv␣
↪groupby_metadata_fields="metadata.index,metadata.sourcetype,metadata.datamodel,metadata.nodename
| fields metadata.index, metadata.sourcetype, metadata.datamodel,␣
↪metadata.nodename, fieldname, total_events, distinct_value_count,␣
↪percent_coverage, field_values, regex_expression | fields - _time, _raw

| where fieldname="action"
```

This would be equivalent to run the following search:

```
index=summary sourcetype=trackme:fields_quality metadata.datamodel=Network_Traffic␣
↪metadata.nodename=All_Traffic metadata.sourcetype=cisco:asa metadata.source=*␣
↪metadata.host=* | head 100
```

(continues on next page)
```

(continued from previous page)

```
| table _time, _raw
| trackmefieldsqualityextract
| table _time, metadata.index, metadata.sourcetype, metadata.datamodel, metadata.
↪nodename, fieldname, value, is_empty, is_missing

| where fieldname="action"

| stats count, count(eval(is_empty=0 AND is_missing=0)) as count_covered,␣
↪count(eval(is_empty=1 OR is_missing=1)) as count_not_covered
| eval percentage_covered=count_covered/count*100
```

2.2.4 Flex Objects - Adapt TrackMe to any monitoring use case (splk-flx)

Flex Objects: The Ultimate Tracking Component

- **Flex Objects (splk-flx)** is one of TrackMe's most powerful components, designed to transform the results of any Splunk search into fully tracked, monitored, and alerted entities.
- Unlike standard tracking components that follow a predefined schema, Flex Objects lets you define your own search logic, your own entities, your own KPIs, and your own anomaly detection rules.
- Flex Objects comes with a **library of 60+ pre-built use cases** covering Splunk infrastructure, data quality, license management, Splunk Cloud, SOAR, Cribl, and host monitoring - ready to deploy in minutes.
- **Enterprise Edition & Unlimited Edition** feature - Flex Objects is available to Enterprise and Unlimited edition customers.
- Flex Objects is particularly efficient for **Outliers detection**, **high-scale scenarios** with thousands of entities, and **custom grouping** strategies across any kind of data in Splunk.

Hint

Key references

- For a deep dive into the administration of Flex trackers, see *FLX — Flex Objects*.
- For Machine Learning Outlier detection concepts, see *Outlier detection*.
- For specific use case implementations, see the dedicated white papers referenced in *Real-World Use Cases*.

How Flex Objects Works

The Concept

Turn any Splunk search into fully tracked, monitored, and alerted entities.

Every Splunk environment is unique - different data sources, different infrastructure, different monitoring requirements. TrackMe's standard tracking components (splk-dsm for data sources, splk-cim for CIM compliance) cover the most common scenarios, but there will always be use cases that don't fit a predefined mold.

Flex Objects is the bridge between your Splunk search expertise and TrackMe's monitoring, alerting, and incident management capabilities. If you can write a Splunk search, you can create a Flex tracker.

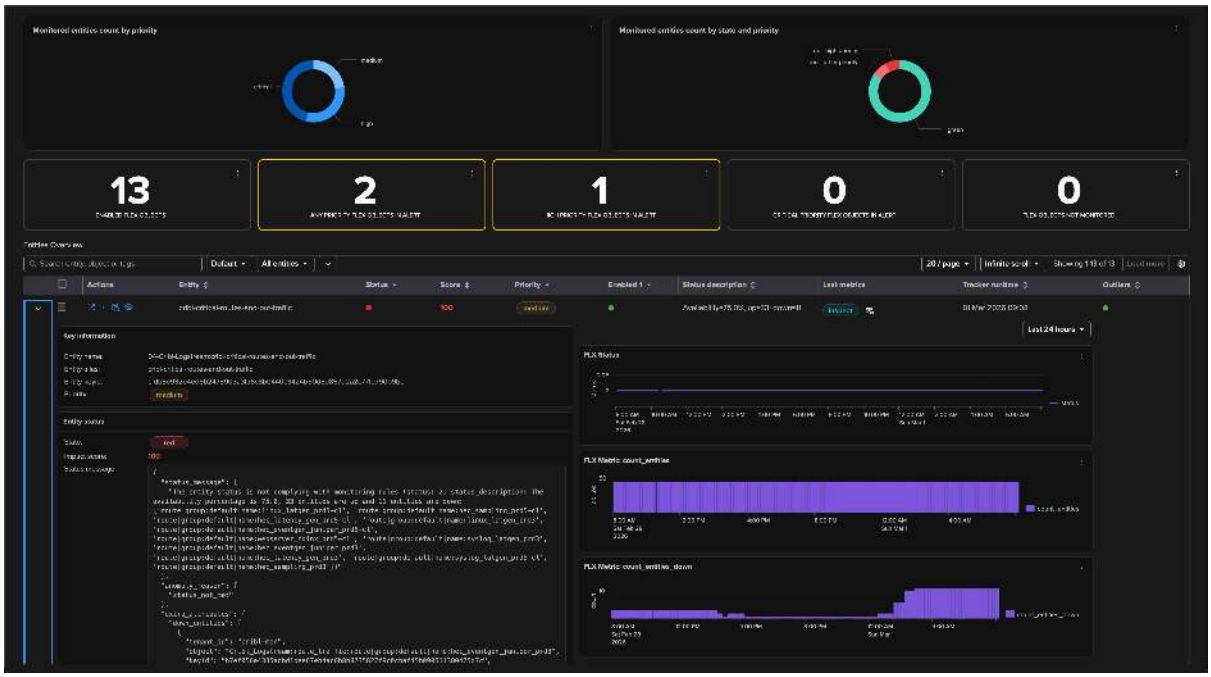
✏ 1. Define Write any SPL search or pick from 60+ pre-built templates

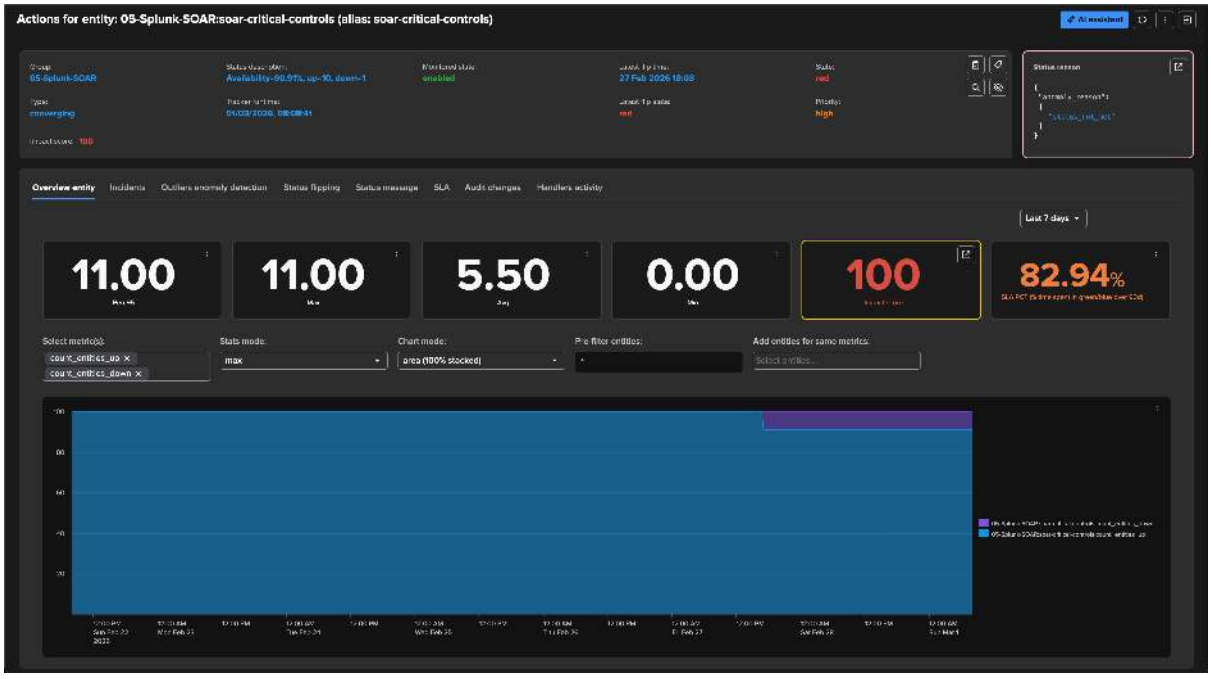
2. Schedule TrackMe runs the search on a cron schedule

3. Discover Each result row becomes a tracked entity

4. Track KPIs, metrics, and ML Outlier detection

5. Alert Stateful alerting, emails, and active commands





Define or Select

Two paths to get started - pick a pre-built use case or write your own search.

Path 1: The Library - Flex Objects ships with **60+ pre-built use case templates** organized by vendor and category (Splunk Infrastructure, Data Quality, License, Cloud, SOAR, Cribl, Host Monitoring). Each template includes a complete Splunk search, pre-configured KPIs, and outlier detection rules. Select a template, customize the parameters to your environment, and deploy in minutes.

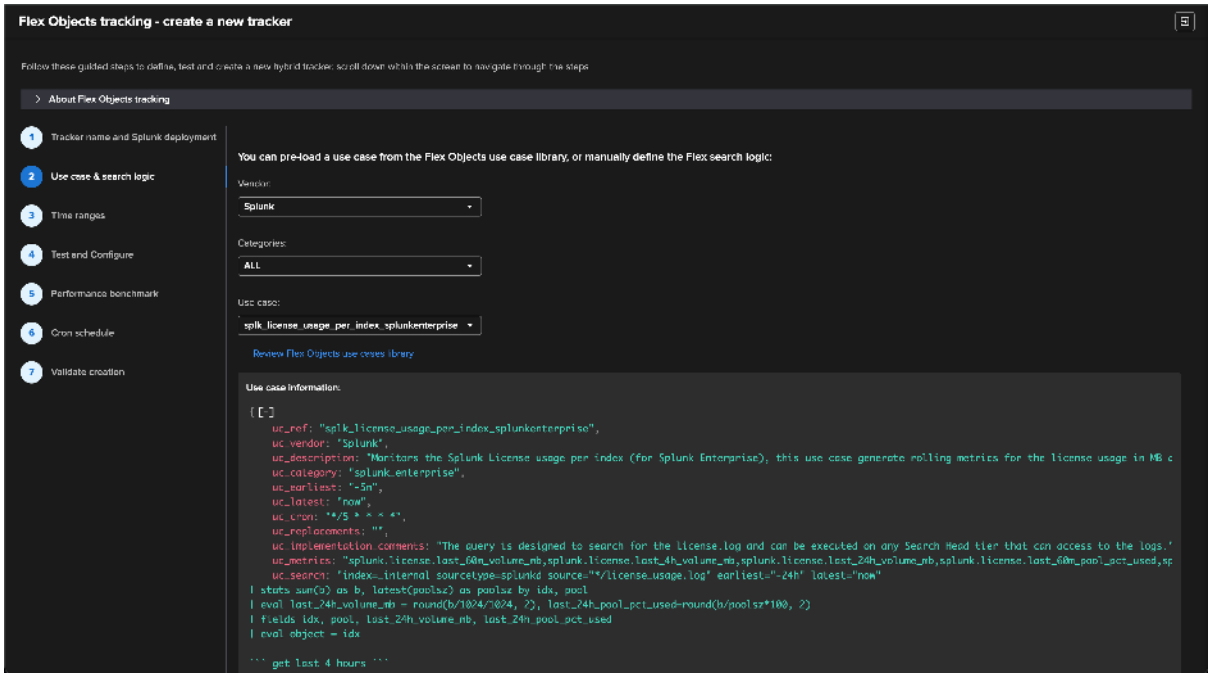
Path 2: Custom Search - Write any Splunk search that produces results following the Flex search contract. At minimum, each result must have an `object` (entity name) and a `status` (1=green, 2=orange, 3=red). Add optional fields for KPIs, descriptions, and ML anomaly detection as needed.

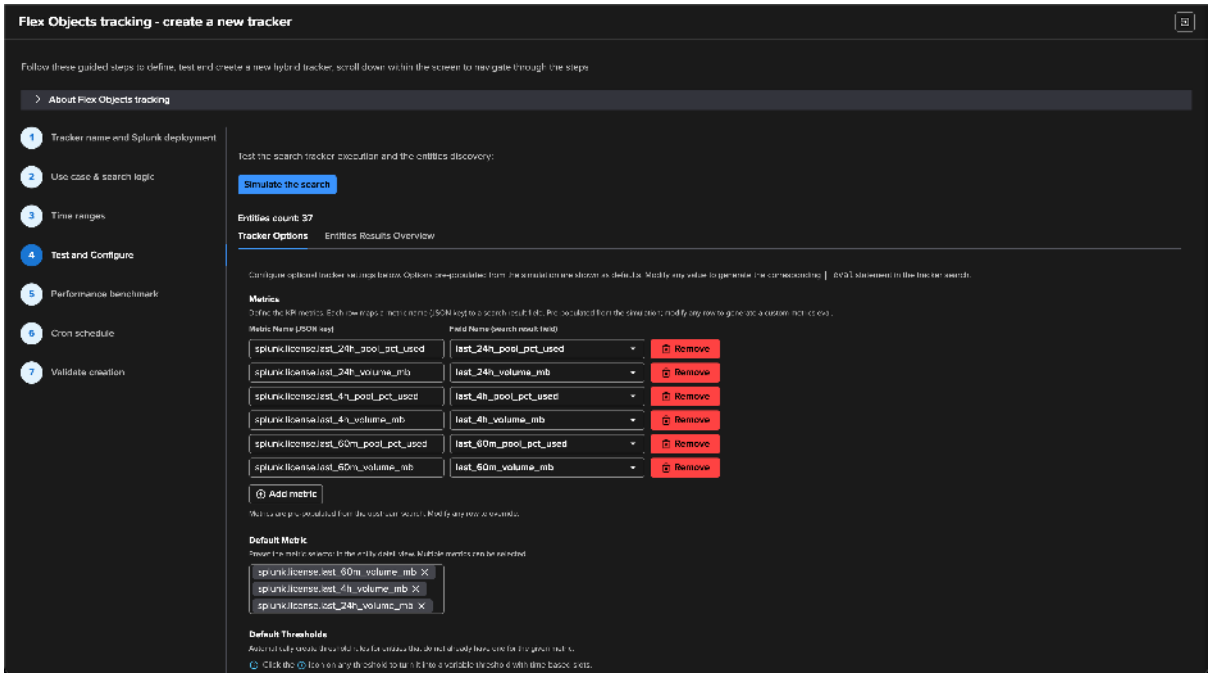
From the Library 60+ templates across 8 categories

Filter by vendor and category, preview the full search logic, customize and deploy.

Custom Search Any SPL producing entities

Use `tstats`, `| rest`, `mstats`, custom lookups, or any SPL command - if it returns rows, it can be a Flex tracker.





Tracker Types

Two types of Flex trackers for different monitoring needs.

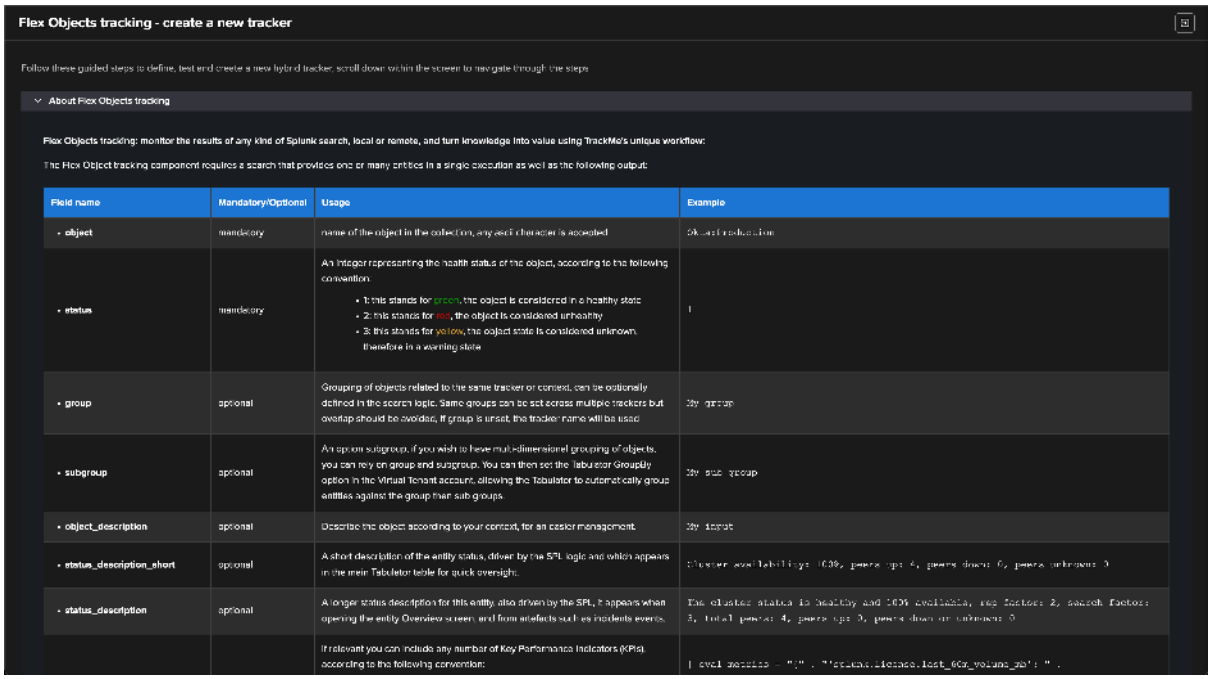
When creating a Flex tracker, you choose between two fundamentally different approaches depending on your goal:

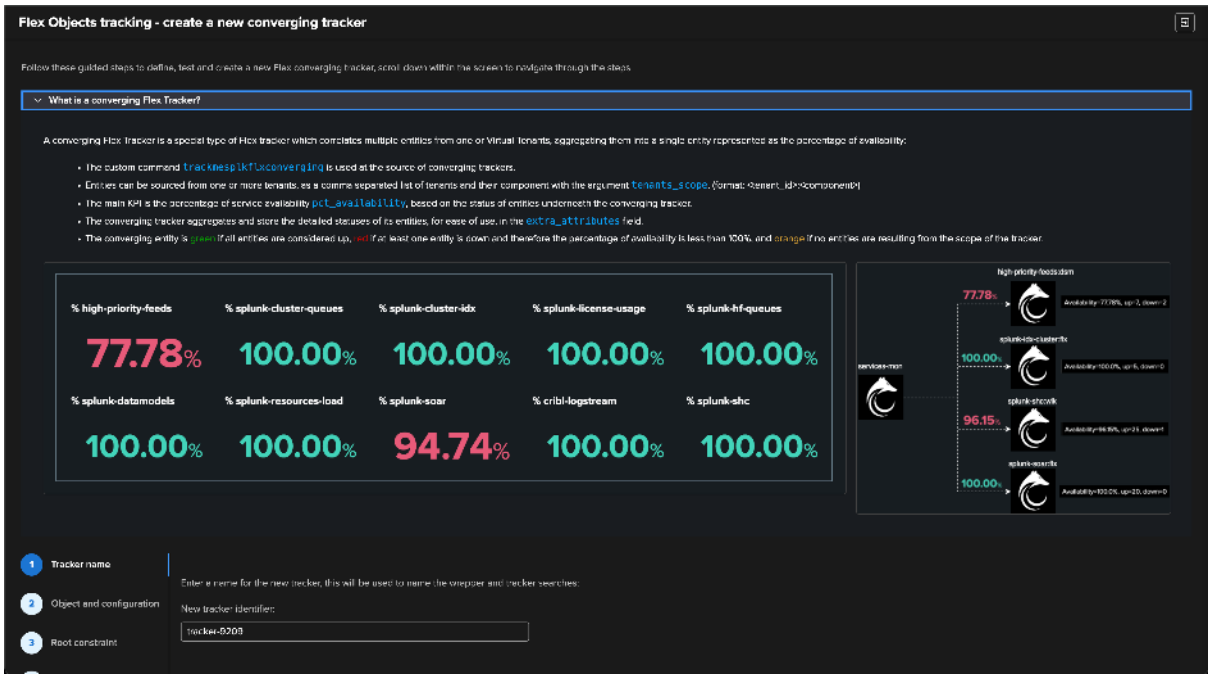
Use Case Tracker Entity discovery from a Splunk search

Your search produces one row per entity. Each entity is tracked individually with its own status, KPIs, metrics, and outlier detection. This is the standard Flex tracker for monitoring infrastructure, services, data quality, and more.

Converging Tracker Aggregated availability from existing entities

Correlates multiple Flex entities from one or more tenants, aggregating them into a single converging entity represented as a percentage of availability. Ideal for service-level monitoring and executive dashboards.





TrackMe Orchestrates

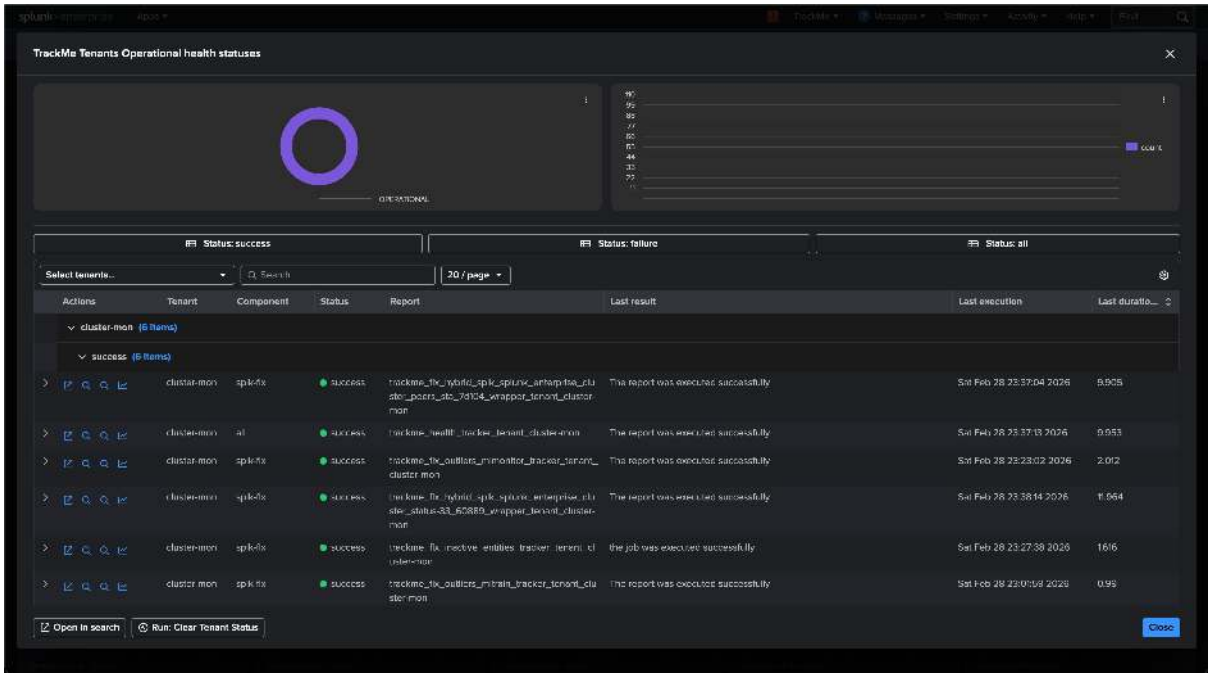
Once created, TrackMe takes over the heavy lifting.

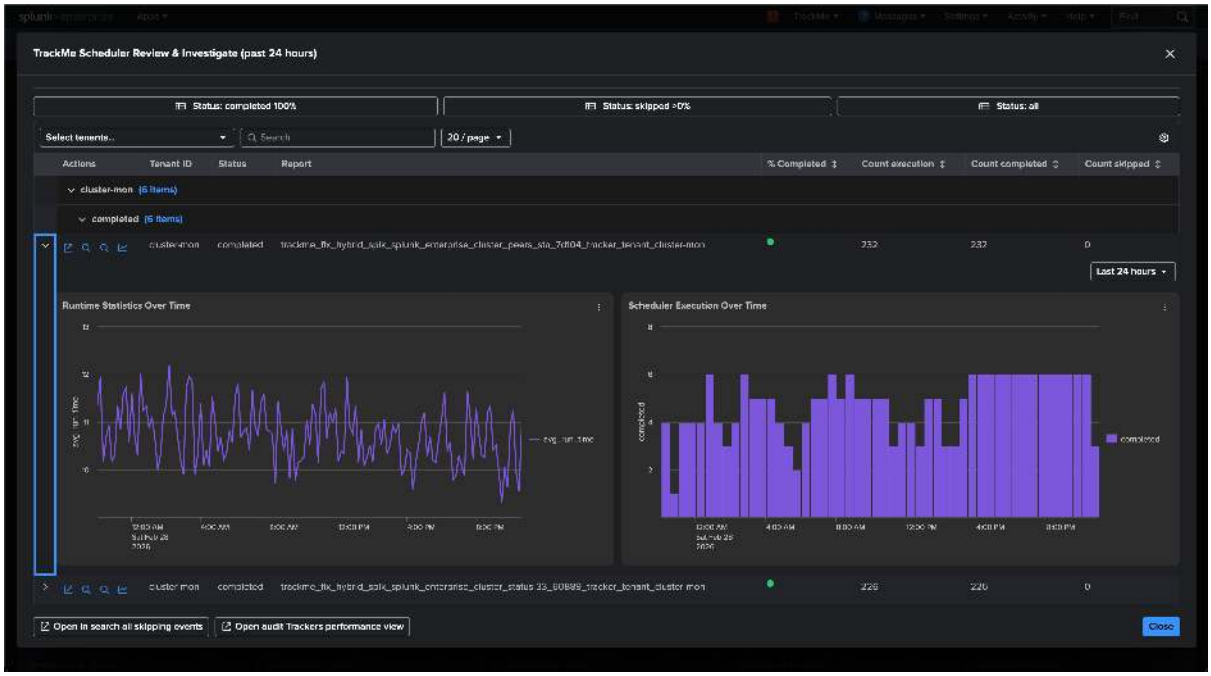
Your Flex tracker becomes a scheduled report that TrackMe executes automatically. On every run:

- The Splunk search is executed against the target deployment (local or remote)
- Each result row is matched to an existing entity or discovered as a new one
- Entity states are persisted in the KVstore with full history
- KPIs defined in the `metrics` field are extracted and stored
- Metric events are ingested into the Splunk `trackme_metrics` index for long-term trending

- Entities that stop appearing are tracked for inactivity based on configurable thresholds

TrackMe automatically randomizes cron schedules to distribute load, handles batch KVstore operations for performance at scale, and manages the full entity lifecycle from discovery to deletion.





Metrics & ML

Track any number of KPIs per entity with built-in Machine Learning anomaly detection.

The `metrics` field in your Flex search defines Key Performance Indicators for each entity. TrackMe tracks these over time and ingests them as Splunk metric events, enabling trending, dashboards, and alerting on any KPI.

The `outliers_metrics` field activates **Machine Learning Outlier detection** on selected metrics:

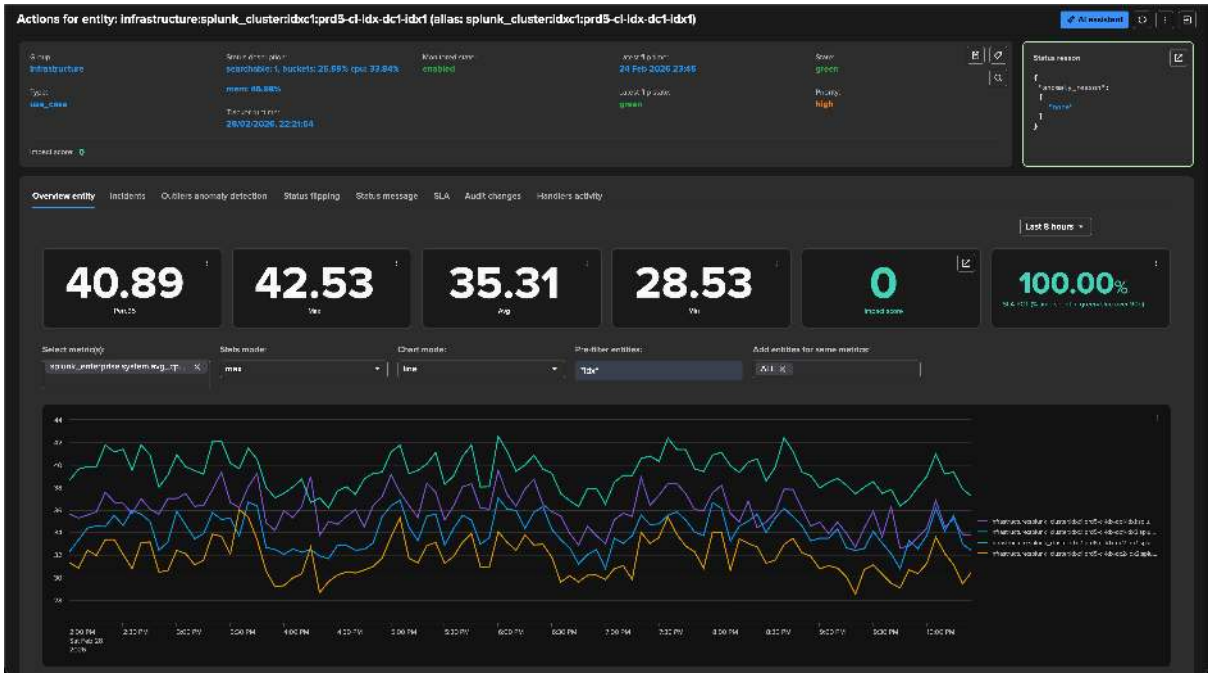
- TrackMe builds a statistical model learning the normal behavior of each metric
- Dynamic upper and lower thresholds are calculated automatically

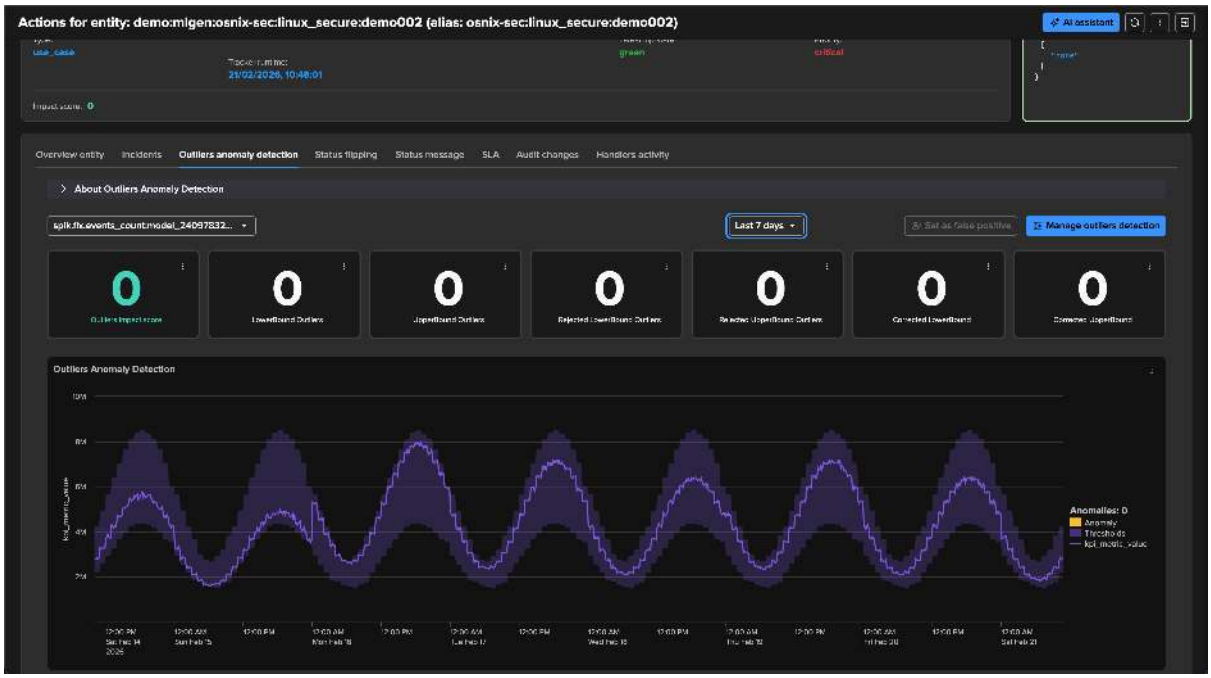
- **Time factors** add seasonality awareness - the model knows that Monday 9 AM looks different from Sunday 3 AM
- Anomalies are detected when current values fall outside the predicted range

KPIs Track CPU, event counts, delay, completion %, size, or any numeric metric per entity

Outlier Detection ML models learn normal behavior and alert on anomalies - no static thresholds needed

Seasonality Time factors (hour, day+hour, weekday+hour) ensure the model respects natural patterns





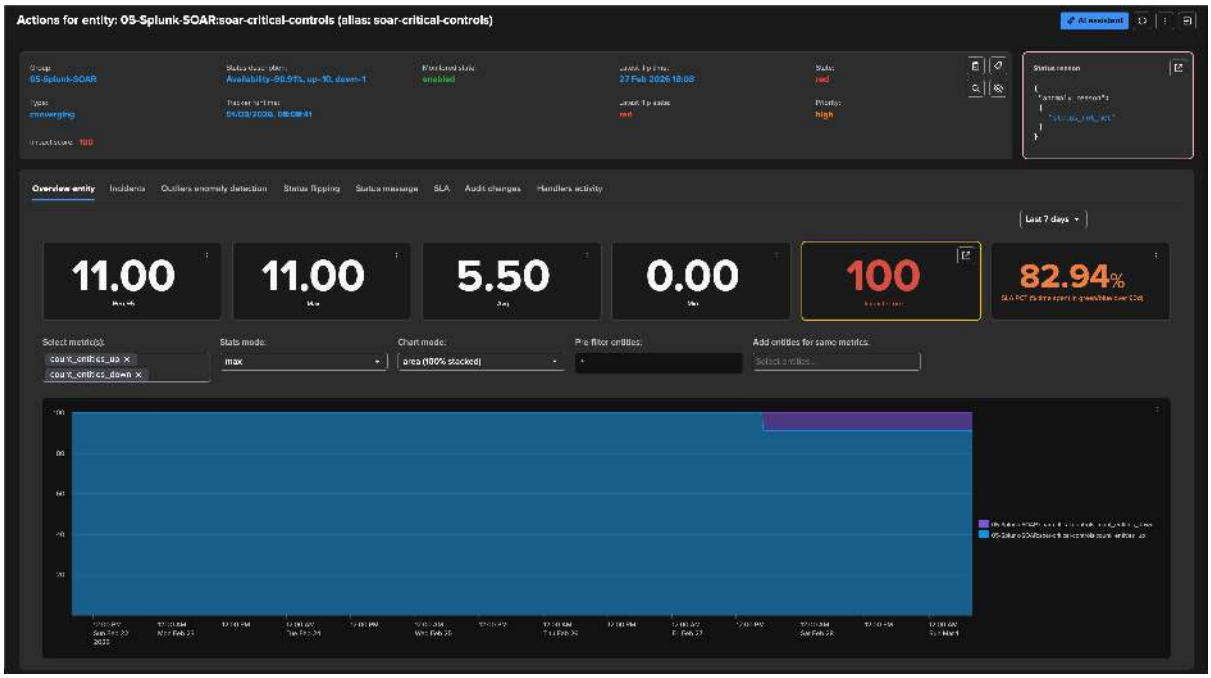
Incidents & Workflow

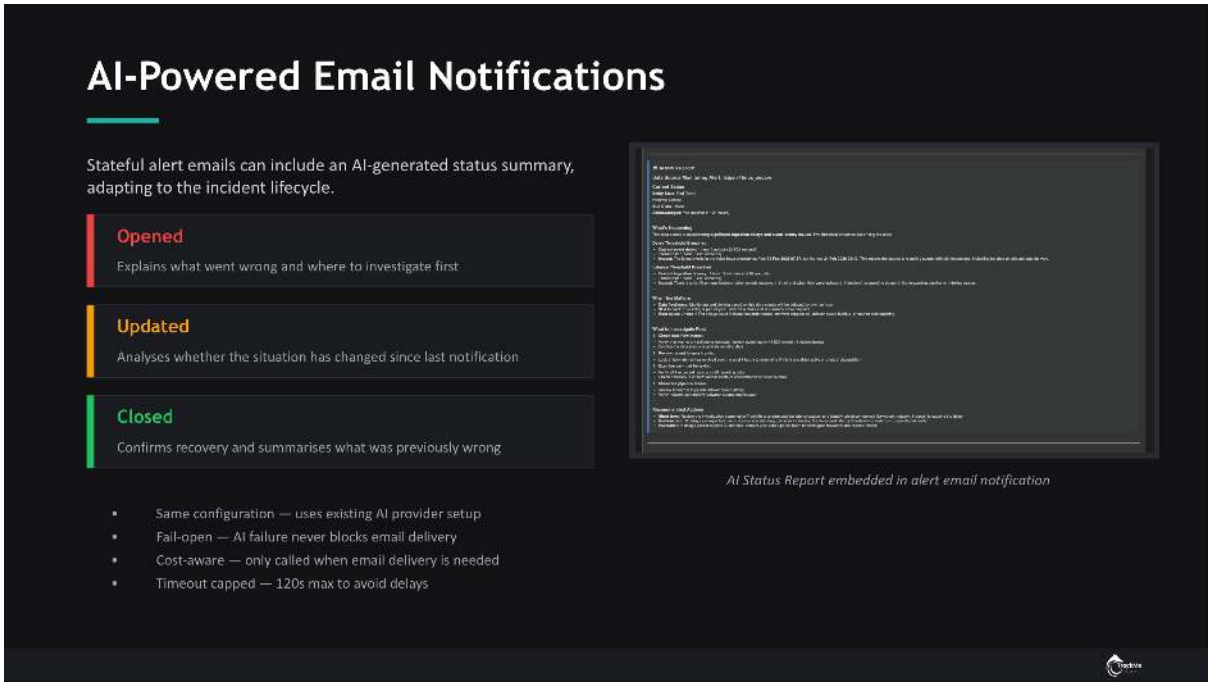
Flex entities are first-class citizens in the TrackMe Stateful Alerting workflow.

When a Flex entity changes status (green to orange/red, or an outlier is detected), TrackMe's **Stateful Alerting** engine manages the full incident lifecycle automatically:

- **Incident creation** - a new incident is opened and persisted in a state-aware manner
- **Incident updates** - as the entity condition evolves, the incident is updated with new context
- **Incident closure** - when the entity returns to a healthy state, the incident is automatically closed
- **Rich HTML email notifications** - with embedded metrics charts for immediate visual context
- **AI-generated status reports** - optional AI-driven analysis included in email notifications, adapted to the incident lifecycle stage (opened, updated, closed)
- **Active commands** - execute generating or streaming commands on incident open, update, or close for advanced integrations (ticketing, webhooks, etc.)
- **SLA tracking** - measure entity availability over time for compliance reporting

Flex entities also benefit from all TrackMe features: priority management, maintenance windows, logical groups, tags, status flipping analysis, audit changes, and the AI Assistant for intelligent investigation. See *Stateful alerting* for full details.





Hint

For detailed administration documentation including the search contract reference, creating trackers step-by-step, KPI configuration, ML Outlier detection setup, and managing trackers, see the *FLX — Flex Objects* guide.

Real-World Use Cases

Flex Objects powers a wide range of monitoring scenarios. The following white papers provide in-depth, step-by-step implementations:

White Paper	Description
Use TrackMe to detect abnormal events count drop in Splunk feeds	Detect abnormal drops in event counts using Flex Objects with ML Outlier detection. Covers both rolling and absolute metric approaches.
Analyse log messages logging level to detect behaviour anomalies using TrackMe's Flex Object and Machine Learning Anomaly Detection	Monitor Splunk internal log levels (INFO, WARN, ERROR, FATAL) with Flex Objects and detect unusual spikes using ML.
Tracking Splunk Cloud SVC consumption in TrackMe	Track Splunk Cloud SVC consumption at global and per-app levels using Flex Objects templates from the library.
Monitor Splunk Indexer Clusters	Monitor Indexer Cluster health, peer status, and bucket balance using Flex Objects with remote deployment accounts.
Monitor Splunk Search Head Clusters	Monitor Search Head Cluster global status, member health, and search activity using Flex Objects.
Use Case Demo: 360 Services Monitoring with TrackMe	A comprehensive 360-degree monitoring approach combining Flex Objects with other TrackMe components for full-stack visibility.

Summary

Flex Objects is the key to unlocking TrackMe's full potential for any monitoring use case. Whether you're starting from the pre-built library or writing custom searches from scratch, the component provides:

- **A simple search contract** - just `object` and `status` to get started, with optional `metrics` and `outliers_metrics` for advanced monitoring

- **60+ ready-to-use templates** - deploy pre-built use cases for Splunk infrastructure, data quality, license, cloud, SOAR, and Cribl monitoring
- **ML-powered anomaly detection** - detect anomalies in any KPI with configurable seasonality awareness
- **High-scale performance** - optimized for environments with thousands of entities
- **Converging visibility** - aggregate entity health into service-level availability metrics

Combined with TrackMe's alerting framework, virtual tenants, and SLA tracking, Flex Objects makes it possible to build a comprehensive, data-driven monitoring platform on top of Splunk.

For step-by-step administration instructions, see the *FLX — Flex Objects* guide.

2.3 TrackMe Use Cases Referential — Overview

What this referential is

This is a **comprehensive, cross-cutting map of everything TrackMe can be used for**, organised so an existing customer (or a prospective one) can audit their current footprint against the full capability surface and spot what they are not yet leveraging.

It is **not** a tutorial — for step-by-step walkthroughs, see the *Quickstart* and the various white papers. It is **not** a feature pitch either — every entry maps to a concrete TrackMe component, configuration touchpoint, and (where applicable) a pre-built use case template that ships in the product.

Audience
TrackMe administrators auditing coverage, Splunk SREs scoping a TrackMe rollout, architects and team leads prioritising which features to enable next.

Last updated
TrackMe v2.3.23

2.3.1 Why a referential

Most TrackMe customers use a fraction of what the platform offers. The combination of:

- **seven monitoring components** (DSM, DHM, MHM, VOL, FLX, FQM, WLK),
- **three dedicated tenant types** that raise findings instead of tracking entities — User Activity Monitoring (UAM: who is doing what on the platform), Cribl Stream and Cribl Edge,
- **a deep library of cross-cutting features** (policies, ML outliers, stateful alerting, impact scoring, virtual tenants, configuration guardian, AI Assistant, remote Splunk fleets, SOAR integration, …),
- **65 pre-built FLX use case templates** that ship with the product,
- **a growing ecosystem of companion add-ons** (Cribl Stream / Edge, Google SecOps, lookups, XSOAR, conf-manager, SOAR connector),

means that "what TrackMe can do" is genuinely hard to summarise on a single page. This referential breaks it into five layers, each answering a different question.

2.3.2 The five layers

1. Use Cases by Intent "**What do I want to monitor?**" — organised by user goal: ingestion freshness, Splunk platform health, license / cost, scheduled-search health, field-parsing quality, custom KPIs, non-Splunk systems, intelligent alerting, multi-tenant scale, downstream integrations. The shortest path from a real-world question to the TrackMe component that answers it.

TrackMe Use Cases — Organised by User Intent 2. Capability × Component Matrix "**Which features apply to which monitoring components?**" — every cross-cutting capability (priority policies, SLA, variable delay, ML outliers, hybrid trackers, AI status reports, …) mapped against the seven components, with one-line use cases unlocked and the configuration touchpoint for each.

TrackMe Capability × Component Matrix 3. FLX Template Catalog "**What pre-built use cases can I enable today?**" — the full catalog of the 65 FLX templates shipped in the product, grouped by category (Splunk infrastructure, license, Splunk Cloud, SOAR, Cribl Stream / Edge, good practices, host OS, …) with metrics, schedule, source data, dependencies, and ML-outlier flag per entry. Closes with a gap-analysis checklist.

FLX (Flex Objects) Use Case Template Catalog 4. Ecosystem & Companion Add-ons "**What else can I plug in?**" — the companion technology add-ons and the SOAR connector that extend TrackMe beyond Splunk: Cribl Stream / Edge, Google SecOps, lookup files, Cortex XSOAR, resilient configuration replay, and Splunk SOAR playbook orchestration of TrackMe entities.

TrackMe Ecosystem — Companion Add-ons 5. Adoption Roadmap "**What should I focus on next?**" — the six-phase customer journey we typically see (DSM feeds → DHM hosts → VOL license-volume outliers → optional WLK interlude → FLX expansion and third-party → steady state). Descriptive, not prescriptive; each phase opens with the customer question that triggers it, calls out anti-patterns to avoid, and notes Foundation / Enterprise / Unlimited edition variants.

TrackMe Adoption Roadmap

2.3.3 How to use this referential

For a **coverage audit** of an existing TrackMe deployment, work through the layers in this order:

1. **Start with the FLX template catalog** (layer 3) — the most concrete "what am I missing?" pass. The gap-analysis checklist at the bottom of that page walks you through every domain (license, indexer cluster, ingestion, SH workload, good practices, data quality, Cribl, SOAR, host OS) one question at a time.
2. **Then read the capability matrix** (layer 2) — once you know which components and templates you are using, cross-reference whether you have priority policies, SLA classes, ML outlier detection, logical groups, disruption queues, smart status investigations, AI status reports, etc. wired in for those components. The matrix shows you the per-component support and the configuration touchpoint.
3. **Use the by-intent catalog** (layer 1) when a stakeholder asks a question in plain English ("can we monitor X?") — find the goal, follow the cross-references.
4. **Consult the ecosystem chapter** (layer 4) when your scope extends beyond a single Splunk instance — Cribl, Google SecOps, SOAR / XSOAR integration, lookup-file monitoring, etc.
5. **Cross-check the adoption roadmap** (layer 5) to position yourself — "we are solid on phase 1 and phase 2, just starting on phase 3" — and to see what we typically teach customers about next.

For **scoping a new TrackMe rollout** or **planning an extension**, the adoption roadmap (layer 5) is the right starting point — it tells you which capabilities to focus on first and which to defer. Then use the capability matrix to set expectations, by-intent to align on goals with stakeholders, the FLX catalog to identify quick wins from pre-built templates, and the ecosystem chapter for integrations and external data sources.

2.3.4 How TrackMe is structured (recap)

The referential assumes you are familiar with TrackMe's core concepts. If not, the very short recap below is enough to navigate the five layers; each concept also links to its deeper documentation.

The seven monitoring components

Every TrackMe entity belongs to one of seven monitoring components. The three-letter codes are load-bearing — they appear in REST paths, KV collections, filenames, and the wizard UI.

Code	Full name	What it monitors
DSM	Data Source Monitoring	Data feeds modelled as `(index, sourcetype)` combinations — the fundamental "is my data flowing" axis. Also supports a `lookups` search mode that tracks CSV / KVstore lookups as entities.
DHM	Data Host Monitoring	Per-host × per-sourcetype activity — "who is sending what". Hybrid trackers in 2.3.23+ support an optional `breakby_extra_fields` dimension on top of the combo grain.
MHM	Metric Host Monitoring	Hosts sending **metric** data, grouped by metric category — the counterpart of DHM on metric indexes.
VOL	Volume Outliers	The licensed volume of every index, read incrementally from the license usage logs in 5-minute buckets — ML outliers (drops and / or spikes, direction chosen per index), inactivity, daily licensed volume, 30-day trend and month projection. One entity per index; the history is backfilled at creation. See *VOL — Volume Outliers*.
FLX	Flex Objects	Any Splunk SPL turned into tracked entities with custom KPIs. Sixty-five pre-built templates ship in the catalog (layer 3).
FQM	Field Quality Monitoring	Field parsing quality and CIM compliance — coverage %, success %, per-field metrics.
WLK	WorkLoad Knowledge	Scheduled-search execution health — skip rate, error count, execution delay, version drift, orphan owners, app enablement.

Beyond the entities — the dedicated tenant types. Three *tenant types* are not components: their tenants have no entities, and their policies raise **findings**, triaged as Finding groups (see *Findings, Finding groups and findings actions*).

- **User Activity Monitoring** (UAM, 2.4.18+, generally available since 2.4.19) reads the audit trail and the introspection of a deployment through one or more search head tiers and answers *who is doing what* — accounts classified as human, service or system, their scheduled searches and knowledge objects, their search activity and resource usage — with twelve built-in policies plus custom policies in SPL, state-aware notifications and the UAM AI Agent. See *User Activity Monitoring*.
- **Cribl Stream** (2.4.19+) monitors a Cribl Stream deployment — the Leader, Worker Groups, Workers, Sources, Destinations, Pipelines and Routes — from the Cribl metrics in a Splunk metric index and the Leader API, with traffic machine learning models and the Cribl Stream AI Agent. See *Cribl Stream*.
- **Cribl Edge** (2.4.19+) monitors the Fleets of a Cribl Edge Leader and their Edge Nodes, at any fleet size. See *Cribl Edge*.

Virtual Tenants

Every TrackMe deployment is sliced into **Virtual Tenants** — isolated containers each with their own KV collections, RBAC roles, indexes, scheduling, default thresholds, and (optionally) a remote Splunk deployment target. Components are enabled per tenant. See *Creating a tenant* and *Managing tenants*.

State, scoring, alerting

Every entity is in one of four states — `green` (healthy), `orange` (warning), `red` (critical), or `blue` (protected by group or grace window). The state is determined by a hybrid score that adds a rolling `base_score` from the metrics index to per-condition impact scores and threshold scores. See *QUICK START - TrackMe Impact-Based Alerting (IBA)* and *Stateful alerting*.

Stateful alerting

State transitions (green → orange / red, red → green, …) drive a single stateful record per `(entity, alert configuration)`. The alert action fires "Alert Opened", "Update", and "Alert Closed" notifications — optionally enriched with embedded SVG → PNG charts and LLM-generated AI status reports. See *Stateful alerting*.

License editions

Feature availability is gated by license edition. The referential calls out edition-specific gates inline where relevant. The short version:

Edition	Type	Notes
Foundation	Subscription / 90-day trial	DSM, DHM, MHM, VOL only. No FLX, no FQM, no WLK. No remote deployments. No hybrid trackers.
Enterprise	Subscription	All seven components. FLX, FQM and WLK enabled. Hybrid trackers capped at 8 per tenant.
Unlimited	Subscription	All features, unlimited scale, remote deployments.
Developer	Self-service / 30 days	All features for local development; max 3 activations per instance.

See *EULA License* and *License registration* for details.

2.3.5 What this referential does NOT replace

- **Step-by-step walkthroughs.** The *Quickstart* and the white papers remain the right place to learn TrackMe.
- **Component-specific deep dives.** Each component has dedicated admin / user guide pages: *FLX — Flex Objects*, *WLK — Workload Knowledge*, *Use Case Demo: Fields Quality (CIM and non-CIM)*, *Use Case Demo: This is All About Feeds*, etc.
- **REST API documentation.** See *REST API reference* and the in-product REST API Reference page.
- **Release notes.** See *Release notes*.

The referential **complements** those documents by giving you a single flat map of the capability surface, with cross-references back into the existing documentation wherever you want depth.

2.3.6 Conventions used across this referential

- Component codes (`DSM`, `DHM`, …) are rendered as inline code.
- KV collection names are rendered as inline code: `kv_trackme_dsm_tenant_{tenant_id}`.
- REST endpoints use the `/trackme/v2/...` prefix and are rendered as inline code.
- Cross-references to other documentation pages use Sphinx `:ref:`<label>`` so they stay live across documentation versions.
- FLX template references use their `uc_ref` (filename without `.json`) — for example `splk_license_pool_usage` corresponds to `package/lib/flx_library/splk_license_pool_usage.json`.

TrackMe Use Cases — Organised by User Intent

How this page is organised

Each section answers a real-world question ("I want to know when…", "I want to monitor…", "I want to integrate with…"). For each goal we give you the **shortest path** from intent to action:

- which **component(s)** deliver the use case,
- whether it is **out-of-the-box**, **configurable**, or requires **custom SPL**,
- a pointer to a **pre-built FLX template** if one exists (see *FLX (Flex Objects) Use Case Template Catalog* for full details),
- and a cross-reference to the deeper admin / user / white-paper guide.

Cadence
This page changes every time TrackMe grows new capabilities. Current snapshot: TrackMe v2.3.23.

I want to know when data stops flowing

The foundational TrackMe use case. The platform was built around this problem, and three of the seven components answer different facets of it.

Detect when an `(index, sourcetype)` feed stops receiving data

Component(s)
`DSM`

Status
Out-of-the-box. Auto-discovered by the DSM tracker.

How
Each `(index, sourcetype)` becomes a DSM entity; the tracker measures ingestion delay, latency, and event count. Static or variable delay thresholds trip `orange` / `red` state.

Tuneables
variable delay (time-of-day / day-of-week slots), lagging classes, adaptive delay (auto-recompute thresholds from history), priority / SLA / tag policies, monitoring-time policy.

See also
Use Case Demo: This is All About Feeds, *Impact scoring & thresholds*, *Impact scoring & thresholds*, *DSM — Data Source Monitoring*.

Detect when a specific host stops sending data

Component(s)
`DHM`

Status
Out-of-the-box. Hosts × sourcetypes are auto-discovered.

How
One DHM entity per host × sourcetype combination (or per host alone in merged mode). 2.3.23+ adds the optional `breakby_extra_fields` knob for richer combos (e.g. include `source`).

Tuneables
same as DSM (variable delay, lagging classes, adaptive delay, policies, monitoring-time).

See also
Notes, *Hybrid trackers*.

Detect silent metric-sending hosts

Component(s)
`MHM`

Status
Out-of-the-box. `mstats`-based discovery and tracking.

How
One MHM entity per host × metric category. Detects when a host stops emitting metrics that it previously emitted.

Tuneables
static delay thresholds, priority / SLA / tag policies. Variable delay and lagging classes are **not** supported on MHM.

See also
Notes.

Detect silent CSV or KVstore lookup files

Component(s)
`DSM` in `search_mode=lookups`

Status
Configurable. Requires the companion add-on `TA-trackme-lookupmonitor` installed on the SH.

How
The hybrid-tracker wizard exposes a `Lookups monitoring` mode that turns every CSV file and KVstore collection into a DSM entity, with filesystem mtime and accurate row count.

Tuneables
same as regular DSM (priority, SLA, …); thresholds apply on delay only — latency is neutralised because lookups have no `_indextime`.

See also
Lookup monitoring, *QUICK START - Design and automate through lookup knowledge*.

Detect event drop-outs at the index level (independent of host / sourcetype)

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_detect_drop_events_count_absolute` (hourly window), `splk_detect_drop_events_count_rolling` (rolling 5-minute), and `splk_hosts_tracking` (per-host).

How
Computes per-index event count and distinct host count, with native ML outlier detection on the volume so abnormal day-over-day drops are surfaced even if the static threshold would not have caught them.

See also
Use TrackMe to detect abnormal events count drop in Splunk feeds.

Detect routing or parsing misconfiguration (events in `lastchanceindex`)

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_lastchanceindex`.

How
Watches the `lastchanceindex` for any traffic; non-zero counts are a strong signal that a pipeline misroutes events.

I want to monitor Splunk platform health (the full stack)

TrackMe ships an opinionated set of FLX templates that cover the most common "is Splunk itself healthy?" questions. All of them run as scheduled FLX entities and participate in TrackMe's stateful alerting, ACK system, smart status, AI Assistant and impact scoring.

Indexer cluster status (Splunk Enterprise)

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_splunk_enterprise_cluster_status` (global — availability, peers up / down / unknown), `splk_splunk_enterprise_cluster_peers_status` (per-peer — bucket %, primary %, balancing deviation, plus introspection CPU / mem join).

See also
Monitor Splunk Indexer Clusters.

Search-head cluster status

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_splunk_shc_global_status` (captain-level flags: maintenance mode, min_peers_joined, rolling_restart, service_ready, kvstore_maintenance), `splk_splunk_shc_members_status` (per-member lost / down / pending).

Dependency
A TrackMe **remote account** targeting any SHC member is required for both templates.

See also
Monitor Splunk Search Head Clusters, *Remote Splunk deployments*.

Bucket health (timestamp parsing, premature rolls, quarantine)

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_bucket_health_per_index` — every 30 min, `| dbinspect`-based; surfaces premature small buckets and quarantined buckets, both classic timestamp-parsing failure symptoms.

Knowledge-bundle size on the SH tier

Component(s)
`FLX`

Status
Pre-built FLX template (with third-party dependency).

Templates
`splk_bundle_size`. Requires the Splunkbase app `sa-littlehelper` (#6368) which provides `| bundlefiles`.

Why it matters
bloated bundles silently slow search dispatch across the entire SH tier.

KV-store readiness and per-collection size

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_kvstore_status` (service readiness — alerts when KV goes degraded / down), `splk_kvstore_size` (per-collection vs total size with thresholding).

Pipeline queue saturation

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_queues_filling` — parsing / aggregator / typing / indexer queue fill metrics. The canonical backpressure indicator meaning the indexer tier needs more horsepower or the input is ingesting too fast.

Parsing issues (LineBreaking / Aggregator / DateParser)

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_parsing_issues_per_component` — hourly aggregation of WARN / ERROR from the canonical bad-props.conf symptom signatures.

Data Model Acceleration (DMA) completeness

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_dma` — complete %, size, run duration, bucket count with ML outlier detection. Surfaces stuck or under-performing accelerations.

HEC ingestion errors

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_splunk_hec_errors` — parsing-error breakdown by `parsing_err`, with source-IP dcount to localise blame.

Universal Forwarder fleet version compliance and dropout

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_uf_clients_versions_tracking` (UF version compliance — picks highest version as target, alerts on % non-compliant), `splk_deployment_server_clients` (silent UF dropout — alerts on missing phone-home).

Search-head workload and scheduler health

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_search_head_activity` (dispatched, eligible, lag, runtime, scheduler cycles, with ML outliers), `splk_search_head_healthmon_artifact_count_remote` (per-SHC-member response time and artifact count via remote search).

See also
Monitor Splunk Workload with TrackMe's Workload component.

Per-instance CPU and memory consumption

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_splunk_infra_cpu_used`, `splk_splunk_infra_mem_used` — Splunk-introspection-based per-instance avg / p95 / max.

Distinction
Use these for the **Splunk process** view. For the host OS view of the underlying servers, use the `ta_nix_*` and `ta_windows_*` templates (see the host OS section below).

Log-level variations (catch error storms early)

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_splunk_infra_log_level_variations` — counts INFO / WARN / ERROR / FATAL across the Splunk infra with ML outliers for trend deviation.

See also
Analyse log messages logging level to detect behaviour anomalies using TrackMe's Flex Object and Machine Learning Anomaly Detection.

DB Connect modular-input health

Component(s)
`FLX`

Status
Pre-built FLX template (with dependency).

Templates
`splk_dbconnect`. Requires Splunk DB Connect.

I want to monitor cost and license consumption

Since TrackMe 2.4.18 the **VOL** (Volume Outliers) component answers the per-index licensed-volume question out of the box, on every edition including Foundation. Licensing also remains one of the most heavily templated areas of the FLX library — six dedicated templates plus the daily-variation pair, covering both Splunk Enterprise and Splunk Cloud — for pool-level, SVC and storage views, and as the legacy alternative to VOL for custom needs.

Detect abnormal drops or spikes of licensed volume per index — know who consumes my license

Component(s)
`VOL`

Status
Out-of-the-box. Enable the component on a tenant (local or remote deployment, Splunk Enterprise or Splunk Cloud); every index becomes an entity, the history (default 30 days) is backfilled at creation.

How
One small incremental search per tenant every 5 minutes reads the license usage logs in 5-minute buckets. Native ML outliers on the rolling volume (drops, spikes, or both — chosen per index) and an inactivity policy (static or by day / hour, overridable per index) drive the entity state; the daily licensed volume, a 30-day trend and a month projection give the cost reading. The **Global license usage (VOL)** tab shows key figures, top consumers, movers, pools and quotas.

Tuneables
detection direction per index, inactivity policy, `vol_mloutliers_priority_filter` / `vol_mloutliers_filter_expression`, priority / SLA / tag policies.

See also
VOL — Volume Outliers, *Volume Outliers — in depth*, *Volume outliers on the Splunk license usage with Volume Outliers (VOL)*. The FLX license templates below remain the legacy path (see the white paper for the comparison).

Splunk Enterprise license pool consumption

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_license_pool_usage` (per-pool % used + GB used, with ML outliers), `splk_license_usage_global_splunkenterprise` (rolling 60 min / 4 h / 24 h — designed for near-real-time anomaly detection), `splk_license_usage_per_index_splunkenterprise` (same but per-index to pinpoint a spike).

Splunk Cloud license, storage and SVC consumption

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_license_usage_global_splunkcloud`, `splk_license_usage_per_index_splunkcloud`, `splk_splunk_cloud_storage_usage` (storage vs licensed), `splk_splunk_cloud_svc_usage` (overall SVC usage % with outliers), `splk_splunk_cloud_svc_usage_by_app` (per-app SVC attribution), `splk_splunk_cloud_svc_usage_by_consumer_service` (per-consumer attribution).

See also
Tracking Splunk Cloud SVC consumption in TrackMe.

Daily variation detection on global / per-index volume

Component(s)
`FLX`

Status
Pre-built FLX templates.

Templates
`splk_detect_daily_variations_volume_global`, `splk_detect_daily_variations_volume_index`, `splk_volume_ingested_per_day`. All ML-outlier-enabled and scheduled in the 03:05 — 04:15 UTC quiet hours. For the per-index variant, prefer the **VOL** component (above) — it covers the same signal continuously, with backfill, on every edition.

Detect oversized lookup files before they hurt bundle replication

Component(s)
`FLX`

Status
Pre-built FLX template.

Templates
`splk_large_lookup_files` — every 12 hours via `/services/data/transforms/lookups`, with ML outliers on total lookup size.

I want to monitor scheduled-search execution health

The `WLK` (WorkLoad Knowledge) component is purpose-built for this and includes signals you cannot get from FLX alone.

Detect scheduled searches that skip, error, or run long

Component(s)
`WLK`

Status
Out-of-the-box. Auto-discovered.

How
Every scheduled search becomes a WLK entity with skip rate, error count, execution-time metrics. Dynamic thresholds support a **tenant-default fallback row** (`object_id == "default"`) so you can manage the whole tenant's thresholds from one record and override per entity as needed.

See also

WLK — Workload Knowledge, *WLK — Workload Knowledge*, *Monitor Splunk Workload with TrackMe's Workload component*.

Detect silently broken scheduled searches

Component(s)

`WLK`

Status

Out-of-the-box. Three WLK-only signals fire here.

How

`orphan` (owner user no longer exists), `app enablement` (parent app disabled — search no longer dispatches), `versioning` (savedsearch definition has changed since the fingerprint was taken, surfacing unannounced edits).

Audit "all-time" or user-owned scheduled searches (good-practice violations)

Component(s)

`FLX`

Status

Pre-built FLX templates.

Templates

`splk_good_practices_alltime_scheduled` (enabled scheduled searches with `-` / `all time` earliest — a notorious cost driver), `splk_good_practices_run_as_user_scheduled` (scheduled searches running as a named user — offboarding fragility), `splk_good_practices_detect_dynamic_sourcetype` (dynamic / numerically suffixed sourcetypes that bloat metadata).

I want to monitor field-parsing quality and CIM compliance

This is the dedicated remit of the `FQM` component.

Track field coverage and parsing success per dataset

Component(s)

`FQM`

Status

Out-of-the-box (with custom templates per CIM data-model).

How

FQM defines field-quality checks per (source, sourcetype, host), producing percentage_passed / percentage_failed and per-field counts. CIM-aware templates ship in the FQM wizard so common data models (Authentication, Network_Traffic, Web, …) can be onboarded quickly.

Tuneables

priority, SLA, tag policies, monitoring-time policy, dynamic thresholds per metric.

See also

Use Case Demo: Fields Quality (CIM and non-CIM).

Aggregate FQM outcomes into a single FLX-tracked health metric

Component(s)

`FLX`

Status

Pre-built FLX template.

Templates

`splk_splunk_fields_quality` — aggregates the FQM check outcomes into per-(source, sourcetype, host) % passed / % failed and applies ML outliers for drift detection. Useful when you want one aggregate view next to your other FLX entities.

I want to detect anomalies without writing thresholds by hand

Native ML outlier detection (DensityFunction)

Component(s)

`FLX` recommended; `VOL` by design (the outlier verdict is the entity state, enabled by default, available in all editions) and the recommended route for volume anomalies; `DSM` optional (off by default); `DHM` selective; `MHM` / `FQM` / `WLK` not recommended.

Status

Configurable. Enabled per tenant via `vtenant_account.mloutliers_<component>`; VOL has its own scope (`vol_mloutliers_priority_filter` / `vol_mloutliers_filter_expression`).

How

TrackMe trains a per-entity, per-metric DensityFunction model (Gaussian KDE / Normal / Exponential / Beta) with optional seasonality (hour-of-day, day-of-week, dow × hod). Low-confidence predictions are suppressed so a half-trained model does not page the operator.

Pre-wired templates

20 of the 65 FLX templates ship with `outliers_metrics` already declared — license / volume, Cribl traffic, SOAR runtime, SH activity, parsing-quality drift, etc. See the `Outlier-friendly?` column in *FLX (Flex Objects) Use Case Template Catalog*.

See also

Outlier detection.

Custom per-entity SPL checks (hybrid trackers)

Component(s)

DSM, DHM, MHM, FLX, FQM, WLK (not VOL — its single incremental collector is the tracker)

Status

Configurable. Enterprise edition caps at 8 hybrid trackers per tenant; Foundation rejects; Unlimited is uncapped.

How

Per entity, configure a custom SPL check that contributes `score` / `state` / `anomaly_reason` / `enrichment` to the entity's final state. Useful when the default component logic cannot reach the data, or when you need a domain-specific check on top of the built-in tracker.

See also

Hybrid trackers.

I want to monitor anything I can express as SPL

Use a pre-built FLX template

Component(s)

`FLX`

Status

Out-of-the-box. Sixty-five templates ship in the catalog.

How

The Virtual Tenants FLX wizard guides you through picking a template by category, customising replacements (index name, …), and creating the saved search. The full catalog lives at *FLX (Flex Objects) Use Case Template Catalog*.

Author a custom FLX use case

Component(s)
`FLX`

Status
Configurable. Available in every edition that includes FLX.

How
The wizard accepts arbitrary SPL that must produce rows with `object`, `status`, `status_description`, `metrics` (JSON dict), optionally `outliers_metrics` (JSON dict), and optionally `max_sec_inactive` for inactivity alerting. The SPL becomes a saved search; the rows become FLX entities; thresholds / outliers / policies apply.

See also
FLX — Flex Objects, *Flex Objects - Adapt TrackMe to any monitoring use case (splk-flx)*.

Apply time-aware thresholds to an FLX KPI (business hours vs nights)

Component(s)
`FLX`

Status
Configurable.

How
FLX dynamic thresholds support a **variable** mode with day-of-week × hour-of-day slots. Each slot carries its own threshold value, so a metric can be alerted on at one level during business hours and another at night.

I want to be alerted intelligently (and only when it matters)

This section enumerates the noise-reduction and prioritisation features that turn raw state transitions into actionable signal.

Prioritise entities so the right alerts get the right urgency

Capability
Priority policies (regex, lookup, SPL search).

How
Policies automatically assign priority (`low` / `medium` / `high` / `critical` / `pending`) to entities by name pattern, lookup membership, or live SPL match. Manual overrides always win.

See also
Priority, *Priority*.

Bucket entities into SLA classes (platinum / gold / silver / custom)

Capability
SLA policies + `trackme_settings.conf [sla]`.

How
SLA classes are tenant- or system-defined with their own uptime targets and reporting windows. SLA policies apply them automatically across entities. Maintenance windows and bank holidays are excluded from SLA timers when configured.

See also
Using SLA alerting to build a 2-tier monitoring system, *Maintenance mode*, *Bank holidays*.

Tag entities for routing and grouping

Capability
Tag policies (union semantics — multiple matches accumulate).

How
Regex / lookup / SPL policies assign one or more free-form tags to entities — used for filtering in the UI, downstream search, and alerting rules.

See also
Tags.

Demote false positives — disruption queue (grace period)

Capability
Disruption queue.

How
An entity that goes red is held in `blue` state until it has been continuously red for `disruption_min_time_sec`. Any green tick resets the timer. Configured at tenant default and per-entity override.

See also
Disruption queue, *The entity state machine*.

Don't alert when a cluster is mostly healthy — logical groups

Capability
Logical groups.

How
Cluster N entities (cross-component supported); while green % stays above `object_group_min_green_percent`, struggling members are demoted to `blue` ("protected by the group"). When too many members are red, all members surface as red so the underlying cluster issue gets escalated.

See also
Logical groups.

Mute outside business hours — monitoring-time policy

Capability
Monitoring-time policy.

How
Per-tenant (and per-entity override) day-of-week × hour-of-day window outside which the entity is forced `orange` (paused). Useful when feeds legitimately stop overnight or on weekends.

Tighter thresholds during business hours — variable delay

Capability
Variable delay (DSM / DHM only).

How
Day-of-week × hour-of-day delay-threshold matrix. Tight thresholds during the business day, looser at night, looser still on weekends. The system falls back to the static threshold for any uncovered slot.

Recompute thresholds from history — adaptive delay

Capability

Adaptive delay (DSM / DHM only).

How

Persistently-red `delay_threshold_breached` entities have their thresholds automatically recomputed from the last 30 days of metrics. 24-hour cool-off prevents oscillation. Opt-in via `allow_adaptive_delay` on the entity. Since 2.3.23, the adaptive path also recomputes individual variable-delay slot thresholds.

Acknowledge known issues — sticky and unsticky ACK

Capability

Acknowledgments.

How

An ACK silences notifications without hiding the entity's real state. **Sticky** ACKs require manual close; **unsticky** ACKs auto-expire after `ack_period` (default 24 h). Reason-change revocation can be enabled so the ACK is removed if the underlying anomaly reason changes.

See also

Acknowledgments.

Auto-acknowledge entities on alert fire

Capability

Auto-ack alert action.

How

Triggered from any saved search firing; acks all returned entities sticky / unsticky with a configurable duration and comment. Useful for maintenance windows known upstream, or to short-circuit known-noisy periods.

Embed the right context in the alert email

Capability

Stateful alerting email + embedded 24h charts + AI status reports.

How

One email per state transition (open / update / close), correctly threaded via `In-Reply-To`. Optional SVG → PNG 24-hour charts embedded inline. Optional LLM-generated 2 – 3 paragraph AI investigation summary embedded in the body, with full entity context (priority, recent ACK history, active Guardian alerts, etc.).

See also

Stateful alerting, *AI Assistant*.

Exclude maintenance windows and bank holidays from SLA timers

Capability

Maintenance KDB + bank holidays.

How

The Maintenance KDB records planned and unplanned windows scoped to global / tenant / component / single-entity. SLA accounting and the monitoring-time policy both honour active windows. Bank holidays are calendars of rules (countries, states and regions from the catalog, plus custom closures); each tenant inherits the default calendars, selects its own or uses none.

See also

Maintenance mode, *Bank holidays*.

I want to investigate and resolve fast when alerts fire

Trigger automated investigations — Smart Status

Capability
Smart Status investigations.

How
Triggered by the `trackme_smart_status` alert action. Generates component-specific investigation SPL (delay / future data / latency issues for DSM/DHM; skip / error / orphan for WLK; outliers and inactivity for FLX). Throttled to **max 1 / 24 h per entity**. Detects abnormal state-flipping patterns (high variance of flip count). Results indexed to `trackme_summary` for review in the Tenant Home modal.

See also
Status flapping, *The entity state machine*.

Ask the AI Assistant in plain English

Capability
AI Assistant chat (10 contexts).

How
Per-page chat widget that knows the page's context — Virtual Tenants, Tenant Home, single entity, REST API Reference, Backup & Restore, Maintenance Mode, Maintenance KDB, Bank Holidays, License Management. Per-entity context includes the entity's current state, policies, recent ACK history, active Guardian alerts. Supports OpenAI, Azure OpenAI, Anthropic, Google Vertex, Mistral, Ollama, and Splunk Hosted. Optional anonymisation of entity / index names via SHA-256 hashing before LLM submission.

See also
AI Assistant.

Hand off context to the next operator — notes and labels

Capability
Notes (Markdown annotations) + **labels** (catalog-backed coloured chips).

How
Notes are free-form Markdown attached to an entity with an audit trail (immutable — delete + recreate to edit). Labels are curated, colour-coded, multi-select chips defined once per tenant. Eight default labels are seeded on tenant creation. Use labels for lifecycle workflow (`under-review` → `in-progress` → `resolved`) and notes for narrative context ("re-deploy at 03:00 on 2026-05-08, root cause INC-12345").

Generate notable events for Splunk ES correlation

Capability
Notable event alert action.

How
Triggered by the `trackme_notable` alert action. One event per firing of the saved search to a notable index (default `trackme_notable`), with drilldown links back into the TrackMe UI.

See also
Notable events.

I want to monitor non-Splunk systems

This is where the **companion add-ons** unlock TrackMe beyond Splunk itself. See *TrackMe Ecosystem — Companion Add-ons* for the full inventory.

Monitor a Cribl Stream deployment or a Cribl Edge fleet end to end

Component(s)
`Cribl Stream` and `Cribl Edge` (dedicated tenant types, 2.4.19+).

Status
Out-of-the-box. A Cribl Stream tenant follows the Leader, the Worker Groups, the Workers and the Sources, Destinations, Pipelines and Routes of one deployment, with traffic machine learning models; a Cribl Edge tenant follows the Fleets of a Cribl Edge Leader and their Edge Nodes, at any fleet size. Both raise findings instead of tracking entities; no companion add-on is needed.

Dependency
A Cribl connection (read-only access to the Leader API) and, for Cribl Stream, the Cribl internal metrics in a Splunk metric index.

See also
Cribl Stream and Cribl Edge, *Cribl Stream*, *Cribl Edge*, *Findings, Finding groups and findings actions*.

Monitor Cribl Stream pipelines, routes, packs, destinations

Component(s)
`FLX`

Status
Pre-built FLX templates (10 templates).

Templates
`cribl_logstream_health_inputs`, `_health_outputs`, `_hosts_cpu_usage`, `_output_destination_pressure`, `_pack_traffic`, `_pipeline`, `_route_traffic`, `_total_traffic_inputs`, `_total_traffic_outputs`, plus `cribl_edge_fleet_metrics`.

Dependency
Cribl-shipped internal metrics indexed in Splunk (any `Splunk_TA_cribl`-equivalent setup).

See also
Cribl Stream monitoring with Flex Objects, *Cribl Stream & Cribl Edge*.

Monitor Cribl Edge node heartbeats via the Cribl API

Component(s)
`FLX`

Status
Pre-built FLX template (with companion-TA dependency).

Templates
`cribl_edge_fleet_api` — the only template that **hard-depends** on `TA-trackme-cribl` (uses `| cribl`).

Monitor Google SecOps (Chronicle) log-feed ingestion

Component(s)
`FLX` or hybrid trackers, custom-built.

Status
Custom SPL via the `| secops` command provided by `TA-trackme-google-secops`.

How
UDM-search-based entities, one per `metadata.log_type`, tracking event count and last-seen. Effectively extends DSM-equivalent monitoring to data living in Chronicle.

Important
This add-on has a **hard licensing dependency on trackme-app** — the `| secops` command refuses to run without a valid TrackMe license.

Monitor Splunk SOAR (Phantom) deployment health

Component(s)
`FLX`

Status
Pre-built FLX templates (9 templates).

Templates
`splk_soar_actions_adhocs_failures`, `_actions_playbooks_failures`, `_assets_health`, `_automation_brokers_manage`, `_concurrent_playbooks`, `_forwarding_splunk`, `_infra_load`, `_infra_memory`, `_services_health`.

Dependency
Splunk App for SOAR integration on the SH; SOAR-to-Splunk forwarding for the data-side templates.

See also
Splunk SOAR, *TrackMe App on SOAR*.

Monitor Linux and Windows host CPU / memory

Component(s)
`FLX`

Status
Pre-built FLX templates (4 templates).

Templates
`ta_nix_cpu_usage` and `ta_nix_mem_usage` (require TA-nix), `ta_windows_cpu_usage` and `ta_windows_mem_usage` (require Splunk_TA_windows). Per-host avg / max / p95.

Aggregate a remote regional TrackMe into a central pane

Component(s)
DSM, DHM, MHM, FLX, FQM, WLK (not VOL)

Status
Configurable. Replica trackers.

How
One-way replication of a source TrackMe's entity set into a local tenant. The local decision maker **does not** re-evaluate replicated entities — the source's state is trusted, by design. Useful for a global SOC with regional TrackMe instances.

I want to operate at scale across multiple tenants / customers

This section enumerates the multi-tenancy, automation, and resilience features that make TrackMe deployable as a managed service or a multi-business-unit platform.

Isolate by tenant — Virtual Tenants

Capability
Virtual Tenants.

How
Each tenant has its own KV collections (suffixed `_tenant_{tenant_id}`), RBAC role triplet (`admin` / `power` / `user`), default thresholds, index scoping, scheduling, and an optional `tenant_account` to target a remote Splunk deployment instead of the local one. Configuration lives in a `vtenant_account` JSON object on the tenant record.

See also
Creating a tenant, *Managing tenants*.

Aggregate across tenants without new infrastructure — Virtual Groups

Capability
Virtual Groups.

How
Read-only UI cards aggregating entities from N tenants (and N components per tenant), optionally filtered by priority. RBAC-controlled visibility. Useful for cross-tenant cards like "all high-priority entities in finance across three regions". Virtual Groups do **not** participate in decision maker / alerting / scoring — they are pure read-only aggregation views.

See also
QUICK START - Cross-tenant domain views with Virtual Groups.

Monitor any number of remote Splunk deployments

Capability
Remote Splunk accounts.

How
Per-account HTTPS URL, bearer token (encrypted, auto-rotated every N days), per-account RBAC role restrictions, multiple URLs per account for HA / DR with automatic failover. Per-tenant `tenant_account` selector points the tenant at local or any configured remote.

Edition gate
Foundation does **not** support remote deployments.

See also
Remote Splunk deployments.

Detect admin misconfiguration automatically — Configuration Guardian

Capability
Configuration Guardian.

How
Continuous background scan of common misconfiguration patterns, each emitting a structured alert with `recommended_actions` an admin (or the AI Assistant) can act on. Eight checks ship in v2.3.23: capability gaps on the tenant owner, missing indexes, remote-account token expiry, remote-account connectivity, AI-provider reachability, stale backups, incomplete backup runs, dead health tracker. Two severity tiers (warning / critical); per-tenant and system-wide scopes; full audit trail in `index=trackme_audit sourcetype=trackme:audit:guardian`.

Bulk-edit entity priority, policy, lag, tags

Capability
Mass operations UI + REST.

How
Multi-select in the Tenant Home tables, then bulk-apply priority / SLA / tags / monitoring-time / ACK / disable / re-enable. Equivalent REST endpoints under `/trackme/v2/<component>/...` and `/trackme/v2/ack/*`.

See also
Performing mass operations in TrackMe.

Replay configuration changes resiliently

Capability
TA-trackme-conf-manager (companion add-on).

How
A KV-backed transactional layer that accepts a TrackMe REST transaction, persists it, and replays it on a 15-minute schedule until it succeeds. Useful for SOAR playbooks, infrastructure-as-code pipelines, and any orchestrator that must guarantee a configuration change eventually lands. See *TrackMe Ecosystem — Companion Add-ons* for details.

Back up and restore tenants independently — multi-archive 3.0.0

Capability
Multi-archive backup & restore (release 2.3.22+).

How
A backup run produces N+1 independent archives — one per enabled tenant + one global archive — each individually validated (`zstd -t` + SHA-256) and individually restorable. A failure in one archive does not block the others, by design. Three restore modes: single archive, whole run, or legacy flat (pre-2.3.22 monolithic). SHC-aware (per-archive operations delegate to the owning peer). Missing-tenant safety guard automatically recreates a tenant record from the archive's own `vtenant_account` JSON if restoring on an install where the tenant is absent.

See also
Backing up and Restoring TrackMe.

I want to integrate with my downstream incident-response stack

Push to Splunk ES — notable events

Capability
Notable event alert action.

How
`trackme_notable` writes events to a notable index (default `trackme_notable`) consumable by Splunk Enterprise Security's notable event framework.

See also
Notable events.

Push to Splunk SOAR (Phantom) — containers and active commands

Capability
Splunk SOAR push (built-in) + **active commands** on stateful alerts.

How
TrackMe stateful alerts can run **active commands** on open / update / close — any generating or streaming search command, parameterised with the alert's payload. The most common use

is `| trackmesplksoar` to push containers / events into SOAR. `trackme-app-on-soar` (a Phantom-side connector) provides the inverse integration: SOAR playbooks calling TrackMe REST to ACK entities, enable / disable maintenance, retrain ML models, manage logical groups, etc.

Push to Cortex XSOAR (Palo Alto) — bidirectional incident lifecycle

Capability
TA-trackme-xsoar (companion add-on).

How
Active-command integration on TrackMe stateful alerts: `commands_opened` creates an XSOAR incident, `commands_updated` patches it with new state, `commands_closed` closes it. A built-in resilient retry store (KV-backed, 15-minute replay) guarantees incident parity even through network blips or XSOAR outages. See *TrackMe Ecosystem — Companion Add-ons*.

See also
Palo Alto XSOAR Integration.

Trigger any TrackMe REST endpoint from any saved search firing

Capability
Free-style REST call alert action.

How
`trackme_free_style_rest_call` invokes any `/trackme/v2/*` endpoint (GET / POST / DELETE) when the saved search fires. Useful for custom orchestration: bulk-ACK from a correlation search, force-disable entities from an upstream change-management signal, trigger a smart status investigation from an external context.

I want to extend or customise TrackMe

Add a custom check to an existing entity (any component)

Capability
Hybrid trackers (per-component).

How
A custom SPL check that runs alongside the default component logic and contributes `score` / `state` / `anomaly_reason` / `enrichment` to the entity's final state.

Edition gate
Foundation rejects; Enterprise caps at 8 per tenant; Unlimited is uncapped.

Replicate a tracked entity set into another TrackMe instance

Capability
Replica trackers.

How
One-way replication, source state trusted (no local re-evaluation). Useful when a central TrackMe must present entities owned by remote regional TrackMes.

Persist arbitrary TrackMe configuration as code

Capability
TA-trackme-conf-manager + `/trackme/v2/*` REST API.

How
Define entities, policies, thresholds, ACKs, maintenance windows via REST; wrap them in conf-manager transactions for guaranteed delivery. Suitable for Ansible / Terraform / GitOps integration.

Orchestrate TrackMe from Splunk SOAR playbooks

Capability
trackme-app-on-soar (a Splunk SOAR / Phantom connector, not a Splunk TA).

How
Exposes TrackMe REST endpoints as SOAR actions: `test connectivity`, `ack_get` / `ack_manage`, `maintenance_*`, `tenants_ops_status`, `remote_accounts_check_connectivity`, `ml_outliers_*`, `component_get_entity` / `component_manage_entity`, `smart_status`, `logical_group_*`. Asset configured with a Splunk bearer token. Powers playbook-driven runbooks (e.g. ACK on upstream CMDB change, disable maintenance after deploy completes).

See also
TrackMe Ecosystem — Companion Add-ons, *TrackMe App on SOAR*.

I want to know who is doing what on my Splunk

User Activity Monitoring (UAM, introduced in TrackMe 2.4.18, generally available since 2.4.19) answers the people-and-automation side of the platform as a dedicated tenant type — no entities, findings instead. It reads the audit trail and the introspection of a deployment through one or more search head tiers. See *User Activity Monitoring* and the white paper *Who is doing what on your Splunk? User Activity Monitoring (UAM)*.

Find the scheduled searches owned by people, dispatched all time or in real time

Component(s)
`UAM` (tenant type)

Status
Out-of-the-box. Create a UAM tenant; the inventory policies `personal_schedule`, `all_time_schedule` and `realtime_schedule` are on by default.

How
The inventory trackers read the saved searches, users and roles of every tier and record every change; the owner's class (human, service, system) decides which policies apply.

Tell people from service accounts, and catch the account that ran an all-time search

Component(s)
`UAM` (tenant type)

Status
Out-of-the-box. Human accounts are detected from Splunk Web activity and browser logins, service accounts from sustained automation or from a naming rule; `all_time_search` is on by default at severity high.

How
The activity tracker reads the audit trail from a durable checkpoint and indexes one compact record per search and window; the Users tab gives every account its class, findings, activity and resource usage.

Find the accounts and searches that consume the search capacity

Component(s)
`UAM` (tenant type)

Status
Out-of-the-box. `resource_consumption` and `resource_intensity` derive their thresholds from the measured search capacity of the environment.

How
: Resource usage per search is integrated from the introspection of the search heads and the indexers; the account deep-dive lists the most expensive searches.

What if my goal isn't covered above?

The pre-built FLX template library is one of TrackMe's broadest surface areas but it is not exhaustive. The *FLX (Flex Objects) Use Case Template Catalog* page ends with a **"Coverage gaps not addressed out of the box"** section listing the recurring asks we know about (auth-failure spikes, scheduler skip-rate per user / app beyond what WLK does, app-version drift, etc.).

When you have a goal not addressed by a template or a built-in feature, your three options, in increasing order of effort, are:

1. **Author a custom FLX use case** through the wizard — see *FLX — Flex Objects*.
2. **Add a hybrid tracker** to an existing entity — see *Hybrid trackers*.
3. **Build the data path** via a companion TA (Cribl, Google SecOps, lookup monitor) and feed the data into FLX. See *TrackMe Ecosystem — Companion Add-ons*.

If a use case feels generally applicable across customers, contributing a JSON file back to `package/lib/flx_library/` makes it available to every TrackMe deployment.

TrackMe Capability × Component Matrix

What this page is

A flat, exhaustive map of every cross-cutting TrackMe capability against the seven monitoring components (`DSM`, `DHM`, `MHM`, `VOL`, `FLX`, `FQM`, `WLK`). For each `(capability × component)` intersection it records:

- whether the capability **applies** to that component,
- the **use case unlocked** by turning it on (one line each),
- the **configuration touchpoint** (UI page, system setting, KV collection, `vtenant_account` field).

Use this page when you know **which components** a tenant has enabled and want to audit which **cross-cutting features** are wired in for those components. It pairs naturally with *TrackMe Use Cases — Organised by User Intent* (which asks the inverse question: given a goal, which component delivers?).

Legend

In every applicability table:

- `Y` — fully supported on that component.
- `P` — partial support; the cell footnote explains the caveat.
- – — not applicable on that component (see *What does not apply, and why* at the bottom of this page).

The seven components — recap

For the full description see *TrackMe Use Cases Referential — Overview*. Short form:

Code	Full name	Tracks
DSM	Data Source Monitoring	(index, sourcetype) feeds. Includes the lookups search mode.
DHM	Data Host Monitoring	Host × sourcetype activity. 2.3.23+ supports breakby_extra_fields.
MHM	Metric Host Monitoring	Hosts × metric category, mstats-based.
VOL	Volume Outliers	Licensed volume per index from the license usage logs (5-minute buckets, incremental). ML outliers (drops / spikes, direction per index), inactivity, daily volume, trend, month projection. 2.4.18+; see *VOL — Volume Outliers*.
FLX	Flex Objects	Custom SPL turned into tracked entities. 65 pre-built templates.
FQM	Field Quality Monitoring	Field parsing quality, CIM compliance.
WLK	WorkLoad Knowledge	Scheduled-search execution health, versioning, orphan, app enablement.

The three **dedicated tenant types** sit outside this matrix on purpose: **User Activity Monitoring** (UAM, 2.4.18+, generally available since 2.4.19), **Cribl Stream** and **Cribl Edge** (2.4.19+). They have no entities, so the state, scoring and alerting capabilities below do not apply to them. Each raises **findings** from a policy catalogue instead, with its own investigation workflow and notifications. See *Findings, Finding groups and findings actions*, *User Activity Monitoring* and *Cribl Stream and Cribl Edge*.

State, scoring, alerting

These capabilities are largely uniform across components — TrackMe was designed so the alerting and scoring experience is the same regardless of what is being monitored.

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Hybrid impact scoring (`total_score`)	Y	Y	Y	Y	Y	Y	Y	Same additive formula across all seven; per-component weight names.
4-state model (green / orange / red / blue)	Y	Y	Y	Y	Y	Y	Y	Same machine across all seven components.
Stateful alerting (open / update / close)	Y	Y	Y	Y	Y	Y	Y	Common `trackme_stateful_alert` action.
Acknowledgments (sticky / unsticky)	Y	Y	Y	Y	Y	Y	Y	Common ACK collection.
Auto-ACK alert action	Y	Y	Y	Y	Y	Y	Y	Triggered on any saved-search firing.
Notable events alert action	Y	Y	Y	Y	Y	Y	Y	One event per fire; not de-duplicated by TrackMe.
Smart Status investigations	Y	Y	P	P	Y	P	Y	DSM / DHM / FLX / WLK have explicit per-component investigation templates; MHM, VOL and FQM inherit the generic outliers template.
Disruption queue (grace period)	Y	Y	Y	Y	Y	Y	Y	Identical code path across components.
Email delivery (SMTP)	Y	Y	Y	Y	Y	Y	Y	Same SMTP account; same stateful helper.
Embedded 24h charts in alert emails	Y	Y	Y	Y	Y	Y	Y	`generate_charts=1` on the alert action. VOL emails carry the rolling volume charts, the outliers chart and a daily licensed-volume bar chart.
AI status reports in alert emails	Y	Y	Y	Y	Y	Y	Y	`ai_status_report=1` on the alert action.
Free-style REST call alert action	Y	Y	Y	Y	Y	Y	Y	Targets any `/trackme/v2/*` endpoint.

Use case unlocked (one line per capability):

- **Hybrid impact scoring —** Each anomaly type contributes additively, so one critical breach trips red immediately while several minor ones accumulate into orange before tripping critical.
- **4-state model —** One uniform "what colour is my donut" semantic across every component, every UI surface, every downstream consumer.
- **Stateful alerting —** One email per real state transition, not one email per evaluation cycle; opens / updates / closes thread together.
- **Acknowledgments —** Silence known issues without losing the underlying state signal. Sticky vs unsticky lets you pick auto-expiry.
- **Auto-ACK —** Pre-emptively suppress notifications for entities matching a pattern ("ACK for 2 h on any red in this group").
- **Notable events —** Feed TrackMe state into Splunk ES / correlation searches / incident platforms via a notable-index event.
- **Smart Status —** When an entity goes red, an investigation search runs once / 24 h and surfaces likely root-cause hypotheses.

- **Disruption queue —** Fewer false-positive pages from 30-second blips; alerts only fire after the configured grace duration of continuous red.
- **Email delivery —** Notifications land in inboxes correctly threaded with embedded charts, no external image fetches.
- **AI status reports —** Recipient sees a 2 – 3 paragraph contextual investigation directly in the email body, not just a link.
- **Free-style REST call alert action —** Wire any TrackMe REST mutation (entity CRUD, mode flip, ACK bulk-op) into a saved-search firing without writing a new alert action.

Classification and protection (policies)

This is the largest cluster of cross-cutting features. Several of them are DSM / DHM specific because they relate to delay / latency thresholds.

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Priority policies (regex / lookup / SPL)	Y	Y	Y	Y	Y	Y	Y	Per-component policy collection.
Tag policies (regex / lookup / SPL)	Y	Y	Y	Y	Y	Y	Y	Multiple matches union.
SLA policies (regex / lookup / SPL)	Y	Y	Y	Y	Y	Y	Y	"Last wins" when multiple policies match.
Labels (catalog-backed coloured chips)	Y	Y	Y	Y	Y	Y	Y	Single catalog per tenant.
Notes (Markdown annotations)	Y	Y	Y	Y	Y	Y	Y	One tenant collection.
Variable delay (time-slot thresholds)	Y	Y	—	—	—	—	—	DSM / DHM only.
Lagging classes (named delay / lag rule sets)	Y	Y	—	—	—	—	—	DSM / DHM only.
Adaptive delay (automated threshold recompute)	Y	Y	—	—	—	—	—	DSM / DHM only. 2.3.23+ also recomputes variable-delay slots.
Variable dynamic thresholds (time-slot KPI thresholds)	—	—	—	—	Y	—	—	FLX only. Different mechanism from DSM/DHM variable delay.
WLK tenant-default threshold row	—	—	—	—	—	—	Y	WLK-only fleet-wide fallback (`object_id == "default"`).
Logical groups (blue protection)	Y	Y	Y	Y	Y	Y	Y	Cross-component membership supported.
Blocklist / Allowlist (regex)	Y	Y	Y	Y	Y	Y	Y	Per-component allowlist collection holding both rule types.
Monitoring-time policy	Y	Y	Y	Y	Y	Y	Y	Tenant default + per-entity override.

Use case unlocked:

- **Priority policies —** Don't manually set priority on 5,000 entities; a regex on the index name covers them.
- **Tag policies —** Routing labels (`team:auth`, `env:prod`) attach automatically and survive entity recreation.
- **SLA policies —** Cleanly bucket entities into platinum / gold / silver uptime tiers per regex or lookup.
- **Labels —** Visual lifecycle workflow (`under-review` → `in-progress` → `resolved`) with curated colours.

- **Notes —** Persist investigation context for the next operator without polluting structured fields.
- **Variable delay —** Don't alert on the expected nightly-batch window; business-hours threshold stays tight.
- **Lagging classes —** Manage thresholds once for 40 high-frequency feeds by editing one class instead of 40 entities.
- **Adaptive delay —** Persistently-red `delay_threshold_breached` entities get their thresholds auto-recomputed from history.
- **Variable dynamic thresholds (FLX) —** Tighter KPI thresholds during business hours, looser overnight, on the same metric.
- **WLK tenant-default threshold row —** Manage skip% / error count / delay thresholds for the whole tenant from one record; per-entity overrides as exceptions.
- **Logical groups —** Don't alert when only 1 of 100 hosts is down; the cluster's green % protects struggling members.
- **Blocklist / Allowlist —** Scope discovery to `index=prod_*` only; never track `sourcetype=.*:debug`.
- **Monitoring-time policy —** Auto-pause monitoring outside business hours; entities go orange (silent) instead of false-positive red.

Discovery, sampling, and quality

These are mostly component-specific signals — DSM-only sampling features, FQM-only CIM templates, WLK-only signals, and DHM-only extras.

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Data sampling (regex format models)	Y	—	—	—	—	—	—	DSM-only — needs raw events.
Elastic sources (external collectors)	Y	—	—	—	—	—	—	DSM-only.
Lookups monitoring (`search_mode=lookups`)	Y	—	—	—	—	—	—	DSM-only; requires `TA-trackme-lookupmonitor`.
CIM-aware field-quality templates	—	—	—	—	—	Y	—	FQM-only.
Sourcetype-explosion safeguard	Y	—	—	—	—	—	—	DSM-only entity-creation hot path.
WLK orphan / versioning / app enablement	—	—	—	—	—	—	Y	WLK-only signals.
DHM `breakby_extra_fields`	—	Y	—	—	—	—	—	DHM hybrid trackers, 2.3.23+, Custom break-by mode only.
History backfill at creation	—	—	—	Y	—	—	—	VOL-only: the license-usage history (default 30 days, 0–400) is replayed automatically so outliers models and the cost trend are usable as soon as the replay completes.
Inactivity policy (static or day-of-week / hour-of-day)	—	—	—	Y	—	—	—	VOL-only: tenant-level policy, overridable per index; an index that stops consuming license turns red.
Outlier detection direction per entity (drops / spikes / both)	—	—	—	Y	—	—	—	VOL-only: chosen per index.
30-day trend, month projection, Global license usage analytics	—	—	—	Y	—	—	—	VOL-only: per-index trend and projection; the **Global license usage (VOL)** Tenant Home tab covers key figures, insights, top consumers, movers, pools, named scopes, working days and holidays, days over quota, opt-in costs and a monthly chargeback per cost centre.

ML and advanced trackers

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Native ML outlier detection	Y	P	P	Y	Y	P	P	**Recommended** for FLX (natural fit); **the primary state signal for VOL** (enabled by default, default model on the rolling 24 h volume, own `vol_mloutliers_*` scope) and the recommended route for volume anomalies in all editions. Optional on DSM (off by default) and selectively useful on DHM. Not recommended for MHM (sparse / categorical), FQM (slow-moving), WLK (discrete metrics). Defaults at tenant creation: on for FLX and VOL; off for DSM, DHM, WLK and FQM.
Hybrid trackers (custom per-entity SPL check)	Y	Y	Y	—	Y	Y	Y	One registry per component. Enterprise caps at 8 per tenant; Foundation rejects; Unlimited uncapped. Not applicable to VOL (its single collector is the tracker).
Replica trackers (one-way entity replication)	Y	Y	Y	—	Y	Y	Y	Source and target component must match. Local decision maker does **not** re-evaluate replicated entities.

Use case unlocked:

- **Native ML outlier detection** — Get alerted on volume / KPI anomalies without writing thresholds; the model learns the normal pattern with optional weekly seasonality.
- **Hybrid trackers** — Add a custom SPL check that contributes to an entity's score; useful when the default tracker cannot reach the data or you need a domain-specific check on top of the built-in tracker.
- **Replica trackers** — Single pane of glass in a central TrackMe across regional TrackMes without running searches on each for every UI refresh.

Integrations

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Remote Splunk accounts (`splunkremotesearch`)	Y	Y	Y	Y	Y	Y	Y	Per-tenant `tenant_account` selects local or a configured remote. Foundation edition does not support remote deployments.
AI Assistant chat (per-entity context)	Y	Y	Y	Y	Y	Y	Y	Entity-level context types exist for all seven components.
AI ML Advisor (interactive + automated batch)	Y	Y	—	Y	Y	Y	Y	Inspects / remediates native ML outlier models; the automated batch covers DSM, DHM, VOL, FLX, FQM, WLK.
AI Components Advisor (Feed Lifecycle / FLX Threshold / FQM / Component Health)	Y	Y	Y	—	Y	Y	Y	No Components Advisor covers VOL; the ML Advisor and the Concierge do.
Topology Studio views (entity nodes)	Y	Y	Y	Y	Y	Y	Y	Any entity from any tenant and component can be placed on a view.
Tenant Home topology graph (link / network)	Y	Y	Y	—	Y	Y	Y	VOL has one entity per index — no hierarchy to draw.
Splunk SOAR push (containers + enrichment)	Y	Y	Y	Y	Y	Y	Y	Component-agnostic; works on any rows producing entities.

Use case unlocked:

- **Remote Splunk accounts —** Monitor any number of remote Splunk deployments from a central TrackMe with HA URLs and automatic token rotation.
- **AI Assistant chat —** Ask "why is this entity red?" on the Tenant Home page and get a context-aware LLM answer that knows the entity's state, policies, recent ACK history, and active Guardian alerts.
- **Splunk SOAR push —** Auto-create SOAR containers from TrackMe alerts for runbook-driven remediation; broker-failover safe.

Multi-tenancy and operations

Cross-cutting capabilities that sit above components. They apply uniformly to every component a tenant has enabled.

Capability	DSM	DHM	MHM	VOL	FLX	FQM	WLK	Notes
Virtual Tenants (isolation, RBAC, indexes)	Y	Y	Y	Y	Y	Y	Y	Components are enabled per tenant via `tenant_components`.
Virtual Groups (read-only cross-tenant cards)	Y	Y	Y	Y	Y	Y	Y	`tenants_scope` carries per-tenant component lists.
RBAC 3-tier (user / power / admin)	Y	Y	Y	Y	Y	Y	Y	Same model regardless of component.
Maintenance mode (runtime alert silencing)	Y	Y	Y	Y	Y	Y	Y	Global or per-tenant; suppresses alerting-path actions.
Maintenance KDB (windows, SLA exclusion)	Y	Y	Y	Y	Y	Y	Y	Scope cascade global / tenant / component / entity.
Bank holidays (SLA exclusion)	Y	Y	Y	Y	Y	Y	Y	Per tenant: inherit the default calendars, selected calendars or none.
Backup & restore (multi-archive 3.0.0)	Y	Y	Y	Y	Y	Y	Y	Tenant archive carries every component's tenant collections.
Configuration Guardian	Y	Y	Y	Y	Y	Y	Y	All registered checks are system- or tenant-scoped, not component-specific.
Schema migrations (per-tenant version)	Y	Y	Y	Y	Y	Y	Y	Each migration may touch any component's collections.
License enforcement (read-only, edition gates)	Y	Y	Y	Y	Y	Y	Y	Foundation gates FLX, FQM and WLK creation (VOL is included in Foundation); Enterprise caps hybrid trackers per tenant.

Configuration touchpoints

Where each capability is configured through TrackMe's native interfaces. System-wide settings and integration accounts are available from the **Configuration** menu; AI providers are under **Artificial Intelligence**. `vtenant_account` is the JSON blob inside the tenant record.

Capability	Touchpoint
Hybrid impact scoring weights	Tenant-level: `vtenant_account.impact_score_*`; entity-level `impact_score_weights` JSON.
Stateful alerting	Alert-action parameters on the saved search (Alert Editor); state in `kv_trackme_common_stateful_alerting_tenant_{tid}`.
Acknowledgments	Tenant Home entity → Ack modal; REST `/trackme/v2/ack/*`.
Auto-ACK / Notable / Free-style REST call / Smart Status	Alert-action parameters on the firing saved search.
Email delivery	Configuration → Manage Email delivery accounts → `trackme_emails.conf`.
AI status reports in alert emails	Alert-action `ai_status_report=1` + `ai_provider_name`; provider configured under Artificial Intelligence → Manage AI Provider accounts.
Disruption queue	System default in `trackme_settings.conf [splk_general]`; per-tenant `vtenant_account.default_disruption_min_time_sec`; per-entity `disruption_min_time_sec`.
Priority / Tag / SLA policies	Tenant Home per-component "Policies" modal; REST `/trackme/v2/splk_<priority|tag|sla>_policies/*`.

continues on next page

Table 1 – continued from previous page

Capability	Touchpoint
SLA classes	Configuration → System settings → SLA (`trackme_settings.conf [sla]`).
Labels (catalog + assignments)	Tenant Home "Manage Labels" modal; REST `/trackme/v2/labels/*`.
Notes	Entity overview "Notes" panel; REST `/trackme/v2/notes/*`.
Variable delay (DSM / DHM)	DSM / DHM entity → "Variable delay threshold" modal; REST `/trackme/v2/splk_variable_delay/*`.
Lagging classes (DSM / DHM)	Tenant Home DSM / DHM "Lagging classes" modal; REST `/trackme/v2/splk_lagging_classes/*`.
Adaptive delay	Per-entity `allow_adaptive_delay`; tracker `trackme_<dsm|dhm>_adaptive_delay_tracker_tenant_<tid>`.
FLX / FQM / WLK dynamic thresholds	Tenant Home per-component "Thresholds" modal; REST `/trackme/v2/splk_<flx|fqm|wlk>/*`.
Logical groups	Tenant Home per-component "Logical groups" modal; REST `/trackme/v2/splk_logical_groups/*`.
Blocklist / Allowlist	Per-component wizard / feed configuration; REST `/trackme/v2/splk_blocklist/*`.
Monitoring-time policy	`vtenant_account.monitoring_time_policy`; per-entity override.
Data sampling (DSM)	DSM tab → "Data sampling" modal; REST `/trackme/v2/splk_data_sampling/*`.
Elastic sources (DSM)	DSM "Elastic sources" wizard; REST `/trackme/v2/splk_elastic_sources/*`.
Lookups monitoring (DSM)	Hybrid Trackers create wizard, Step 1 `search_mode=lookups`; requires companion TA `TA-trackme-lookupmonitor` installed.
WLK orphan / versioning / app enablement	WLK wizard + per-app `kv_trackme_wlk_apps_enablement_tenant_{tid}`.
Sourcetype-explosion safeguard	`trackme_settings.conf [splk_general] sourcetype_max_cap_per_index`.
Native ML outlier detection	Tenant Home per-component "Outliers rules" modal; tenant-level `vtenant_account.mloutliers_<component>`; defaults in `trackme_settings.conf [splk_outliers_detection]`.
VOL detection direction, inactivity policy, backfill	Tenant Home VOL tab (per-index direction and inactivity override, backfill control) and the Global license usage (VOL) tab; tenant inactivity policy and `vol_mloutliers_priority_filter` / `vol_mloutliers_filter_expression` in `vtenant_account`; REST `/trackme/v2/splk_vol/*`.
Hybrid trackers	Tenant Home per-component "Hybrid Trackers" modal / wizard; REST `/trackme/v2/splk_hybrid_trackers/*`; license-edition gated.
Replica trackers	Virtual Tenants "Replica Wizard"; REST `/trackme/v2/splk_replica_trackers/*`; executor `trackme_replica_executor` saved search.
Remote Splunk accounts	Configuration → Manage Remote deployment accounts → `trackme_account.conf`; Audit & troubleshoot → Audit - Splunk Remote Accounts Overview.
AI Assistant (provider config)	Artificial Intelligence → Manage AI Provider accounts → `trackme_ai_provider.conf`; master switch `trackme_settings.conf [trackme_general] enable_ai_assistant`.
AI Assistant (per-tenant)	`vtenant_account.ai_provider_name`, `ai_anonymize_entity_names`.
Splunk SOAR	`vtenant_account.soar_*`; REST `/trackme/v2/splk_soar/*`; commands `trackmesplksoar` and `trackmesplksoarlookup`.
Virtual Tenants	Virtual Tenants → Configure tenant (per-tenant 3-dot menu); REST `/trackme/v2/vtenants/admin/*`.
Virtual Groups	Virtual Tenants page Create Virtual Group wizard; REST `/trackme/v2/virtual_groups/*`.

continues on next page

Table 1 – continued from previous page

Capability	Touchpoint
RBAC (per-tenant roles)	Splunk roles (`trackme_<admin|power|user>_<tid>`) + tenant record's `rbac_<admin|power|user>_roles` fields.
Maintenance mode	Maintenance Mode page; REST `/trackme/v2/maintenance/*`; tracker `trackme_maintenance_mode_tracker`.
Maintenance KDB	Maintenance KDB page; REST `/trackme/v2/maintenance_kdb/*`.
Bank holidays	Manage Bank Holidays page; REST `/trackme/v2/bank_holidays/*`; per-tenant scope `vtenant_account.bank_holidays_scope` and `bank_holidays_calendars`.
Backup & restore	Backup & Restore page; REST `/trackme/v2/backup_and_restore/*`; scheduler `trackme_backup_scheduler`.
Configuration Guardian	Surfaced as toasts on Virtual Tenants page; REST `/trackme/v2/configuration/admin/guardian_alerts`, `dismiss_guardian_alert`, `run_guardian_checks`.
Schema migrations	Per-tenant `schema_version` field; runs at tenant create / upgrade / load.
License	License page; REST `/trackme/v2/licensing/*`; watermark in `trackme_settings.conf` (HMAC-SHA256).

What does not apply, and why

DSM-only capabilities

- **Data sampling —** Inspects raw events; needs `index + sourcetype + _raw`. DHM works off ingest metadata (no raw text), MHM is metric data, FLX / FQM / WLK build their own metric shape.
- **Elastic sources —** A DSM entity is the right granularity for "is this external collector producing data?".
- **Lookups monitoring —** Lookup files / KVstore collections are configuration artefacts, not data feeds; DSM is the closest model. Operates with neutralised latency (no `_indextime` exists for lookups) and a single delay-threshold alerting hook.
- **Sourcetype-explosion safeguard —** Bulk DSM creation discovers an `(index, sourcetype)` matrix that can blow up if a pipeline mis-routes events. Other components do not pivot on this discovery axis.

DSM + DHM only (not MHM / VOL / FLX / FQM / WLK)

- **Variable delay —** Day-of-week × hour-of-day thresholds make sense for data feeds and per-host streams that have legitimate cadence variation. MHM uses static thresholds.
- **Lagging classes —** Same rationale; only meaningful for delay / latency-based components.
- **Adaptive delay —** Recomputes `data_max_delay_allowed` (and variable-delay slot thresholds since 2.3.23) from historical metrics. Only meaningful for components with a single `delay` axis to recompute.

WLK-only signals

- **Orphan, versioning, app enablement —** They describe properties of a Splunk scheduled search and its hosting app. Not applicable to data feeds, hosts, custom SPL trackers, or field-quality entities.
- **Tenant-default threshold row (``object_id == "default"``) —** WLK-specific fallback for "manage thresholds once for the whole tenant, override per entity as exceptions".

FQM-only

- **CIM-aware templates —** FQM is purpose-built for "is this CIM data-model field being parsed correctly?". The other components do not evaluate per-field coverage / success metrics.

DHM-only (2.3.23+)

- ``**breakby_extra_fields**`` — Extra metadata dimensions on top of `(index, sourcetype)` for DHM hybrid trackers in Custom break-by mode. Specific to how DHM groups per-host activity.

FLX-only

- **Variable dynamic thresholds (time-slot KPI thresholds)** — FLX supports day-of-week × hour-of-day slots on its dynamic threshold evaluator. This is a different mechanism from DSM / DHM variable delay — variable delay applies to feed delay thresholds, variable dynamic thresholds apply to any FLX KPI.

VOL-only

- **History backfill, inactivity policy, detection direction, month projection, Global license usage analytics** — VOL tracks one signal (licensed volume per index, from the license usage logs) whose state is the ML outlier verdict plus inactivity. There are no delay / latency thresholds, no dynamic thresholds and no raw events to sample, so none of the feed- or threshold-specific capabilities apply; the VOL-specific rows above exist because that signal needs a history to learn from (backfill), a silence rule (inactivity policy) and a cost reading (trend, projection, global analytics).
- **No hybrid or replica trackers** — the VOL tracker is a single incremental collector per tenant; there is no per-entity SPL to customise and no replica path.
- **No Tenant Home topology graph** — one entity per index leaves no hierarchy to draw; VOL entities are placed in Topology Studio views like any other component.

Outlier-detection recommendation

FLX is recommended (numeric KPIs are natural density-function candidates); on VOL outliers are the point of the component and are on by default — VOL, available in all editions, is the recommended route for volume anomalies, keeping outliers detection separate from feed monitoring. DSM is optional and off by default at tenant creation. DHM is selective ("per-host volume can be noisy"). MHM, FQM, WLK are not recommended:

- **MHM** — Metric streams are too sparse or too categorical for density modelling.
- **FQM** — Field-quality metrics are slow-moving and regime-dependent; thresholds are the right tool.
- **WLK** — Scheduler metrics are discrete (skip count, error count); again, thresholds are better.

Smart Status template coverage

Smart Status investigation templates are documented for DSM, DHM, FLX, WLK anomalies (delay, future data, latency, hosts dcount, inactivity, threshold, skip, error, orphan). MHM and FQM fall through to a generic outliers template — marked `P` in the matrix.

Replica trackers and the decision maker

Replica trackers replicate an entity set but the **local decision maker does not re-evaluate** them — it trusts the source's state. So while the matrix shows `Y` across the six components that support them (replica trackers work on any component except VOL), the surrounding capabilities (logical groups, disruption queue, policies) only apply to **non-replicated** entities in that component; on replicated entities they are inert by design.

License-edition gating

- Foundation edition supports DSM / DHM / MHM / VOL only; FLX, FQM and WLK rows in the matrix are still `Y` (the capability exists), but Foundation tenants cannot create FLX / FQM / WLK entities.
- Enterprise caps hybrid trackers at 8 per tenant; Foundation rejects hybrid-tracker creation; Unlimited is uncapped.
- Read-only mode (license expired) disables creation / editing across all seven components without removing the capabilities themselves.

FLX (Flex Objects) Use Case Template Catalog

What this page is

The full catalog of every pre-built FLX use case template that ships with TrackMe — 65 templates in v2.3.23, grouped by category, with metrics, schedule, source data, dependencies, and ML-outlier flag per entry.

The page ends with a **gap-analysis checklist** organised by domain (license, indexer cluster, ingestion, SH workload, good practices, data quality, Cribl, SOAR, host OS, …) — work through it one question at a time when auditing an existing TrackMe deployment.

Catalog version
TrackMe v2.3.23 (65 templates).

Where the source lives
`package/lib/flx_library/<uc_ref>.json` inside the TrackMe Splunk app — one JSON file per template.

Introduction

TrackMe's **Flex Objects (FLX)** component turns any Splunk SPL search into a tracked entity with custom KPIs, dynamic thresholds and stateful alerting. Out of the box, TrackMe ships **65 pre-built FLX templates** that cover the most common monitoring needs across Splunk Enterprise, Splunk Cloud, Splunk SOAR, Cribl Stream / Cribl Edge, and the canonical Splunk technology add-ons (TA-nix, Splunk_TA_windows).

Every template declares:

- `uc_ref` — template identifier (matches the filename without `.json`).
- `uc_vendor` — broad provenance: `Splunk` or `Cribl`.
- `uc_category` — finer-grained grouping used in the wizard.
- `uc_description` — one-sentence intent shown before creation.
- `uc_earliest` / `uc_latest` — relative time bounds of the SPL.
- `uc_cron` — schedule for the generated saved-search.
- `uc_metrics` — flat list of KPI names produced by the search.
- `uc_implementation_comments` — pre-requisites, caveats, documentation links.
- `uc_search` — the SPL backing the use case (not reproduced here — see source).

Of the 65 templates:

- **2 vendors** are represented — Splunk (54 templates) and Cribl (11).
- **11 categories** group them — see the per-category tables below.
- **20 templates** opt into native ML outlier detection by emitting an `outliers_metrics` block in their SPL (flagged `yes` in the *Outlier-friendly?* column).
- Schedules range from every 5 min (the majority) through half-hourly, hourly and twice-daily, down to a handful of once-a-day batch searches anchored at quiet hours (license rollups around 03:00 – 04:00 UTC, field-quality at 06:00 UTC).

How to read the schedule column

- `*/5 * * * *` → every 5 minutes
- `*/15 * * * *` → every 15 minutes
- `*/30 * * * *` → every 30 minutes
- `0 * * * *` → hourly on the hour

- `0 */12 * * *` → every 12 hours (00:00 and 12:00 UTC)
- `5 3 * * *` → daily at 03:05 UTC
- `10 4 * * *` → daily at 04:10 UTC
- `15 4 * * *` → daily at 04:15 UTC
- `0 6 * * *` → daily at 06:00 UTC

All schedules run against the **tenant's local time-zone interpretation** once dispatched by the Splunk scheduler.

How to read the source-data column

- `_internal` — Splunk's own indexed logs (`splunkd.log`, `license_usage.log`, `metrics.log`, …).
- `_introspection` — host resource usage, KV-store stats, scheduler diagnostics.
- `_dsphonehome` — deployment-server phone-home events.
- `cribl_metrics` — Cribl-emitted internal metrics indexed on the Splunk side.
- `_cmc_summary` / `summary` — Splunk Cloud monitoring summary events (CMC).
- `mgmt API (| rest)` — Splunk REST endpoint executed in-search.
- `Cribl API (| cribl)` — out-of-band call via `TA-trackme-cribl`.
- `SOAR API (| trackmesplksoar)` — out-of-band call to a SOAR controller.
- `Custom index` — anything else (`phantom_action_run`, `lastchanceindex`, `trackme:fields_quality`).
- `tstats` / `mstats` — tsidx / metric store; the actual index is parameter-driven.

How to read the dependency column

- `none` — pure Splunk; runs against indexers / SH out of the box.
- `TA-trackme-cribl` — required for any `| cribl …` command.
- `Splunk_TA_cribl + cribl_metrics index` — required for `mstats` against Cribl-emitted metrics indexed in Splunk.
- `TA-nix` — required for `cpu_metric` / `vmstat_metric` source-types.
- `Splunk_TA_windows` — required for `Perfmon:*` source-types.
- `Splunk DB Connect` — required to monitor JDBC inputs.
- `Splunk App for SOAR / SOAR integration` — required for `| trackmesplksoar`.
- `sa-littlehelper` — Splunk SA app providing `| bundlefiles` (Splunkbase #6368).
- `TrackMe remote account` — when the search is meant to run against a remote Splunk via `splunkremotesearch`.

See *TrackMe Ecosystem — Companion Add-ons* for the full companion-add-on inventory.

Catalog by category

cribl_edge

Two templates covering Cribl Edge fleet health, one via the Cribl management API and one via Cribl's internal metrics indexed inside Splunk.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
cribl_edge_f	Cribl	Polls Cribl Edge worker nodes via the Cribl management API and alerts if a node stops heartbeating.	cribl.edge.delay_since_l	every 5 min	Cribl API (| cribl)	TA-trackme-cribl	no
cribl_edge_f	Cribl	Uses Cribl Edge internal metrics indexed in Splunk to compute per-host event-delay and surface silent nodes.	cribl.edge.delay_event_s	every 5 min	mstats on cribl_me	Splunk_TA_ + cribl_met index	no

cribl_logstream

Nine templates that wrap the canonical Cribl Stream health, traffic and resource metrics. Traffic-flow templates (route / pack / pipeline / total in / out) are outlier-friendly so you get drift detection out of the box.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
cribl_logstream	Cribl	Tracks the percentage of healthy Cribl Stream inputs by input type and group.	cribl_logstr health. health_input	every 5 min	mstats on cribl_me	Splunk_TA_	no
cribl_logstream	Cribl	Tracks the percentage of healthy Cribl Stream outputs (devnull excluded) and surfaces unhealthy destinations.	cribl_logstr health. health_outpu	every 5 min	mstats on cribl_me	Splunk_TA_	no
cribl_logstream	Cribl	Watches per-host CPU consumption across the Cribl Stream worker fleet (avg / max / p95).	cribl_logstr {avg,max, perc95}_cpu_	every 5 min	mstats on cribl_me	Splunk_TA_	no
cribl_logstream	Cribl	Detects blocked and back-pressured outputs that are starving the pipeline.	cribl_logstr output. {blocked, backpressure	every 5 min	mstats on cribl_me	Splunk_TA_	no
cribl_logstream	Cribl	Tracks per-Pack event volume in / out and applies ML outlier detection to spot abnormal pack-level traffic.	cribl_logstr pack. pack_{in, out}_events	every 5 min	mstats on cribl_me	Splunk_TA_	yes
cribl_logstream	Cribl	Tracks per-pipeline event in / out / dropped and their pct sent vs pct dropped to flag silently dropping pipelines.	cribl_logstr pipeline. {in,out, dropped}_eve pct_{sent, dropped}_eve	every 5 min	mstats on cribl_me	Splunk_TA_	yes
cribl_logstream	Cribl	Per-route in / out bytes and events with ML outlier detection — catches abnormal traffic shifts on a specific route.	cribl_logstr route. route_{in, out}_{bytes, mbytes, events}	every 5 min	mstats on cribl_me	Splunk_TA_	yes
cribl_logstream	Cribl	Aggregate input throughput per input source (bytes + events) with outlier detection.	cribl_logstr total. total_in_{by events, mbytes}	every 5 min	mstats on cribl_me	Splunk_TA_	yes
cribl_logstream	Cribl	Aggregate output throughput per destination (bytes + events) with outlier detection.	cribl_logstr total. total_out_{b events, mbytes}	every 5 min	mstats on cribl_me	Splunk_TA_	yes

splunk_infrastructure

The largest category — 17 templates covering indexer / SH / KV-store / cluster health, parsing quality, queue saturation, and forwarder fleet tracking. This is where most "is Splunk healthy?" alerts live.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
splk_bucket_health	Splunk	Per-index bucket health — surfaces prematurely-rolled (small) buckets and quarantined buckets (a typical symptom of timestamp parsing failures).	splunk.bucket.{healthy_pct small_pct, quarantined_ total_count oldest_event index_range_	every 30 min	| dbinspect	none	no
splk_bundle_size	Splunk	Knowledge-bundle size per app on the SH tier — a bloated bundle slows search dispatch.	splk.bundle_size_	every 15 min	| bundlefiles	sa-littlehelper (Splunkbase #6368)	no
splk_deployment_se	Splunk	Identifies deployment-server clients that have stopped phoning home (silent UF dropout).	ds.time_since_l	every 5 min	_dsphonehome	none	no
splk_dma	Splunk	Data Model Acceleration completeness, size, run duration and bucket count — surfaces stuck DM accelerations with ML outliers.	dma.{complete_p size_mb, runduration_ buckets_cou	every 5 min	mgmt API (/servicesadmin/summari	none	yes
splk_kvstore_size	Splunk	Per-collection KV-store size against thresholds + total KV-store size.	infrastructu kvstore.alltime.total_size_ size_alert.detected_co	every 5 min	_introspection via /servicesserver/introsp kvstore collect	none	no
splk_kvstore_statu	Splunk	KV-store service readiness — alerts when the KV-store goes degraded / down.	(status only, no numeric metric)	every 5 min	mgmt API (/servicekvstore status)	none	no
splk_large_lookup_	Splunk	Detects oversized lookup files that slow bundle replication, with outlier detection on total lookup size.	lookups.total_size_	every 12 hours	mgmt API (/data/transfolookups	none	yes
splk_parsing_issue	Splunk	Aggregates WARN / ERROR from LineBreakingProcessor / AggregatorMiningProcessor / DateParserVerbose — the canonical bad-props.conf symptoms.	splunk.parsing.errors_count + dcount of sourcetypes / sources / hosts	hourly	_internal (splunkd.l	none	no
splk_queues_fillin	Splunk	Tracks indexing-pipeline queue fill (parsing, aggregator, typing, indexer) — surfaces backpressure indicating scale issues.	queue.avg_pct_fil queue.max_queue_f …	every 5 min	_internal (metrics.log)	none	no
splk_search_head_a	Splunk	Search-head scheduler activity (eligible / dispatched / completed / lag / runtime) with ML outliers — catches drift	sh.{actions_tr active_hist active_sear delayed,	every 5 min	_internal	none	yes

splunk_data_collection

Nine templates focused on the data flowing **into** Splunk — license volume, event / host drop detection, HEC errors, DB Connect inputs, and basic host tracking.

Note

Since TrackMe 2.4.18 the **VOL** (Volume Outliers) component covers per-index licensed volume out of the box — ML outliers, inactivity, daily volume, trend and projection, with the history backfilled at creation (*VOL — Volume Outliers*). The license-usage templates below (`splk_detect_daily_variations_volume_*`, `splk_license_usage_per_index_*`) remain available for custom needs.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
splk_dbconnect	Splun	DB Connect modular-input health — alerts if a JDBC input is disabled.	(state only, no numeric metric)	every 5 min	mgmt API (/configs conf-db	Splunk DB Connect	no
splk_detect_daily_v	Splun	Daily global license-pool volume with ML outliers — catches abnormal day-over-day spikes.	license.volume_mb	daily @ 04:10 UTC	_internal (license_usa	none	yes
splk_detect_daily_v	Splun	Daily license volume per index with ML outliers — same as global but per-index granularity.	license.pool_volume	daily @ 04:15 UTC	_internal (license_usa	none	yes
splk_detect_drop_ev	Splun	Hourly per-index event count and distinct host count (absolute window) with ML outliers — catches feed drop-outs.	splunk.feeds.idx.{events_coudcount_host	hourly	tstats	none	yes
splk_detect_drop_ev	Splun	Same as absolute but with a rolling time window for near-real-time drop detection.	splunk.feeds.idx.{events_coudcount_host	every 5 min	tstats	none	yes
splk_hosts_tracking	Splun	Simple per-host data-arrival tracking by index + sourcetype — surfaces silent hosts.	delay_event_sdelta_inges	every 5 min	tstats	none	no
splk_lastchanceinde	Splun	Detects events landing in lastchanceindex (a sign of routing / parsing misconfiguration).	lastchancei{events_cousourcetypes	every 5 min	Custom index (lastcha	none	no
splk_splunk_hec_err	Splun	HEC parsing errors broken down by parsing_err with source-IP dcount.	splunk_hec.{errors_couparsers_in_sources_ip_	every 10 min	_internal (HttpInput-DataHandler)	none	no
splk_volume_ingeste	Splun	Per-index daily ingested volume (license-based) with ML outliers to catch unexpected daily drops.	splunk.license.daily_volum	daily @ 03:05 UTC	_internal (license_usa	none	yes

splunk_enterprise

Splunk-Enterprise-specific licensing templates — license pool, license volume rolling windows. (The two cluster-status templates `splk_splunk_enterprise_cluster_peers_status` and `splk_splunk_enterprise_cluster_status` are tagged with this category in source but documented above under *splunk_infrastructure* because they share the cluster-health theme — readers should consult either table.)

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
`splk_license_pool_us`	Splun	Per-pool % used and absolute GB used against the licensed pool quota — alerts when a pool approaches saturation.	`license.{pool_pct_u pool_used_g`	every 5 min	mgmt API (`/services license pools`)	none	yes
`splk_license_usage_g`	Splun	Rolling global license usage at 60 min / 4 h / 24 h horizons (volume + % pool) with ML outliers — designed for near-real-time anomaly detection.	`splunk.license.last_{60m, 4h, 24h}_volume.. pool_pct_us`	every 5 min	`_internal` (license_us	none	yes
`splk_license_usage_p`	Splun	Same as global but per-index — pinpoints which index is driving a license spike.	`splunk.license.last_{60m, 4h, 24h}_volume.. pool_pct_us`	every 5 min	`_internal` (license_us	none	yes

splunk_cloud

Six Splunk-Cloud-only templates — storage, SVC consumption (global, per app, per consumer service) and rolling license volume.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
splk_license_usage_g	Splun	Splunk Cloud global rolling license usage (60 min / 4 h / 24 h) with ML outliers.	splunk.license.last_{60m,4h,24h}_volume	every 5 min	_internal (license_us	none	yes
splk_license_usage_p	Splun	Splunk Cloud per-index rolling license usage with ML outliers.	splunk.license.last_{60m,4h,24h}_volume	every 5 min	_internal (license_us	none	yes
splk_splunk_cloud_st	Splun	Splunk Cloud stack storage used vs licensed and % consumption against acceptable thresholds.	splunk_clou storage.{storage_us used_pct, license_GB}	every 5 min	_cmc_su (splunk	none	no ary)
splk_splunk_cloud_sv	Splun	Splunk Cloud stack SVC usage % vs licensed SVC for the whole stack, with ML outliers.	splunk_clou svc.{pct_svc_us utilized_sv license_svc	every 5 min	_cmc_su (splunk	none	yes
splk_splunk_cloud_sv	Splun	Per-app SVC consumption attribution.	splunk_clou svc.{pct_svc_us utilized_sv	every 5 min	_cmc_su (splunk	none	yes tribution)
splk_splunk_cloud_sv	Splun	Per-consumer-service SVC attribution (adhoc, scheduled, …).	splunk_clou svc.{pct_svc_us utilized_sv	every 5 min	_cmc_su (splunk	none	yes tribution)

splunk_soar

Nine templates wrapping the TrackMe SOAR integration — adhoc / playbook action failures, playbook concurrency, asset health, automation-broker HA, infra load / memory, service health, and Splunk-forwarding back into Splunk.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
splk_soar_actions_ad	Splun	Adhoc SOAR action failures (no playbook) — counts total / success / failed.	soar.adhoc.actions_cou _failed, _success}	every 15 min	Custom index (phanto	SOAR-to-Splunk forwarding	no
splk_soar_actions_pl	Splun	Playbook-driven SOAR action failures — counts total / success / failed.	soar.playbook.actions_cou _failed, _success}	every 15 min	Custom index (phanto	SOAR-to-Splunk forwarding	no
splk_soar_assets_hea	Splun	Active asset connectivity check against SOAR assets via the SOAR API.	(status only)	every 30 min	SOAR API (trackm	Splunk App for SOAR integration + automation user	no
splk_soar_automation	Splun	Automation-broker HA management — monitors broker pool members and updates assets when a broker goes inactive.	(operational state)	every 5 min	SOAR API	Splunk App for SOAR integration	no
splk_soar_concurrent	Splun	SOAR playbook concurrency by status (success / waiting / running / failed / cancelled) with ML outliers.	soar.playbook_st {success, waiting, running, failed, cancelled}	every 5 min	SOAR API	Splunk App for SOAR integration	yes
splk_soar_forwarding	Splun	SOAR → Splunk forwarding health — counts containers indexed and time-since-last-container, surfacing forwarder breakage.	soar.{containers containers_	every 5 min	tstats on phantom_*	SOAR-to-Splunk forwarding	no
splk_soar_infra_load	Splun	SOAR CPU load (1, 5, 15 min) with ML outliers.	(load metrics)	every 5 min	SOAR API	Splunk App for SOAR integration	yes
splk_soar_infra_memo	Splun	SOAR memory used / cached / free + percentages with ML outliers.	(memory metrics)	every 5 min	SOAR API	Splunk App for SOAR integration	yes
splk_soar_services_h	Splun	SOAR services health from the API — surfaces stopped or degraded services.	(status only)	every 5 min	SOAR API	Splunk App for SOAR integration	no

splunk_good_practices

Three templates that flag anti-patterns: searches scheduled with `all time` earliest, searches owned by a real user instead of `nobody`, and dynamic sourcetypes (numerically-suffixed `foo-1234` style).

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
`splk_good_practices_all`	Splun	Enabled scheduled searches running over `all time` — a notorious cost driver.	`good_pract splunk. alltime_sc`	every 12 hours	mgmt API (`saved/ searche`	none	no
`splk_good_practices_det`	Splun	Detects dynamic sourcetypes (regex match on `-\d+$`) for review.	`splunk_goo dyn_source {detected_ total_sour regular_so`	every 12 hours	`tstats`	none	no
`splk_good_practices_run`	Splun	Scheduled searches running on behalf of a named user (vs `nobody` / service account) — a fragility risk on user offboarding.	`good_pract splunk. runasuser_`	every 12 hours	mgmt API (`saved/ searche`	none	no

splunk_data_quality

A single template that wraps TrackMe's fields-quality monitoring approach.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
`splk_splunk_fields_q`	Splun	Aggregates per-(source, sourcetype, host) field-quality check outcomes — % passed / failed and totals; ML outliers for drift.	`percentage_ failed}, total_field failed, passed}`	daily @ 06:00 UTC	Custom (`index= source- type=tr`	TrackMe fields-quality plumbing	yes `quality)`

ta_nix

Two templates leveraging the Splunk TA-nix metric input.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
`ta_nix_cpu_usag`	Splunk	Per-host avg / max / p95 CPU usage from TA-nix `cpu_metric`, enriched with OS / IP metadata.	`ta_nix. {avg,max, p95}_cpu_usa`	every 5 min	`mstats` on `cpu_metr`	TA-nix	no
`ta_nix_mem_usag`	Splunk	Per-host avg / max / p95 memory usage from TA-nix `vmstat_metric`, enriched with total memory.	`ta_nix. {avg,max, p95}_mem_use`	every 5 min	`mstats` on `vm- stat_met`	TA-nix	no

ta_windows

Two templates leveraging the Splunk TA for Windows Perfmon source-types.

uc_ref	Vendor	What it detects / monitors	Metrics produced	Schedule	Source data	Dependencies	Outliers?
ta_windows_cpu_us	Splunl	Per-host avg / max / p95 CPU usage from Perfmon:CPU / % Processor Time.	ta_windows.{avg,max,p95}_cpu_usa	every 5 min	mstats on Perfmon:CPU	Splunk_TA_	no ows
ta_windows_mem_us	Splunl	Per-host avg / max / p95 memory usage from Perfmon:Memory / % Committed Bytes In Use.	ta_windows.{avg,max,p95}_mem_us	every 5 min	mstats on Perfmon:Mem	Splunk_TA_	no ows

Cross-cutting observations

ML outlier coverage

Twenty of the 65 templates pre-wire native ML outlier detection (an `outliers_metrics` block in their SPL). Concentrated in:

- license / volume / SVC consumption — `splk_detect_daily_variations_volume_*`, `splk_license_*`, `splk_volume_ingested_per_day`, `splk_splunk_cloud_svc_usage*`,
- Cribl Stream traffic-flow — `cribl_logstream_{route,pack,pipeline,total_traffic_*}`,
- Splunk infra activity — `splk_search_head_activity`, `splk_search_head_healthmon_artifact_count_remote`, `splk_splunk_infra_log_level_variations`, `splk_dma`, `splk_large_lookup_files`,
- SOAR runtime — `splk_soar_concurrent_playbooks`, `splk_soar_infra_{load,memory}`,
- Data-quality drift — `splk_splunk_fields_quality`,
- Event-count drop detection — `splk_detect_drop_events_count_{absolute,rolling}`.

These are the templates to keep enabled when you turn on native outlier detection in a tenant. See *Outlier detection*.

Schedule cadence distribution

- **5-minute cadence** — 48 templates (the default for near-real-time health).
- **10 – 15-minute cadence** — 3 templates (`splk_bundle_size`, `splk_splunk_hec_errors`, the two SOAR action-failure templates).
- **30-minute cadence** — 3 templates (`splk_bucket_health_per_index`, `splk_splunk_infra_log_level_variations`, `splk_soar_assets_health`).
- **Hourly** — 2 templates (`splk_parsing_issues_per_component`, `splk_detect_drop_events_count_absolute`).
- **Every 12 hours** — 4 templates (the three `splunk_good_practices` + `splk_large_lookup_files`).
- **Daily** — 4 templates (the three license-roll-up templates at 03:05 / 04:10 / 04:15 UTC, and `splk_splunk_fields_quality` at 06:00 UTC).

Important

When enabling a large number of templates simultaneously, watch your SH scheduler load — the 48 five-minute templates dispatched at `*/5 * * * *` will all queue at the same minute mark. Consider staggering by editing `uc_cron` to use offsets (e.g. `*/5 * * * *` for some, `1-59/5 * * * *` for others) at enablement time.

Source-data hot spots

- `license_usage.log` (`_internal`) is touched by 6 templates — license is the single most-monitored signal in the catalog.
- `_internal` and `_introspection` combined back the bulk of Splunk infra templates — no external add-on needed.
- `mstats` is the workhorse for all Cribl, TA-nix and TA-windows templates — metric-store performance matters for these.
- `| rest` against the local management API powers SHC, indexer cluster, KV-store, DMA, lookups, DB-Connect and good-practices templates — these are cheap but require the right capabilities on the running role.

Gap-analysis prompts

Use the catalog above as a checklist. The following questions help you spot coverage gaps you may not have realised you had — work through them one by one when reviewing a tenant's FLX inventory.

License & cost

- Am I monitoring **per-index license volume** so I can attribute spikes and drops? (the **VOL** component, *VOL — Volume Outliers*; legacy template `splk_license_usage_per_index_*`)
- Am I monitoring **global license volume** with ML outlier detection? (`splk_license_usage_global_splunkenterprise` / `..._splunkcloud`; the VOL Global license usage tab for the environment-wide reading)
- Am I monitoring **license pool % used** (Splunk Enterprise)? (`splk_license_pool_usage`)
- On Splunk Cloud, am I tracking **storage usage**? (`splk_splunk_cloud_storage_usage`)
- On Splunk Cloud, am I tracking **SVC usage globally, by app and by consumer**? (`splk_splunk_cloud_svc_usage*`)
- Do I have a **daily licensing roll-up** I can correlate with billing? (`splk_volume_ingested_per_day`, `splk_detect_daily_variations_volume_*`)

Splunk indexer / cluster health

- Am I catching **SHC member dropout**? (`splk_splunk_shc_global_status`, `splk_splunk_shc_members_status`)
- Am I catching **indexer cluster degradation** and balancing deviation? (`splk_splunk_enterprise_cluster_status`, `splk_splunk_enterprise_cluster_peers_status`)
- Am I tracking the **search head remote artifact count**, especially across SHC members? (`splk_search_head_healthmon_artifact_count_remote`)
- Am I monitoring **bucket health** (small + quarantined buckets — the timestamp-parsing canary)? (`splk_bucket_health_per_index`)
- Am I watching **queue saturation** at the indexer tier? (`splk_queues_filling`)
- Am I watching **KV-store status and size**? (`splk_kvstore_status`, `splk_kvstore_size`)
- Am I tracking the **bundle size** on the SH tier? (the silent search- slowdown source) (`splk_bundle_size`)
- Am I watching **lookup file sizes** before they blow up bundle replication? (`splk_large_lookup_files`)

Data collection & ingestion

- Am I catching **silent feed drops** (event count or host count collapsing)? (`splk_detect_drop_events_count_absolute` / `..._rolling`)
- Am I catching **silent host dropout**? (`splk_hosts_tracking`)

- Am I monitoring the **last-chance-index** for routing / parsing misconfiguration? (`splk_lastchanceindex`)
- Am I monitoring **HEC parsing errors** and their source IPs? (`splk_splunk_hec_errors`)
- Am I monitoring **DB Connect** modular inputs? (`splk_dbconnect`)
- Am I monitoring **deployment-server clients** that stop phoning home? (`splk_deployment_server_clients`)
- Am I monitoring **UF version compliance** across my forwarder fleet? (`splk_uf_clients_versions_tracking`)
- Am I catching **parsing-time errors** (LineBreaking / Aggregator / DateParser warnings)? (`splk_parsing_issues_per_component`)

Search-head workload & performance

- Am I monitoring **SH scheduler activity** (lag, dispatched, eligible)? (`splk_search_head_activity`)
- Am I monitoring **DMA acceleration completeness** to catch stuck accelerations? (`splk_dma`)
- Am I monitoring **Splunk log-level variations** to catch error storms early? (`splk_splunk_infra_log_level_variations`)

Splunk good practices

- Am I auditing **all-time scheduled searches**? (`splk_good_practices_alltime_scheduled`)
- Am I auditing **scheduled searches that run as a real user** (offboarding risk)? (`splk_good_practices_run_as_user_scheduled`)
- Am I auditing **dynamic sourcetypes** that bloat the metadata cache? (`splk_good_practices_detect_dynamic_sourcetype`)

Data quality

- Am I running **fields-quality monitoring** with ML outliers on the CIM-mapped data sources? (`splk_splunk_fields_quality`)

Cribl Stream / Cribl Edge

- Am I monitoring **input and output health %** across the Cribl Stream fleet? (`cribl_logstream_health_inputs`, `cribl_logstream_health_outputs`)
- Am I detecting **blocked or back-pressured outputs**? (`cribl_logstream_output_destination_pressure`)
- Am I tracking **route / pack / pipeline traffic shifts** with ML outliers? (`cribl_logstream_{route,pack,pipeline,total_traffic_inputs,total_traffic_outputs}`)
- Am I tracking **Cribl host CPU usage**? (`cribl_logstream_hosts_cpu_usage`)
- Am I tracking **Cribl Edge node heartbeats** (API or indexed metrics)? (`cribl_edge_fleet_api`, `cribl_edge_fleet_metrics`)

SOAR

- Am I tracking **SOAR playbook failures** and adhoc-action failures? (`splk_soar_actions_playbooks_failures`, `splk_soar_actions_adhocs_failures`)
- Am I tracking **playbook concurrency** by status? (`splk_soar_concurrent_playbooks`)
- Am I tracking **SOAR asset health** with an active connectivity check? (`splk_soar_assets_health`)
- Am I managing **automation broker HA**? (`splk_soar_automation_brokers_manage`)
- Am I tracking **SOAR services health** (which daemons are alive)? (`splk_soar_services_health`)

- Am I tracking **SOAR infrastructure load and memory**? (`splk_soar_infra_load`, `splk_soar_infra_memory`)
- Am I tracking **SOAR-to-Splunk forwarding** (so I notice when SOAR stops shipping containers)? (`splk_soar_forwarding_splunk`)

Host OS metrics (if you collect them in Splunk)

- Am I tracking **Linux CPU / memory** for hosts running TA-nix? (`ta_nix_cpu_usage`, `ta_nix_mem_usage`)
- Am I tracking **Windows CPU / memory** for hosts running Splunk_TA_windows? (`ta_windows_cpu_usage`, `ta_windows_mem_usage`)
- Am I monitoring **Splunk-instance CPU / memory** from introspection (separate from the OS-level TA above)? (`splk_splunk_infra_cpu_used`, `splk_splunk_infra_mem_used`)

Coverage gaps not addressed out of the box

A few common monitoring needs are **not** covered by the pre-built FLX library and require either a custom FLX use case (the wizard supports it) or a different TrackMe component:

- **Authentication failure spikes** (login storms, brute-force) — not in FLX library; build a custom FLX, or rely on Splunk ES.
- **Scheduler skipped-search ratios per user / app** — partially covered by the WLK component (see *WLK — Workload Knowledge*).
- **Field-extraction performance per sourcetype** — handled by the FQM component (see *Use Case Demo: Fields Quality (CIM and non-CIM)*).
- **Saved-search execution failures** — handled by WLK, not FLX.
- **Splunkbase app version drift** — no template; would require a custom FLX pulling `/services/apps/local`.
- **Bucket replication factor / search factor mismatch** — partially surfaced by `splk_splunk_enterprise_cluster_peers_status`, but no dedicated alert.
- **Cribl Stream worker node version drift** — no template; equivalent of `splk_uf_clients_versions_tracking` for Cribl would need a custom FLX.
- **Splunk Cloud index growth forecasting** — no template; storage % is monitored but trend-based forecasting is left to custom searches.

If you spot a recurring need not covered above, the FLX wizard is the supported way to extend the catalog — see *FLX — Flex Objects*. Contributing a JSON file back to `package/lib/flx_library/` makes it available to every TrackMe deployment.

Appendix — source files

All 65 templates live under `package/lib/flx_library/<uc_ref>.json` inside the TrackMe Splunk app. The JSON schema is shared across templates; consult any file for the full set of fields including `uc_earliest` / `uc_latest` time bounds, `uc_implementation_comments` for caveats and prerequisites, and `uc_search` for the actual SPL.

TrackMe Ecosystem — Companion Add-ons

What this page is

An inventory of every TrackMe companion technology add-on (TA) and the Splunk SOAR (Phantom) connector that extend TrackMe beyond the main `trackme` Splunk app. For each one: purpose, data it ingests / produces,

Splunk surfaces (commands, REST handlers, alert actions), the TrackMe use cases it unlocks, dependencies, and which FLX templates pair with it (if any).

Audience
TrackMe administrators, architects, and operators scoping what else they can plug into TrackMe.

Three axes of extension

TrackMe alone monitors **data that already lives in Splunk** (indexes, scheduled searches, hosts, sourcetypes, fields, lookups via Splunk REST) and orchestrates alerts / AI within the Splunk surface. The companion add-ons extend TrackMe in three orthogonal directions:

1. **External data sources made first-class TrackMe entities —** Cribl Stream / Edge pipelines and fleet nodes (`TA-trackme-cribl`), Google SecOps log feeds (`TA-trackme-google-secops`), and lookup files / KV-stores at filesystem-mtime precision (`TA-trackme-lookupmonitor`). All can be turned into FLX or hybrid-tracker entities that participate in priority, SLA, ML outliers, stateful alerting and the AI Assistant — exactly like native DSM entities.
2. **Bidirectional incident orchestration with external systems —** `TA-trackme-xsoar` (Cortex XSOAR active-command incident lifecycle with a resilient retry store) and `trackme-app-on-soar` (Splunk SOAR playbook-driven ACKs, maintenance windows, ML retraining, logical-group management and priority / policy bulk-edits).
3. **Operational resilience and deployment flexibility —** `TA-trackme-conf-manager` for transactional, retryable TrackMe REST orchestration (CI / IaC pipelines).

Without the companions you keep an in-Splunk monitoring tool. With them, TrackMe becomes a multi-vendor data-quality control plane that closes the loop into the SOC's ticketing, automation, and configuration-management workflows.

Common architectural patterns

Two patterns appear repeatedly across the companion add-ons:

- **API-bridge pattern —** A single custom command (`cribl` / `secops`) plus a small persistent REST handler for account configuration. Used by `TA-trackme-cribl` and `TA-trackme-google-secops`. From TrackMe's perspective, the command makes external API data look like SPL events so any FLX or hybrid tracker can consume it.
- **Resilient transaction store —** A KV collection (per-account, replicate-false) records pending / failed REST transactions, plus a 15-minute scheduled saved-search replay loop. Used by `TA-trackme-conf-manager` (against TrackMe's own REST) and `TA-trackme-xsoar` (against the XSOAR REST). Guarantees that a transaction eventually lands even through network blips or destination outages.

External data sources

TA-trackme-cribl

Purpose	Two-way Splunk-to-Cribl-API bridge for both Cribl Stream (Logstream) and Cribl Edge, callable from SPL via `| cribl`.
Splunk surfaces	Custom command `cribl` (GET / POST / DELETE with built-in helpers: `get_groups_conf`, `get_global_metrics`, `get_destinations_metrics`, `get_pipelines_metrics`, `get_routes_metrics`, `get_edge_fleets`, `get_edge_nodes`, `get_edge_fleets_conf`); persistent REST handler at `/services/cribl/v1/...` for account access / test connectivity; UCC account config (Cloud or on-prem leader URL, client_id / secret, SSL, RBAC); capability `criblapi`, role `cribl_api`.
TrackMe use cases unlocked	**FLX live-API tracking** of Cribl Edge node health via `cribl_edge_fleet_api` (the only FLX template that hard-depends on `| cribl`). **Hybrid trackers** / ad-hoc SPL where TrackMe entities can be defined directly from Cribl API output (workers count, route traffic, pipeline status, packs) without needing Cribl to forward metrics to Splunk first. Real-time queries of pipeline / route / destination metrics from inside TrackMe scheduled trackers.
Dependencies	Cribl Stream or Cribl Edge deployment with API access; Cribl client_id / secret. Independent of trackme-app at runtime; the FLX template above and the use-case docs are oriented around TrackMe.
FLX templates that pair	**Hard requirement**: `cribl_edge_fleet_api`. **Independent (relies on Cribl-shipped internal metrics in a Splunk metrics index)**: `cribl_edge_fleet_metrics`, `cribl_logstream_health_inputs`, `cribl_logstream_health_outputs`, `cribl_logstream_hosts_cpu_usage`, `cribl_logstream_output_destination_pressure`, `cribl_logstream_pack_traffic`, `cribl_logstream_pipeline`, `cribl_logstream_route_traffic`, `cribl_logstream_total_traffic_inputs`, `cribl_logstream_total_traffic_outputs`. These do not need the TA but operate in the same monitoring family.
See also	*Cribl Stream monitoring with Flex Objects*, *Cribl Stream & Cribl Edge*.

TA-trackme-google-secops

Purpose	Splunk SPL bridge to Google Security Operations (Chronicle) UDM search API.
Splunk surfaces	Custom command `secops` (runs UDM queries through `udmSearch`, auto-applies Splunk's time range, `limit` configurable); REST handler at `/services/secops/v1` for account / test connectivity; UCC account (GCP project ID, SecOps instance UUID, region, service-account JSON key encrypted, RBAC roles); capability `secopsapi`, role `secops_api`.
TrackMe use cases unlocked	Hybrid trackers and FLX entities driven by **Google SecOps log feed ingestion** — e.g. one entity per `metadata.log_type` (NGINX / APACHE / …) tracking event count, last-seen, ingest delay, or anomalies. Effectively extends DSM-equivalent monitoring to data living in Chronicle, with the same toolkit (priority, SLA, stateful alerting, AI Assistant) used for Splunk-side feeds.
Dependencies	**Hard dependency on trackme-app** — the README explicitly states: *"TrackMe must be installed and licensed on the search head(s) where this application is deployed. The ``secops`` custom command will fail with a licensing error"* — the TA reuses TrackMe's licensing framework. GCP service account with `roles/chronicle.viewer` + `roles/serviceusage.serviceUsageConsumer`. Network reachability to `{region}-chronicle.googleapis.com`.
FLX templates that pair	None ship — operators build SecOps trackers directly via the `| secops` command.

TA-trackme-lookupmonitor

Purpose	Generative SPL command that enumerates CSV-file and KV-store lookups visible to the running user with reliable filesystem mtimes and accurate row counts.
Splunk surfaces	Custom generating command `trackmelookupsmonitor` (`local = true` — runs on the dispatching SH only); UCC config with logging-level controls. No dashboards / REST API / alert actions.
TrackMe use cases unlocked	This is the **data source behind TrackMe's "Lookups monitoring" search mode in the Hybrid Trackers wizard** — see *Lookup monitoring*. It lets a tenant create TrackMe entities, one per lookup, tracking last-modification freshness and growth / shrinkage of row count — so you can build alerts like "this critical KV-store collection hasn't been updated in 24 h" or "this CSV lookup just lost 90 % of its rows". Pair with `splunkremotesearch` to inventory lookups across remote SHs (the TA must be installed on the remote SH too; trackme-app itself does not need to be there).
Dependencies	None external. Stand-alone usable; integrates with trackme-app only via the Hybrid Trackers wizard.
FLX templates that pair	None — lookups monitoring is implemented as a dedicated hybrid-tracker search mode rather than via FLX templates. Note: `splk_large_lookup_files` solves an adjacent problem (oversized lookups) using a Splunk REST call (`/services/data/transforms/lookups`) — independent of this TA.
See also	*QUICK START - Design and automate through lookup knowledge*, *Lookup monitoring*.

Bidirectional incident orchestration

TA-trackme-xsoar

Purpose	Cortex XSOAR (Palo Alto) REST-API integration with a built-in resilient retry store for incident-creation calls.
Splunk surfaces	Custom commands `xsoar` (generic GET / POST / DELETE), `xsoarstreamincident` (streaming command that creates / updates / closes incidents, keyed by `external_incident_id`), `xsoarresilient` (replay loop); persistent REST handler at `/services/xsoar/v1/...`; scheduled saved search `xsoarresilient` (every 15 min, enabled by default) replaying failed REST calls; UCC account configuration (key + key ID), capability `xsoarapi`.
Storage	Two KV collections (replicate-false): `kv_xsoar_resilient_store` (pending / failed transactions — account, endpoint, body, status, attempts, last_error), `kv_xsoar_incidents_store` (XSOAR incident IDs ↔ external IDs mapping so updates / closures from TrackMe stateful alerts can reach the right XSOAR incident).
TrackMe use cases unlocked	Bidirectional bridge between TrackMe stateful alerts and Cortex XSOAR incidents — the README documents the exact wiring as **active commands** in TrackMe stateful alerts: `commands_opened` creates an XSOAR incident, `commands_updated` patches it with new state, `commands_closed` closes it. The resilient store guarantees incident parity even through network blips or XSOAR outages. **Use case**: TrackMe entity goes red → XSOAR ticket auto-opens; entity recovers → ticket auto-closes.
Dependencies	Cortex XSOAR API key + key ID; network reachability to XSOAR. No external trackme-app dependency at install time (FIPS- compatible, standalone or SHC), but is purpose-built for TrackMe stateful-alert integration.
FLX templates that pair	None. The `splk_soar_*` family of FLX templates targets **Splunk SOAR (Phantom)**, not XSOAR.
See also	*Palo Alto XSOAR Integration*.

trackme-app-on-soar (Splunk SOAR connector)

Purpose	A **Splunk SOAR (Phantom) app**, *not* a Splunk TA — runs inside SOAR and exposes TrackMe REST endpoints as SOAR actions so playbooks can drive TrackMe entities.
SOAR surfaces (actions)	`test connectivity`; `ack_get`, `ack_manage` (sticky / unsticky, set, extend); `maintenance_status`, `maintenance_enable`, `maintenance_disable`; `tenants_ops_status` (per-tenant OPERATIONAL / DEGRADED); `remote_accounts_check_connectivity`; `ml_outliers_train_models`, `ml_outliers_run_monitor`, `ml_outliers_reset_models`, `ml_outliers_get_models`, `ml_outliers_add_period_exclusion`; `component_get_entity`, `component_manage_entity` (enable / disable / delete + per-action extras `manage_dsm_sampling`, `update_hours_ranges`, `update_wdays`, `update_priority`, `update_lag_policy`, `update_dcount_host`, `update_manual_tags`); `smart_status`; `logical_group_get_group_for_entity`, `logical_group_manage`.
TrackMe use cases unlocked	SOAR-driven, playbook-orchestrated TrackMe operations: auto-ACK an entity from a SOAR playbook when an upstream maintenance ticket opens; un-ACK when it closes; trigger Smart Status investigation from SOAR after correlating with another SIEM signal; bulk priority / lag policy / hours-ranges adjustments driven by an external CMDB; on-demand ML model retraining / model exclusion windows around known noisy periods (deployments, batch jobs); enable / disable global maintenance from a SOAR incident-response playbook before scheduled changes; logical-group membership management from SOAR (group entities by app / service when the inventory changes upstream).
Dependencies	Splunk SOAR (Phantom) 6.0.2+. Splunk bearer token with TrackMe RBAC. Network reachability to Splunkd HTTPS. Requires trackme-app on the Splunk side.
FLX templates that pair	None — this is a SOAR-side connector, not a Splunk add-on. The `splk_soar_*` FLX templates monitor a Splunk SOAR deployment's *health*; they consume Splunk-side SOAR-forwarded data and TrackMe's own `trackmesplksoar` command, independent of this SOAR connector.
See also	*TrackMe App on SOAR*, *Splunk SOAR*.

Operational resilience

TA-trackme-conf-manager

Purpose	Resilient transactional layer for replaying failed configuration changes against the TrackMe REST API — accepts a config transaction, persists it, and re-attempts on a schedule until it lands.
Splunk surfaces	Custom search command `trackmeconfmanager` (modes `live` / `get` / `simulation`); persistent REST handler at `/trackme_conf_manager/v1`; scheduled saved search `trackme_conf_manager_producer` (every 15 min, **disabled by default** — operator opt-in) that calls `| trackmeconfmanager mode="live"` to replay pending transactions; diagnostic saved searches for transactions, simulation, access logs, KV-store content.
Storage	KV collection `kv_trackme_conf_manager` (replicate-false).
TrackMe use cases unlocked	Idempotent / retryable orchestration of TrackMe REST calls — useful for SOAR playbooks, infra-as-code (Ansible / Terraform- style) deployments, and CI pipelines that bulk-configure tenants, entities, policies, ACKs, maintenance windows, etc. Submit a transaction once, the TA keeps trying until it succeeds.
Dependencies	Requires trackme-app (it wraps TrackMe REST calls). No external system.
FLX templates that pair	None — pure orchestration, not a data source.

At-a-glance dependency map

Quick reference: who needs whom.

Add-on	Needs trackme-app?	External system needed
`TA-trackme-cribl`	No (works standalone, but TrackMe use cases require it)	Cribl Stream or Cribl Edge with API access
`TA-trackme-google-secop`	**Yes — hard licensing dependency**	GCP Chronicle SecOps with service account
`TA-trackme-lookupmonit`	No (integrates via Hybrid Trackers wizard)	None
`TA-trackme-xsoar`	No (FIPS-compatible, standalone)	Cortex XSOAR with API key
`TA-trackme-conf-manage`	**Yes — wraps TrackMe REST**	None
`trackme-app-on-soar`	**Yes — calls TrackMe REST**	Splunk SOAR (Phantom) 6.0.2+

TrackMe Adoption Roadmap

What this page is

A **descriptive** map of the journey we typically see TrackMe customers travel through, organised in six phases. It is **not** a prescriptive "you must do X before Y" ladder — every customer moves at their own pace, and the right sequencing depends on team maturity, scale, and what brought them to TrackMe in the first place.

What we **do** observe consistently is that **certain capabilities are counter-productive if enabled too early** — a customer still stabilising on data-source monitoring will be hurt, not helped, by turning on ML outliers and AI status reports on day one. This page makes those anti-patterns explicit so you can resist the temptation to enable everything at once.

Audience
: Existing TrackMe customers looking for "what should I focus on next?", new customers planning a rollout, account teams and partners wanting a shared mental model.

Companion pages
: *TrackMe Use Cases — Organised by User Intent* (what you *can* do), *TrackMe Capability × Component Matrix* (which features apply to which components), *FLX (Flex Objects) Use Case Template Catalog* (pre-built use cases), *TrackMe Ecosystem — Companion Add-ons* (companion add-ons).

The shape of the journey

The six phases below are the rhythm we see across most TrackMe deployments — from small Foundation tenants to large multi-tenant Unlimited estates:

Phase	Focus	Customer question that triggers it
1	**Data source monitoring** (DSM)	*"Is my data still arriving as expected?"*
2	**Hosts and endpoints** (DHM)	*"How do I know an individual host stopped sending data?"*
3	**Volume outliers with ML** (the VOL component — 2.4.18+, every edition; FLX volume tenant or DSM merged-mode outliers as the legacy alternatives)	*"Now that I track feeds and hosts, how do I detect abnormally low or high volumes?"*
4	**Workload Knowledge** (WLK) — *optional interlude*	*"Can I extend TrackMe to monitor Splunk's own scheduled-search health?"* — usually prompted by us, not by the customer
5	**Flex expansion, Splunk infra, third-party**	*"What else can I monitor with TrackMe?"*
6	**Steady state** — governance, growth, what's next	*"How do we keep TrackMe alive, growing, and shared across teams?"*

Note

Phase 4 is deliberately framed as an **optional interlude**, not a sequential gate. Workload Knowledge is one of TrackMe's most valuable components, but it is rarely what attracts customers to the product in the first place — it is a capability we proactively teach about when the customer is ready, rather than one they ask for. Some customers adopt WLK between phase 2 and phase 3; others much later; some not at all.

How we work with you through the phases

There are no fixed durations and no hard gates. The pattern we follow:

- We **periodically prompt you** about what's typically next — through release notes, account-team conversations, or the AI Assistant surfacing capabilities you have not yet enabled.
- You **decide pace and order** based on what your team is ready for, what the data is telling you, and what your stakeholders are asking about.
- The *TrackMe Use Cases — Organised by User Intent* and *FLX (Flex Objects) Use Case Template Catalog* pages are the **menu**; this page is the **suggested order**.

Phase 1 — Data source monitoring

The customer question that opens this phase

"Is my data still arriving as expected — and how do I get told the moment it stops?"

This is the phase that brought most customers to TrackMe in the first place, and it is where every deployment starts. The goal is to know, reliably and quickly, when a data feed is no longer arriving on time — nothing more, nothing less.

Primary focus

- **Component**: `DSM` (Data Source Monitoring), tracking `(index, sourcetype)` feeds.
- **Primary KPI**: ingestion **delay** (how long ago we last received data). Secondary KPI: **latency** (the gap between event time and index time).
- **Tenant pattern**: one or two DSM-only tenants, usually scoped by organisational responsibility (e.g. one tenant per data team, or one per environment).

See *QUICK START - Starting with TrackMe: (feed tracking quickstart)* for the canonical walkthrough.

What we typically build first

- The default DSM tracker, discovering `(index, sourcetype)` entities automatically.
- Static delay thresholds tuned to the customer's expectations, or **variable delay** thresholds (day-of-week × hour-of-day) if there are predictable business-hours / overnight patterns.
- Email-based stateful alerting (open / update / close) so each real state transition produces exactly one notification thread.
- Initial design of the **alerting workflow**: do notifications go to email only, to a third-party ITSM / ticketing platform, or both? This decision is usually revisited later, but it is worth agreeing on a starting point at phase 1.

Fighting the noise

The most important phase-1 skill is **classification** — separating the few feeds that genuinely matter from the many that do not. The TrackMe concepts that earn their keep here:

- **Priority policies** (regex / lookup / SPL) — assign critical / high / medium / low / pending priorities without touching individual entities.
- **Tag policies** — attach routing labels (`team:auth`, `env:prod`) that survive entity recreation.
- **SLA policies** — bucket entities into platinum / gold / silver classes for uptime accounting.
- **Notes** and **labels** — document feeds as the team learns about them ("re-deploy at 03:00 on 2026-05-08, root cause INC-12345").

See *Priority*, *Tags*, and *Using SLA alerting to build a 2-tier monitoring system*.

Organisational dimension

Phase 1 is where the customer's **team learns the product** — what an entity is, what a tenant is, how the stateful alerting workflow feels, what categorisation conventions to use. Most customers spend **significant time** here, and that is healthy: skipping ahead before the team is comfortable creates noise debt that compounds in every later phase.

What to not do yet

Resist the temptation to enable the following in phase 1 — they will generate noise faster than the team can metabolise it:

- **ML outlier detection** — the data has not had time to train stable models, and even if it has, the team is not yet equipped to triage outlier alerts.
- **AI status reports in alert emails** — useful, but adds cognitive load before the basics are mastered.
- **Hybrid trackers**, **logical groups**, and **smart-status investigations** — all valuable later, but premature here.

The right phase-1 alert is a clean "this feed has stopped, here is the priority and SLA class, here is who to call". Build that solidly before layering anything else on top.

Edition variants

- All editions support phase 1 in full.
- Foundation has DSM, DHM, MHM and one tenant only — perfect for phase 1.

Phase 2 — Hosts and endpoints

The customer question that opens this phase

"Now that I monitor my feeds, how do I know when an individual host stops sending data — even if its index and sourcetype are still busy from other hosts?"

This is the natural follow-up to phase 1. Feeds answer "is this data flowing at all?". Hosts answer "is **this specific machine** flowing?". Most customers reach phase 2 within weeks or a few months of phase 1.

Primary focus

- **Component**: `DHM` (Data Host Monitoring), tracking host × sourcetype activity.
- **Tenant pattern**: a **dedicated DHM tenant** (sometimes several). Mixing host tracking into the existing feeds tenant is the most common phase-2 mistake — the volumes and the operational lifecycle are different enough that they deserve their own container.
- **Break-by mode**: most deployments start with one entity per `(host, sourcetype)` pair. TrackMe 2.3.23+ supports `breakby_extra_fields` on DHM hybrid trackers, which lets you add extra metadata dimensions (e.g. `source`) to the combo grain — use this when `(host, sourcetype)` alone does not separate the activity enough.

See *Hybrid trackers* and *Notes*.

The scale challenge

Large customers can have **tens of thousands of endpoints** across heterogeneous fleets — servers, network gear, Windows desktops, Linux containers, IoT, third-party agents. Three considerations dominate:

- **Inventory quality** — does the customer have a usable CMDB? If yes, integrate it (priority, tags, SLA all driven by lookup or SPL-search policies against the CMDB). If no, this is the right moment to start one.
- **Discovery scope** — use the DHM **blocklist** and **allowlist** aggressively. Tracking every device on the wire is rarely what you want; tracking the hosts that belong to a known inventory is.
- **Tenant design** — multiple DHM tenants by responsibility area (e.g. one per OS family, one per business unit) is often clearer than one mega-tenant.

See *CMDB integration* for the CMDB integration patterns and *QUICK START - Design and automate through lookup knowledge* for the lookup-driven approach.

Organisational dimension

Phase 2 typically pulls in **a wider set of stakeholders** than phase 1: endpoint owners, OS teams, CMDB owners, sometimes security. The operational rhythm of "an endpoint went silent" is genuinely different from "a feed went silent" — it usually means a host is down, an agent is broken, or someone decommissioned a machine without telling anyone. Phase 2 is where TrackMe starts being a **cross-team conversation**.

What to not do yet

- **ML outlier detection on DHM** — per-host event volume is too noisy in most environments to model usefully. The DHM defaults in TrackMe (`mloutliers_dhm=0`) reflect this — leave outliers off here.
- **Logical groups** before the discovery scope is stable — group membership is only useful once you trust what is being discovered.

Edition variants

- All editions support DHM.
- Foundation supports DHM but is limited to one tenant — for very large endpoint fleets, Enterprise or Unlimited is usually a better fit because you can split the load across multiple tenants.

Phase 3 — Volume outliers with Machine Learning

The customer question that opens this phase

"Now that I monitor feeds and hosts for primary KPIs, how do I detect that I am receiving unusually low or unusually high volumes of events — without writing thresholds by hand?"

Phase 3 introduces TrackMe's **machine-learning outlier detection** as a behavioural-anomaly layer **on top of** the deterministic phase 1 + phase 2 monitoring. Since 2.4.18 the recommended pattern is the **VOL** component; two legacy patterns remain for customers who set them up on earlier releases or have needs beyond the per-index licensed volume.

The recommended pattern (2.4.18+): the VOL component

VOL — Volume Outliers (*VOL — Volume Outliers*) is the seventh monitoring component and exists precisely for this phase. Enable it on a tenant — a few clicks in the tenant-creation wizard, local or remote deployment, Splunk Enterprise or Splunk Cloud — and:

- every index becomes an entity fed by the license usage logs in 5-minute buckets, incrementally (one small search per tenant every 5 minutes);
- the history (default 30 days) is **backfilled at creation**, so the ML models and the cost trend are usable on day one instead of after a training period;
- ML outliers on the rolling volume are the entity state — enabled by default, with the **detection direction** (drops, spikes, or both) chosen per index — plus an **inactivity policy** for indexes that stop consuming license;
- the daily licensed volume, a 30-day trend, a month projection and the **Global license usage (VOL)** tab answer *"who consumes my license, and is that changing?"* without any SPL.

VOL is available on **Foundation, Enterprise and Unlimited** — the edition split below no longer decides the pattern. See *Volume outliers on the Splunk license usage with Volume Outliers (VOL)* for the design and the comparison with the FLX templates.

Beyond the entities: User Activity Monitoring

Once the data and the cost are covered, the remaining blind spot of a Splunk platform is the people and the automation that use it. **User Activity Monitoring** (*User Activity Monitoring*, generally available in 2.4.19, any licence beyond Foundation) is a dedicated tenant type for that phase: one tenant per deployment, no entities, findings instead — the scheduled searches owned by people or dispatched all time, the accounts that run all-time searches, the consumers of the search capacity — with the accounts classified as human, service or system and an investigation workflow on every finding. See the white paper *Who is doing what on your Splunk? User Activity Monitoring (UAM)*.

The legacy Enterprise / Unlimited pattern: a dedicated FLX volume-outliers tenant

This was the recommended pattern before VOL, and remains the advanced alternative when you need KPIs the component does not carry (pool-level % used, Splunk Cloud SVC / storage) or a custom SPL. The shape:

- A **dedicated tenant** for volume outliers, kept separate from the main feeds tenant.
- Built on the FLX pre-built use cases `splk_license_usage_global_splunkenterprise` / `splk_license_usage_per_index_splunkenterprise` (or the Splunk Cloud equivalents) — see *FLX (Flex Objects) Use Case Template Catalog*.
- Why FLX over per-sourcetype DSM outliers: the license-usage feeds are **scalable and pre-aggregated** (MB per index, even at large scale) and they focus on the **index level**, which is the right granularity for volume anomaly detection. Per-sourcetype noise is filtered out by construction.
- Native ML outlier detection (DensityFunction with optional weekly seasonality) on the rolling 60-minute / 4-hour / 24-hour KPIs.

See *Outlier detection* for the ML configuration and *QUICK START - TrackMe Impact-Based Alerting (IBA)* for how outlier breaches contribute to entity state.

The legacy Foundation pattern: built-in DSM outliers in merged mode

Foundation customers do not have FLX; before VOL they could achieve similar behaviour with the **built-in DSM outlier detection** running on a DSM tracker in **merged mode**. Merged mode aggregates the entity's event-count metrics across sourcetypes for the same index, giving the ML model a clean per-index volume signal to learn from.

The trade-off: the volume-outlier signal lives **inside the main feeds tenant** rather than in a dedicated container. This is operationally simpler but conceptually less clean — most teams find it easier to separate "is this feed flowing?" from "is this feed volume anomalous?" even though the underlying data overlaps.

Organisational dimension

Phase 3 is where TrackMe usage starts to look more like an **L3 / specialist activity**. The questions get sharper:

- Who triages a volume outlier alert? (Different role from the L1 / L2 triage for a delay alert in phase 1.)
- How is priority propagated from the main feeds tenant into the volume-outliers tenant? Most commonly: a **priority policy** (lookup-based or SPL-search-based) in the volume-outliers tenant reads from the main feeds tenant so an entity that is critical for feed monitoring is also critical for volume monitoring — automatically.
- What is the alert workflow for outlier signals? Often quieter than delay alerts (no auto-pager), routed to a dashboard or a daily digest rather than waking someone up at 03:00.

What to not do yet

- **Enabling outliers on every component indiscriminately** — DHM, MHM, FQM, WLK are generally not good outlier candidates (see *TrackMe Capability × Component Matrix*). Outliers are a focused per-component opt-in, not a fleet-wide switch.
- **Volume outliers in the main feeds tenant on Enterprise / Unlimited** — defeats the purpose of having FLX. Keep them separate.
- **Rebuilding VOL with FLX templates on 2.4.18+** — the component already covers per-index licensed volume with backfill; reserve the templates for what it does not carry.

Edition variants

- **Every edition (2.4.18+)**: the VOL component, recommended.
- **Foundation** (legacy): built-in DSM outliers, merged-mode tracker, single tenant.
- **Enterprise** and **Unlimited** (legacy / advanced): dedicated FLX volume-outliers tenant.

Phase 4 (optional interlude) — Workload Knowledge

The customer question that opens this phase

"Can I extend TrackMe to monitor Splunk's own scheduled-search workload — skip rates, errors, slow runs, orphaned owners?"

This is the phase customers most often arrive at **because we tell them about it**, not because they asked. Workload Knowledge (`WLK`) is one of TrackMe's most valuable components, but it is rarely the use case that attracted them to the product in the first place.

Why we proactively teach it

WLK fills a category that Splunk itself does not address well: the **health of the scheduler estate** — which searches skipped, which errored, which take dramatically longer than they used to, which run as a user who no longer exists, which live in an app that has been disabled. Most large Splunk estates accumulate scheduler debt silently over years; WLK surfaces it in a structured way.

See *WLK — Workload Knowledge*, *WLK — Workload Knowledge*, *Monitor Splunk Workload with TrackMe's Workload component*.

Where it slots into the journey

Not strictly. Some customers adopt WLK **between phase 2 and phase 3** because they hit a scheduler-noise problem early. Some adopt it **alongside phase 5** as part of the broader Splunk-infrastructure expansion. Some never adopt it. We do not gate other phases on it.

Primary focus

- **Component**: `WLK`, tracking scheduled searches.
- **Tenant pattern**: a dedicated WLK tenant.
- **Tenant-default threshold row —** a WLK-specific feature where a single `object_id == "default"` record provides the fleet-wide fallback threshold; per-entity rows act as exceptions. Use this pattern to manage thresholds at the tenant level with a small number of overrides, rather than configuring every entity.
- **Signals to watch**: skip rate, error count, execution-time drift, versioning (the savedsearch definition has changed since the fingerprint was taken — surfaces unannounced edits), orphan owners, app enablement.

What to not do yet

- **ML outliers on WLK —** scheduler metrics are discrete (skip count, error count); thresholds are the right tool, not density-function models.

Edition variants

- **Foundation**: does **not** include WLK. Customers on Foundation must upgrade to Enterprise or Unlimited to enter this phase.
- **Enterprise** and **Unlimited**: full WLK support.

Phase 5 — Flex expansion, Splunk infrastructure, third-party

The customer question that opens this phase

"What else can I monitor with TrackMe — both inside Splunk and outside?"

Once phases 1 – 3 are operational and the team is comfortable, phase 5 opens up the full breadth of TrackMe's monitoring catalogue. There is no single "right" order here — the choice is driven by what is most valuable to the customer.

Common phase-5 workstreams

- **Splunk platform deep-dive —** indexer cluster status, SHC member health, bucket health, KV-store readiness, queue saturation, parsing errors, DMA acceleration, HEC errors, UF version compliance, knowledge-bundle size. See the `splunk_infrastructure` and `splunk_data_collection` categories in *FLX (Flex Objects) Use Case Template Catalog*.
- **License and cost monitoring —** pool usage, rolling volume windows, per-index attribution. (Splunk Cloud: storage and SVC consumption by app and by consumer service.) Per-index licensed volume is covered by the VOL component since phase 3; the templates add the pool, SVC and storage views.
- **Splunk good-practices auditing —** all-time scheduled searches, user-owned searches, dynamic sourcetypes (the `splunk_good_practices` category).
- **Splunk SOAR monitoring —** playbook concurrency and failures, asset health, automation broker HA, infra load / memory, services health, SOAR-to-Splunk forwarding. See *Splunk SOAR*.
- **Cribl Stream / Cribl Edge monitoring** (if the customer has Cribl in the stack) — since 2.4.19, the dedicated Cribl Stream and Cribl Edge tenant types monitor a deployment end to end with findings (see *Cribl Stream and*

Cribl Edge); the FLX templates remain for input / output health, pipeline traffic, route shifts with ML outliers, host CPU. See *Cribl Stream monitoring with Flex Objects* and *TrackMe Ecosystem — Companion Add-ons* for the companion add-on.

- **Field-quality monitoring (FQM)** for CIM compliance and parsing accuracy. See *Use Case Demo: Fields Quality (CIM and non-CIM)*.
- **Host OS monitoring** for Linux (TA-nix) and Windows (Splunk_TA_windows) fleets — CPU / memory per host with avg / max / p95.

Organisational dimension

Phase 5 is where TrackMe stops being a tool that one team runs and becomes a tool that **many teams consume**. Different workstreams have different owners — the Splunk platform team for infrastructure, the licensing / FinOps team for cost monitoring, the SOC for SOAR, the data team for parsing quality. **Virtual Groups** become valuable here as read-only cross-tenant aggregation views for executives or central teams (see *QUICK START - Cross-tenant domain views with Virtual Groups*).

This is also the phase where customers often integrate TrackMe with their **downstream incident-response stack** — Splunk ES (notable events), Cortex XSOAR (active commands), Splunk SOAR playbooks. See *TrackMe Ecosystem — Companion Add-ons*.

What to not do yet

- **Enable every FLX template at once** — the catalog is large; 48 of the 65 templates run on a 5-minute cadence by default, so a bulk enablement can spike the scheduler load. Stagger by editing `uc_cron` offsets at enablement time, or roll out workstreams one quarter at a time.

Edition variants

- **Foundation**: phase 5 is largely inaccessible — no FLX, no WLK.
- **Enterprise** and **Unlimited**: full phase 5.
- **Unlimited**: also unlocks unlimited hybrid trackers and remote Splunk deployments.

Phase 6 — Steady state: governance, growth, what's next

The customer question that opens this phase

"TrackMe is now a central part of how we run monitoring — how do we keep it alive, growing, and shared across the team?"

Phase 6 is the **steady state**, not a destination. The platform is widely adopted, multiple teams receive alerts from it or work inside it, and the question shifts from "what do we turn on next?" to "how do we keep what we have healthy, and how do we keep growing?".

Unlike phases 1 – 5, phase 6 does not have a feature checklist. It has four themes that all operate continuously.

People — building a champion network

- **Expand the champion base over time.** A single TrackMe expert is a single point of failure. Spread knowledge across multiple team members, ideally across multiple teams.
- **Cross-team training.** SOC, IT ops, observability, business owners — each consumes TrackMe differently. Run targeted training sessions per audience, not one-size-fits-all.
- **Rotation and handoff hygiene.** When a champion leaves the team or the company, their TrackMe knowledge needs to leave with them intentionally, through documented handoff, not through luck.

Process — periodic review and gap analysis

- **Periodic gap analysis against the** *FLX (Flex Objects) Use Case Template Catalog*. Every quarter (or whatever cadence fits): walk the catalog with the team and ask "is there anything we should have enabled and have not yet?". The catalog grows with every TrackMe release.
- **Quarterly Configuration Guardian sweep.** Guardian flags drifting configuration (missing capabilities, stale tokens, missing indexes, unreachable AI provider, stale backup archives, dead health tracker). Treat the Guardian alerts list as part of the ongoing platform review, not as one-off pop-ups.
- **Tenant lifecycle hygiene.** Decommission tenants for projects that have wound down. Prune dormant entities. Review priority / tag / SLA policies for relevance — yesterday's regex might catch the wrong things today.

Platform — keeping the foundation healthy

- **Configuration Guardian as a continuous safety net —** see *TrackMe Capability × Component Matrix* for the full list of checks.
- **Backup and restore discipline.** TrackMe 2.3.22+ ships a multi-archive backup format where every tenant and the global state are independent archives. Keep the backup scheduler enabled, test restore periodically, and use the per-tenant restore mode for targeted recovery rather than blanket rollbacks. See *Backing up and Restoring TrackMe*.
- **License and cost management.** As the platform grows, license-edition fit can drift — what was right at adoption may not be right at steady state. Review periodically.
- **Version-upgrade hygiene.** Read release notes, schedule upgrades with the same care as Splunk itself, and use a non-production tenant to validate before rolling out.

Forward look — what's coming next

- **New FLX templates ship with most TrackMe releases —** re-read the *FLX (Flex Objects) Use Case Template Catalog* after each release to see what is new.
- **Companion add-ons evolve** — Cribl, XSOAR, conf-manager, Google SecOps all gain features over time; check *TrackMe Ecosystem — Companion Add-ons* periodically.
- **AI Agents** — the next major evolution of the AI Assistant work is moving towards autonomous AI Agents that can act on TrackMe state (triage, ACK, investigate, recommend remediations). This is on the TrackMe roadmap and will become a phase-6 topic in its own right once it ships.
- **Periodic check-in with the vendor.** We (TrackMe) will periodically reach out about what's new and what is worth your time. Treat these conversations as part of the adoption journey rather than as interruptions — the platform is still growing, and so is your usage of it.

Closing thought

TrackMe is never finished. The platform keeps growing, the customer keeps growing, and the adoption journey is iterative — most customers revisit earlier phases as their estate evolves (new business units, acquisitions, new data sources, new Splunk deployments to monitor remotely). The six phases above are a **map**, not a **ladder**, and the right answer to "where am I on the roadmap?" is almost always **"in several places at once"**.

If you are unsure where to focus next, the shortest path is:

1. Run the **gap-analysis checklist** at the bottom of *FLX (Flex Objects) Use Case Template Catalog*.
2. Scan the *TrackMe Use Cases — Organised by User Intent* for goals you have not yet addressed.
3. Cross-check the *TrackMe Capability × Component Matrix* for features you could enable on components you already use.
4. Reach out to us — the periodic teach-back conversation is exactly what this page is designed to support.

CHAPTER

THREE

ARTIFICIAL INTELLIGENCE:

3.1 Artificial Intelligence in TrackMe

3.1.1 Overview

TrackMe 2.4.0 makes **TrackMe Agentic** generally available — a family of AI capabilities that help operators investigate, tune, and remediate their Splunk data monitoring directly inside the product. Where TrackMe has always *detected* data availability and quality problems, the AI layer now helps you *understand* and *resolve* them, grounding every answer in the live state of your environment and keeping the operator firmly in the loop.

The AI layer is organised around **four surfaces**, all built on the same Splunk Agent SDK (the `splunklib.ai` module shipped with the Splunk Enterprise SDK for Python) runtime, the same provider abstraction, and the same audit trail:

- **AI Assistant** — the conversational front door. A context-aware chat assistant available on every entity, page and feature of TrackMe (*AI Assistant*).
- **AI Routines — your own standing instructions**: user-authored, scheduled, natural-language AI tasks that watch for a condition and then notify you or — with explicit, granular consent — act (*AI Routines*).
- **AI Advisors** — five specialists that *inspect* and *remediate* a specific monitoring surface (ML models, feed thresholds, FLX thresholds, field-quality dictionaries, component health), plus the **AI Concierge**, a catalog-driven generalist for the long tail of operations (*The AI Advisors*, *The AI Concierge*).
- **AI Agents automation** — the same advisors running unattended on a nightly schedule, scoped by per-tenant policy (*AI Agents automation*).
- **AI Agents for findings** (2.4.19) — an agentic operator for the dedicated findings tenants: the **UAM AI Agent** (User Activity Monitoring), the **Cribl Stream AI Agent** and the **Cribl Edge AI Agent** share one framework. They triage findings the way an operator would, on demand or in an hourly scheduled triage, recommend a decision and, when the tenant allows it, apply it under their own **AI Agent** identity (*AI Agents for findings*).

Every action is **trustworthy, auditable, and traceable** by design: recommendations are typed and grounded in real data, writes are RBAC-checked at the REST boundary, and every change an agent makes is recorded both in the per-entity audit trail and in dedicated audit dashboards (*Auditing AI activity*).

Important

Opt-in only — The entire AI layer is completely inert until an administrator explicitly configures at least one AI provider. No data is sent to any external service and no LLM calls are made until you opt in. You retain full control over which provider is used and where data is processed — from fully air-gapped on-premises models (Ollama) to Splunk's own hosted LLMs on Splunk Cloud. See *Configuring AI Provider accounts*.

3.1.2 Requirements & compatibility

TrackMe remains **fully compatible** with all supported Splunk releases — the AI layer is additive and opt-in. The Python / Splunk requirements differ by capability:

Capability	Minimum Python	Minimum Splunk
AI Assistant (chat) and *AI Concierge*	Python 3.9.x	Any Splunk release supported by TrackMe
AI Advisors (ML, Feed Lifecycle, FLX Threshold, FQM, Component Health) and *AI Agents automation*	Python 3.13.x	Splunk 10.2.x and later (Enterprise or Cloud)
AI Routines (user-authored scheduled AI tasks)	Python 3.13.x	Splunk 10.2.x and later (Enterprise or Cloud)
AI Agents for findings (UAM, Cribl Stream, Cribl Edge)	Python 3.13.x	Splunk 10.2.x and later (Enterprise or Cloud)

Important

The AI Advisors are *agentic* features built on the Splunk Agent SDK, which requires **Python 3.13.x** — available only from **Splunk 10.2.x** (Splunk Enterprise or Splunk Cloud). TrackMe enforces this automatically: an Advisor cannot be launched on an incompatible release (a clear message explains the requirement), and the AI Assistant will not propose an Advisor when it detects an incompatible system. The **AI Assistant** and the **AI Concierge** run on **Python 3.9.x and later**, so they remain available on previous Splunk releases.

In short: TrackMe stays fully compatible everywhere; the advanced AI Advisors require Splunk 10.2.x and later. See the *compatibility page* for the full matrix.

3.1.3 The AI Journey

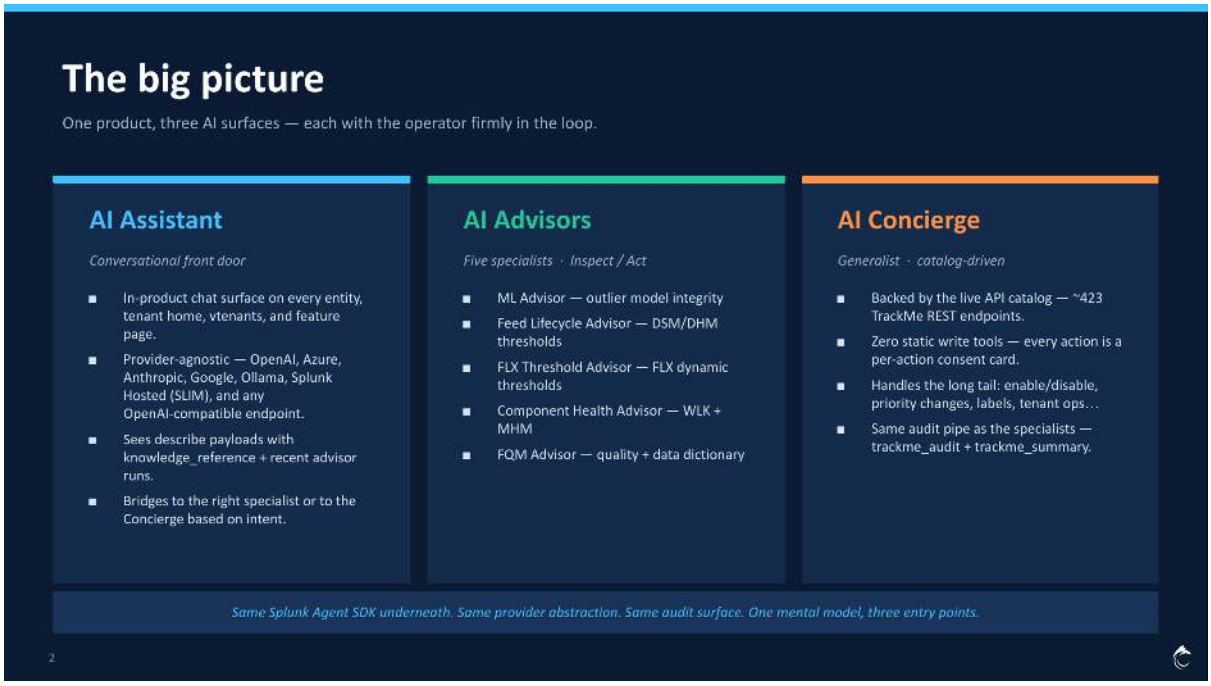
TrackMe's AI capabilities were built in layers, and they read best in that order. The AI Assistant was *level 1* of the journey — a conversational surface that understands your environment. The Advisors and the Concierge are *level 2* — agents that act, with consent. AI Agents automation is *level 3* — those same agents operating unattended within guardrails you define. **AI Routines are level 4** — you author your *own* autonomous tasks in natural language: describe what to watch for, and TrackMe evaluates it on your schedule, notifies you, or acts under the consent you granted (*AI Routines*). Alongside these levels, TrackMe 2.4.19 brings the **AI Agent** to the dedicated findings tenants: an agentic operator that triages findings, applies the decisions the tenant allows and logs every one of them (*AI Agents for findings*).

The slides below present the architecture and the core concepts. Each tab focuses on a single idea; the detailed walkthroughs (with product screenshots) live in the dedicated pages of this section.

The big picture

One product, three AI surfaces — each with the operator firmly in the loop.

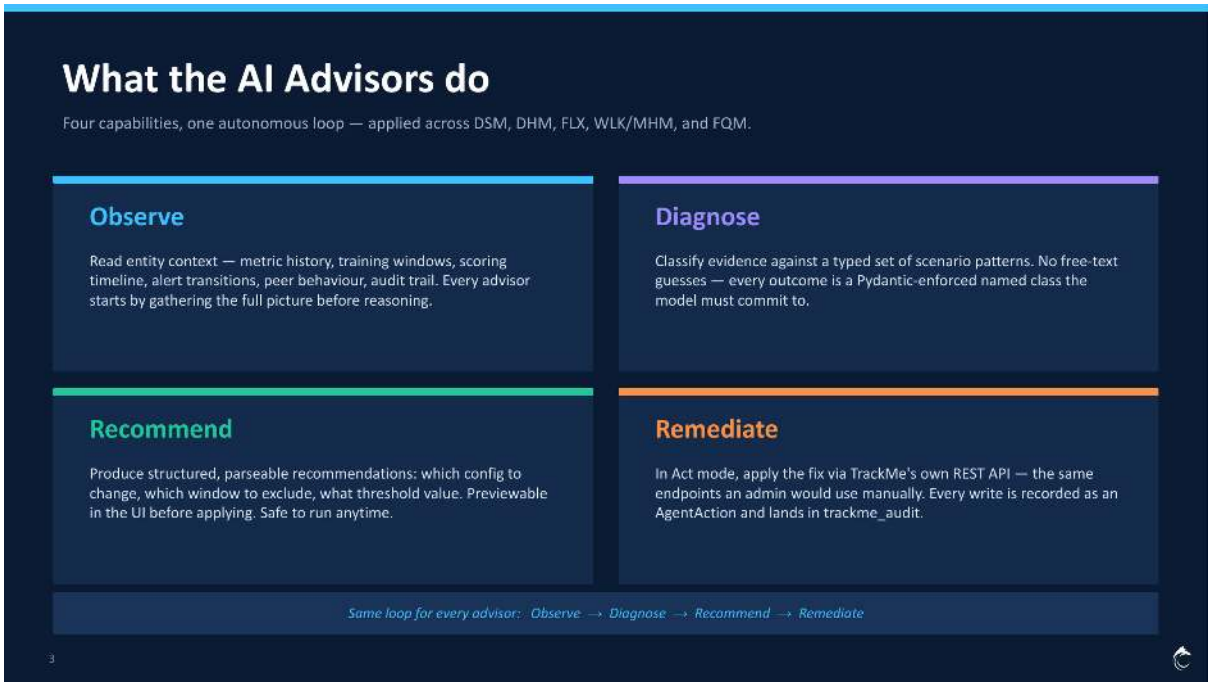
The **AI Assistant** is the conversational front door on every entity, tenant and feature page. The **AI Advisors** are five specialists that inspect and, with consent, act. The **AI Concierge** is the catalog-driven generalist for everything else — backed by the live TrackMe REST API. Same Splunk Agent SDK underneath, same provider abstraction, same audit surface.



What the Advisors do

Four capabilities, one autonomous loop — applied across DSM, DHM, FLX, WLK/MHM and FQM, and to VOL through the ML Advisor.

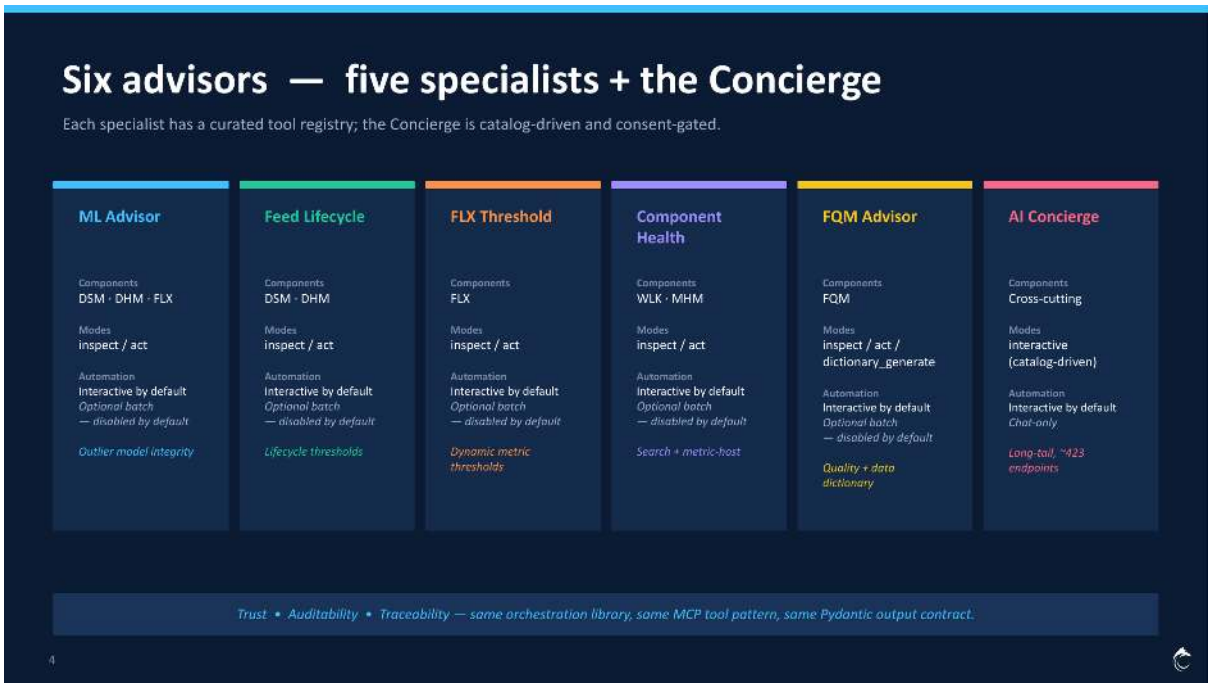
Every advisor follows the same loop: **Observe** (read entity context, metric history, scoring, audit trail), **Diagnose** (classify the evidence against a typed set of scenarios — no free-text guesses), **Recommend** (produce structured, reviewable recommendations), and — in *act* mode — **Remediate** (apply the fix through TrackMe's own REST API, recording every write to the audit trail).



Six advisors

Five specialists plus the Concierge.

Each specialist owns a curated tool registry scoped to its monitoring surface — **ML Advisor** (outlier model integrity), **Feed Lifecycle** (DSM/DHM thresholds), **FLX Threshold** (FLX dynamic thresholds), **Component Health** (WLK + MHM), and **FQM Advisor** (field quality and data dictionary). The **AI Concierge** is catalog-driven and consent-gated. They share one orchestration library, the same MCP tool pattern, and the same Pydantic output contract. User Activity Monitoring, Cribl Stream and Cribl Edge tenants add the **UAM AI Agent**, the **Cribl Stream AI Agent** and the **Cribl Edge AI Agent** on the same foundation (*AI Agents for findings*).



Architecture

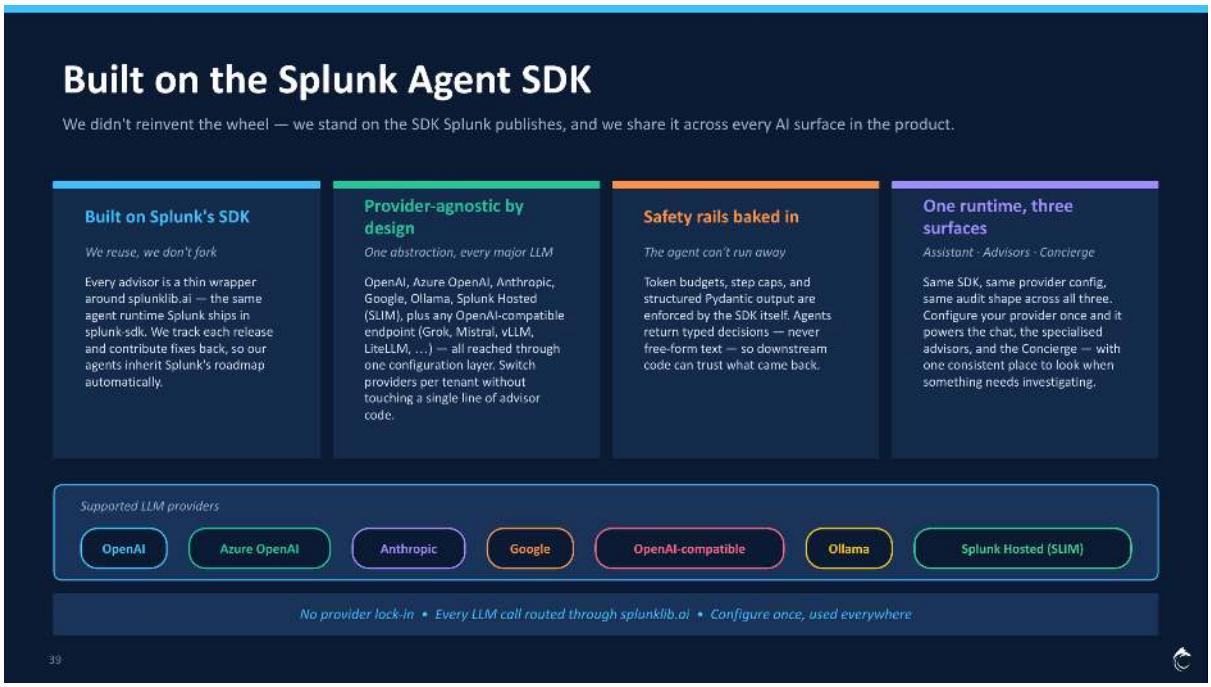
One shared control plane.

The Assistant and the chat bridge sit on the entry side; the Advisors and the Concierge dispatch through the same SDK runtime. A REST handler launches a daemon thread that runs the `splunklib.ai.Agent` (LangGraph) loop against either MCP tools (specialists) or the live API catalog (Concierge). RBAC is enforced at every REST boundary, concurrency is capped, every run is bounded with retries, and every outcome is audited end-to-end.

Built on the Agent SDK

We stand on the SDK Splunk publishes, and share it across every AI surface.

The advisors are built on the Splunk Agent SDK (`splunklib.ai.Agent`) rather than direct LLM API calls: it ships the LangGraph orchestration engine, the MCP tool registry, structured output via Pydantic, and middleware hooks for tracing and limits. The provider abstraction means the same advisor code runs across OpenAI, Azure OpenAI, Anthropic, Google, Mistral, Ollama, OpenAI-compatible endpoints and Splunk Hosted — **no provider lock-in**.

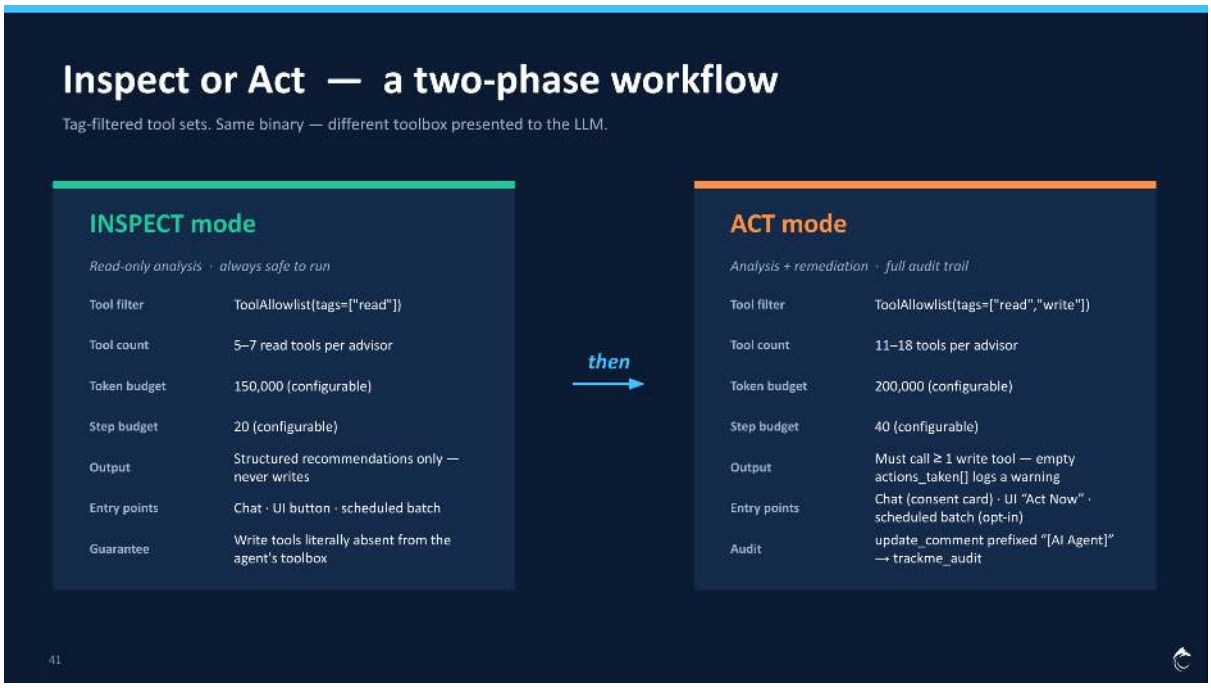


Inspect or Act

Tag-filtered tool sets, same binary — a different toolbox presented to the LLM.

Every specialised advisor honours a two-phase contract. **Inspect** mode is read-only and always safe to run: 5–7 read tools, a smaller token/step budget, structured recommendations only, *no* writes — the write tools are literally absent

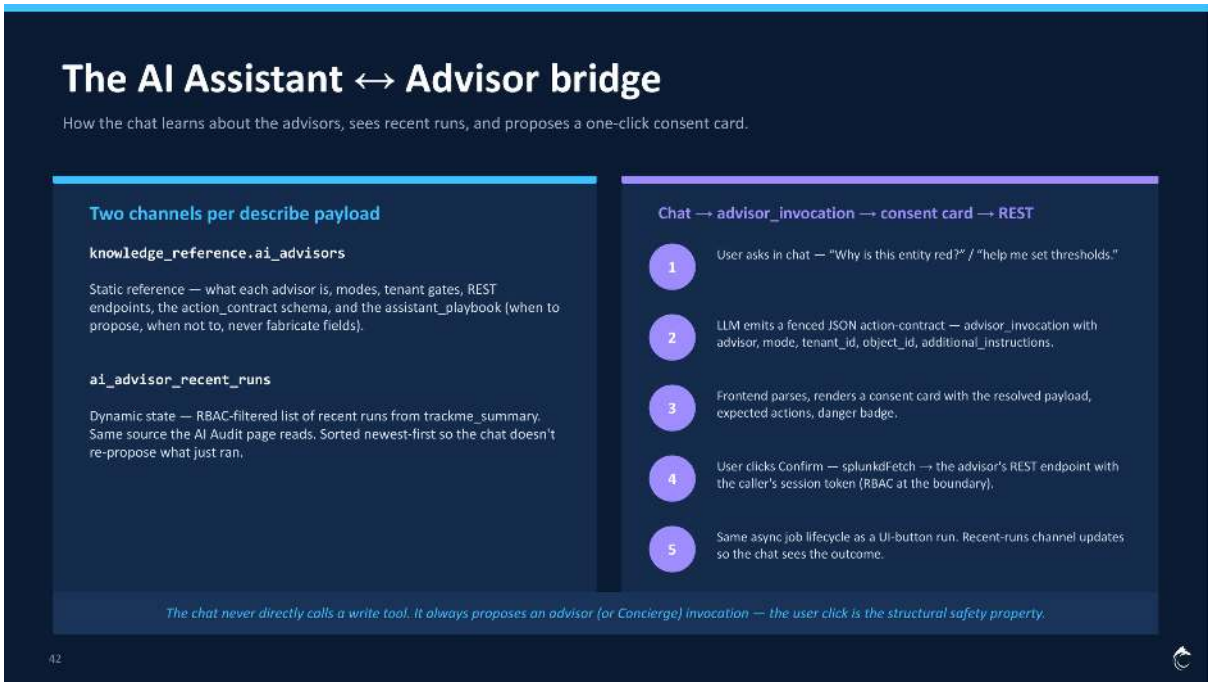
from the agent's toolbox. **Act** mode adds the write tools (11–18), a larger budget, and a hard rule that every write is verified by a follow-up read; each write is prefixed `[AI Agent]` and lands in the audit trail.



The Assistant ↔ Advisor bridge

How the chat learns about the advisors, sees recent runs, and proposes a one-click consent card.

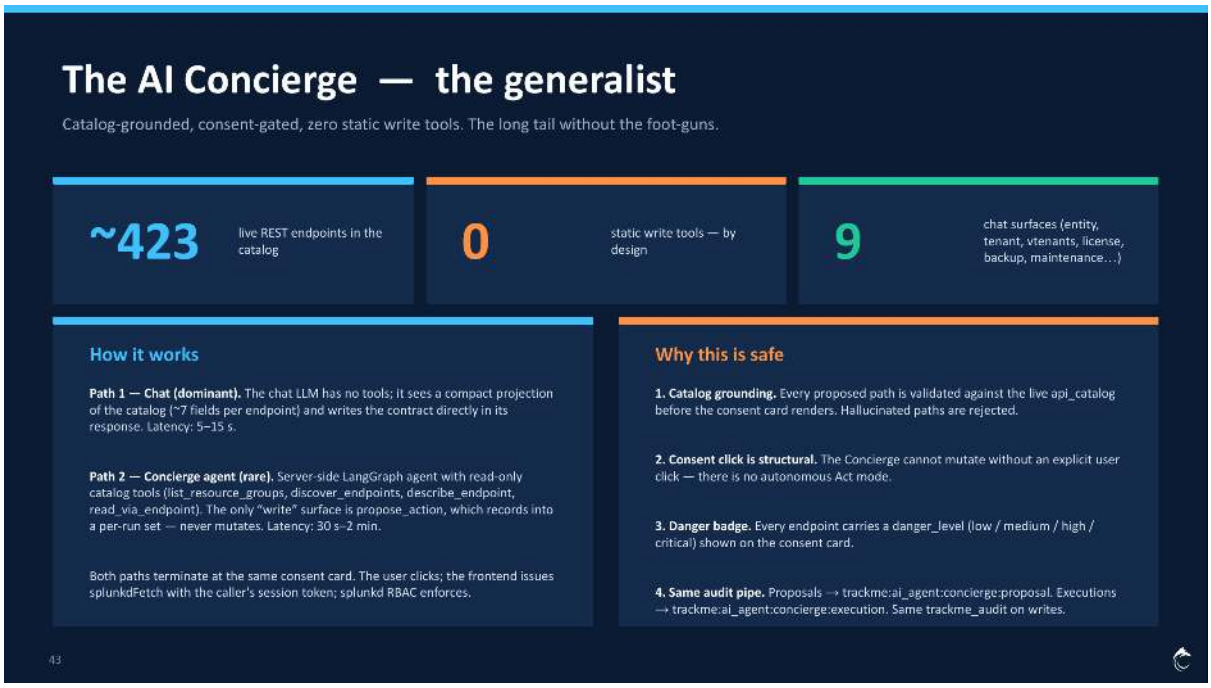
Each describe payload carries two channels: static `knowledge_reference` (what each advisor is, its modes, gates and contract) and dynamic `ai_advisor_recent_runs` (RBAC-filtered recent runs). When the user describes a symptom, the assistant emits a typed `advisor_invocation` contract that the chat renders as a consent card. **The chat never directly calls a write tool —** it always proposes an advisor (or Concierge) invocation, and the user's click is the structural safety property.



The AI Concierge

Catalog-grounded, consent-gated, zero static write tools — the long tail without the foot-guns.

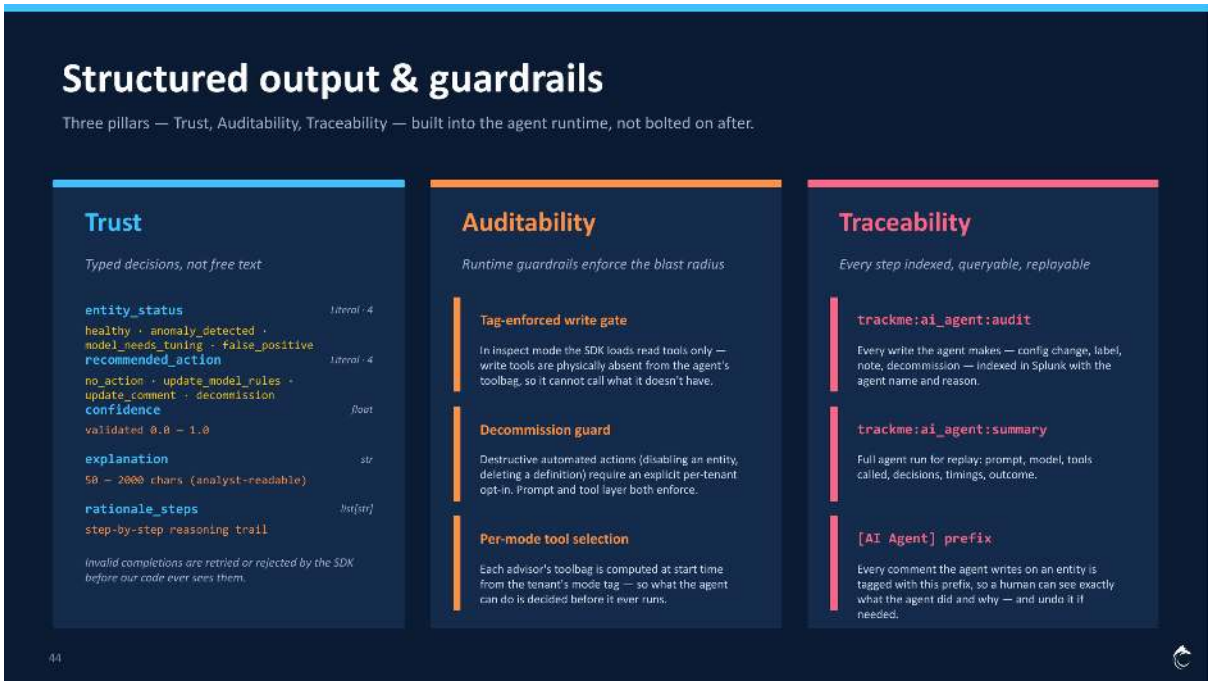
The Concierge grounds itself in the live TrackMe REST API catalog (~423 endpoints) and proposes structured action contracts that the chat consent card renders for explicit, per-action approval. It has **zero static write tools by design**: every proposed path is validated against the live catalog, destructive actions require typed confirmation, and the user's confirmation click is what fires the REST call — through their own credentials, RBAC-checked.



Structured output & guardrails

Three pillars — Trust, Auditability, Traceability — built into the agent runtime, not bolted on after.

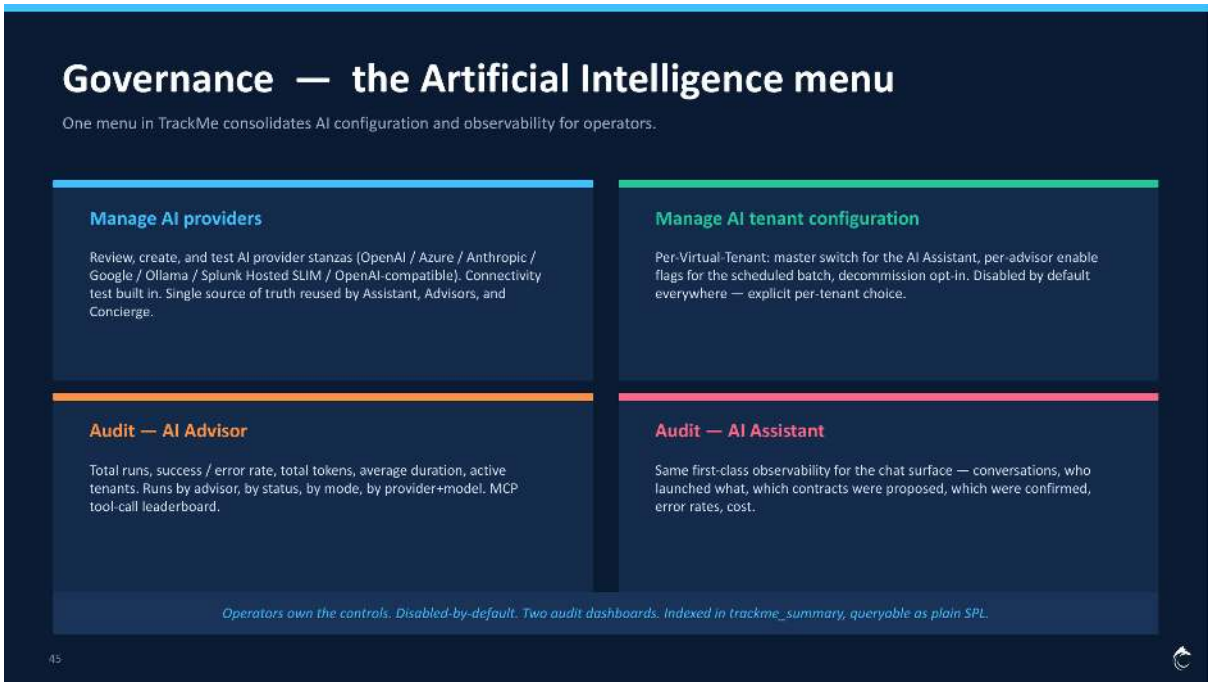
Trust: typed decisions, not free text — every agent emits a Pydantic envelope (`entity_status` / `summary` / `recommendations` / `actions_taken` / `reasoning_trace`); invalid completions are retried or rejected by the SDK. **Auditability**: runtime guardrails enforce the blast radius — tag-filtered write gate, decommission guard, per-mode tool selection. **Traceability**: every step is indexed and queryable, and every entity write carries the `[AI Agent]` prefix so a human can see exactly what changed and why.



Governance

One menu in TrackMe consolidates AI configuration and observability for operators.

The **Artificial Intelligence** menu brings together everything an operator needs: *Manage AI providers* (create and test provider accounts), *Manage AI tenant configuration* (per-tenant master switches, per-advisor enablement, the decommission guard — disabled by default everywhere), and the two audit dashboards for **AI Advisor** and **AI Assistant** activity. Operators own the controls, everything is disabled by default, and all activity is indexed to the summary index and queryable in plain SPL.



3.1.4 The three pillars

Every design decision across the AI layer traces back to three principles:

Pillar	What it means in practice
Trust	The agent never makes up entity state. Every claim traces to a tool call, and the system prompts forbid speculation. Outputs are *typed* — a Pydantic schema forces a structured envelope rather than free-form prose, and invalid completions are retried or rejected by the SDK. Read-only **inspect** mode is the default for unfamiliar entities.
Auditability	Runtime guardrails — not soft prompts — enforce the blast radius: a tag-filtered write gate (write tools are absent in inspect mode), a decommission guard (disabled by default), and per-mode tool selection. Hard runtime caps (token, step, and wall-clock budgets) are enforced by SDK middleware and a watchdog, so a misbehaving run hits a real wall.
Traceability	Every tool call and every advisor run is indexed to the tenant summary index (`trackme:ai_agent:*`), and every entity write carries an `[AI Agent] <reason>` prefix in the per-entity audit trail. You can answer "which conversation triggered this change, and why?" with a single SPL query.

3.1.5 What's in this section

This **Artificial Intelligence** section walks the full journey, with product screenshots at each step:

Page	What it covers
Configuring AI Provider accounts	Configuring one or more AI provider accounts (OpenAI, Azure, Anthropic, Gemini, Mistral, Ollama, Custom, Splunk Hosted) and the global AI settings. **Start here.**
AI Assistant	The conversational AI Assistant — capabilities, opening it from any page, the chat interface, context enrichment, AI status reports in alert emails, and troubleshooting.
AI Routines	**AI Routines** — describe a monitoring task in plain English; TrackMe watches for it on a schedule, then notifies you or (with consent) acts. Templates, the Evaluate dry-run gate, permission families, cost transparency, and auditing.
The AI Concierge	The AI Concierge — the catalog-driven generalist reached from the Assistant for operational requests, with consent cards and validation gates.
The AI Advisors	The AI Advisor family — inspect/act, the consent-card bridge, and the FLX Threshold Advisor.
AI Feeds Advisor	The AI Feeds Advisor (Feed Lifecycle) — DSM/DHM threshold tuning.
AI ML Advisor	The AI ML Advisor — outlier model inspection and remediation.
AI FQM Advisor	The AI FQM Advisor — field-quality thresholds and data-dictionary management.
AI Component Health Advisor	The AI Component Health Advisor — WLK and MHM health.
AI Agents automation	AI Agents automation — running the advisors unattended on a nightly schedule, scoped by per-tenant policy.
AI Agents for findings	AI Agents for findings — the UAM, Cribl Stream and Cribl Edge AI Agents: how they triage findings, inspect and act, the decisions they may take, scheduled triage, settings and the decision log.
Auditing AI activity	Auditing AI activity — the AI Advisor and AI Assistant audit dashboards.
AI Compliance, Privacy and Data Governance	AI compliance, privacy and data governance — the reference for compliance, security and privacy teams: data flows, what is (and is not) sent to the LLM, the complete tool inventory, guardrails, RBAC, audit, and egress requirements.

3.2 Configuring AI Provider accounts

3.2.1 Overview

Every TrackMe AI capability — the *AI Assistant*, the *AI Advisors*, the *AI Concierge*, *AI Agents automation*, and the AI status report in stateful-alert emails — runs through an **AI provider account**: a stored connection to an LLM endpoint. This is the foundational step of the AI journey.

You can configure **one or more** provider accounts (for model comparison, cost optimisation, redundancy, or data-residency reasons), and TrackMe is **provider-agnostic** — the same AI code runs across OpenAI, Azure OpenAI, Anthropic, Google Gemini, Mistral AI, Ollama, any OpenAI-compatible endpoint, and Splunk's own hosted models.

Important

Opt-in only — Until at least one provider account is configured, the entire AI layer is completely inert: no data is sent to any external service and no LLM calls are made. The choice of provider is yours — from fully air-gapped on-premises models to managed cloud services — and no data is ever shared between configured providers.

Tip

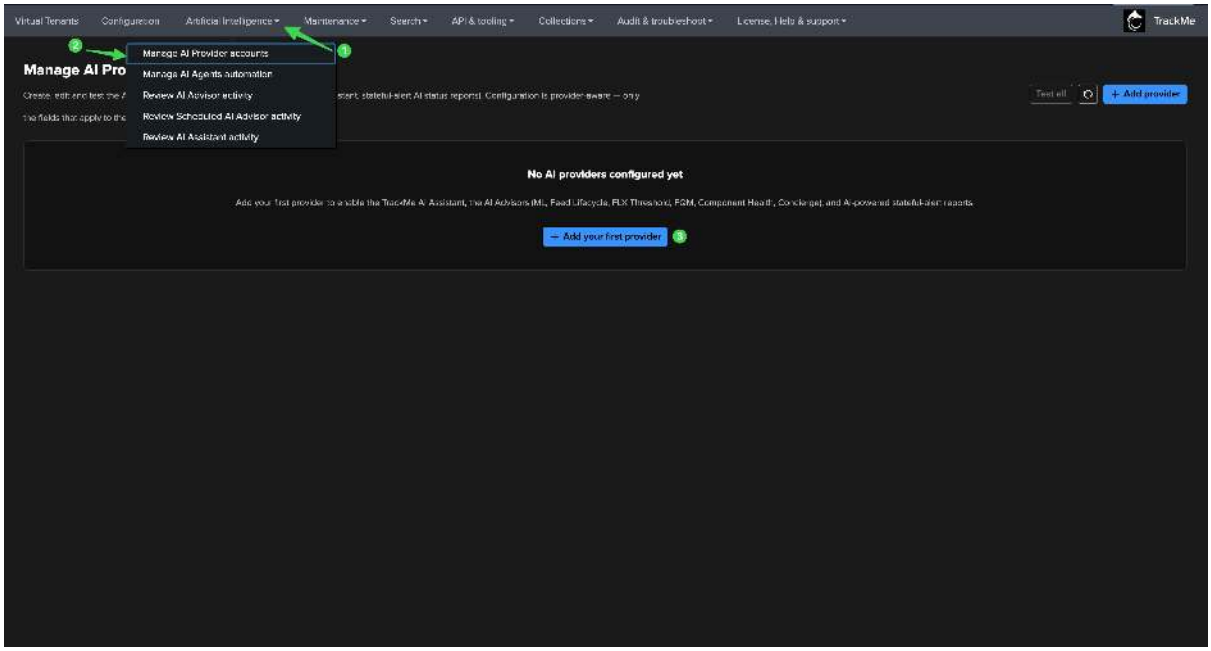
Full control over your AI infrastructure — Organisations with strict data privacy, data sovereignty, or regulatory requirements retain complete control over which AI provider is used and where data is processed. TrackMe can be connected to:

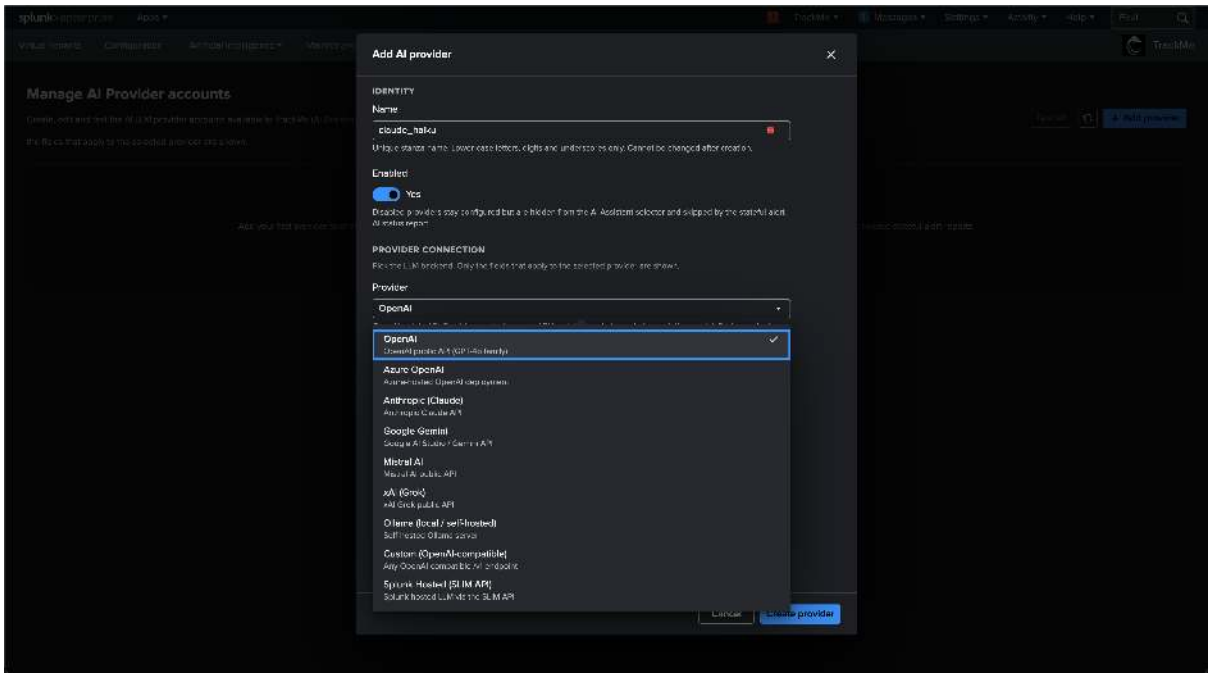
- **Splunk's own hosted LLMs** via the Splunk Hosted (SLIM API) provider type on Splunk Cloud, with zero configuration beyond selecting the provider and model — no API keys, no base URL, fully managed by the Splunk platform
- **Self-hosted open-source LLMs** via Ollama, keeping all data entirely on-premises with zero external API calls
- **Private or corporate LLM deployments** via the Custom (OpenAI-compatible) provider type, enabling integration with any internally hosted endpoint that implements the OpenAI chat completions format
- **Cloud providers of your choice**, including region-specific deployments (e.g. Azure OpenAI in a specific geography) to meet data residency requirements

3.2.2 Managing provider accounts

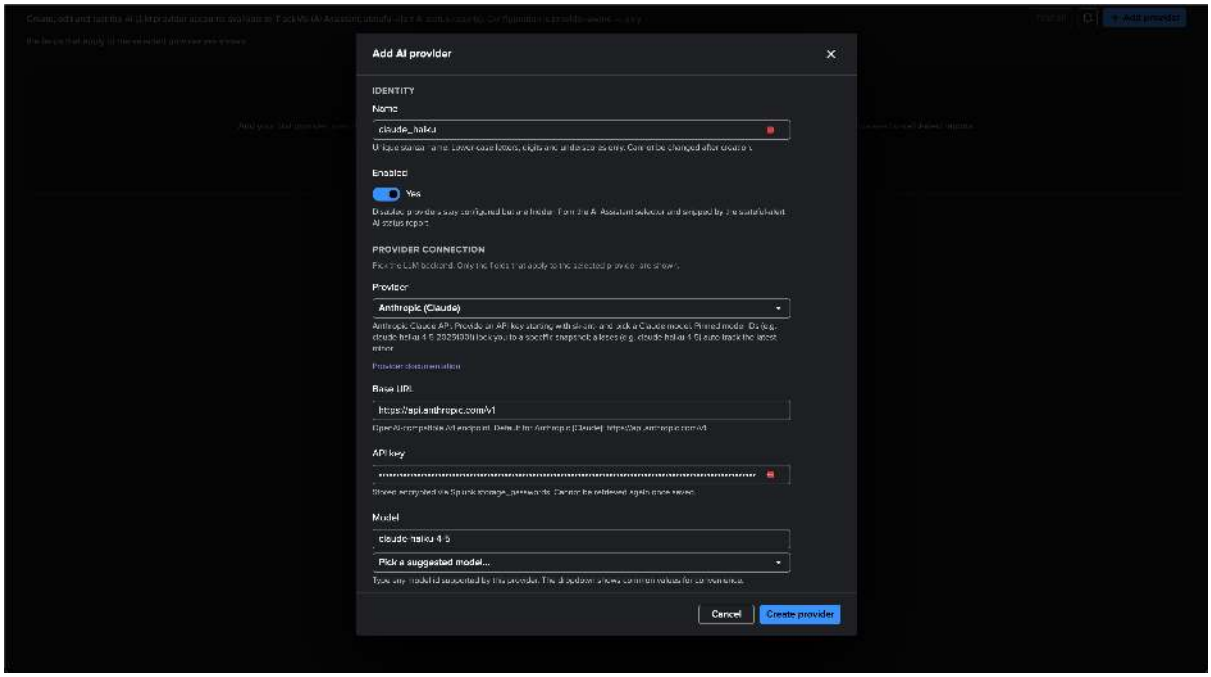
In TrackMe 2.4.0, provider accounts are managed from a dedicated page reachable from the top navigation: **Artificial Intelligence > Manage AI Provider accounts**.

The page lists every configured provider account with its provider type, enabled state, model, base URL, and last connectivity test result. From here you can **Add provider**, **Test all**, and — from the per-row actions menu — **Edit**, **Clone**, **Test connectivity**, or **Delete** an account.





When you click **Add provider**, the **Add AI provider** modal opens. Give the account a unique name, pick the provider backend, and fill in the fields that apply to that backend — only the relevant fields are shown for the selected provider. The example below configures an Anthropic (Claude) account using the `claude-haiku-4-5` model; the **Pick a suggested model** dropdown shows common values for convenience.



Add AI provider

Delete

Note

The account **Name** is the unique stanza identifier (lower-case letters, digits and underscores only) and cannot be changed after creation. Disabled accounts stay configured but are hidden from the AI Assistant provider selector and skipped by the stateful-alert AI status report.

3.2.3 Provider Fields

Field	Default	Description
AI Provider	OpenAI	The AI provider type. Supported values: `OpenAI`, `Azure OpenAI`, `Anthropic (Claude)`, `Google Gemini`, `Mistral AI`, `xAI (Grok)`, `Ollama (local / self-hosted)`, `Custom (OpenAI-compatible)`, `Splunk Hosted (SLIM API)`.
Base URL	*(optional)*	The base URL for the AI provider API. Required for all providers except **Splunk Hosted**, which auto-discovers its endpoint from the Splunk Cloud platform. See the *Supported Providers* section below for provider-specific URLs.
Azure API Version	2024-10-21	Required for Azure OpenAI only. The API version to use (e.g. `2024-10-21`). See Azure OpenAI documentation for available versions.
API Key	*(optional)*	The API key for authenticating with the AI provider. Stored encrypted via Splunk `storage_passwords` and cannot be retrieved again once saved. Leave empty for providers that do not require authentication (e.g. Ollama, Splunk Hosted).
Model	gpt-4o	The model name to use. Some providers support version aliases (e.g. `gpt-4o`, `mistral-large-latest`) that always target the latest release. See *Model Aliases* below.
Max Tokens	4096	Maximum number of tokens in the AI response. Higher values allow longer responses but increase cost and latency.
Temperature	0.3	Controls randomness in AI responses. Lower values (e.g. 0.1) produce more deterministic outputs, higher values (e.g. 0.8) produce more creative outputs.
Request Timeout	600	Maximum time in seconds to wait for an AI provider response. The default of 600 seconds (10 minutes) accommodates slow models or initial model downloads (e.g. Ollama pulling a model on first use).
Context Window (Ollama)	8192	Context window size in tokens for Ollama models. Must be large enough to accommodate the system prompt, context data, and conversation history. Only applies to the Ollama provider. Increase this value if context is being truncated.
Custom Prompt	*(empty)*	Optional additional instructions appended to the system prompt. Use this to customise the AI assistant's behaviour, add domain-specific context, or enforce response formatting preferences.

Tip

Use **Test connectivity** (per-row) or **Test all** after creating an account to validate the endpoint, credentials, and model name before relying on the provider. The test calls `POST /trackme/v2/ai/admin/test` under the hood.

3.2.4 Supported Providers

Named Providers

The following providers are explicitly supported with dedicated dropdown options. All use the OpenAI chat completions API format except Anthropic (which uses its native Messages API) and Splunk Hosted (which uses the SLIM API with automatic SCS authentication).

OpenAI

- **Provider**: `OpenAI`
- **Base URL**: `https://api.openai.com/v1`
- **API Key**: Required (from platform.openai.com)
- **Example models**: `gpt-4o`, `gpt-4o-mini`, `gpt-4.1`, `o4-mini`

Azure OpenAI

- **Provider**: `Azure OpenAI`
- **Base URL**: `https://<resource-name>.openai.azure.com/openai/deployments/<deployment-name>`
- **API Key**: Required (Azure portal)
- **Azure API Version**: Required (e.g. `2024-10-21`)
- **Example models**: Use the deployment name configured in Azure

Note

Azure OpenAI uses a different authentication mechanism (`api-key` header instead of `Authorization: Bearer`) and requires a mandatory `api-version` query parameter. TrackMe handles both automatically when the Azure provider type is selected.

Anthropic

- **Provider**: `Anthropic (Claude)`
- **Base URL**: `https://api.anthropic.com/v1`
- **API Key**: Required (from console.anthropic.com)
- **Example models**: `claude-sonnet-4-5-20250929`, `claude-sonnet-4-20250514`, `claude-haiku-4-5`, `claude-opus-4-6-20260213`

Note

Anthropic does not support `-latest` aliases. Use either generation-specific aliases (e.g. `claude-sonnet-4-5`) which auto-update within a generation, or pinned snapshot IDs (e.g. `claude-sonnet-4-5-20250929`) for deterministic behaviour. See Anthropic's model documentation for the full list.

Note

Anthropic uses a native Messages API rather than the OpenAI chat completions format. TrackMe automatically handles the API differences when the Anthropic provider type is selected.

Google Gemini

- **Provider**: `Google Gemini`
- **Base URL**: `https://generativelanguage.googleapis.com/v1beta/openai`
- **API Key**: Required (from Google AI Studio)
- **Example models**: `gemini-3-flash-preview`, `gemini-3-pro-preview`, `gemini-2.5-flash`, `gemini-2.5-pro`

Note

Google Gemini uses its OpenAI-compatible endpoint for integration. The API key is passed as a Bearer token in the Authorization header, which TrackMe handles automatically. Gemini 3 models are currently in preview and use the `-preview` suffix in their model names.

Mistral AI

- **Provider**: `Mistral AI`
- **Base URL**: `https://api.mistral.ai/v1`
- **API Key**: Required (from console.mistral.ai)
- **Example models**: `mistral-small-latest`, `mistral-medium-latest`, `mistral-large-latest`

Ollama

- **Provider**: `Ollama (local / self-hosted)`
- **Base URL**: `http://<ollama-host>:11434/v1`
- **API Key**: Not required
- **Example models**: `mistral`, `llama3.2`, `phi3`, `qwen2.5`

Hint

Ollama is a self-hosted inference server that provides full data privacy and control over your AI infrastructure. It runs powerful open-source models without sending any data to external APIs, making it ideal for environments with strict data governance requirements or air-gapped networks. On first use with a new model, TrackMe automatically triggers the model download on the Ollama server, which can take several minutes. The default request timeout of 600 seconds accommodates this.

Splunk Hosted (SLIM API)

- **Provider**: `Splunk Hosted (SLIM API)`
- **Base URL**: Leave empty (auto-discovered)
- **API Key**: Not required (auto-managed)
- **Example models**: `gpt-oss-120b`, `gpt-oss-20b`, `foundation-sec-1.1-8b-instruct`

Important

The Splunk Hosted (SLIM API) provider is **only available on Splunk Cloud** instances where Splunk has enabled the SLIM (Splunk Language and Intelligence Model) API. It is not available on Splunk Enterprise (on-premises) deployments.

How it works:

Unlike all other provider types, Splunk Hosted requires no manual credential or endpoint configuration:

- **No Base URL**: The SLIM API endpoint is automatically discovered from the Splunk Cloud platform using the SCS (Splunk Cloud Services) tenant information. Leave the Base URL field empty.
- **No API Key**: Authentication uses short-lived SCS tokens that are transparently obtained and refreshed by TrackMe at each request. No API key needs to be entered or managed.
- **Model selection**: You only need to choose a model. Available models can be discovered via the TrackMe REST API (see below).

Discovering available models:

You can query the available SLIM API models using the TrackMe REST API:

```
| trackme url="/services/trackme/v2/ai/admin/models" mode="get"
```

This returns the list of models currently available on your Splunk Cloud instance, including their `model_name` (display name) and `model_id` (the value to enter in the Model configuration field).

Hint

About the models — `gpt-oss-120b` is a ~117B parameter Mixture of Experts model suitable for general-purpose tasks requiring high quality. `gpt-oss-20b` is a smaller ~21B parameter model offering faster responses at lower cost. `foundation-sec-1.1-8b-instruct` is a security-focused model designed for cybersecurity analysis and security operations use cases. Model availability may vary depending on your Splunk Cloud deployment and entitlements.

Custom (OpenAI-Compatible)

The **Custom** provider type works with any API endpoint that implements the OpenAI chat completions format (`POST /chat/completions`). This includes a wide range of enterprise and open-source providers:

Provider	Base URL	Example Models
xAI (Grok)	`https://api.x.ai/v1`	`grok-3`, `grok-3-mini`
Together AI	`https://api.together.xyz/v1`	`meta-llama/Llama-3-70b-chat-hf`
Groq	`https://api.groq.com/openai/v1`	`llama-3.3-70b-versatile`, `mixtral-8x7b-32768`
Perplexity	`https://api.perplexity.ai`	`sonar-pro`, `sonar`
Cohere	`https://api.cohere.com/compatibility/v1`	`command-r-plus`, `command-r`
AWS Bedrock	`https://bedrock-runtime.<region>.amazonaws.com/openai/v1`	`anthropic.claude-sonnet-4-20250514-v1:0`
DeepSeek	`https://api.deepseek.com/v1`	`deepseek-chat`, `deepseek-reasoner`
OpenRouter	`https://openrouter.ai/api/v1`	Any model available on OpenRouter
NVIDIA NIM	`http://<nim-host>:8000/v1`	Depends on deployed model
LM Studio	`http://<lmstudio-host>:1234/v1`	Depends on loaded model

Note

When using the Custom provider type, ensure that the API endpoint is reachable from the Splunk search head running TrackMe and that it supports the standard OpenAI chat completions request and response format.

Note

A note on GitHub Copilot — GitHub Copilot is not a supported AI provider. Although community projects exist that proxy Copilot's internal endpoint (`api.githubcopilot.com`) as an OpenAI-compatible API, this endpoint is not an officially supported public API. It is designed exclusively for GitHub's own IDE extensions (VS Code, JetBrains, CLI), and using it through third-party applications violates GitHub's Terms of Service. Relying on it would expose your organisation to account suspension risk and potential breakage without notice. If you are in the Microsoft/GitHub ecosystem, use **Azure OpenAI** or **OpenAI** directly instead — these provide official, stable API access to the same underlying models that power Copilot.

Model Aliases

Some providers support **version aliases** that always point to the latest release of a model family. Using aliases avoids having to update the configuration when a new model version is released:

- **Mistral**: `mistral-small-latest`, `mistral-medium-latest`, `mistral-large-latest` — auto-update to the newest version within each model tier.
- **OpenAI**: `gpt-4o`, `gpt-4o-mini` — effectively aliases that point to the latest patch.
- **Anthropic**: Does **not** support `-latest` aliases. Use generation-specific aliases (e.g. `claude-sonnet-4-5`) or pinned snapshot IDs (e.g. `claude-sonnet-4-5-20250929`).

Check your provider's documentation for available aliases and version pinning options.

Multi-Provider Setup

TrackMe supports configuring **multiple AI providers** simultaneously. This is useful for:

- **Model comparison**: Try different models on the same question to compare analysis quality
- **Cost optimisation**: Use a cheaper model for routine questions and a premium model for complex investigations
- **Redundancy**: Fall back to an alternative provider if the primary is unavailable
- **Data privacy**: Run Ollama alongside a cloud provider — use the self-hosted option for sensitive environments and the cloud provider for general use
- **Platform-native option**: On Splunk Cloud, use Splunk Hosted alongside external providers — keep data within the Splunk platform while having an external model available as an alternative

To set up multiple providers, create multiple accounts on the **Manage AI Provider accounts** page, each with a descriptive name (e.g. `openai_gpt4o`, `ollama_mistral`, `anthropic_claude`).

When multiple providers are available, users see a provider selector dropdown in the AI chat panel that displays each provider's name and model, and the AI Advisors and Concierge let you pick which provider to run with.

3.2.5 Global AI settings

Beyond provider accounts, a small set of global toggles live under **Configuration > General**, in the **Artificial Intelligence** group. These control the AI Assistant feature switch, the concurrency cap, and data anonymisation.

Setting	Default	Description
Enable AI assistant	Yes	Enable or disable the AI assistant feature across all TrackMe UIs. When disabled, the AI assistant button is hidden from all users.
Max concurrent AI chats	10	Maximum number of concurrent AI chat requests across all users. Additional requests are rejected with an HTTP 429 response until a slot becomes available.
Anonymize entity names for AI	No	When enabled, entity names (object and alias fields) are anonymized using SHA256 hashing in describe endpoint responses consumed by AI providers. This protects potentially sensitive infrastructure details (hostnames, IPs, machine names) while preserving the object_id for entity identification. The AI assistant is guided to use object_id references instead of entity names.
Anonymize index names for AI	No	When enabled, Splunk index names are anonymized using SHA256 hashing in describe endpoint responses consumed by AI providers. This applies to data source (DSM), data host (DHM), and metric host (MHM) entities. Index names are replaced with their SHA256 hashes in entity information, investigation searches, and metric details. Investigation searches will contain hashed index names that users must replace with actual values before execution.

Note

The global `Enable AI assistant` toggle is enabled by default so that administrators can discover the feature, but — as stated above — no AI functionality is active until at least one provider account is configured.

3.2.6 Next steps

With at least one provider account configured, you are ready to use the rest of the AI layer:

- *AI Assistant* — the conversational assistant.
- *The AI Advisors* — the AI Advisor family (inspect / act).
- *The AI Concierge* — the catalog-driven AI Concierge.
- *AI Agents automation* — running the advisors unattended.

3.3 AI Assistant & Concierge

TrackMe's conversational surfaces: the **AI Assistant** answers questions and guides remediation in context, and the **AI Concierge** turns natural-language intent into the right TrackMe action.

3.3.1 AI Assistant

Overview

The TrackMe AI Assistant is an integrated, context-aware AI chat assistant available across the entire TrackMe product. It helps users investigate entity health issues, manage operational workflows, and get instant guidance on any TrackMe feature — all directly within the Splunk interface.

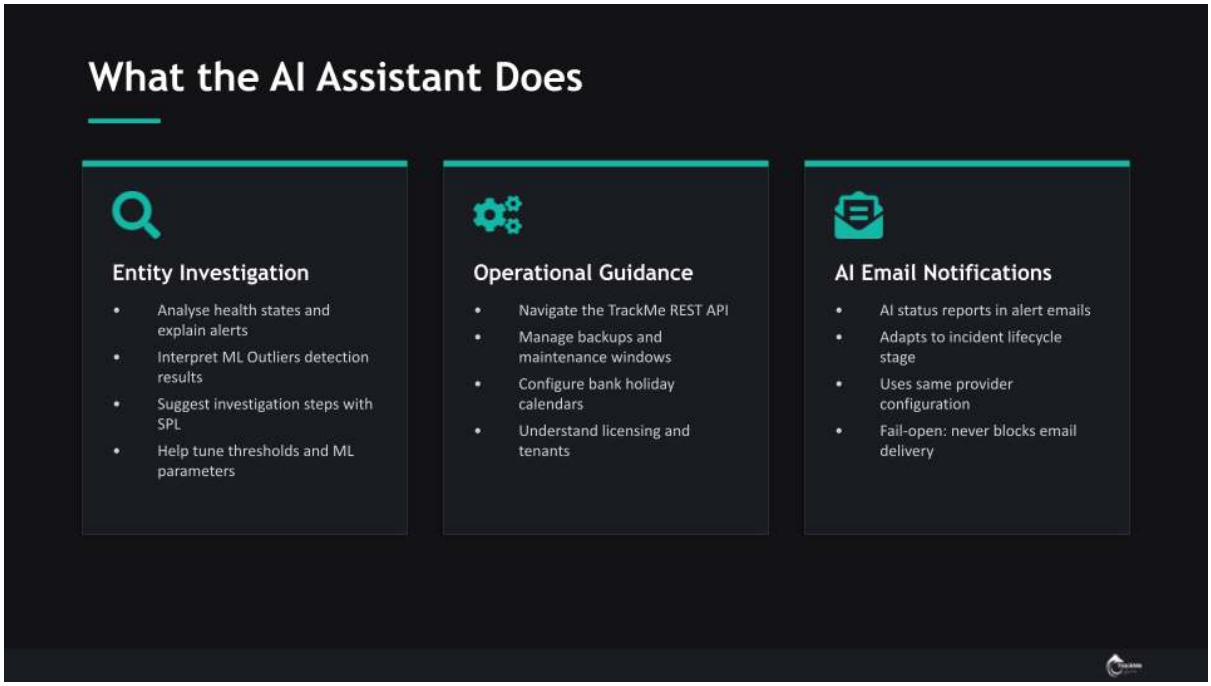
Note

Compatibility — The AI Assistant is compatible with **Python 3.9.x and later**, so it is available on the same Splunk releases as the rest of TrackMe. The advanced *AI Advisors* additionally require Splunk 10.2.x and later (Python 3.13.x); see *Artificial Intelligence in TrackMe* (Requirements & compatibility) and the *compatibility page*.

Capabilities

Three pillars of AI-powered assistance across TrackMe.

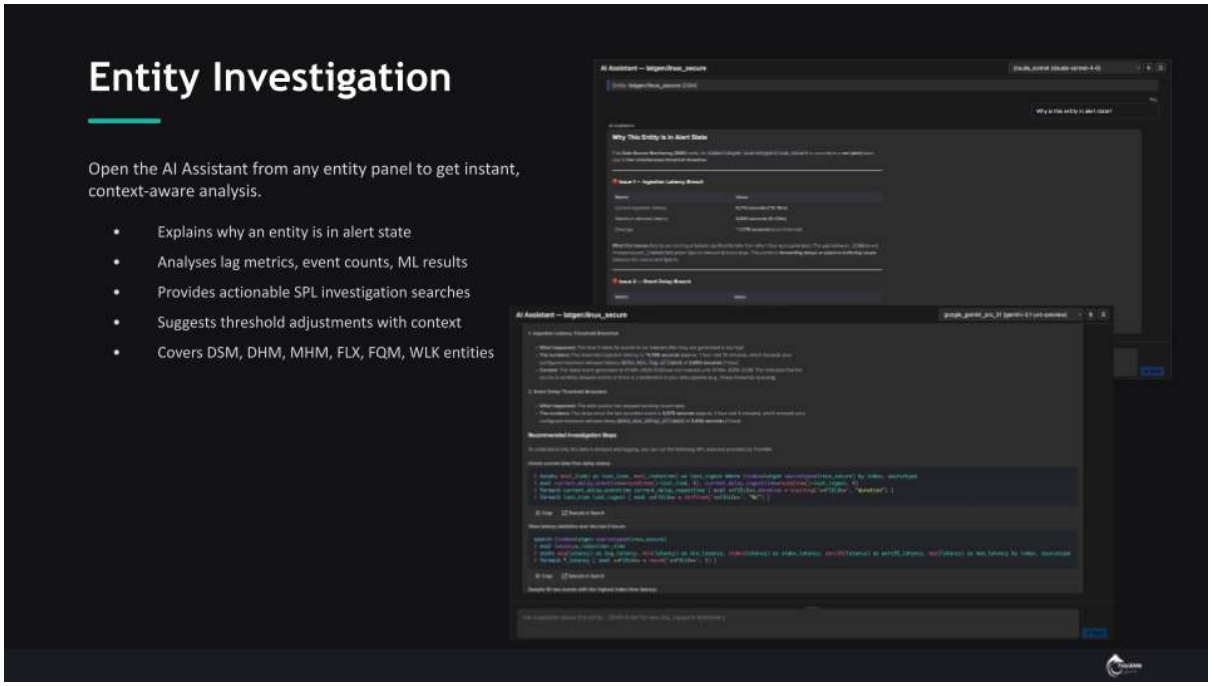
The AI Assistant covers entity investigation, operational guidance across all TrackMe features, and AI-powered email notifications — all from a single, context-aware chat interface.



Entity Investigation

Open the AI Assistant from any entity panel to get instant, context-aware analysis.

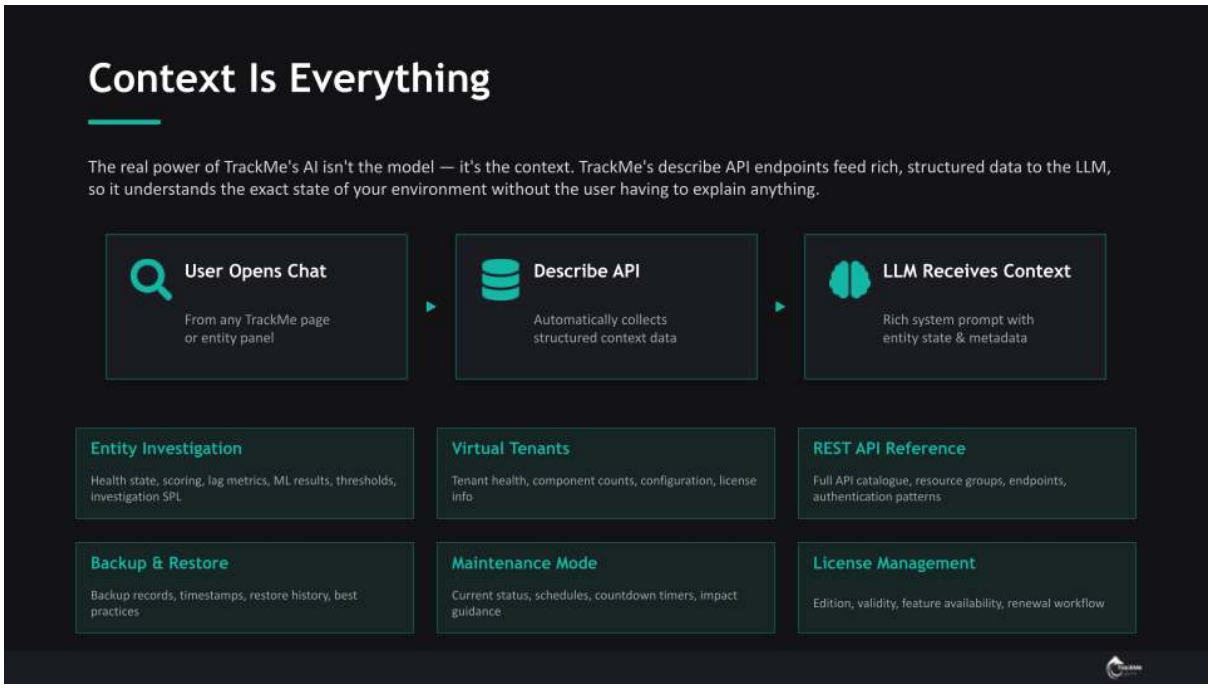
The assistant explains why an entity is in alert state, analyses lag metrics, event counts, and ML results, provides actionable SPL investigation searches, and suggests threshold adjustments with full context. Covers DSM, DHM, MHM, VOL, FLX, FQM, and WLK entities.



Context Is Everything

The real power of TrackMe's AI isn't the model — it's the context.

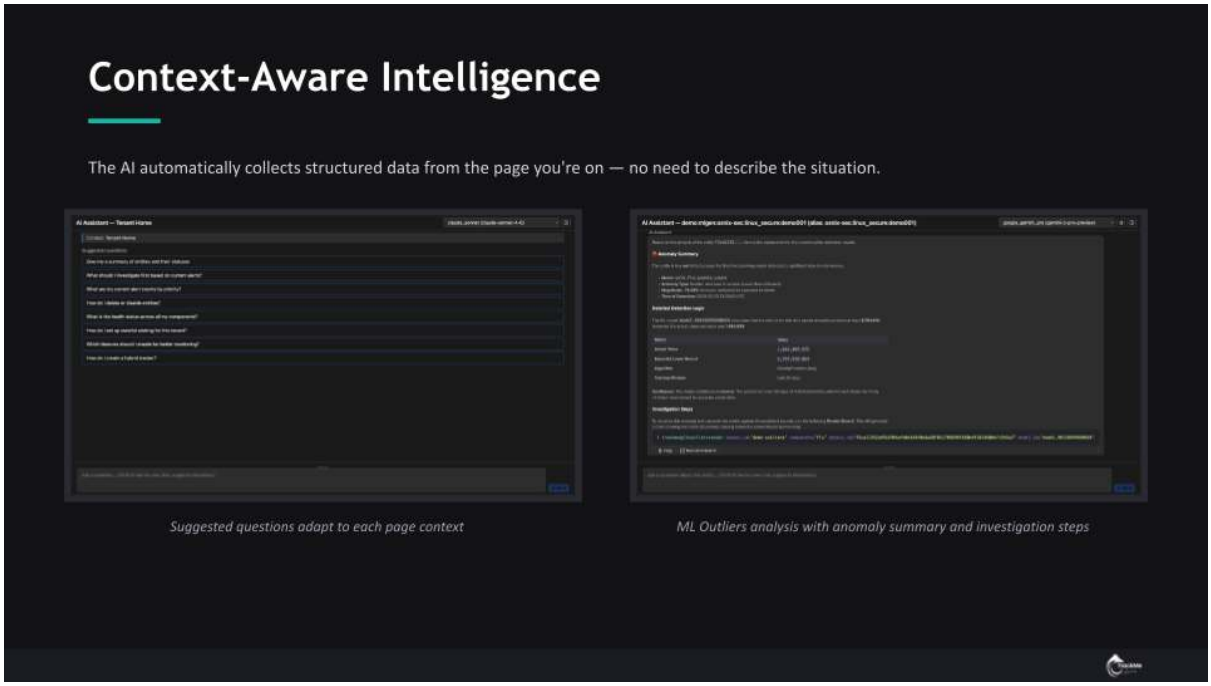
TrackMe's describe API endpoints feed rich, structured data to the LLM, so it understands the exact state of your environment without the user having to explain anything. Context types include entity investigation, virtual tenants, REST API reference, backup & restore, maintenance mode, and license management.



Context-Aware Intelligence

The AI automatically collects structured data from the page you're on — no need to describe the situation.

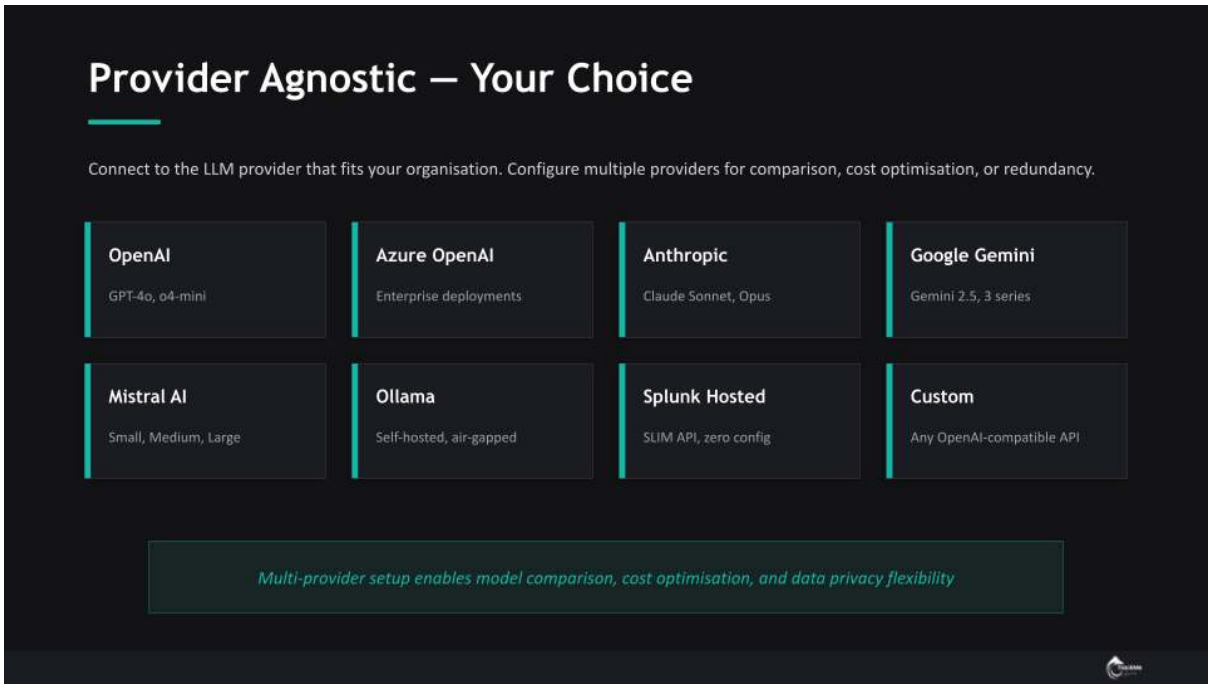
Suggested questions adapt to each page context, and the assistant provides targeted analysis whether you're investigating an entity alert, exploring ML Outliers anomalies, or navigating the REST API.



Provider Agnostic

Connect to the LLM provider that fits your organisation.

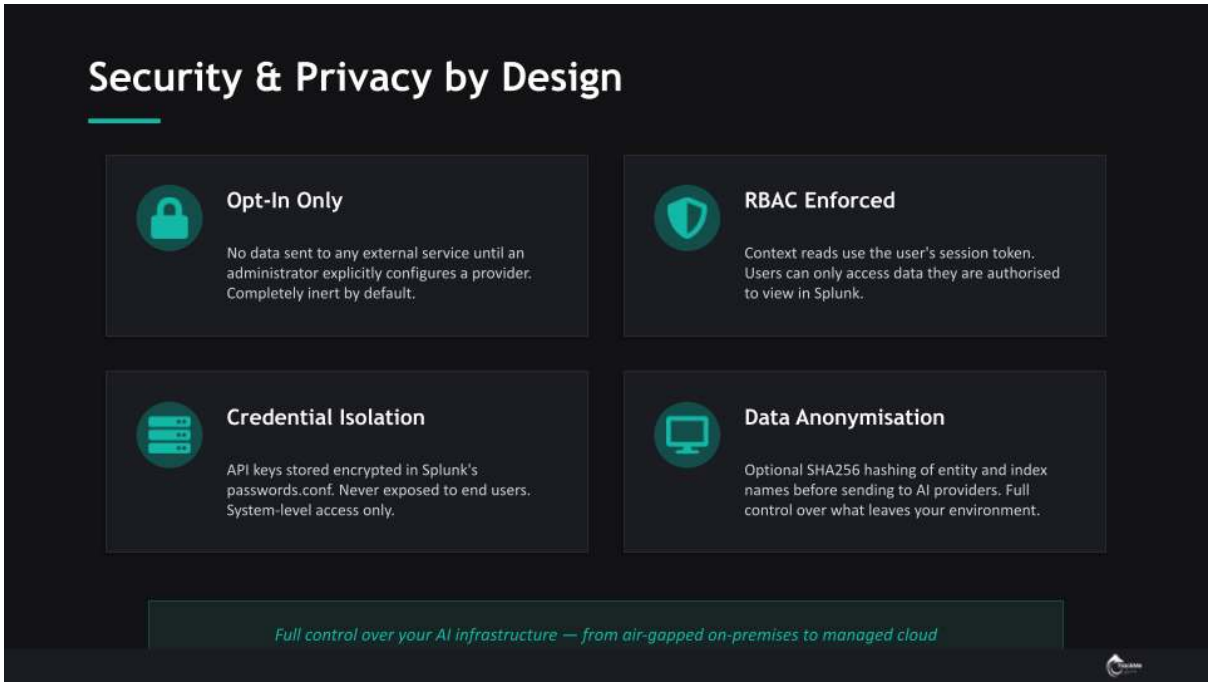
Configure multiple providers for comparison, cost optimisation, or redundancy. Supported providers include OpenAI, Azure OpenAI, Anthropic, Google Gemini, Mistral AI, Ollama, Splunk Hosted (SLIM API), and any OpenAI-compatible endpoint.



Security & Privacy

Security and privacy by design — full control over your AI infrastructure.

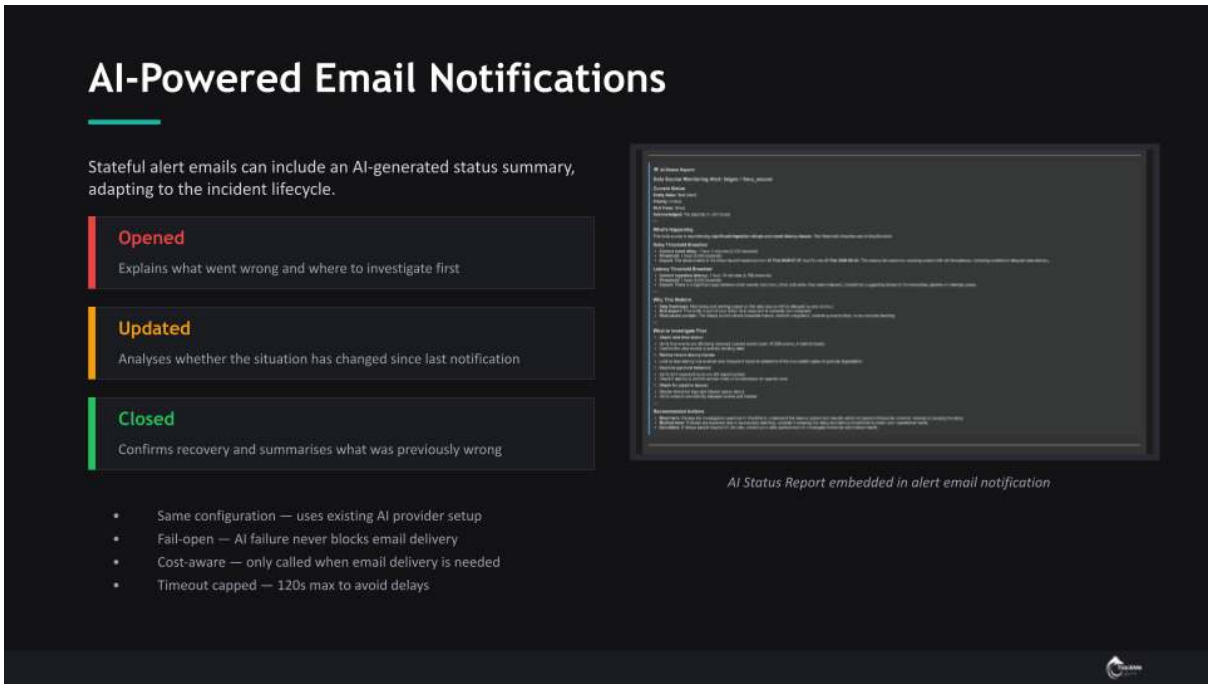
Opt-in only (completely inert until configured), RBAC enforced (users only access data they're authorised to view), credential isolation (API keys stored encrypted, never exposed to end users), and optional data anonymisation (SHA256 hashing of entity and index names).



Email Notifications

Stateful alert emails can include an AI-generated status summary, adapting to the incident lifecycle.

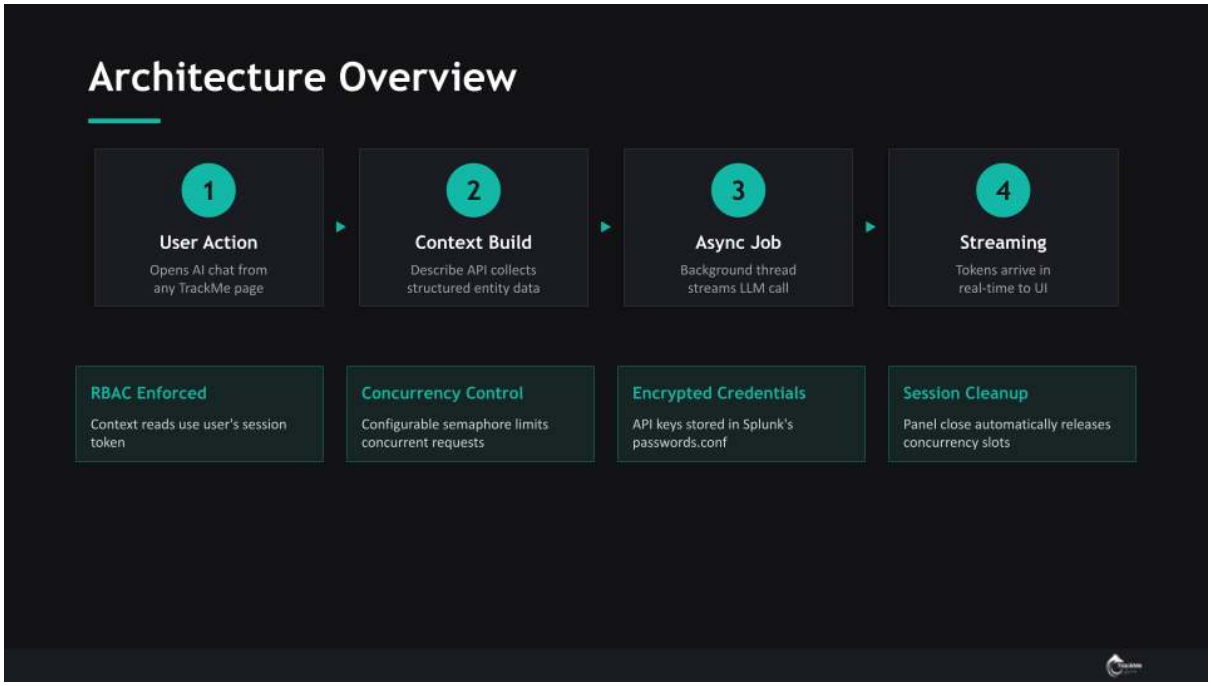
The AI report explains what went wrong on incident open, analyses changes on update, and confirms recovery on close. Uses the same provider configuration, operates fail-open (never blocks email delivery), and is capped at 120 seconds to avoid delays.



Architecture

Asynchronous, streaming architecture with built-in security controls.

The flow proceeds in four steps: user opens chat from any TrackMe page, describe API collects structured entity data, a background thread streams the LLM call, and tokens arrive in real-time to the UI. RBAC enforcement, concurrency control, encrypted credentials, and automatic session cleanup are built in.



Important

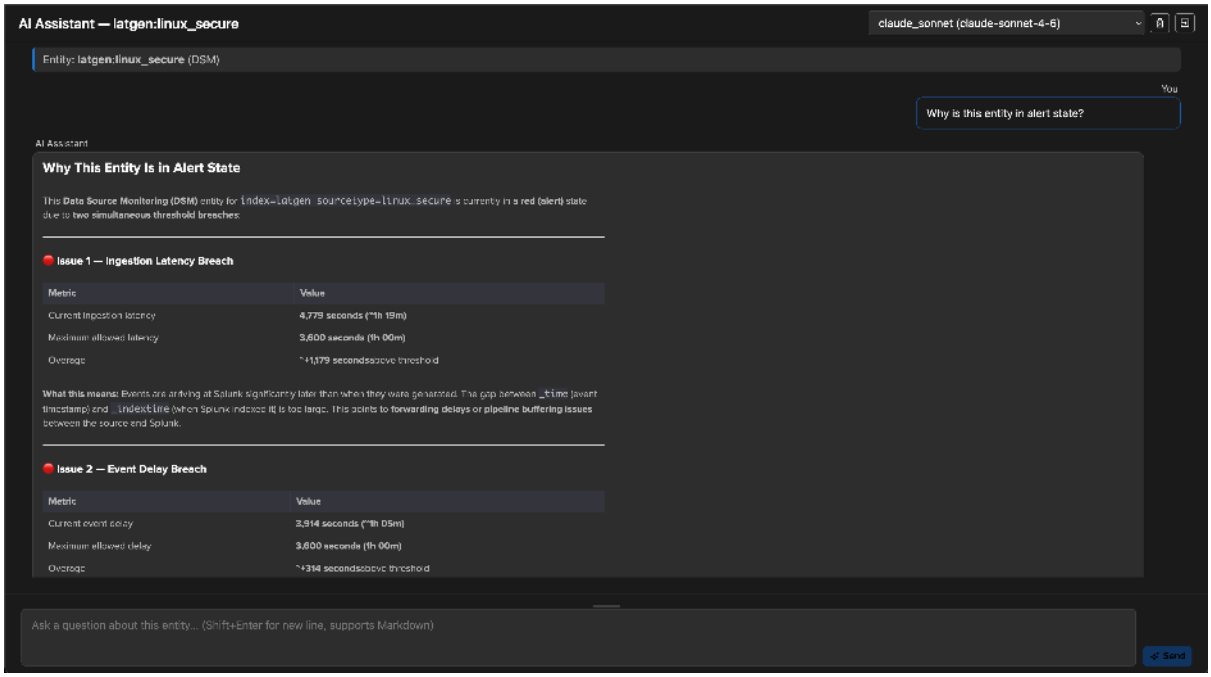
Opt-in only — The AI Assistant is entirely opt-in. While the feature toggle is enabled by default so that administrators can discover it, no AI functionality is active, no data is sent to any external service, and no LLM calls are made until an administrator explicitly configures at least one AI provider. Without a configured provider, the feature is completely inert.

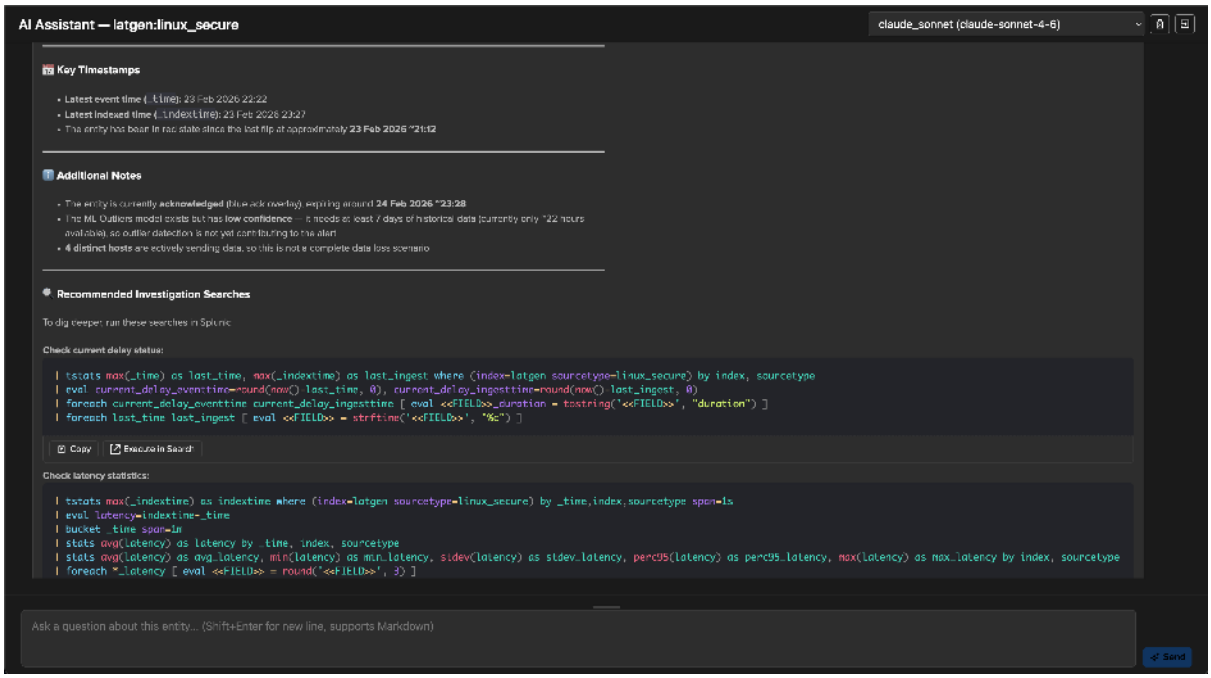
Tip

Full control over your AI infrastructure — Organisations with strict data privacy, data sovereignty, or regulatory requirements retain complete control over which AI provider is used and where data is processed. TrackMe can be connected to:

- **Splunk's own hosted LLMs** via the Splunk Hosted (SLIM API) provider type on Splunk Cloud, with zero configuration beyond selecting the provider and model — no API keys, no base URL, fully managed by the Splunk platform
- **Self-hosted open-source LLMs** via Ollama, keeping all data entirely on-premises with zero external API calls
- **Private or corporate LLM deployments** via the Custom (OpenAI-compatible) provider type, enabling integration with any internally hosted endpoint that implements the OpenAI chat completions format
- **Cloud providers of your choice**, including region-specific deployments (e.g. Azure OpenAI in a specific geography) to meet data residency requirements

The choice of provider is yours — from fully air-gapped on-premises models to managed cloud services — and no data is ever shared between configured providers.





Configuration

Before the AI Assistant can be used, an administrator must configure at least one **AI provider account** and (optionally) review the global AI settings. Both are covered in their own page:

- *Configuring AI Provider accounts* — create and test provider accounts (OpenAI, Azure OpenAI, Anthropic, Google Gemini, Mistral AI, Ollama, Custom, Splunk Hosted), and the global `Enable AI assistant`, concurrency, and anonymisation settings.

Important

At least one AI provider account must be configured for the AI Assistant to function. If no provider is configured, users see an informative error message when they attempt to open the AI chat panel. See *Configuring AI Provider accounts*.

Usage

Opening the AI Assistant

The AI Assistant is available throughout TrackMe via two patterns depending on the context.

From Entity Investigation

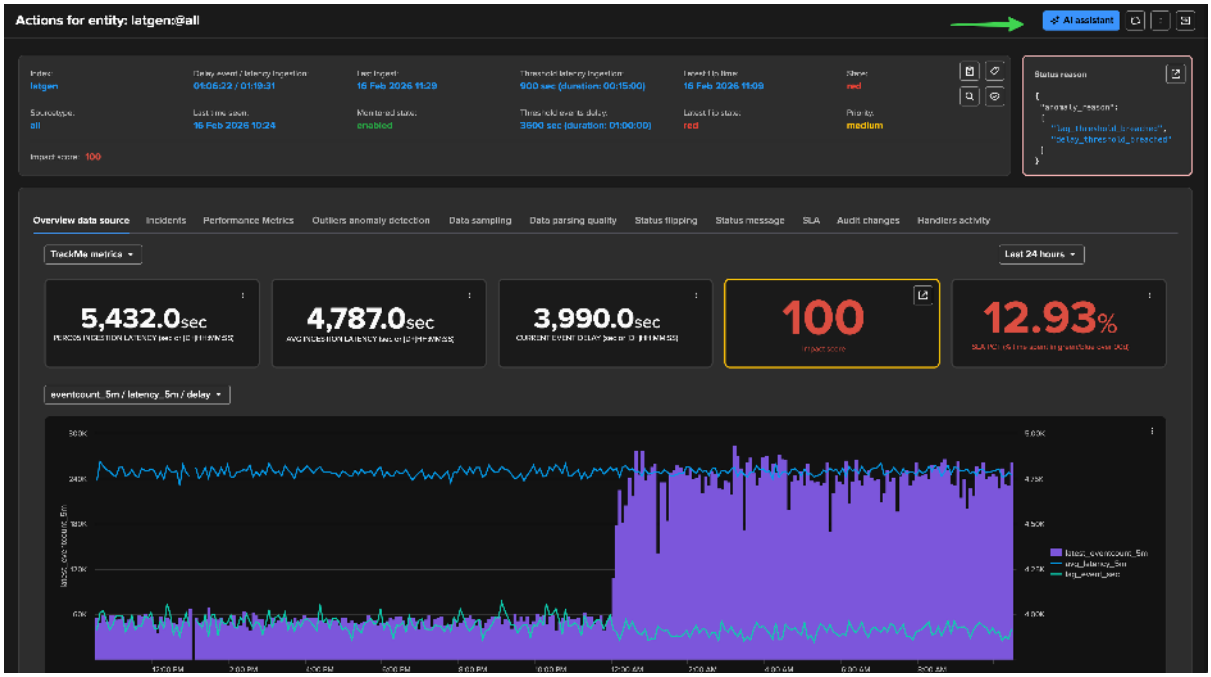
When investigating a specific entity (DSM, DHM, MHM, VOL, FLX, FQM, WLK), the AI Assistant can be opened via:

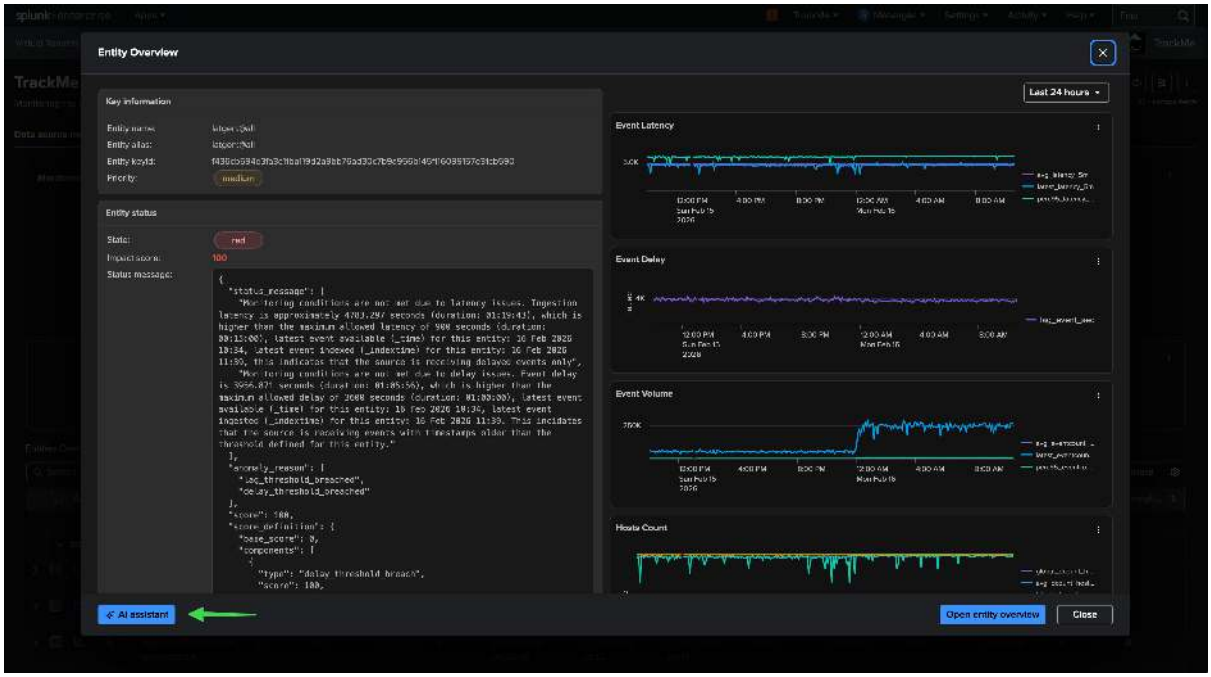
Entity overview panel:

1. Open an entity investigation panel by clicking on an entity in the monitoring dashboard
2. Click the **AI Assistant** button in the panel header
3. The AI chat panel opens as a full-screen slide panel with the entity context pre-loaded

Entity actions menu:

1. Click the three-dot actions menu (kebab menu) on any entity row in the monitoring dashboard
2. Select **Ask AI**
3. The AI chat panel opens directly with the entity context pre-loaded





From TrackMe UI Pages

Each TrackMe UI page features an **AI assistant** button in the top-right header. Clicking it opens the AI chat panel with the relevant context for that page automatically loaded.

The AI Assistant is available from the following pages:

- **Virtual Tenants** — context includes all tenants, their health states, and configuration
- **Tenant Home** — context includes tenant-specific entities and component overview
- **REST API Reference** — context includes the full API catalogue, resource groups, and usage patterns
- **Backup & Restore** — context includes backup records, status, and scheduling information
- **Global Maintenance Mode** — context includes current maintenance status, scheduling, and countdown
- **Maintenance Knowledge Database** — context includes KDB records and per-entity maintenance windows
- **Bank Holidays Management** — context includes the calendars and their rules, active and upcoming holidays, and the default scope
- **License Management** — context includes edition, validity, expiration, and feature information

Note

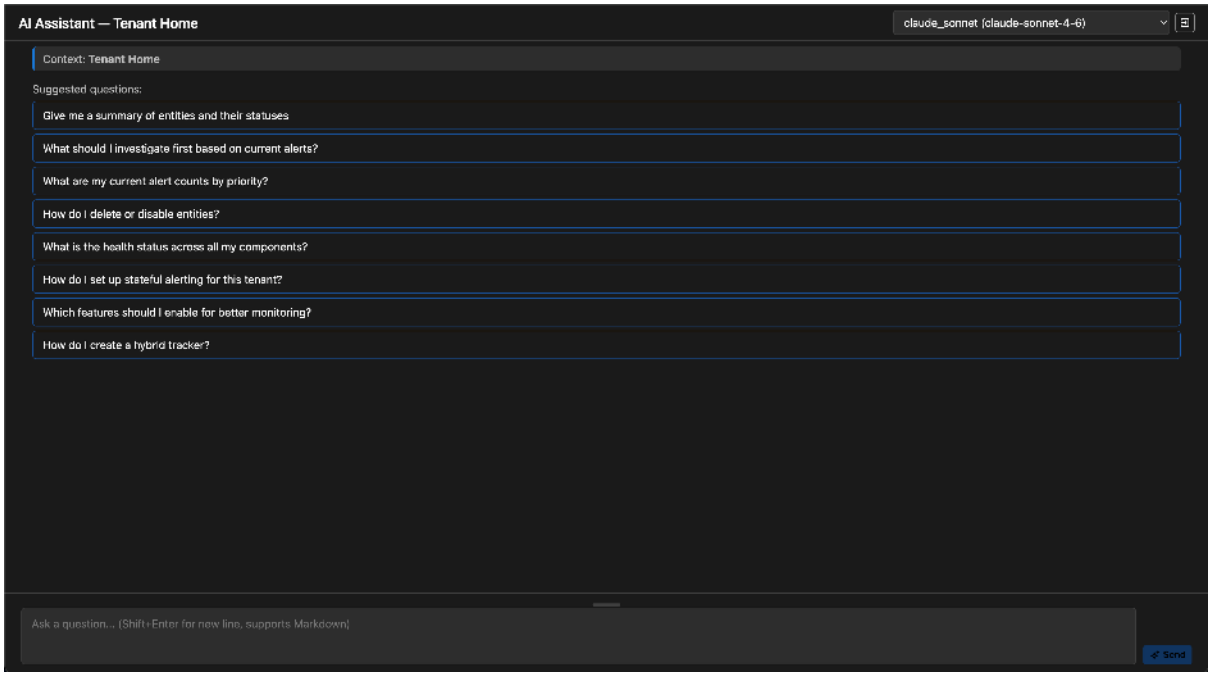
The AI assistant button is only visible when the feature is enabled in the General settings and at least one AI provider is configured.

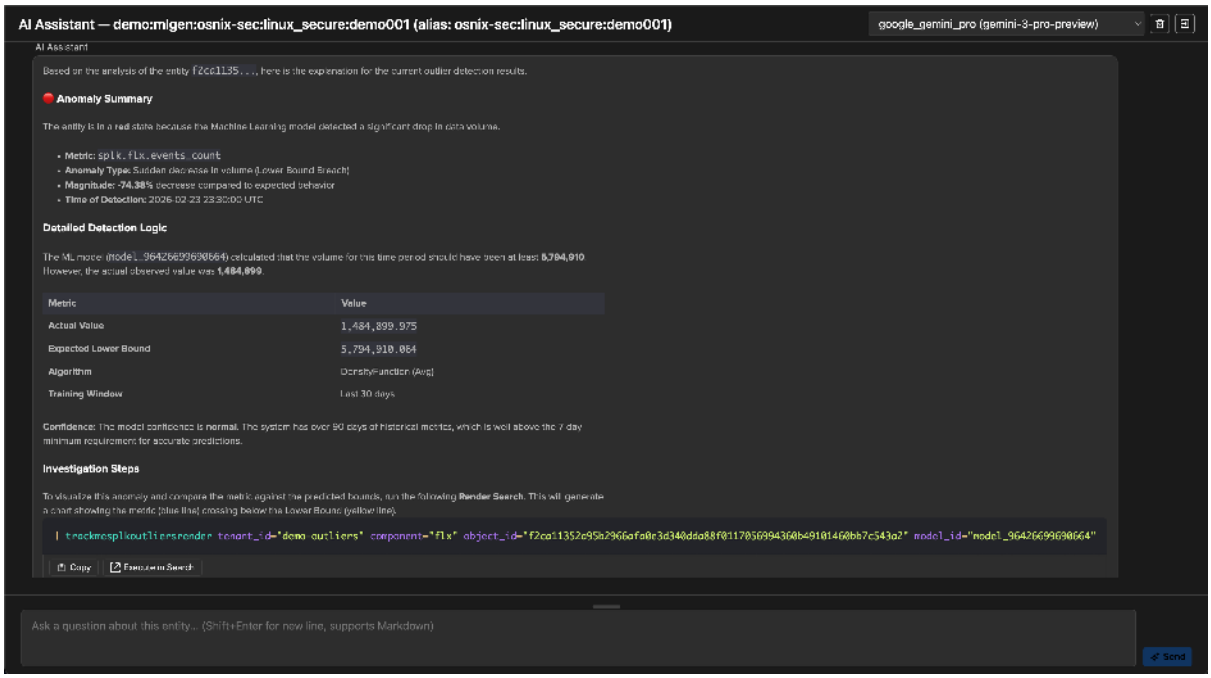
Chat Interface

The AI chat panel provides a conversational interface with the following features:

Suggested questions: When the chat panel opens, context-specific suggested questions are displayed to help get started. The questions are tailored to the page the assistant was opened from. For example, entity investigation suggests questions about health state and thresholds, while the Backup & Restore page suggests questions about backup status and restore procedures.

Free-form questions: Type any question in the input field at the bottom of the panel. Press **Enter** to send (use **Shift+Enter** for a newline).





Streaming responses: AI responses stream in real-time as tokens are generated, providing immediate feedback.

Conversation context: The AI Assistant maintains conversation history within the session. Follow-up questions are understood in the context of previous messages.

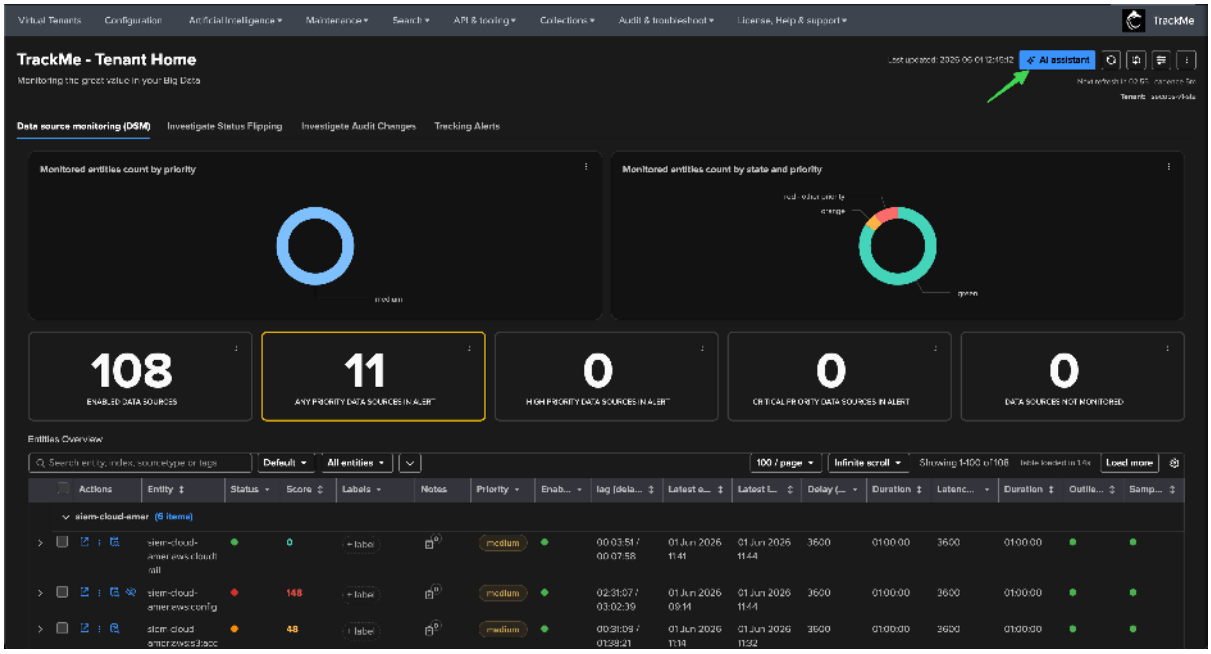
Markdown rendering: AI responses support full Markdown formatting including code blocks, tables, lists, and inline formatting. SPL searches are displayed in syntax-highlighted code blocks for easy copy-paste.

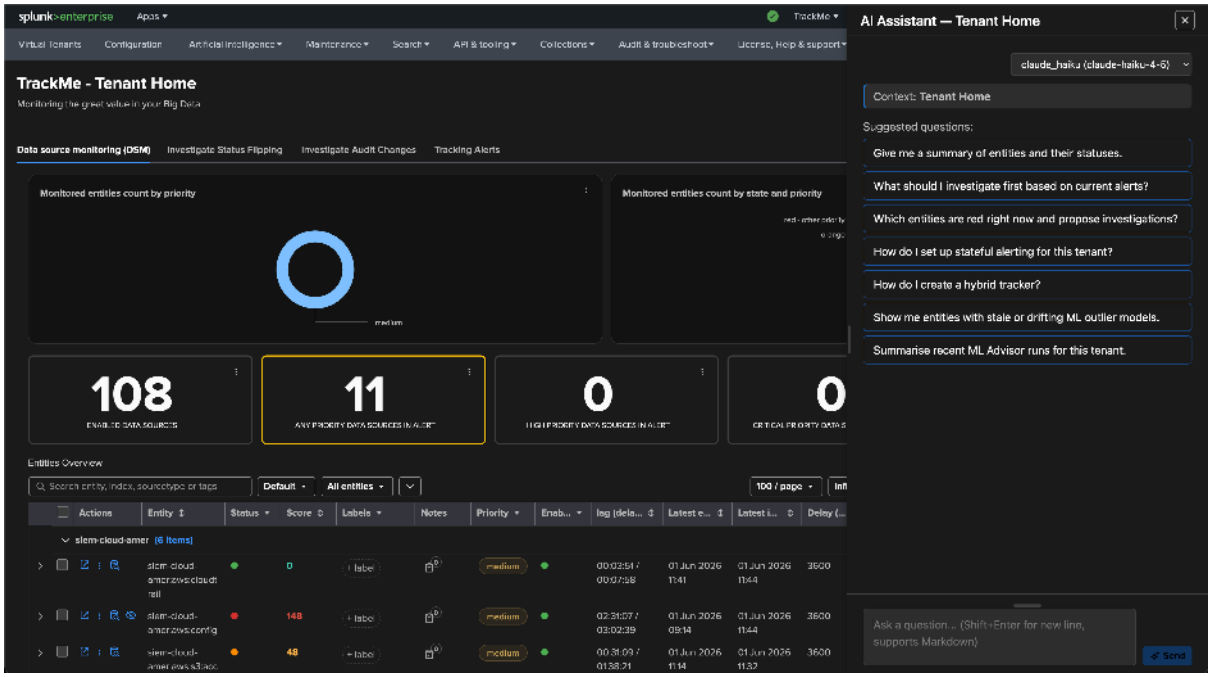
Provider switching: If multiple providers are configured, use the dropdown at the top of the chat panel to switch between providers. Switching providers clears the conversation history.

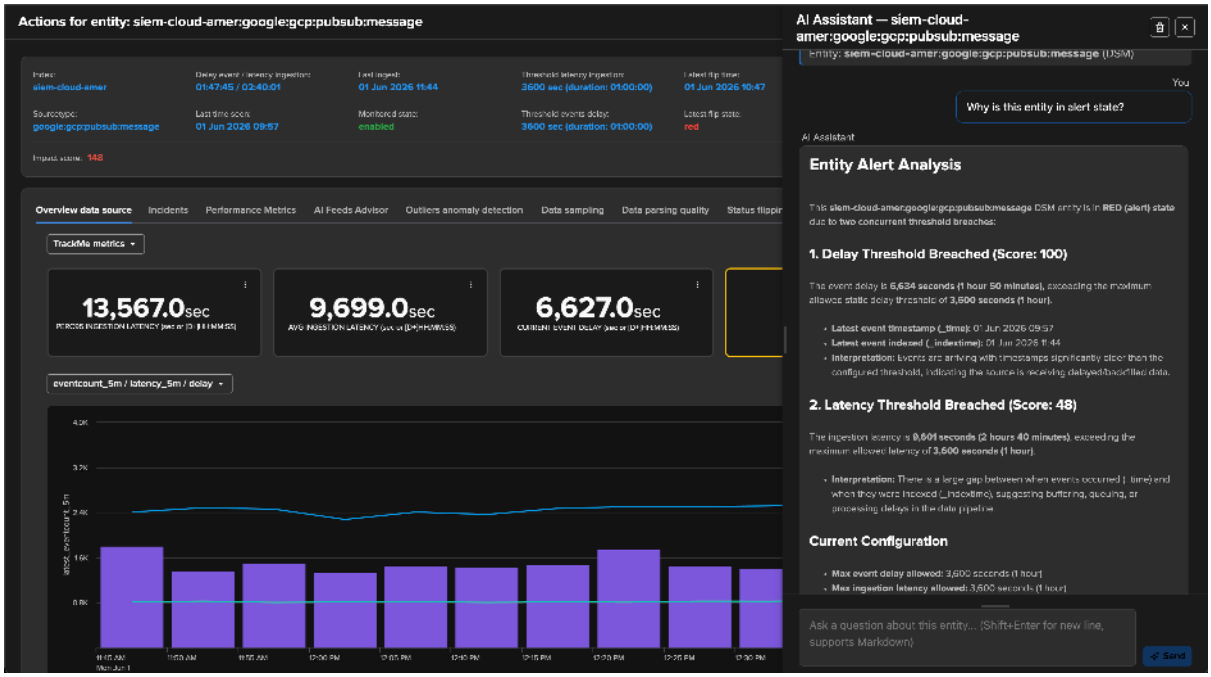
Clear chat: Use the trash icon button to clear the conversation and start fresh.

Worked examples

The simplest way to experience the AI Assistant is to open it from an entity and ask a plain question. In the example below, the assistant is opened from **Tenant Home** and then on a specific DSM entity; the suggested questions adapt to the entity, and a question such as *"What is the difference between latency and delay in TrackMe? How is it calculated?"* is answered with a precise, context-aware explanation grounded in that entity's live metrics.







Actions for entity: siem-cloud-amer:google:gcp:pubsub:message
Overview data source
Incidents
Performance Metrics
AI Feeds Advisor
Outliers anomaly detection
Data sampling
Data parsing quality
TrackMe metrics
13,567.0sec
9,699.0sec
6,627.0sec
eventcount_5m / latency_5m / delay

Send

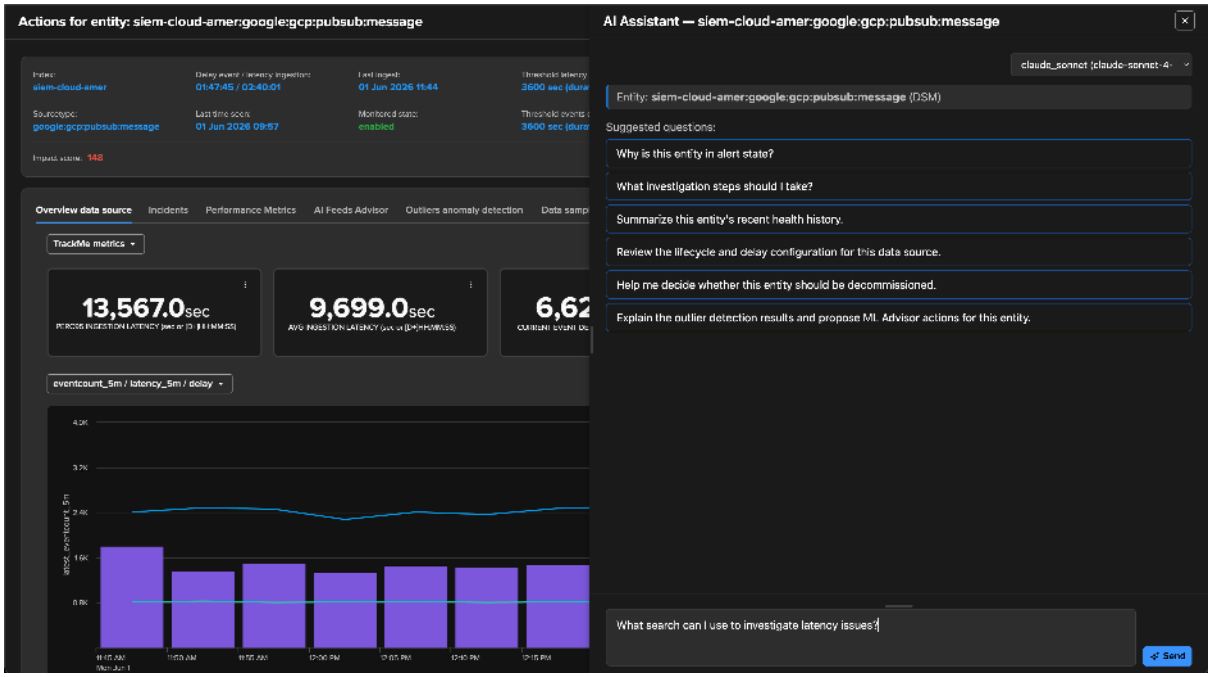
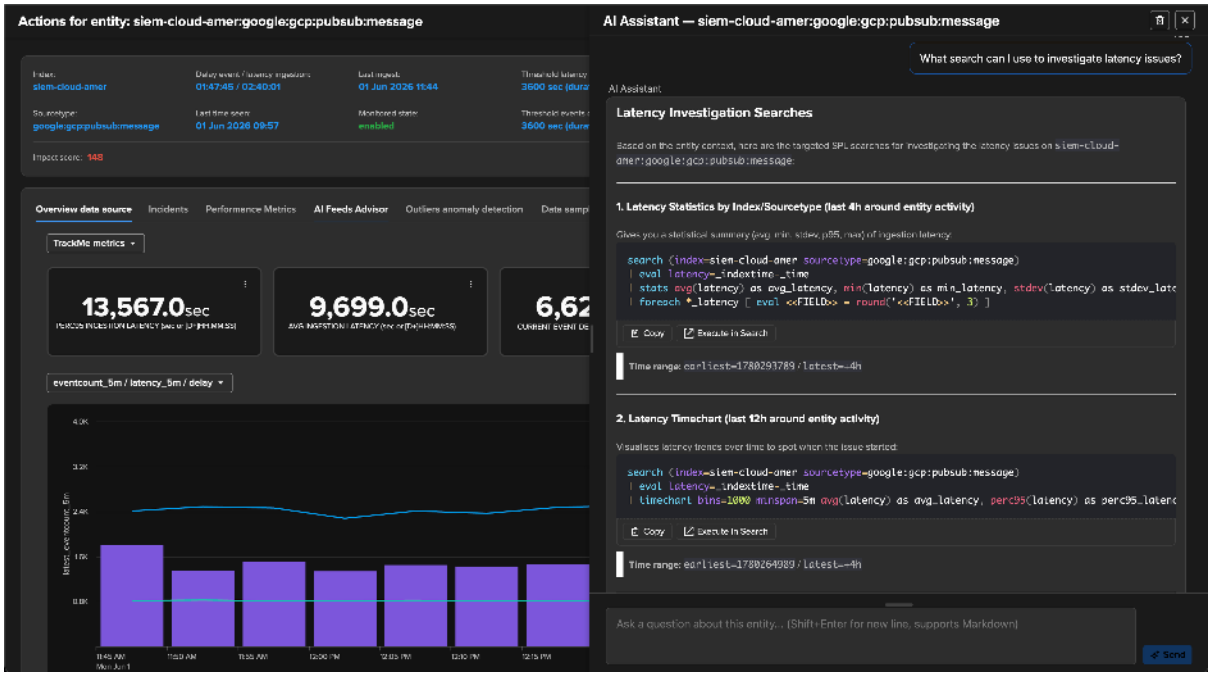
Because the assistant has the entity's full context, it can also produce **ready-to-run SPL searches** tailored to the question — for example when asking *"What search can I use to investigate latency issues?"*. SPL is rendered in syntax-highlighted code blocks with **Copy to clipboard** and **Execute in Search** buttons, so you can move from question to investigation in one click.





Tip

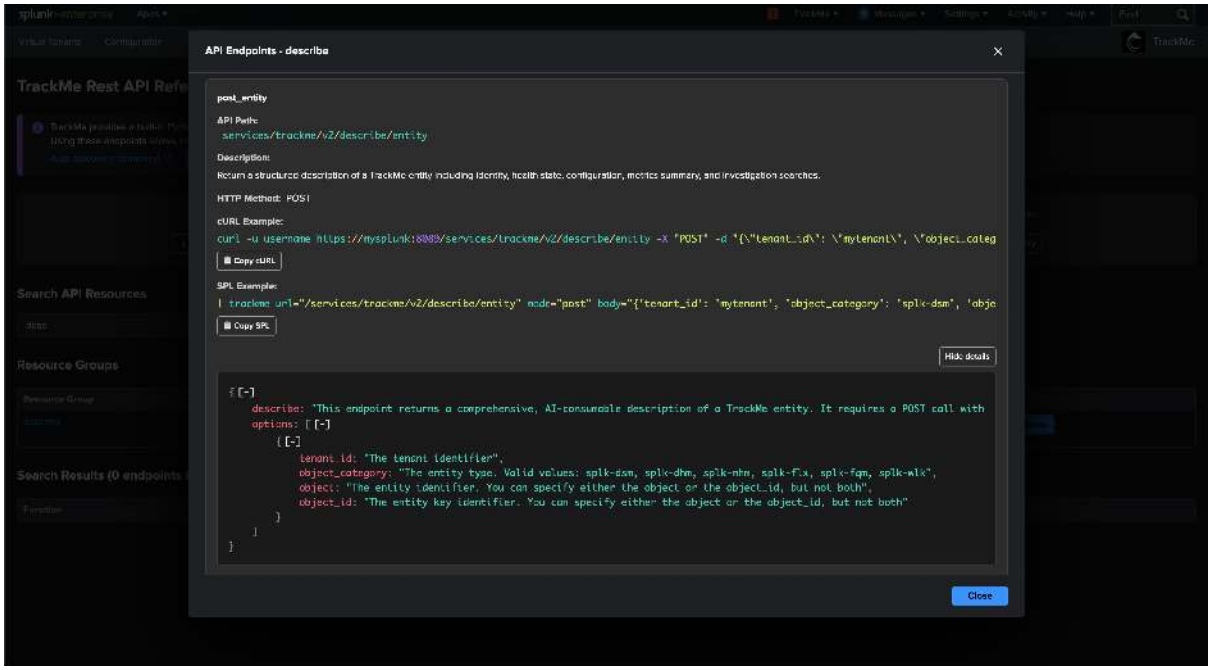
The AI Assistant is the *front door* to the wider AI layer. When you describe a problem it can resolve, the assistant proposes a one-click **consent card** that hands off to a specialist *AI Advisor* or to the *AI Concierge* — see those pages for the full agentic workflow.

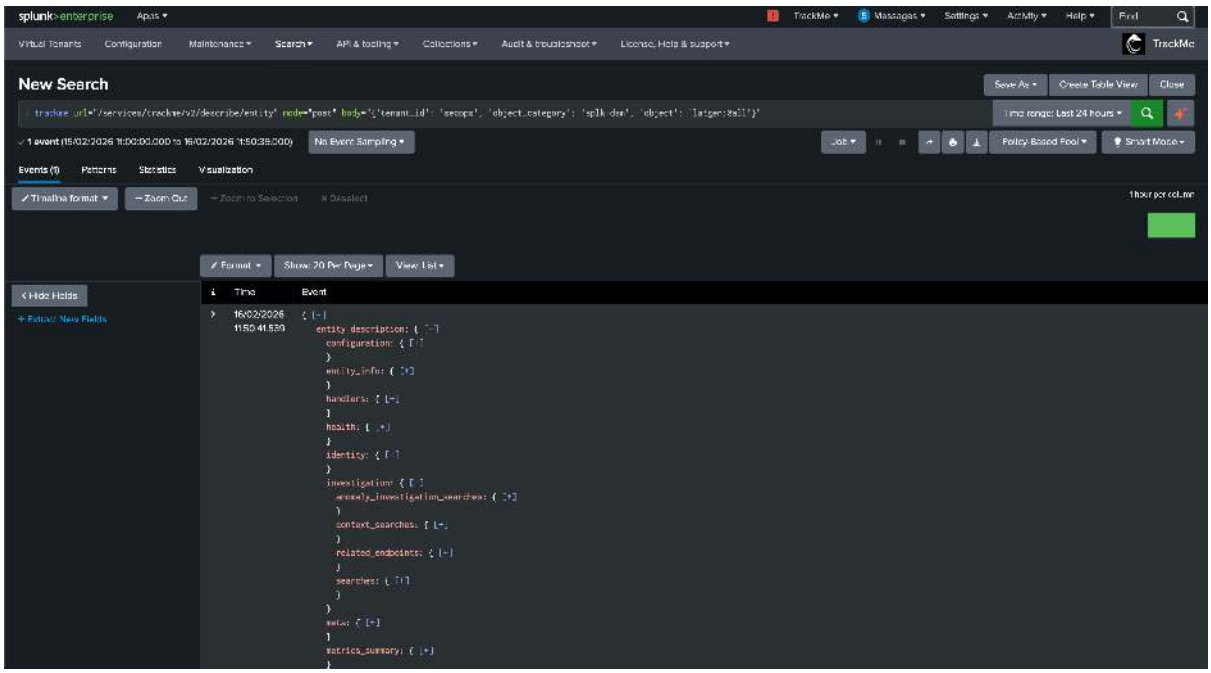
Context Enrichment

When a chat session starts, TrackMe automatically collects structured data relevant to the page the assistant was opened from. This context is passed to the LLM as part of a specialised system prompt, enabling the AI to provide specific, data-driven answers without the user having to describe the situation manually.

The following table summarises what context is collected for each area:

Context	Data Collected
Entity investigation	Health state, scoring, data lag and event count metrics, configured thresholds, ML Outliers detection results, investigation SPL searches, health history, entity metadata (index, sourcetype, host, etc.), and threshold tuning guidance.
Virtual Tenants	All tenants with their health states, component counts, configuration, and license information.
Tenant Home	Tenant-specific entities, health overview, components, and configuration details.
REST API Reference	Full API catalogue including resource groups, endpoints, HTTP methods, authentication patterns, SPL `| trackme` command syntax, and the `describe=true` self-documentation pattern.
Backup & Restore	Backup archive records (timestamps, labels, status, type), restore history, and a knowledge reference covering backup procedures and best practices.
Global Maintenance Mode	Current maintenance status (enabled/disabled/scheduled), start and end times, countdown to auto-disable, and a knowledge reference on maintenance impact.
Maintenance Knowledge Database	KDB record counts, recent records sorted by end time (planned and unplanned types), per-entity maintenance windows, and guidance on KDB management.
Bank Holidays Management	Calendars with their rules, active and upcoming holidays, the system defaults, and what a holiday does for a tenant (alerts, SLA, ML training, monitoring windows).
License Management	Current edition, validity and expiration status, feature availability per edition, developer mode status, and renewal workflow guidance.





Entity Threshold Tuning Guidance

The entity investigation context includes a `thresholds_help` section that provides entity-type-specific advisory guidance for threshold tuning. This enables the AI Assistant to give accurate, actionable advice when users ask about adjusting thresholds:

- **DSM / DHM**: Explains event delay, ingestion latency, future tolerance, adaptive delay, variable delay, and lagging class thresholds. DSM entities additionally include host count monitoring guidance.
- **MHM**: Covers metric lag and future tolerance thresholds, as well as the metric category policy.
- **FLX**: Distinguishes between entity-level settings (inactivity timeout) and use case-level threshold conditions defined in the FLX tracker configuration.
- **FQM**: Explains that thresholds are managed at the FQM tracker level (success rate and coverage conditions).
- **WLK**: Explicitly notes that Workload Monitoring entities do not have user-configurable thresholds, and advises

investigating execution issues instead.

Session Lifecycle

Panel close and job cancellation: When the AI chat panel is closed (or the user navigates away), the frontend automatically cancels any in-flight AI request. This releases the concurrency slot immediately so other users can use the AI Assistant without hitting the concurrency limit. The backend worker thread may continue briefly until the LLM responds, but the response is discarded.

Custom Prompt

Administrators can use the **Custom Prompt** field in the AI Provider configuration to add domain-specific instructions that are appended to the system prompt. Example use cases:

- Enforce response formatting (e.g. always include a "Next Steps" section)
- Add organisation-specific context (e.g. known maintenance windows, team ownership)
- Customise the assistant's tone or verbosity
- Include relevant runbook references or escalation procedures

AI Status Report in Stateful Alert Emails

In addition to the interactive chat assistant, the AI infrastructure powers an optional **AI Status Report** feature in stateful alert email notifications. When enabled, each email notification includes an AI-generated entity status summary embedded directly in the HTML email body.

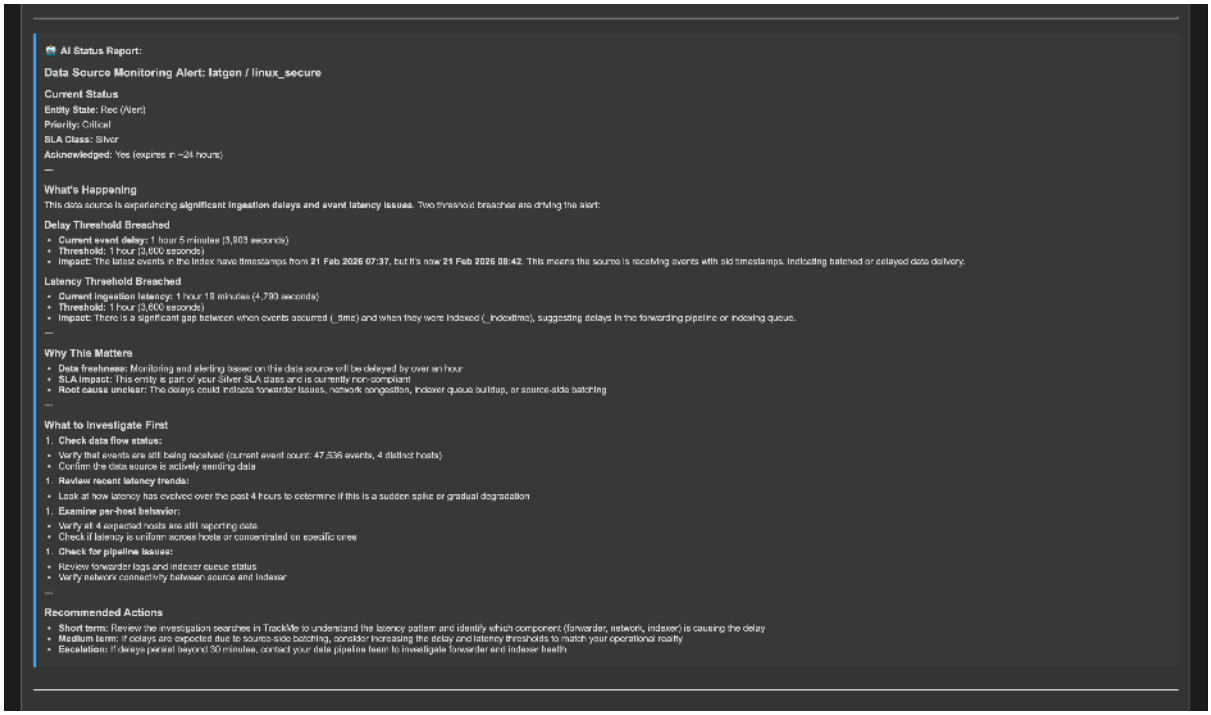
How it works:

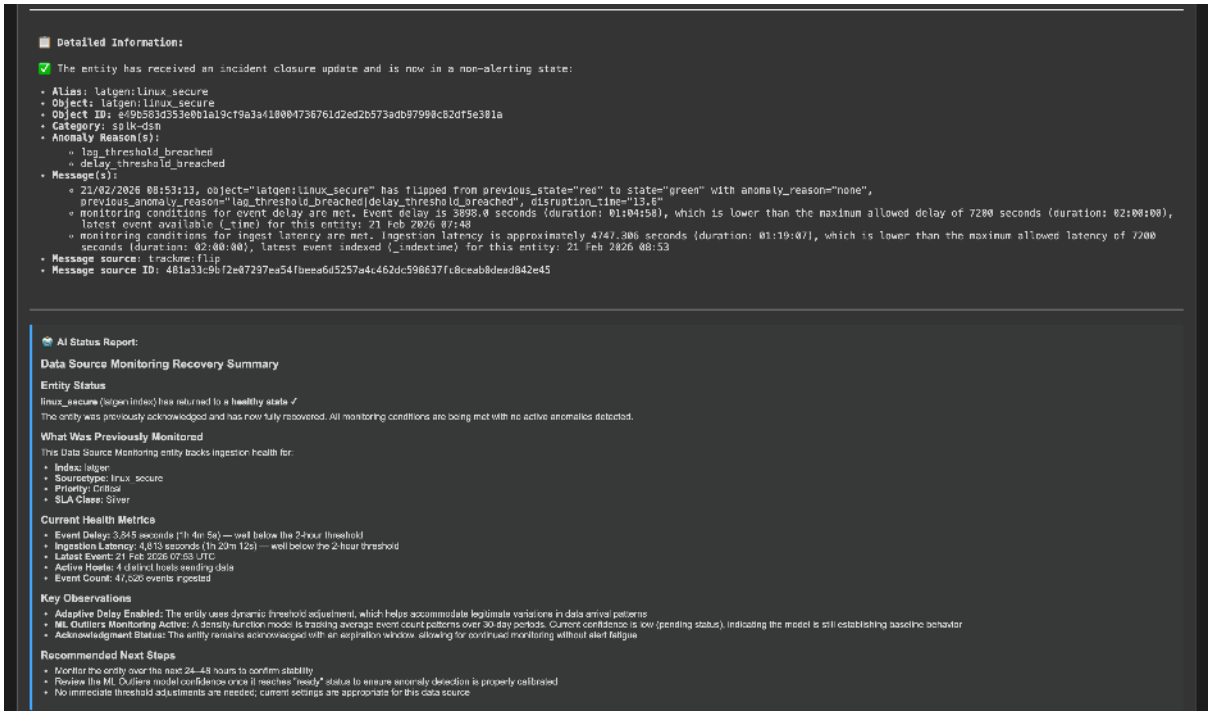
1. When a stateful alert triggers and email delivery is required, TrackMe calls the configured AI provider with the entity context (the same describe data used by the interactive chat).
2. The AI generates a concise, actionable summary tailored to the incident lifecycle stage:
    - **Opened**: Explains what went wrong and where to investigate first
    - **Updated**: Analyses whether the situation has changed since the last notification
    - **Closed**: Confirms the recovery and summarises what was previously wrong
3. The AI response is converted to email-safe HTML and embedded in the notification between the detailed information and charts sections.

Key design principles:

- **Same provider configuration**: The AI Status Report uses the same AI provider(s) configured in **Configuration > AI Provider**. No additional AI setup is required.
- **Fail-open**: If the AI provider is unavailable, slow, or returns an error, the email notification is delivered normally without the AI section. No email is ever blocked by an AI failure.
- **Cost-aware**: The AI report is only generated when email delivery is actually needed. If the entity's priority level is filtered out from email notifications by priority routing, no AI call is made.
- **Timeout capped**: The AI request timeout is capped at 120 seconds for email flows to avoid excessive notification delays.

Example of an email notification with the AI Status Report:





Configuration:

The AI Status Report is configured per stateful alert in the alert creation wizard or in the Splunk alert action editor:

- `AI Status Report`: Enable or disable. Defaults to **enabled** when at least one AI provider is configured.
- `AI Provider`: Optionally select a specific provider when multiple are configured. Defaults to the first available provider.

For detailed setup instructions, see *Stateful alerting*.

Troubleshooting:

AI Status Report operations are logged with the `task=ai_status_report` tag in the alert action logs:

```
index=cim_modactions sourcetype=modular_alerts:trackme_stateful_alert
↪"task=ai_status_report"
```

Error Handling

The AI Assistant handles errors gracefully with clear user-facing messages:

Error Type	Description
AI not configured	No AI provider has been configured. An administrator must set up at least one provider in the Configuration page.
AI disabled	The AI assistant has been disabled by an administrator in the General settings.
AI busy	The maximum number of concurrent AI chat requests has been reached. The user should try again in a moment.
API key missing	The AI provider requires an API key but none is configured. This can occur if a provider was created without saving the API key, or if the credential was lost. Re-enter the API key in the AI Provider configuration.
Provider error	The AI provider returned an error (e.g. invalid API key, model not found, rate limit exceeded). The error message from the provider is displayed.

Troubleshooting

Logs

The AI Assistant logs all requests, errors, and streaming activity to dedicated log files on the Splunk search head. Use the following SPL search to access AI-related logs:

```
index=_internal sourcetype="trackme:rest_api"␣
↪source="/opt/splunk/var/log/splunk/trackme_rest_api_ai_*"
```

Key log events to look for:

Log Pattern	Description
`action="request_started"`	A new AI chat request was submitted. Includes the provider, model, base URL, timeout, context type, and whether context was loaded.
`action="first_token"`	The first token was received from the LLM provider. The `time_to_first_token_sec` field indicates provider responsiveness.
`action="streaming_progress`	Periodic heartbeat during long-running streaming responses (every 30 seconds). Shows elapsed time and characters received.
`action="timeout"`	The LLM request timed out. Check the `timeout_sec` and `elapsed_sec` fields. Consider increasing the Request Timeout setting.
`action="stale_job_cleanup"`	A running job was detected as stale (exceeded its timeout plus a grace period). The concurrency slot was released automatically.
`action="slot_released"`	A concurrency slot was released, either after job completion or via panel close cancellation.
`exception=`	An error occurred during the AI request. The exception message typically includes the HTTP status code and error body from the provider.

Common Issues

"Missing Authorization header" from Google Gemini

The API key is not configured or was not saved correctly for this provider. Edit the provider in **Configuration > AI Provider**, re-enter the API key, and save.

"Model not found" (HTTP 404)

The model name is incorrect. Verify the exact model ID in your provider's documentation. Common mistakes include missing version suffixes (e.g. `gemini-3-pro` vs `gemini-3-pro-preview`) or using aliases that don't exist for the provider.

"AI assistant is at maximum capacity"

All concurrency slots are in use. Either wait for an in-flight request to complete, or increase the **Max concurrent AI chats** setting in **Configuration > General**. If slots appear stuck, check for stale jobs in the logs — they are automatically cleaned up after the configured timeout plus a grace period.

Streaming responses appear slow or stalled

For cloud providers, this is typically caused by network latency or provider-side rate limiting. For Ollama, ensure the server has sufficient resources (CPU/GPU/RAM) for the model. Check the `time_to_first_token_sec` in the logs to distinguish between slow initial response and slow token generation.

Context not loaded

If the AI responds with generic advice rather than specific analysis, check the `entity_context_loaded` field in the request log. A value of `False` indicates the context collection failed. For entity investigations, verify that the entity exists in the specified tenant and that the user has RBAC permissions to access it. For other contexts, check that the relevant TrackMe backend services are running correctly.

3.3.2 The AI Concierge

Overview

The **AI Concierge** is the catalog-driven generalist of the TrackMe AI family. Where the five specialised *AI Advisors* handle curated remediation flows for specific surfaces (ML models, DSM/DHM thresholds, FLX thresholds, FQM dictionaries, WLK/MHM health), the Concierge handles the **long tail** of operational requests by grounding itself in the live TrackMe REST API catalog (~423 endpoints) and proposing structured **action contracts** that you approve from a consent card in the chat.

The Concierge is reached through the *AI Assistant*: when you ask the chat to *do* something operational — disable an entity, change a priority, set a maintenance window, trigger a backup, delete a tenant — and that intent does not map to a specialist advisor, the assistant routes the request to the Concierge.

Important

The Concierge has **zero static write tools by design**. It never mutates anything directly: it *proposes* actions, and your confirmation click is what fires the REST call — through your own Splunk credentials, RBAC-checked at the REST boundary. The consent-card click is the structural safety property.

Note

Unlike the specialised *AI Advisors*, the AI Concierge does **not** require Python 3.13.x / Splunk 10.2.x — it runs on **Python 3.9.x and later**, so it is available on the same Splunk releases as the rest of TrackMe. See *Artificial Intelligence in TrackMe* (Requirements & compatibility).

How it works

The Concierge follows a propose-then-confirm contract:

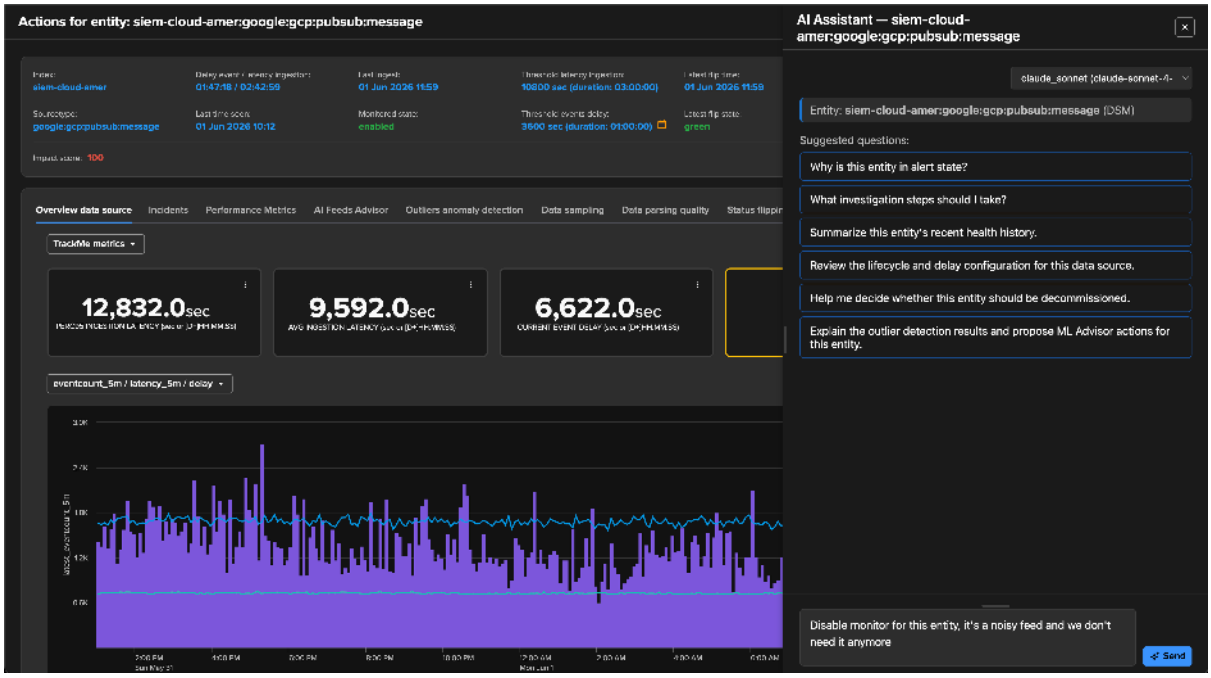
1. **Discover** — it searches the live API catalog for endpoints matching your intent, filtered by surface (entity / tenant_home / vtenants / global) and verb (read / write).
2. **Validate** — every candidate endpoint is checked against the live catalog: the path must exist, the danger level must match, and the body template must carry placeholders for protected fields.
3. **Propose** — it emits a typed `concierge_invocation` action contract carrying one or more proposed actions.

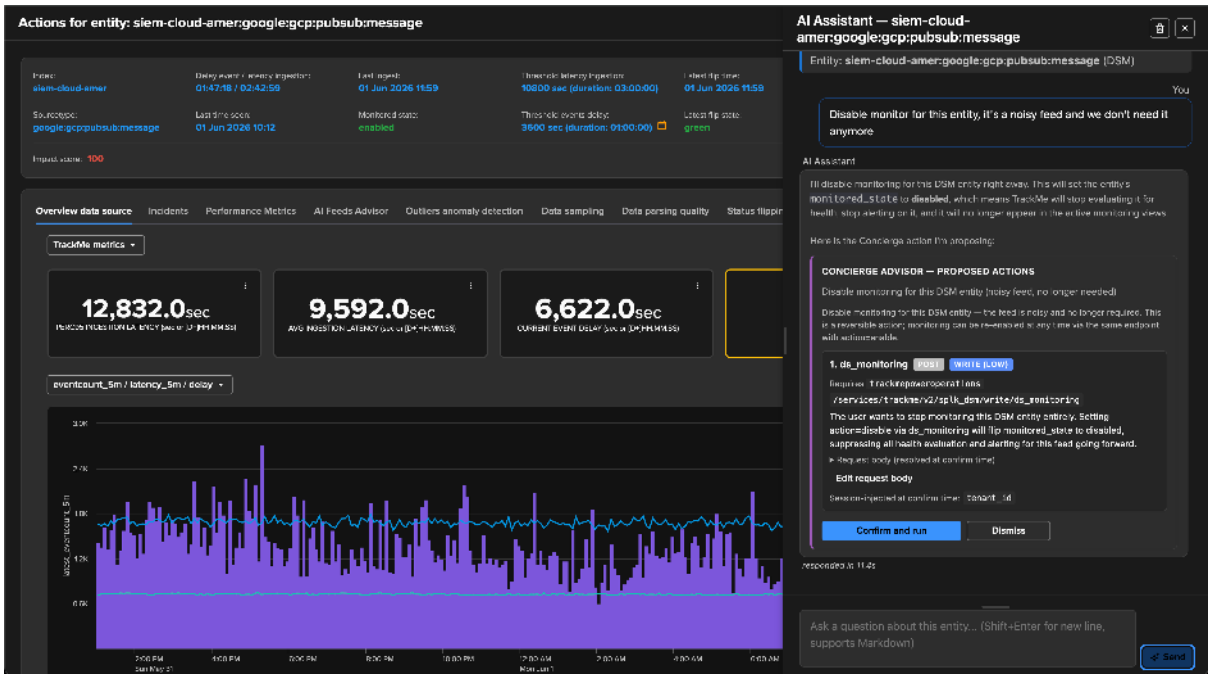
4. **Consent** — the chat renders each action as a card showing the target endpoint, the request body (editable), a danger-level badge, and per-action `Run` / `Edit request body` / `Cancel` controls. Destructive actions require you to type the action name to confirm.

5. **Execute** — your click fires the REST call. Each write is stamped with the `[AI Agent]` prefix in the entity audit trail, exactly like the specialist advisors.

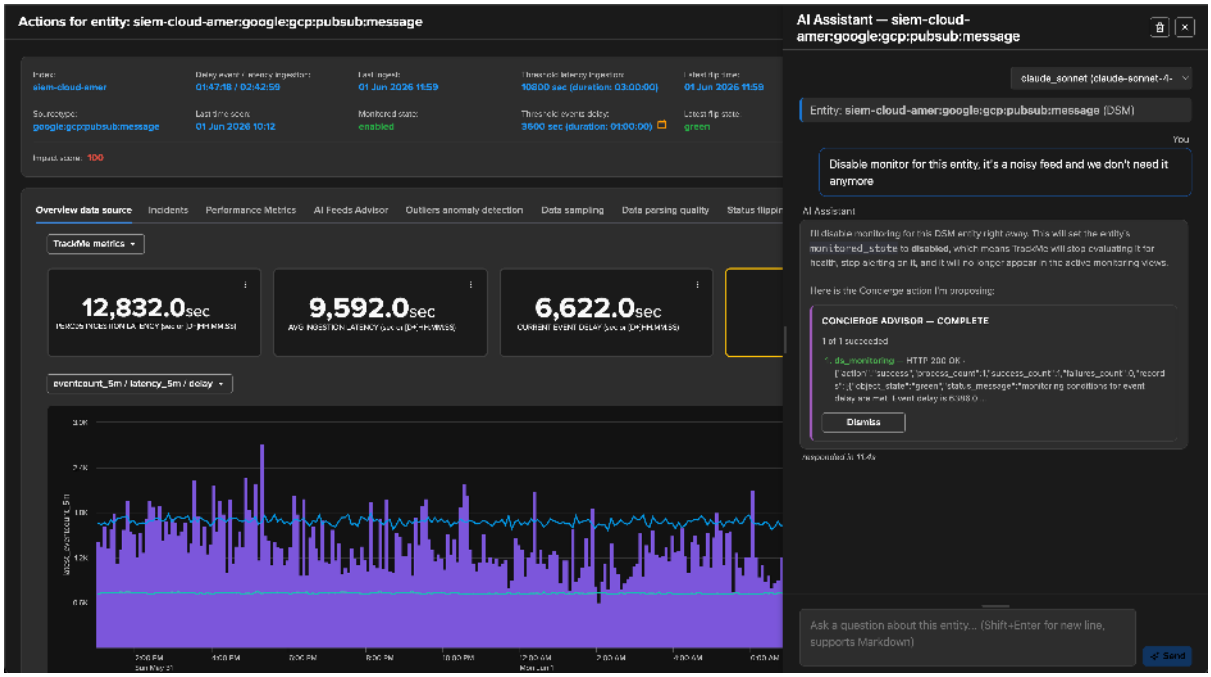
Single-action example

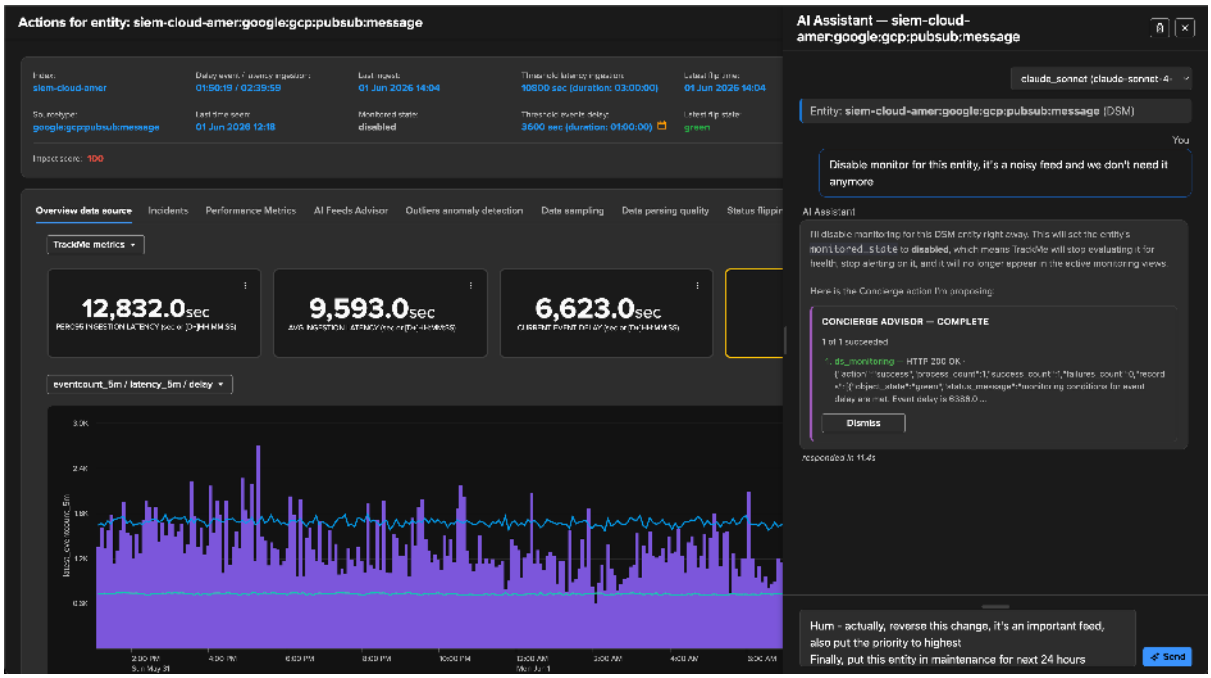
In the example below, the operator is investigating a DSM entity and types a plain-language request into the AI Assistant: *"Disable monitor for this entity, it's a noisy feed and we don't need it anymore"*. The intent does not map to a specialist advisor, so the assistant proposes a **Concierge action** — a consent card that targets the exact REST endpoint with the resolved request body, ready to run or edit.





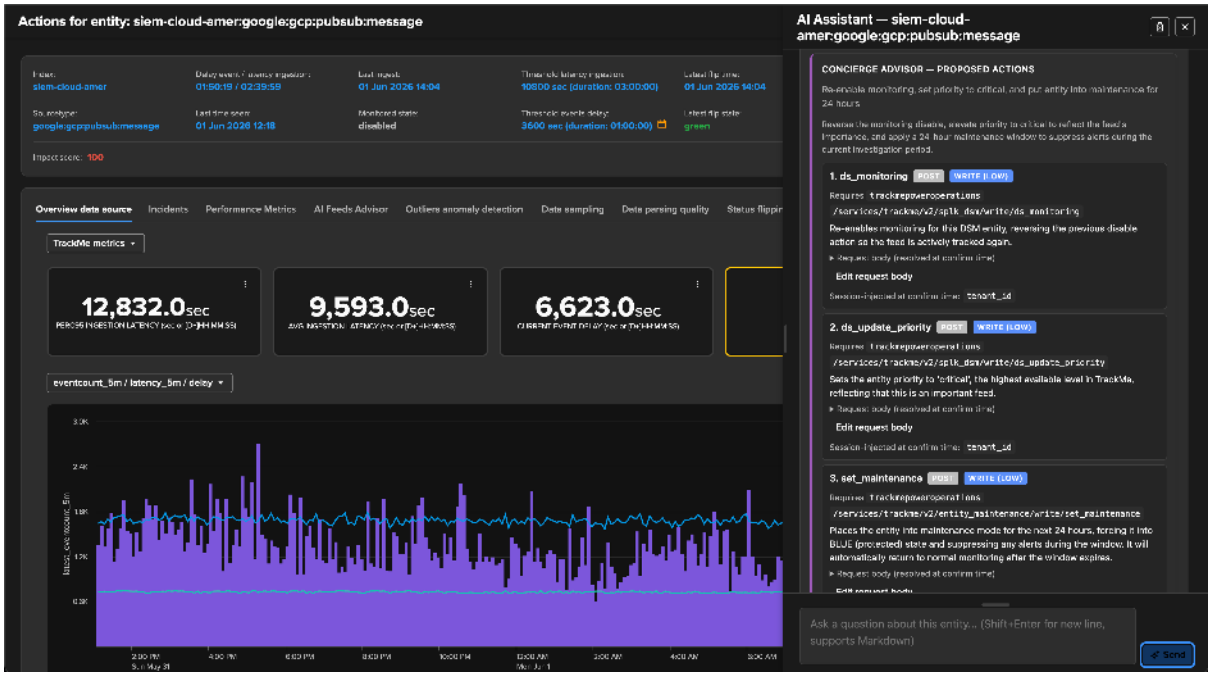
Once you confirm, the Concierge fires the REST call and reports completion inline, with the structured result of the action it performed.

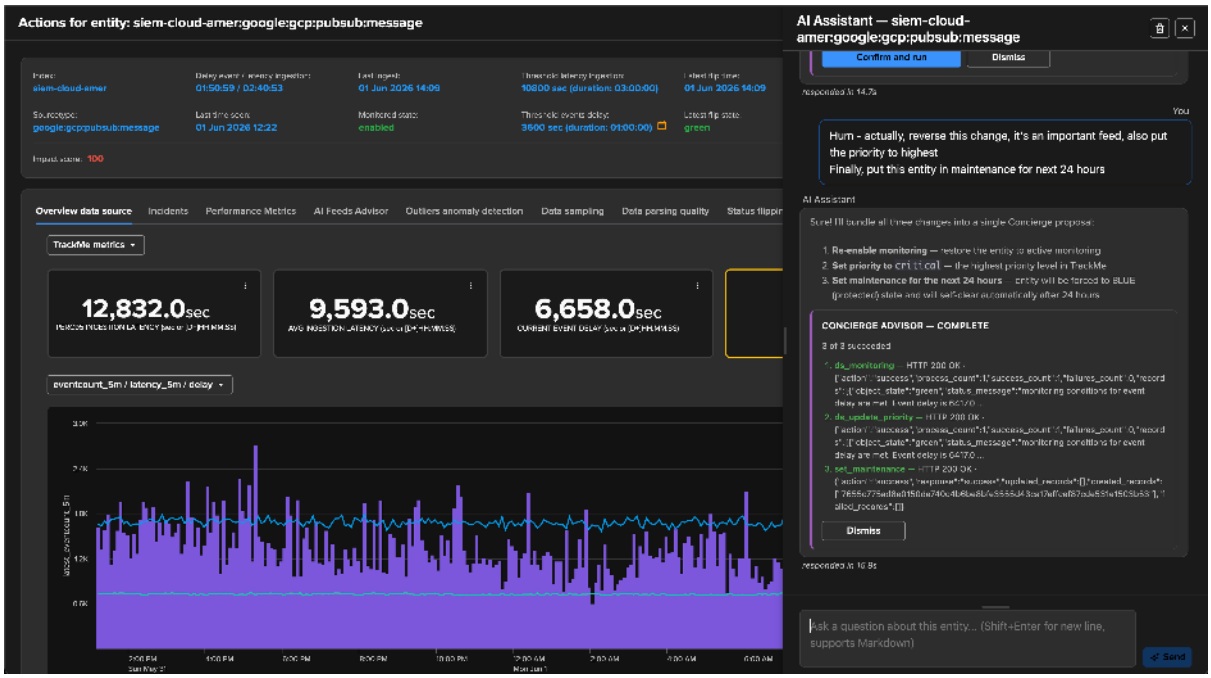




Multi-action proposals

A single request can produce **several** proposed actions when the intent naturally spans more than one operation. In the example below the Concierge proposes a coordinated set of actions (`ds_monitoring`, `ds_update_priority`, `set_maintenance`), each rendered as its own card with the required capability, the target endpoint, the request body, and an **Edit request body** control. You approve, edit, or cancel each action independently.





Where the Concierge is available

The Concierge is wired into every chat surface as the **universal fallback**. On entity, Tenant Home and Virtual Tenants surfaces it layers *under* the specialists — when your intent matches a specialist (e.g. "why is this entity red?" on a DSM entity), the assistant proposes the specialist; only when no specialist matches does it fall through to a Concierge proposal.

On the six feature-level surfaces the specialists do not apply, so the Concierge is the sole bridge target:

- REST API Reference
- Backup & Restore
- Global Maintenance Mode
- Maintenance Knowledge Database
- Bank Holidays Management

- License Management

Safety and validation

The Concierge operates on the full REST catalog, so it has the broadest surface of any AI capability. Several layers of defence-in-depth keep it safe:

Guardrail	What it does
Catalog grounding	Every proposed path is validated against the live API catalog — both before the contract is emitted and again at consent-card render time. Hallucinated or removed paths disable the **Confirm** button with a clear banner.
Consent is structural	The Concierge cannot mutate anything without an explicit user click. There is no autonomous write path.
Danger badge + typed confirmation	Every action carries a danger level (low / medium / high / critical). `destructive` actions require you to type the action name (e.g. `del_tenant`) before **Confirm** enables.
RBAC at the REST boundary	The action fires through *your* Splunk session; an operation you are not authorised for fails at the REST boundary with a clean 403 surfaced on the card — the agent does not bypass RBAC.
Audited end-to-end	Every Concierge proposal is indexed to the tenant summary index (sourcetype `trackme:ai_agent:concierge_advisor:propose`) and every confirmed write carries the `[AI Agent]` prefix in the per-entity audit trail. See *Auditing AI activity*.

Note

Two operational caps apply per tenant: `ai_concierge_max_actions_per_proposal` (default 10) and `ai_concierge_rate_limit_per_minute` (default 5). The Concierge has **no** per-tenant enablement gate and **no** separate destructive-action gate — RBAC, the consent card, and typed confirmation are already the safety layers.

Related

- *AI Assistant* — the conversational front door the Concierge is reached from.
- *The AI Advisors* — the specialised advisors the Concierge complements.
- *Auditing AI activity* — the audit dashboards that record Concierge activity.

3.4 The AI Advisors

3.4.1 Overview

The **AI Advisors** are TrackMe's agentic surface — specialists that read the same KV Store and search indexes a human analyst would, propose remediations grounded in real configuration and recent telemetry, and (in *act* mode) apply changes through the same REST API a UI click would invoke. Every change is auditable, every write is RBAC-checked at the REST boundary, and every recommendation can be replayed.

There are **six advisors** — five specialists plus the catalog-driven *AI Concierge*:

Advisor	What it handles	Documentation
AI Feeds Advisor (Feed Lifecycle)	DSM / DHM threshold tuning, monitoring state, adaptive delay, variable-delay schedules, impact-score weights	*AI Feeds Advisor*
AI ML Advisor	ML outlier model inspection and remediation (period exclusions, retrains, density-threshold tuning, false-positive clears)	*AI ML Advisor*
AI FQM Advisor	Field-quality thresholds and data-dictionary management (per-field validation, CIM compliance, regex testing); wizard-time dictionary generation	*AI FQM Advisor*
AI Component Health Advisor	WLK (workload scheduled-search health) + MHM (metric-host lag) thresholds	*AI Component Health Advisor*
AI FLX Threshold Advisor	FLX dynamic thresholds (add / update / delete / variable-threshold slots), entity state and priority	*(below)*
AI Concierge	Long-tail operational requests grounded in the live REST API catalog	*The AI Concierge*

Note

The advisors are **opt-in**: they require at least one configured *AI provider account*, and each is **disabled by default** until enabled per tenant (see *AI Agents automation* for the automated path). On-demand interactive runs from the UI and the chat are available to authorised operators as soon as a provider is configured.

Important

The AI Advisors require Splunk 10.2.x and later (Python 3.13.x). The five specialised advisors are built on the Splunk Agent SDK, which needs Python 3.13.x — shipped only with Splunk 10.2.x (Splunk Enterprise or Splunk Cloud). TrackMe enforces this automatically: an advisor cannot be invoked on an incompatible release (a clear message explains the requirement), and the *AI Assistant* will not propose an advisor when it detects an incompatible system. The AI Assistant and the *AI Concierge* do **not** require Python 3.13.x — they run on Python 3.9.x and later, so they remain available on previous Splunk releases. See *Artificial Intelligence in TrackMe* (Requirements & compatibility) and the *compatibility page*.

3.4.2 Inspect or Act — the operational contract

Every specialised advisor honours the same two-phase contract:

Mode	Behaviour
inspect	Read-only — always safe to run. The agent analyses and surfaces structured recommendations, then stops. No KV writes, no REST mutations: the write tools are *literally absent* from the agent's toolbox. This is the default for unfamiliar entities and the first stage of the chat bridge.
act	Full remediation. The agent applies the recommended changes through write tools, then re-reads to confirm. A hard rule requires every write to be verified by a follow-up read, and every write is prefixed `[AI Agent] <reason>` in the entity audit trail.

The two phases give the chat bridge a natural two-step flow: the operator describes the problem → the assistant proposes an **inspect** run → the operator reviews the recommendations and clicks **Run Act** (optionally with extra instructions) to apply them.

Note

Hard runtime caps are enforced by SDK middleware and a shared watchdog, not by prompt text — an *inspect* run has a smaller token / step budget and a 10-minute wall-clock cap; an *act* run has a larger budget and a 15-minute cap. A misbehaving run hits a real wall and is recorded as an error.

3.4.3 Two ways to run an advisor

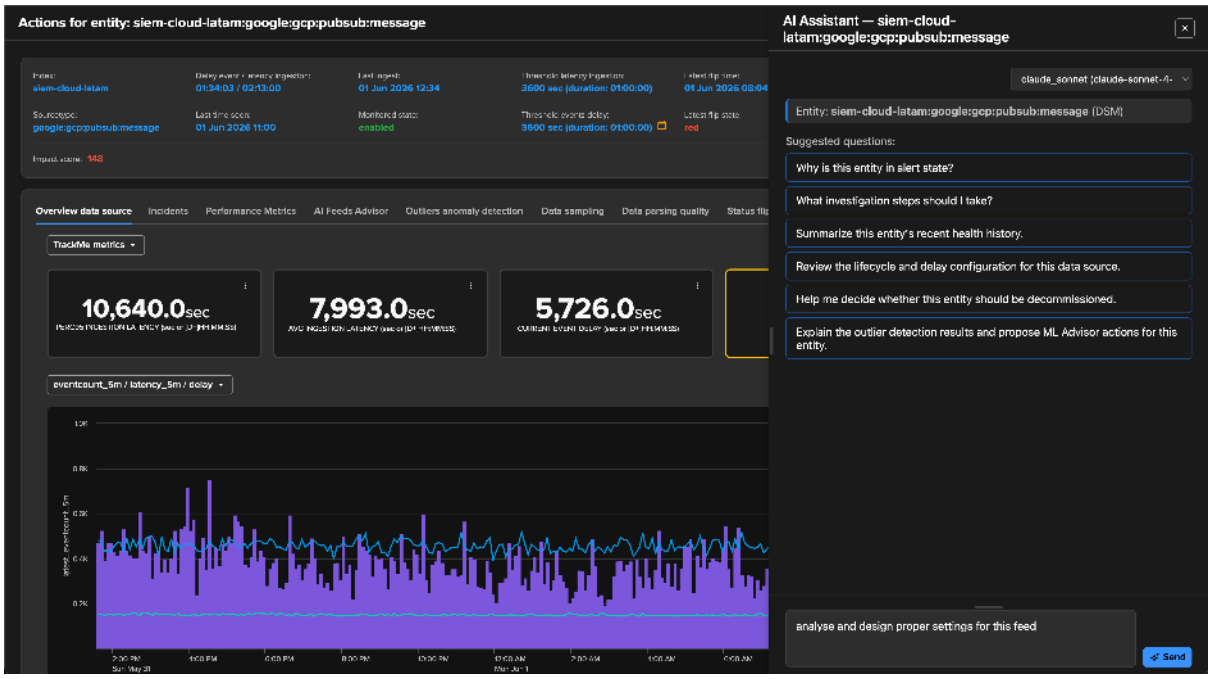
Standalone modal

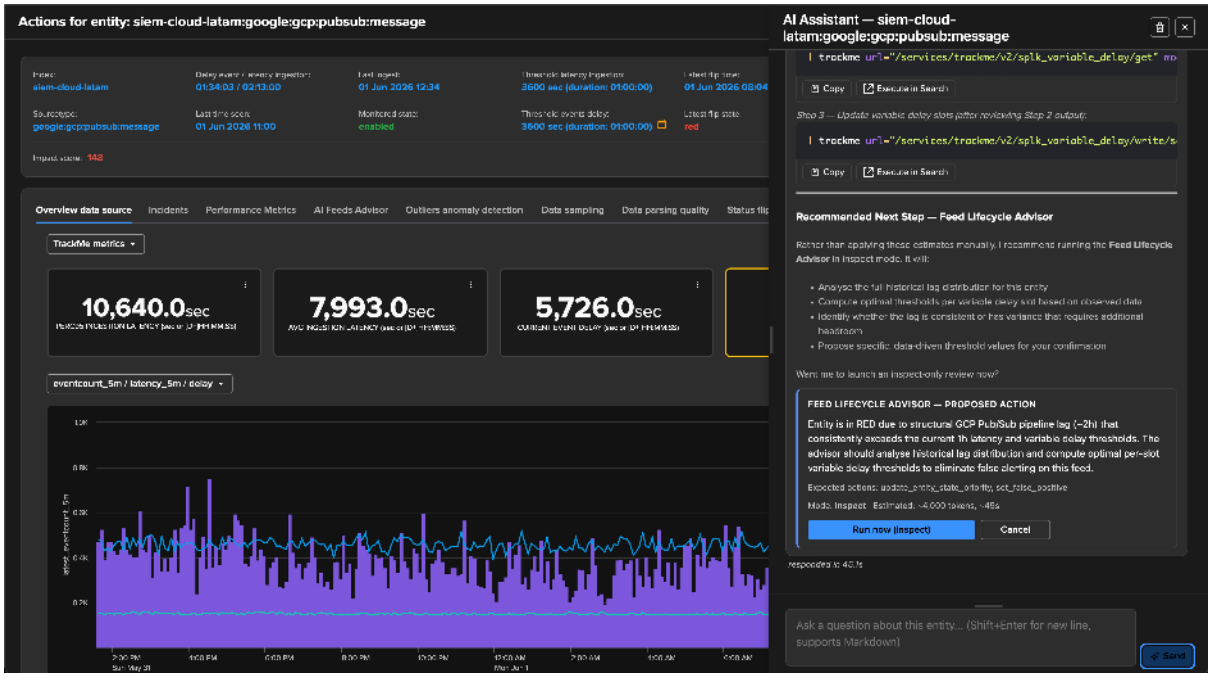
Every entity overview exposes an advisor tab appropriate to its component (for example **AI Feeds Advisor** on DSM/DHM, **AI ML Advisor** on the Outliers tab, **AI FQM Advisor** on FQM, **AI WLK Advisor** on WLK). The modal lets you pick the provider and mode, add optional instructions, and launch the run — showing a live tool-call progress feed and then the structured result with status badge, recommendations, actions taken, and a collapsible reasoning trace.

The chat consent-card bridge

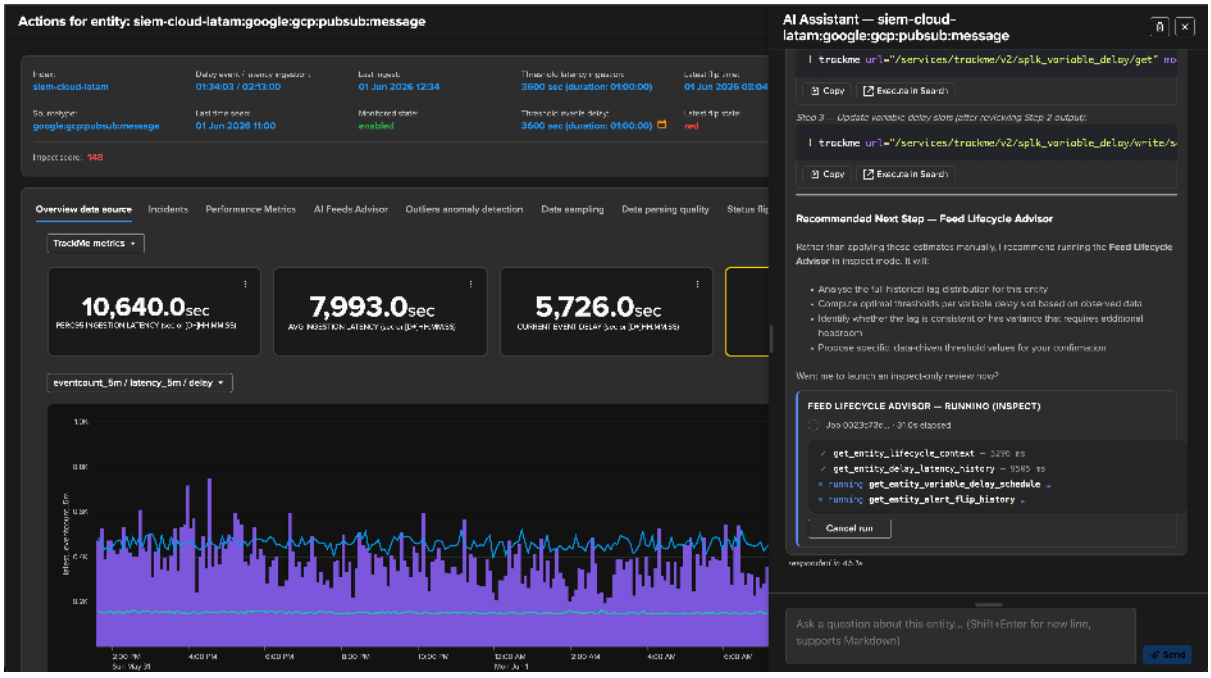
The *AI Assistant* knows about the advisors. When you describe a symptom an advisor can resolve, it proposes a typed **advisor invocation** rendered as an inline **consent card** — without leaving the conversation. The chat *never* calls a write tool directly; it always proposes an advisor (or Concierge) invocation, and your click is the structural safety property.

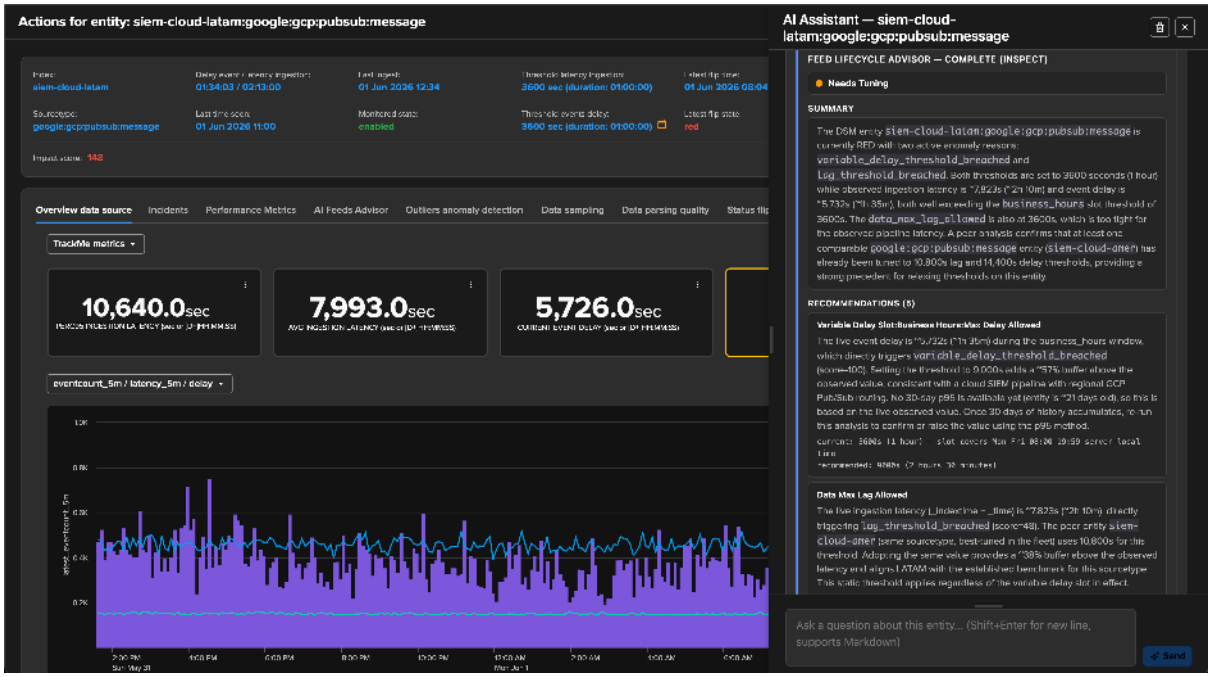
The example below walks the full bridge flow on a DSM entity. The operator opens the assistant on the entity and asks the assistant to *"analyse and design proper settings for this feed"*.



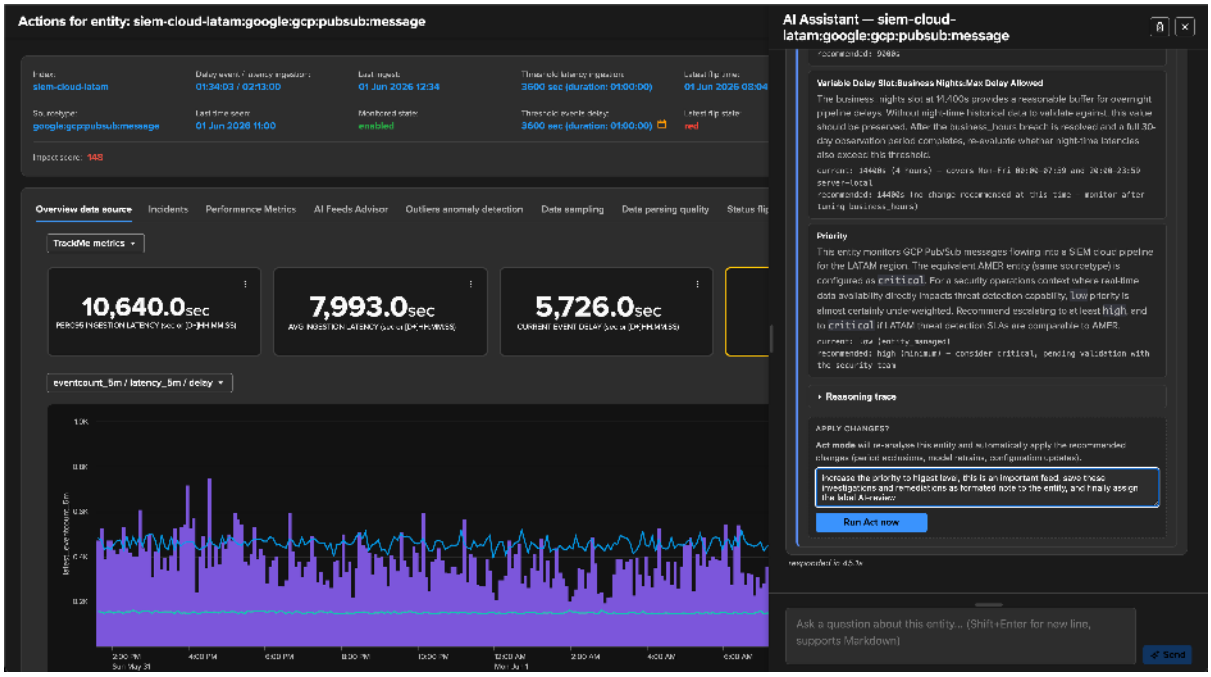


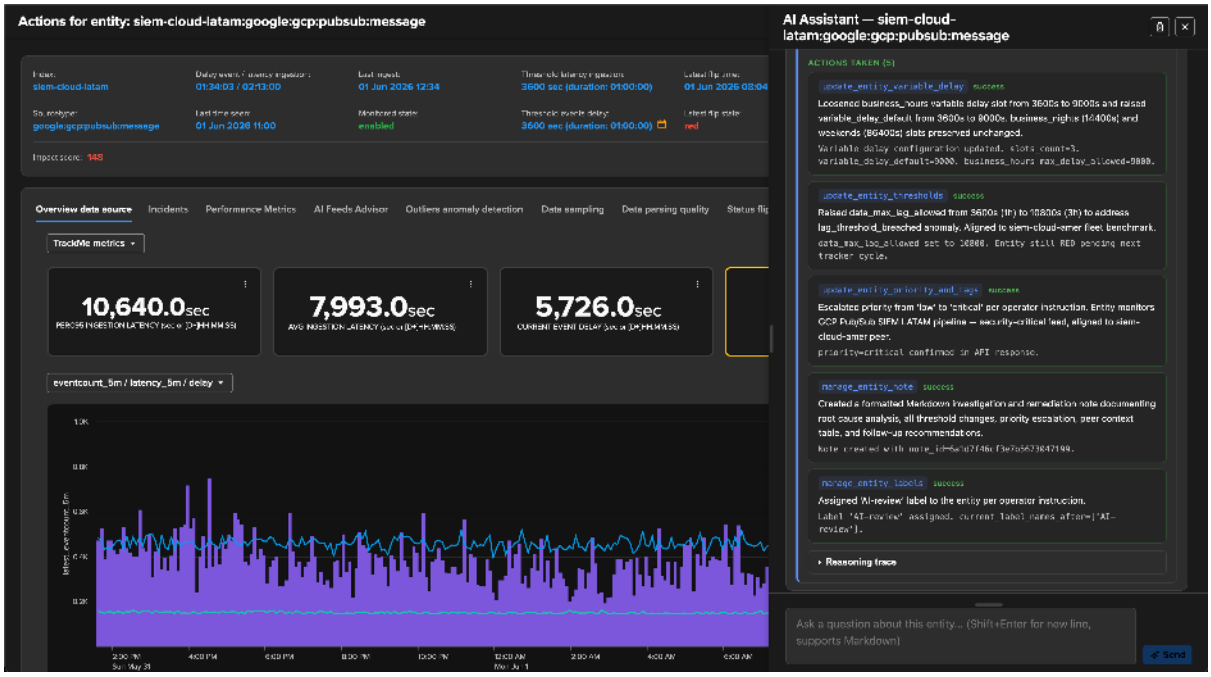
The assistant reasons over the entity's live context and recommends the **Feed Lifecycle Advisor**, launching it in **inspect** mode. A live tool-call feed shows each read the agent performs (`get_entity_lifecycle_context`, `get_entity_delay_latency_history`, `get_entity_variable_delay_schedule`, ...).



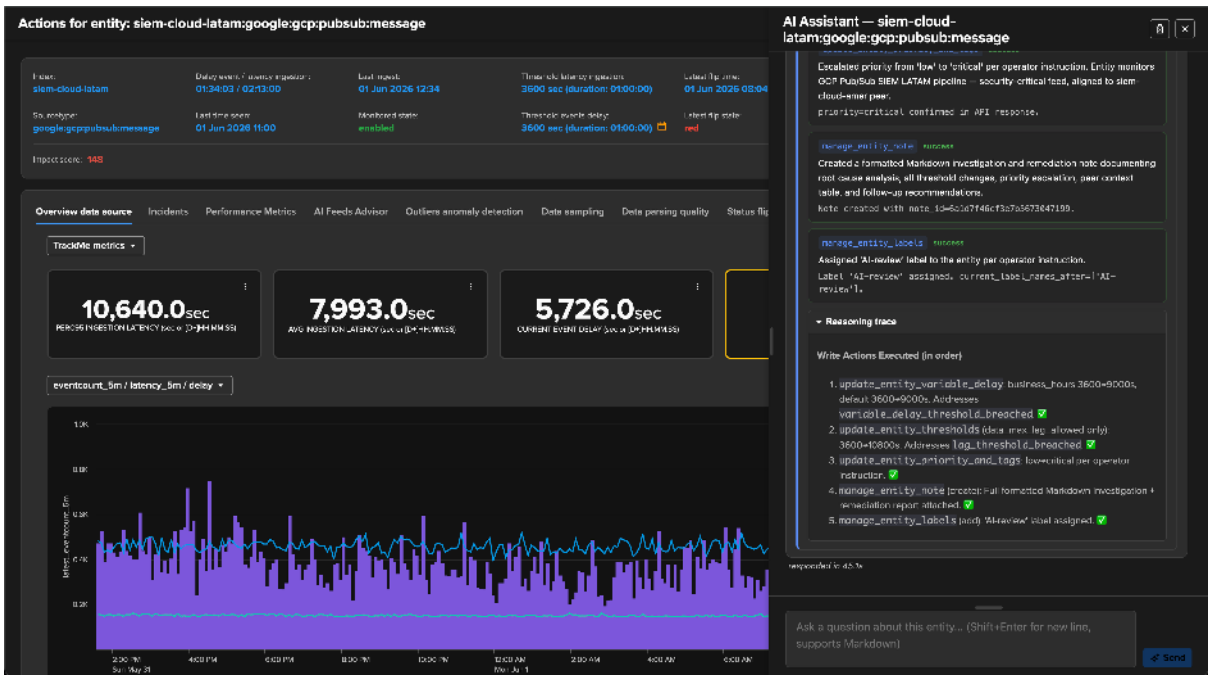


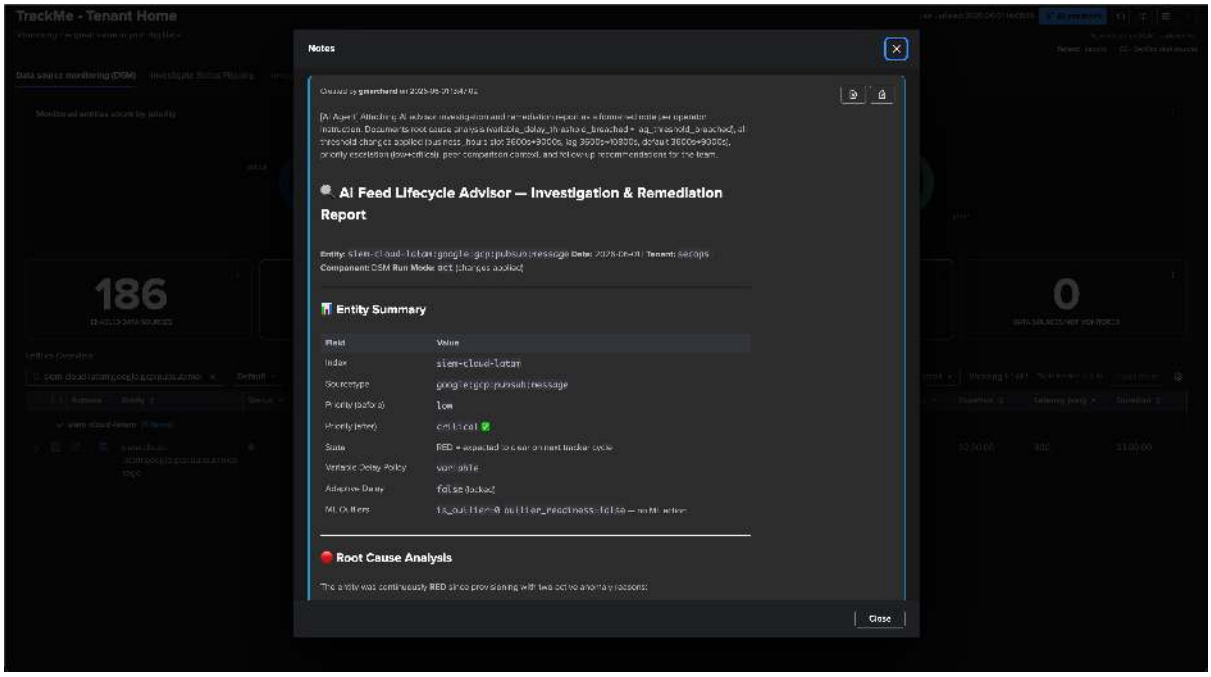
The inspect result is rendered as structured recommendations (here a variable-delay schedule and a priority change) each with current value, recommended value and rationale, plus a collapsible reasoning trace. From the result, a **Run Act now** panel offers an optional *additional instructions* textbox before applying the changes.





When you run **act**, the advisor applies the changes through TrackMe's REST API and verifies each write. It also attaches a formatted **investigation & remediation report** as an entity note, prefixed `[AI Agent]` — documenting the root-cause analysis, the entity summary, and every change applied — so the full story is visible directly on the entity.





3.4.4 Structured output and guardrails

Every advisor run emits a **typed envelope** (validated by the SDK) rather than free-form prose:

- `entity_status` — an at-a-glance verdict (e.g. `healthy` / `needs_tuning` / `decommission_candidate`).
- `summary` — a short executive summary.
- `recommendations` — structured items, each with the field, current value, recommended value and a rationale that cites the tool calls that produced it.
- `actions_taken` — populated in *act* mode only, one entry per write that actually occurred.
- `reasoning_trace` — a step-by-step trace citing the read (and write) tool calls.

The guardrails that bound every run:

- **Ground every claim in data** — the agent's first calls are always reads; a run with zero read tool calls is a bug. Speculation is forbidden by the system prompts.
- **Tag-filtered write gate** — write tools are present only in *act* mode.
- **Decommission guard** — disabling an entity (`monitored_state=disabled`) is gated and disabled by default in the automated path.
- **RBAC at the REST boundary** — the agent inherits the operator's session; an unauthorised write fails cleanly with a 403.
- **Audit reason discipline** — every write requires a meaningful `reason` citing the field, the from/to values, and the operational trigger; trivial reasons are rejected.

3.4.5 The AI FLX Threshold Advisor

The **FLX Threshold Advisor** handles *FLX (Flex Objects)* — the "any SPL search as a tracked entity" component. FLX entities expose custom KPIs (a `metrics` JSON blob computed by the tracker's search), dynamic thresholds (per-metric value comparisons with configurable operators), and optional variable thresholds (time-slot-based values for day-of-week / hour-of-day variation). The advisor answers: *"are these thresholds tuned for this entity's actual behaviour, or did the wizard's defaults drift?"*

When to use it

- A FLX entity is RED and you want to know whether the threshold was wrong (over-tight) or the data is genuinely anomalous.
- A new FLX entity created via the wizard has been running for a week and you want to validate the applied defaults against observed behaviour.
- A metric's breach pattern matches business-hours / off-hours variation and a variable-threshold schedule would fit better than a static one.
- You want to delete obsolete thresholds or review a customised use-case template entity.

What it reads and writes

In **inspect** mode the advisor reads the full FLX entity context, the 24h + 7d metric value history, the threshold-breach history, the entity's use-case template definition, and peer-entity thresholds. In **act** mode it can add / update / delete dynamic thresholds, configure variable-threshold slots, and update the entity's monitoring state or priority (decommission-gated).

Note

The FLX Threshold Advisor is the most hardened advisor against the FLX `condition_true` flag, which inverts alert semantics. **Inverse-style** (`condition_true=true`) means "alert fires when the comparison is FALSE" — used for "healthy if X holds" tracking. **Direct-style** (`condition_true=false`) means "alert fires when the comparison is TRUE" — used for "alert if X holds" tracking. The advisor validates a proposed threshold's direction before recommending it.

Where to find it

The **AI Threshold Advisor** tab appears on FLX entity overview modals, and the chat bridge proposes it for FLX threshold intents. It participates in the nightly automated batch — see *AI Agents automation*.

Tip

Beyond tuning *existing* entities, this advisor can also **build a brand-new FLX tracker from a plain-language description** at wizard time — grounded on the use-case library and validated by a live dry-run. See *Natural-language FLX tracker generation*.

AI Feeds Advisor

Overview

The **AI Feeds Advisor** (the *Feed Lifecycle Advisor*) is the most commonly used advisor in production. It handles **DSM (Data Sources)** and **DHM (Data Hosts)** entities — the bread-and-butter of TrackMe monitoring — and answers the recurring question *"is this entity's lifecycle configuration appropriate for its actual behaviour?"*

A "lifecycle" in TrackMe terms is an entity's runtime configuration story: how long after the last event is "still healthy", what counts as an excessive delay or lag, whether to auto-tune thresholds, whether to apply different thresholds at different times of day, and how to weight delay/latency breaches against other anomaly signals. The advisor reads

the entity's recent history, compares it against peer entities on the same datasource, and proposes lifecycle changes grounded in real telemetry.

See *The AI Advisors* for the shared inspect/act model, the consent-card bridge, and the structured output contract that all advisors share.

When to use it

- An entity is RED with a delay or latency threshold breach and you suspect the threshold is too tight (the most common trigger).
- A new entity was created via the wizard with default thresholds and you want them tuned after a week of observation.
- An entity's delay bursts in clear weekday/weekend or business-hours patterns and a variable-delay schedule may fit better than a static threshold.
- Adaptive delay was previously locked and you want to know if it is safe to unlock now that the pattern has stabilised (or vice versa).
- You want to adjust the entity's impact-score weights, or decide whether an entity should be decommissioned.

What it reads and writes

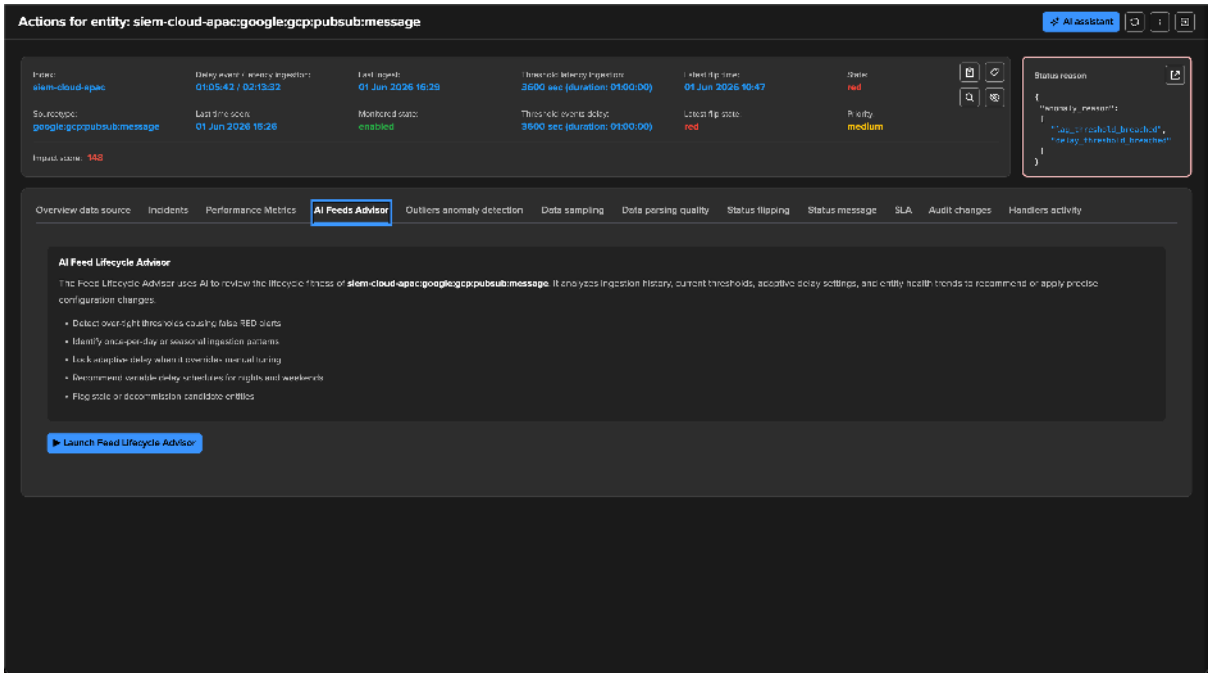
In **inspect** mode the advisor reads the full lifecycle context (configuration, thresholds, state, scoring, adaptive flags), the 7-day delay/latency history, the state-flip history, peer-entity comparison, the current variable-delay schedule, and the adaptive-delay change history.

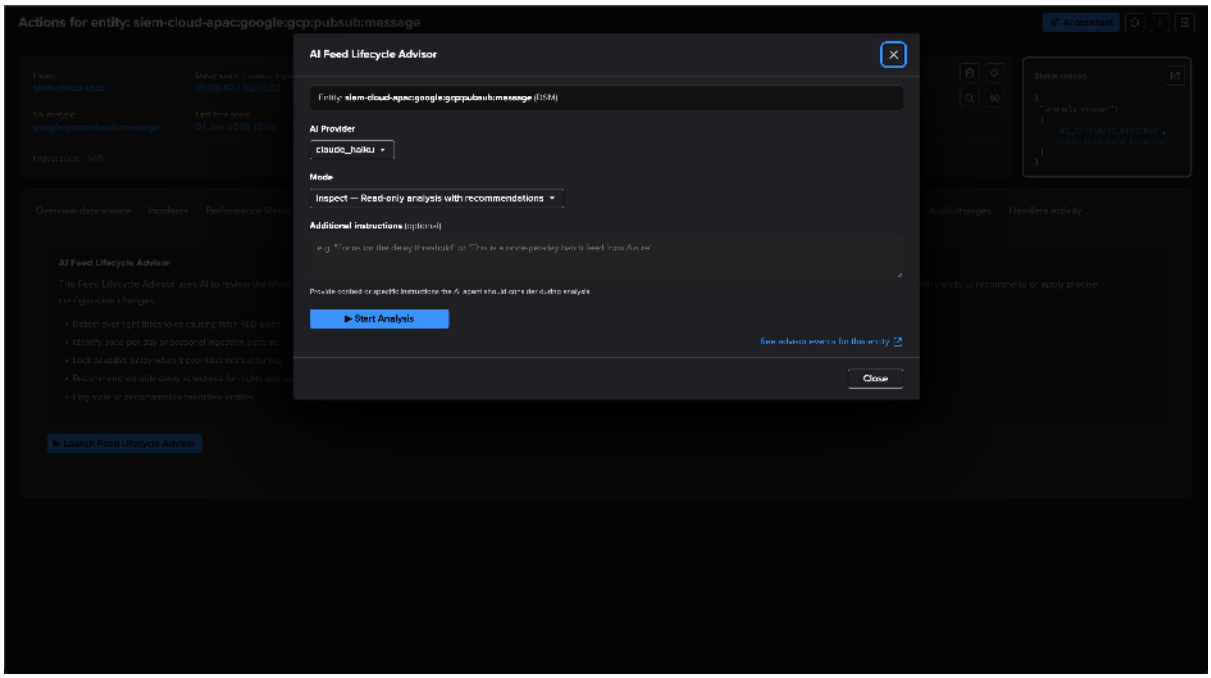
In **act** mode it can additionally:

- update delay / lag thresholds (`data_max_delay_allowed`, `data_max_lag_allowed`),
- set the monitoring state (decommission-gated),
- lock or unlock adaptive delay,
- create or update a variable-delay schedule (per-slot day-of-week / hour-of-day thresholds),
- adjust priority, tags and impact-score weights,
- and attach labels and a formatted investigation note to the entity.

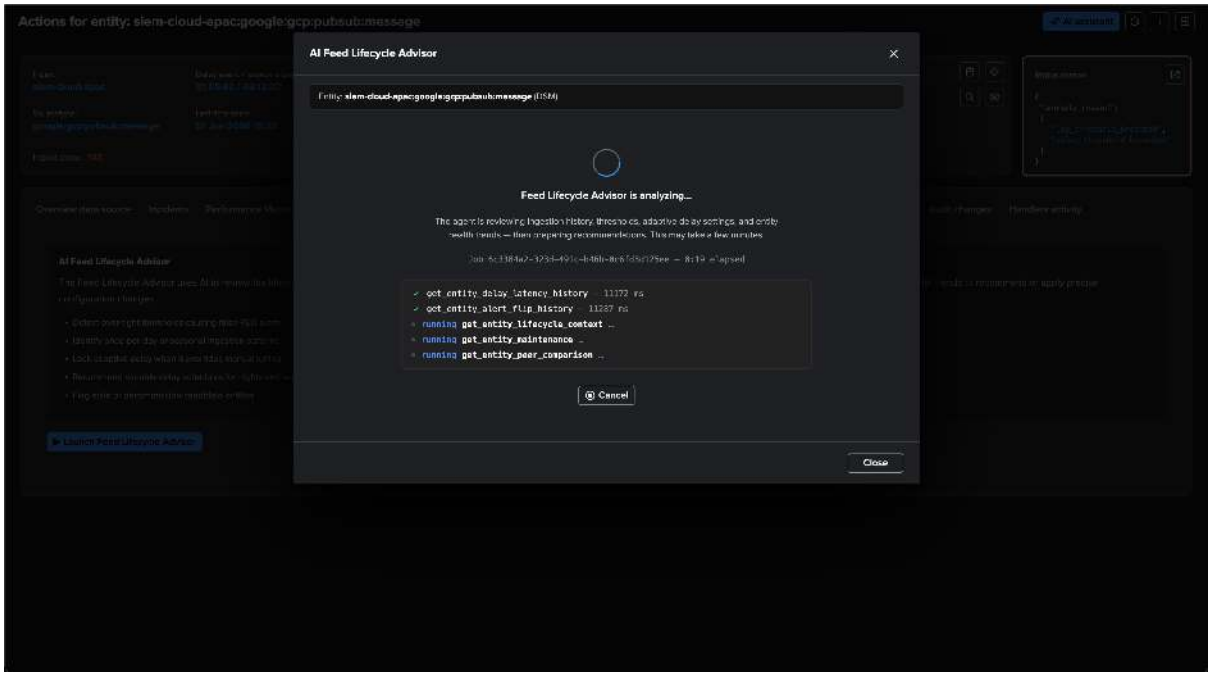
Walkthrough

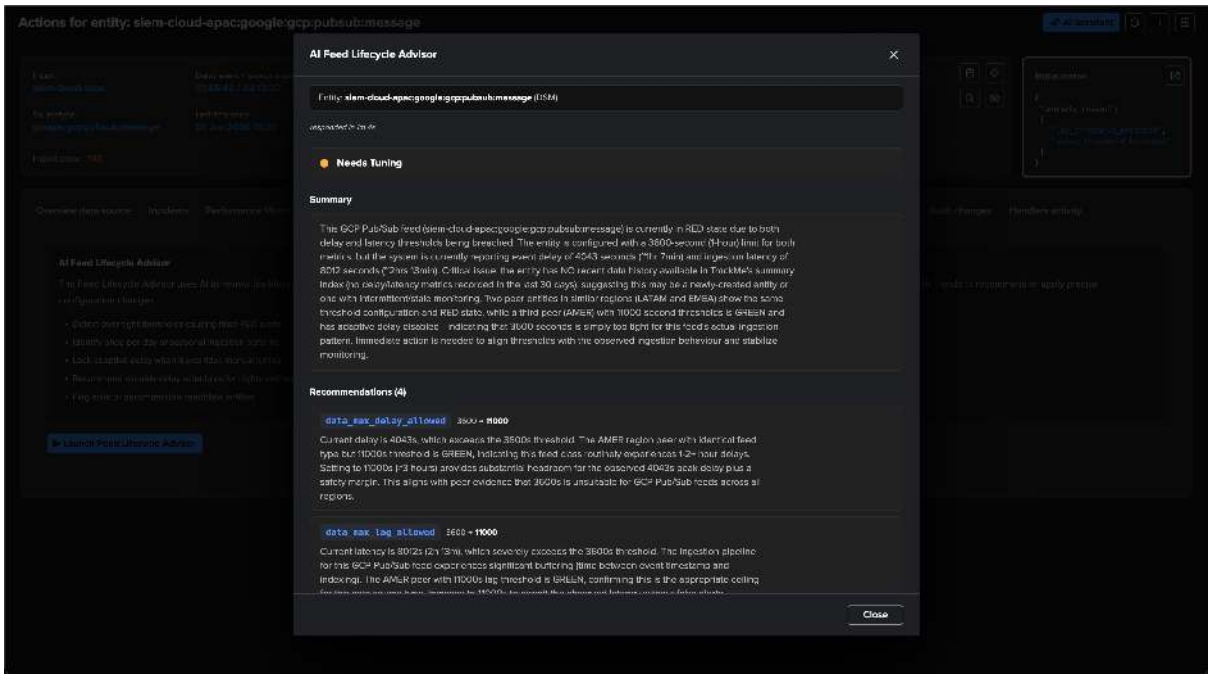
Every DSM and DHM entity overview exposes an **AI Feeds Advisor** tab. It summarises what the advisor does for this entity and offers a **Launch Feed Lifecycle Advisor** button. In this example the entity `siem-cloud-apac:google:gcp:pubsub:message` is RED because of both a lag-threshold and a delay-threshold breach.



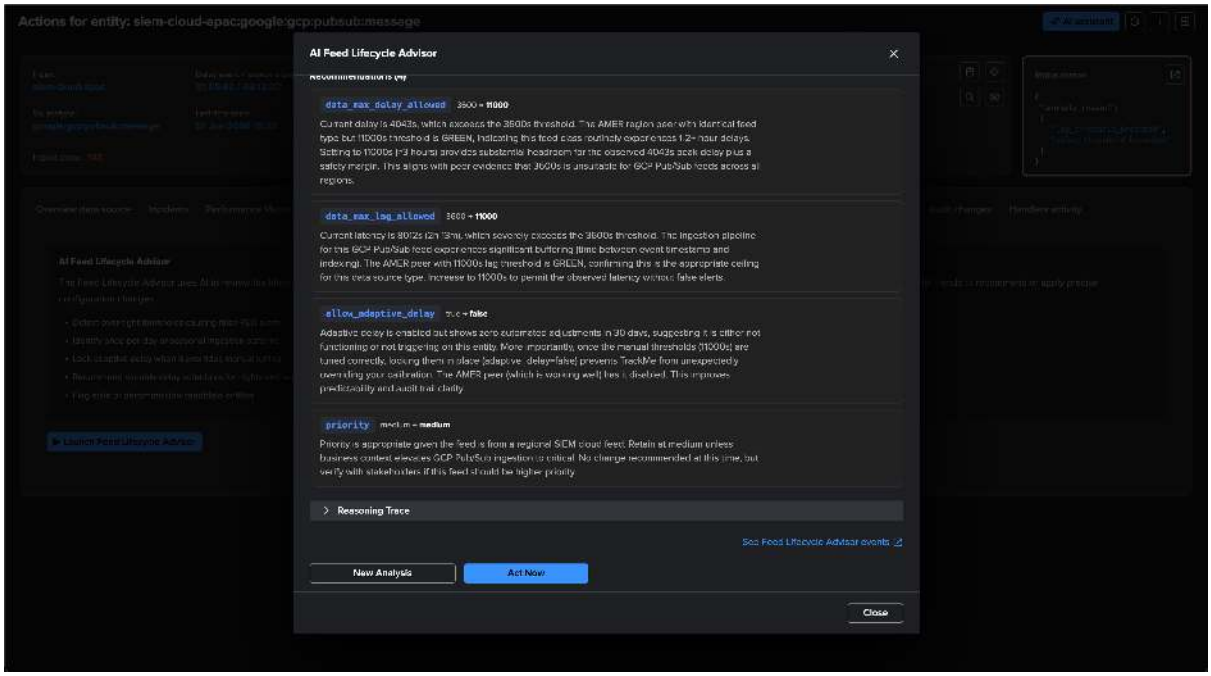


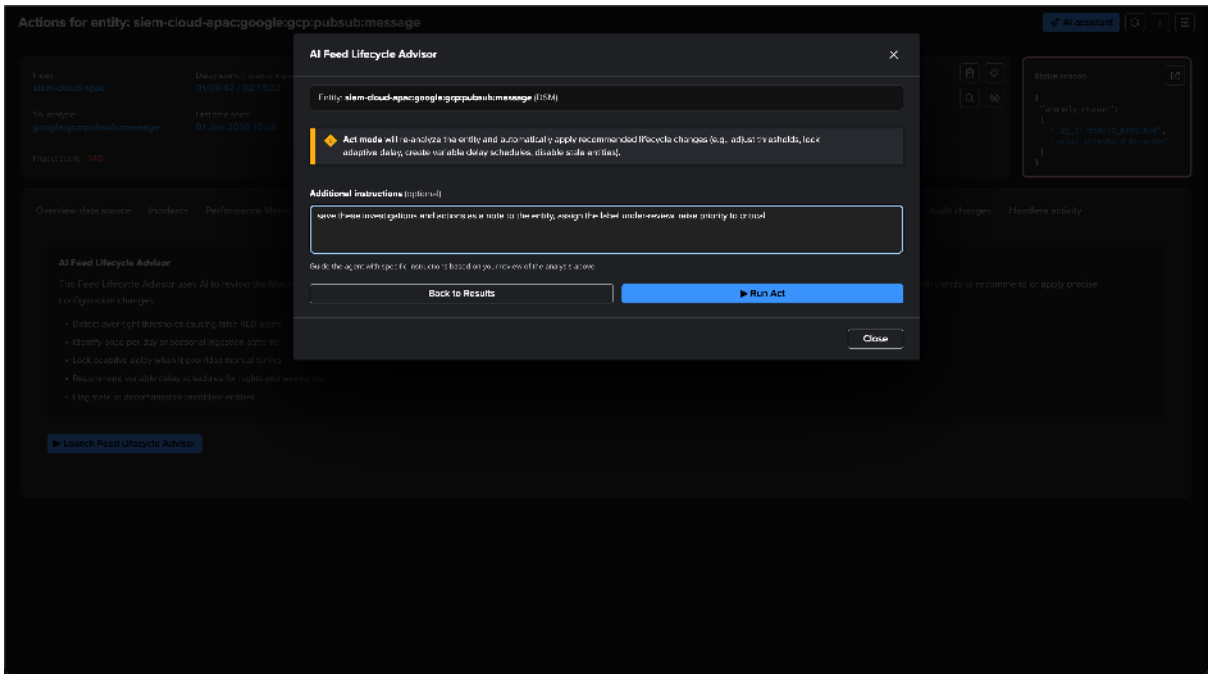
The advisor runs in **inspect** mode first, reading the entity's lifecycle context and history. It returns a structured verdict — here *Needs Tuning* — with an executive summary and a list of recommendations, each carrying the current value, the recommended value, and a rationale grounded in the observed ingestion behaviour and peer comparison.



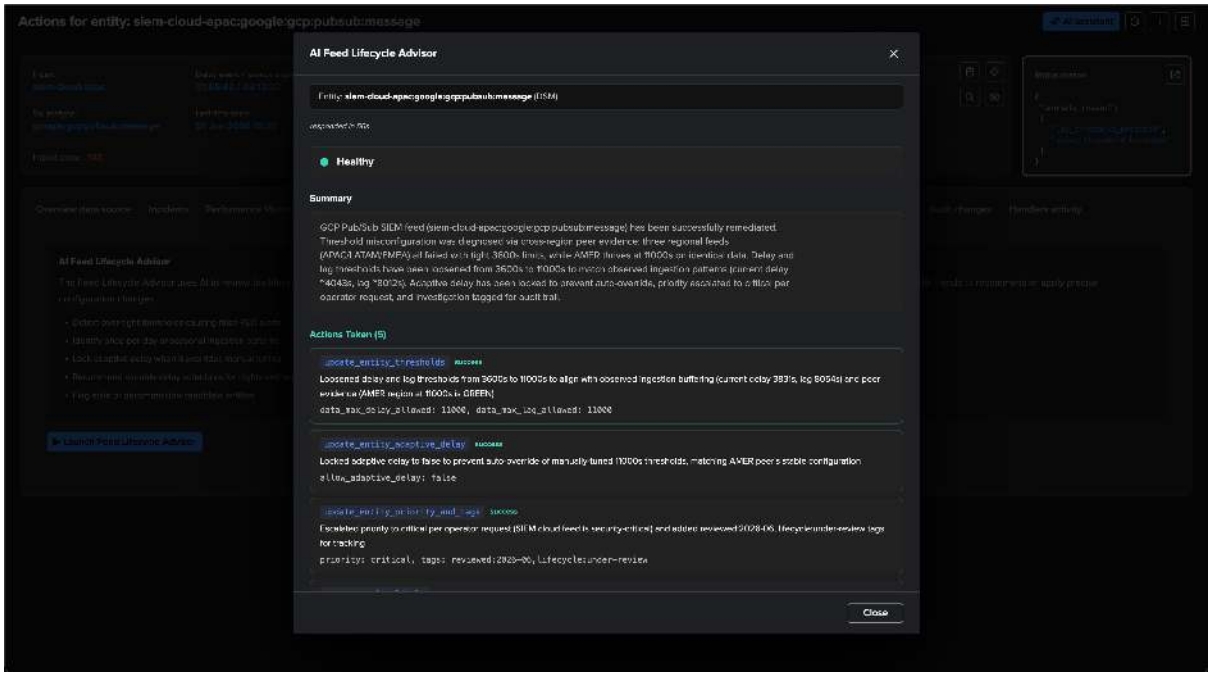


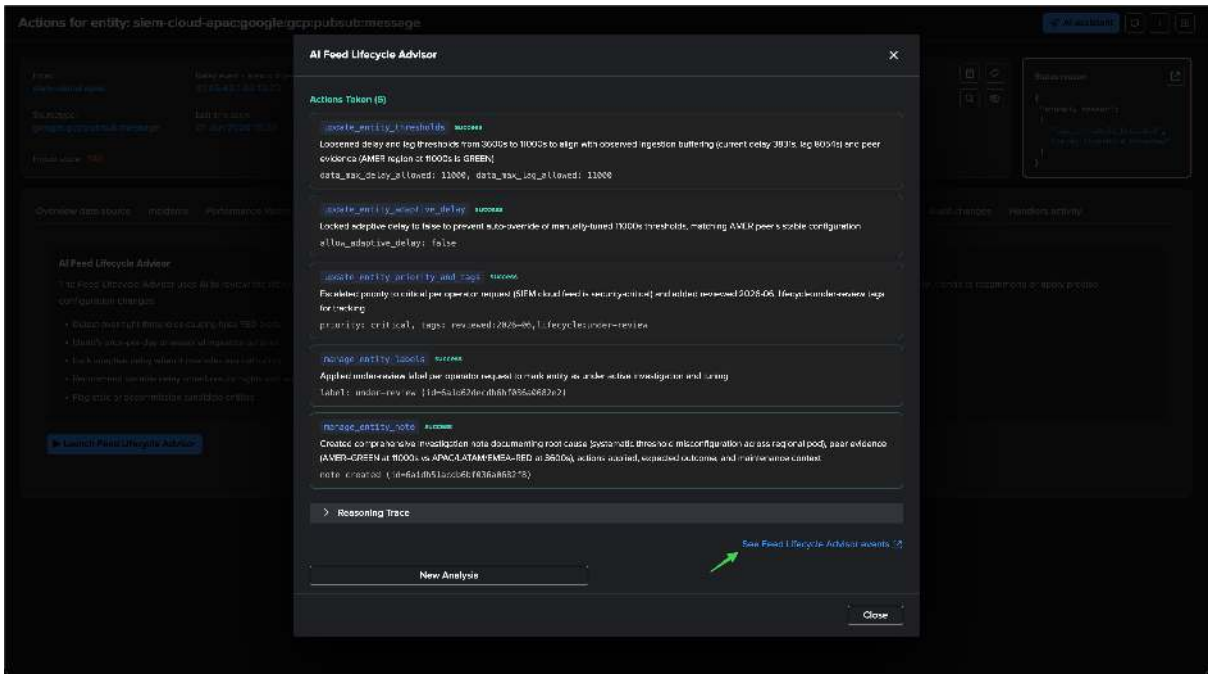
The recommendations are specific and reviewable — for example raising `data_max_delay_allowed` from 3600s to 9000s to align with observed ingestion buffering and peer thresholds, designing a variable-delay schedule for the business-hours pattern, and re-weighting the impact score.



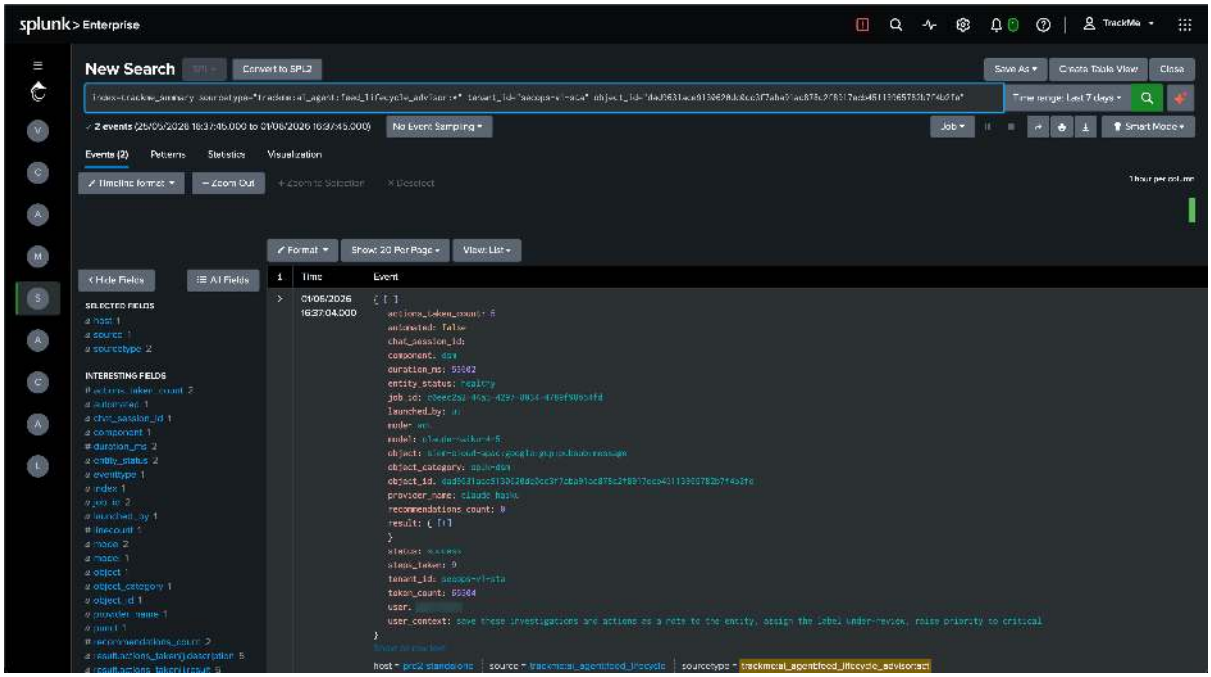


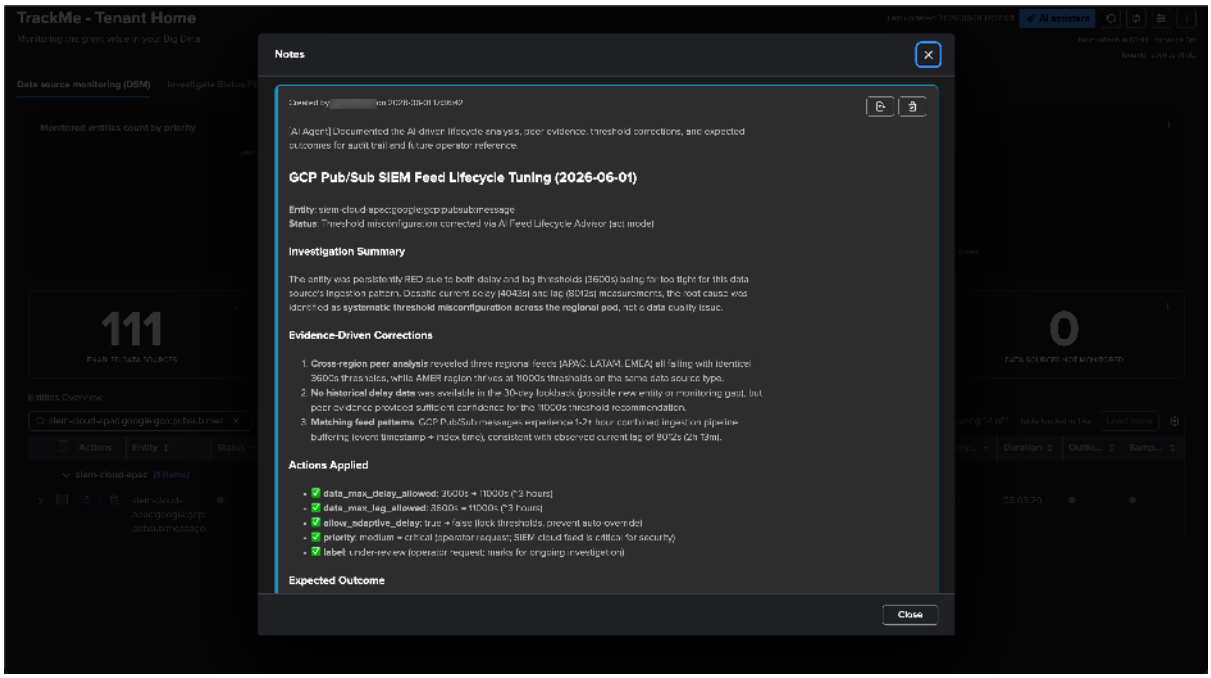
When you choose to apply the changes, the advisor switches to **act** mode and executes each write through TrackMe's REST API, re-reading to confirm the new state.





The **Actions Taken** panel lists every write the advisor performed — threshold updates, the adaptive delay lock, the priority/tags change, and the entity label and investigation note — each with its audit reason. A **reasoning trace** documents the analysis, and a link jumps to the advisor's audit events for this entity.





Note

Coexistence with legacy Adaptive Delay — When the AI Feeds Advisor covers DSM/DHM for a tenant, it takes precedence over the legacy mechanical *Adaptive Delay* and *Variable Delay auto-review* mechanisms, which are automatically disabled for those components so they cannot revert the advisor's per-entity decisions. Re-enabling the legacy mechanisms is a manual action from the Tenant Configuration modal.

Running it from the chat

In addition to the standalone modal, the AI Feeds Advisor can be proposed by the *AI Assistant* as a one-click consent card when you describe a feed problem in chat (e.g. *"this entity is RED, the delay threshold looks too tight"*). See *The AI Advisors* for the full bridge walkthrough.

Automated runs

The AI Feeds Advisor participates in the nightly automated batch, tuning eligible DSM/DHM entities within per-tenant policy (priority filter, freshness window, decommission guard). See *AI Agents automation*.

AI ML Advisor

Overview

The **AI ML Advisor** was the first advisor TrackMe shipped, and the model the others adopted. It inspects and remediates **native Machine Learning outlier-detection models** — the density-function fits, the boundary configurations, the scoring timelines, and the period exclusions. It is the advisor you reach for when you ask *"should I retrain?"*, *"is this outlier real?"*, or *"should I exclude this window from training?"* — questions that previously required reading several SPL queries and the KV Store by hand.

The ML Advisor reasons about the **model internals** — distinct from the component advisors that tune the entity *configuration* on top of the model. It applies to any component with ML outlier detection enabled (DSM, DHM, FLX, FQM, WLK, and — since 2.4.18 — VOL, where the outlier verdict *is* the entity state). The automated batch (*AI Agents automation*) reviews VOL models like the others.

See *The AI Advisors* for the shared inspect/act model, the consent-card bridge, and the structured output contract, and *Outlier detection* for the underlying ML outlier detection feature.

When to use it

- An entity is RED because of an outlier-score breach, but you suspect the model is over-sensitive or the training window included a known incident.
- A retrain just completed and the model now flags healthy traffic as anomalous (a false-positive cascade).
- The `isOutlier` flag is sticky — the score will not return to baseline even after the anomaly has clearly passed.
- A density function's boundaries look wrong compared to the entity's actual traffic distribution.
- The model is "low confidence" and you want to know whether more training data would help.

What it reads and writes

In **inspect** mode the advisor reads the full outlier context (identity, health, score breakdown, model rules, detection state and boundaries, confidence level), the raw metric history, the per-group fitted distributions and fit quality, the outlier-score timeline, the entity's state-transition history, and the full training-window render (metric values, decided boundaries, flagged points).

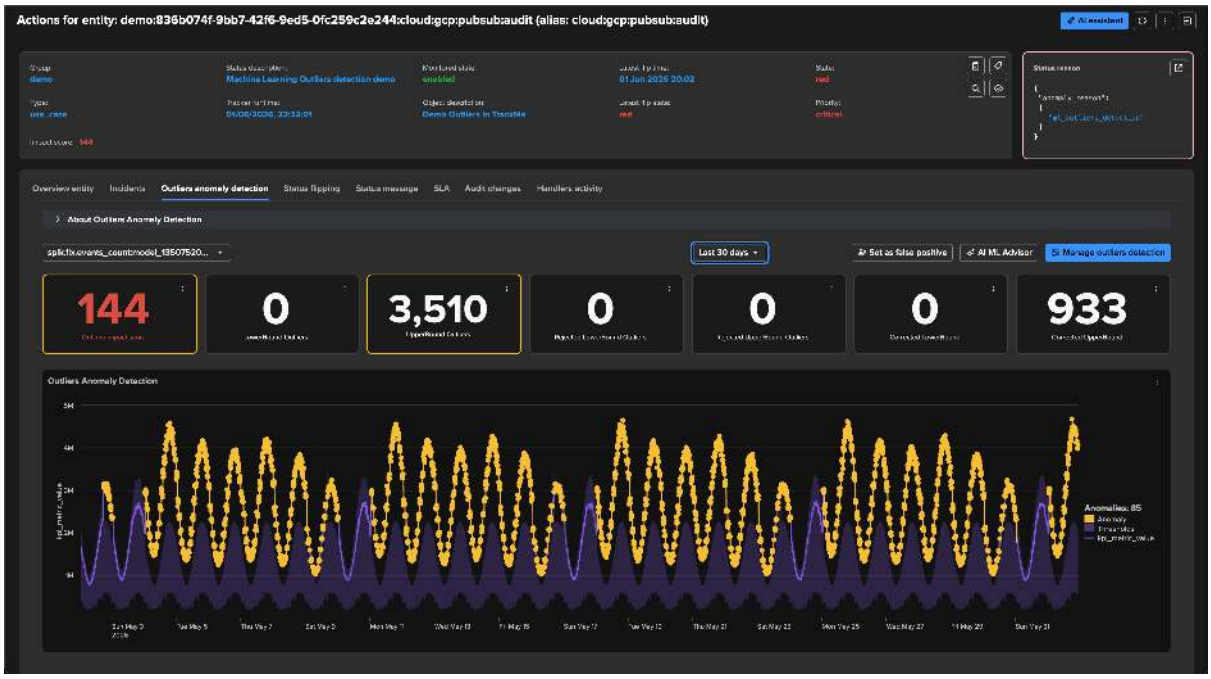
In **act** mode it can additionally:

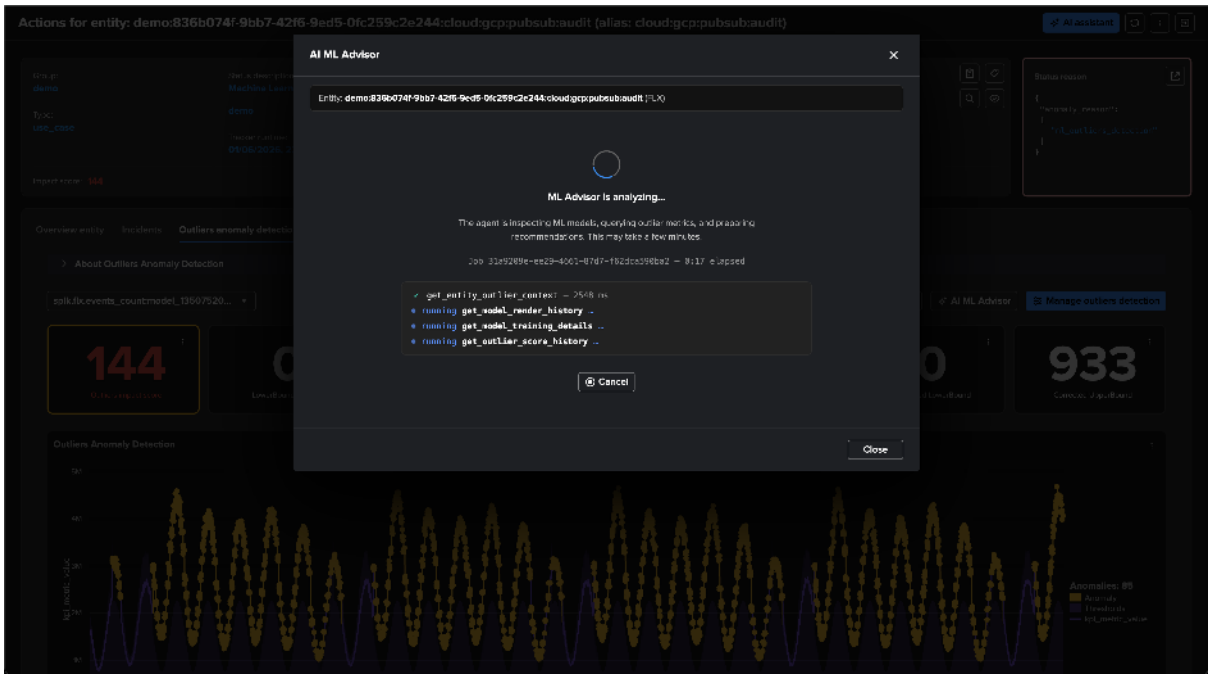
- add a **period exclusion** to remove a contaminated window from the training set,
- **trigger a retrain** (live or simulation),
- **set a false positive** to neutralise the current outlier,
- **update model rules** (density-function bounds, sliding-window size, seasonality flags, …),
- **enable / disable / reset** outlier detection (the disable action is decommission-gated),
- and attach labels and an investigation note to the entity.

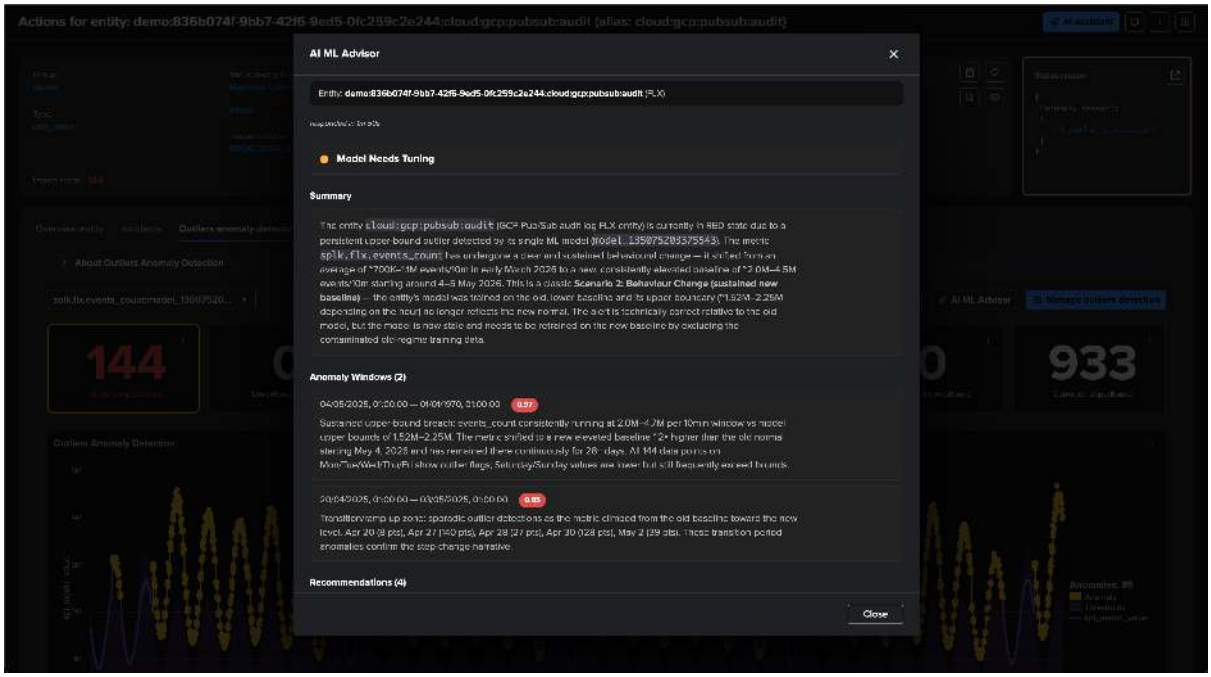
A distinguishing field of the ML Advisor's structured output is `anomaly_windows` — detected periods worth excluding from training, each with a start, end, and reason.

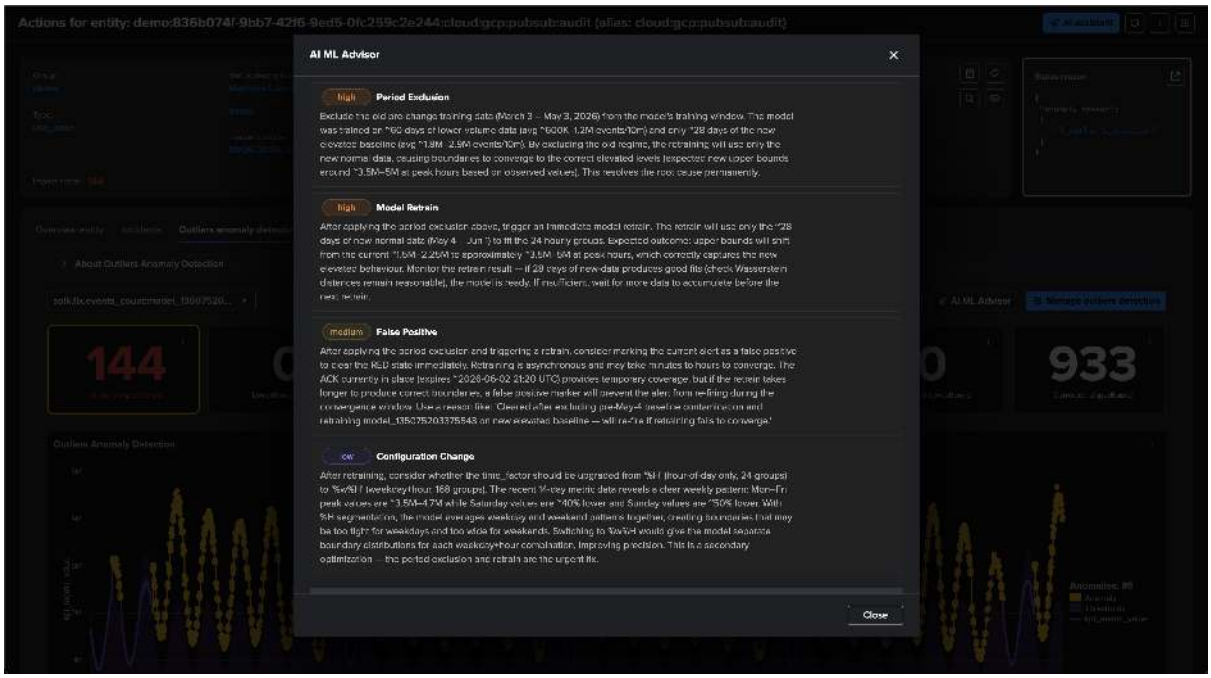
Example 1 — a misbehaving model

The ML Advisor is launched from an entity's **Outliers anomaly detection** tab via the **AI ML Advisor** button. In this example the model is misbehaving — producing a large number of lower-bound outliers that do not reflect a genuine data problem.

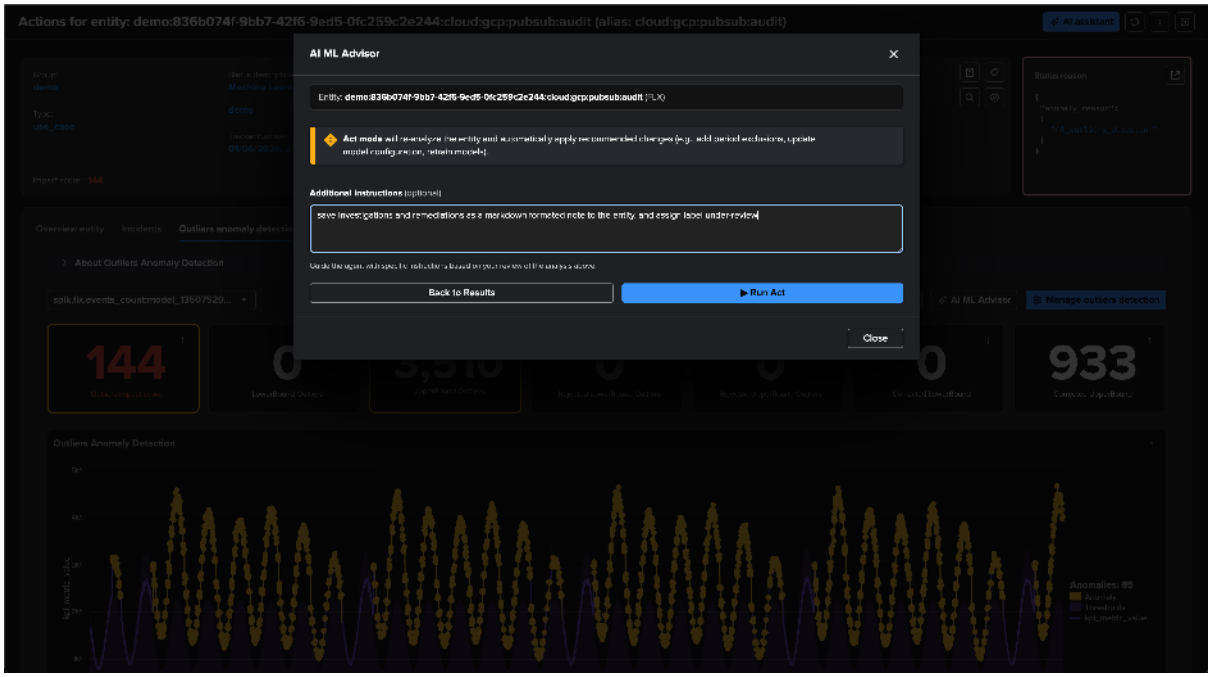








The advisor inspects the model, classifies the situation, and proposes remediation. In **act** mode an *Additional instructions* textbox lets you constrain the agent — for example *"save investigations and remediations as a markdown-formatted note to the entity, and assign label under-review".*



Actions for entity: demo:836b074f-9bb7-42f6-9ed5-0fc259c2e244:cloud:gcp:pubsub:audit (alias: cloud:gcp:pubsub:audit)
AI ML Advisor
Entity: demo:836b074f-9bb7-42f6-9ed5-0fc259c2e244:cloud:gcp:pubsub:audit [TLX]
Act mode will re-analyze the entity and automatically apply recommended changes (e.g., add period exclusions, update model configuration, retrain models).
Additional instructions (optional)
save investigations and remediations as a markdown formated note to the entity, and assign label under-review

Example 2 — a true positive with period exclusions

Not every anomaly is a false alarm. In this example the model has flagged a **genuine** anomaly (a true positive). The advisor inspects the score history and the training render, identifies the contaminated window, and — in act mode — applies **period exclusions** so the incident period does not poison future training, then retrains the model and documents its reasoning.

ML Outliers Anomaly Detection
Machine Learning Outliers Anomaly Detection - Periods exclusions per ML model
Use this screen to manage ML models periods exclusions
Periods Exclusions can be used to exclude periods of time from the ML models training, and avoid models from being impacted by behaviour anomalies:
These periods are not taken into account while training ML models
When performing simulation, these periods are fully excluded (and can therefore appear as gaps in the chart)
When an exclusion period is expired and is out of the ML model training time range, it is automatically deleted when processing the next ML model training
The UI applies addition and deletion of periods exclusions to all ML models for this object
Time is shown in your own local time zone settings.

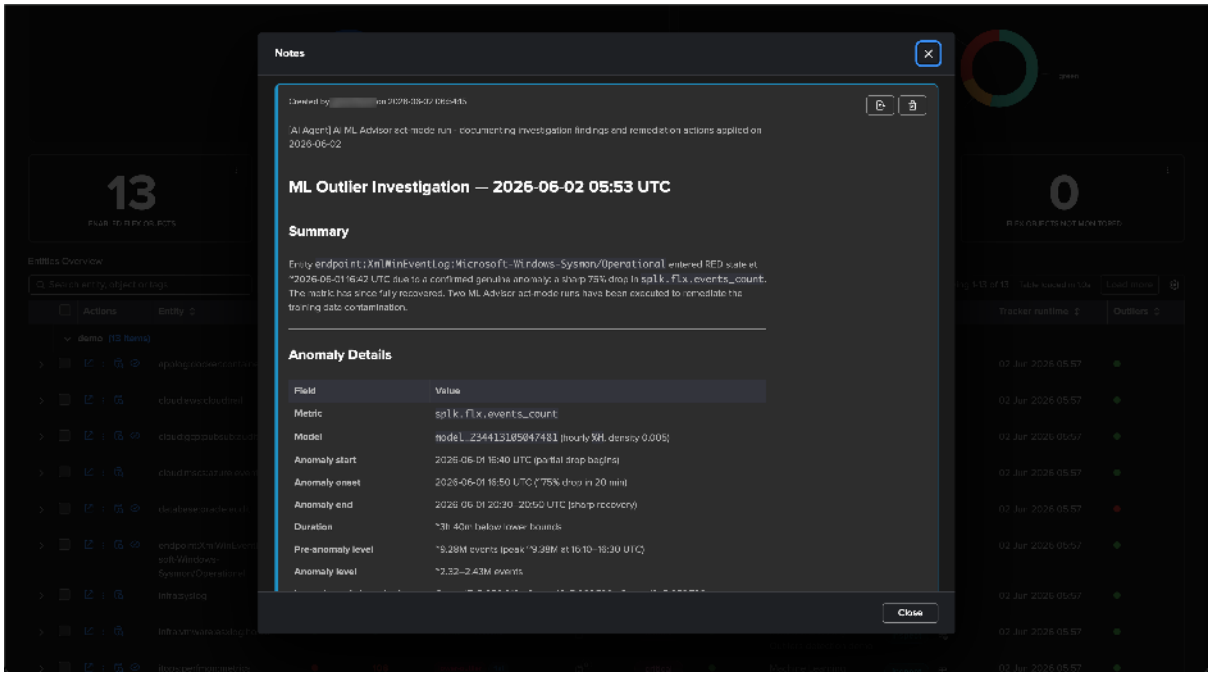
user:
result: "ML models were updated successfully",
comment: "[AI Agent] Extended period exclusion covering the full anomaly window on Jun 1 2026. spik.flx.events_count dropped sharply from ~9.28M to ~2.32M (-75%) at 16:40-16:50 UTC, sustained well below the lower bounds of 5,250,019 (group 17), 5,289,739 (group 18), and 5,253,792 (group 19) until recovery at ~20:30-20:50 UTC. A prior acc-mode run on Jun 1 21:23 UTC only excluded 19:50-20:50 UTC, leaving ~3 hours of severely breached data points (16:40-19:50 UTC) unprotected in the training window. This broader exclusion (16:00-21:00) covers the complete anomaly span so that hourly groups 16-20 are not contaminated on future retrains. No prior occurrence of this magnitude in the 90 day render history - not a normal business pattern.",
tenant_id: "demo-outliers",



Note

Retraining is asynchronous — `trigger_model_retrain` returns once the retrain is *queued*, not once it completes; the model is retrained on the next scheduled fit. **Period exclusions are additive** — adding one does not replace existing exclusions. The advisor's reasoning trace and the on-entity note make both behaviours explicit.

Running it from the chat

The ML Advisor can also be proposed by the *AI Assistant* as a consent card when you describe an ML symptom in chat (e.g. *"this outlier seems wrong"*, *"should I retrain?"*, *"exclude the last two hours from training"*). See *The AI Advisors*.

Automated runs

The ML Advisor participates in the nightly automated batch, reviewing eligible entities with active outliers within per-tenant policy. The model-disable action has its own dedicated guard (`ai_mladvisor_allow_model_disable`, default off). See *AI Agents automation*.

AI FQM Advisor

Overview

The **AI FQM Advisor** handles **FQM (Field Quality Monitoring)** — TrackMe's component for tracking field parsing quality and CIM compliance. It is the most feature-rich advisor of the family: it manages dynamic thresholds *and* a per-tracker **data dictionary** that defines per-field validation logic (regex, datatype, required/optional, expected

values, CIM datamodel mapping). It also has a unique wizard-time **dictionary generation** capability that proposes a starter dictionary from sampled-field statistics — before the entity even exists.

See *The AI Advisors* for the shared inspect/act model and the structured output contract, and *Use Case Demo: Fields Quality (CIM and non-CIM)* for the FQM component itself.

What FQM tracks

FQM answers *"are the fields in this sourcetype being parsed correctly and conforming to CIM expectations?"* For each tracked sourcetype, you define a **data dictionary** mapping field names to validation rules. A scheduled collect-job samples real events and computes `percent_success` (events that pass field validation) and `percent_coverage` (events where the field was present at all); dynamic thresholds turn those numbers into alerts.

This gives the advisor three flavours of work:

1. **Threshold tuning** — "your `percent_success` threshold of 99% is unrealistic for this noisy sourcetype; the observed median is 95% — recommend 90%."
2. **Dictionary maintenance** — "your `src_ip` field has a 15% failure rate because the regex does not match IPv6 — update the regex"; or "you have no validation for `user_id` but it is consistently a 10-digit number — add a rule."
3. **Wizard-time dictionary generation** — propose a starter dictionary from observed field types, value distributions, and CIM datamodel hints.

When to use it

- An FQM entity is RED because of a field-quality threshold breach and you want to validate whether the threshold is realistic.
- A specific field has a high failure rate and you want the advisor to inspect failing samples and propose a regex fix.
- The data dictionary was set up months ago and the sourcetype's payload has drifted (new field, renamed field, format change) — a "review my dictionary" pass.
- You are creating a new FQM tracker via the wizard and want a starter dictionary proposal from sampled-field statistics.

What it reads and writes

In **inspect** mode the advisor reads the full FQM entity context, the data dictionary (and which trackers share it), individual field entries, the quality history, sampled failing events, the collect-job health, peer-entity thresholds, and the CIM datamodel diff. It can also **test a candidate regex** against real sampled values before recommending it.

In **act** mode it can add / update / delete dynamic thresholds, update individual field-dictionary entries, bulk-update the dictionary, and update the entity's monitoring state or priority. A separate **dictionary_generate** mode runs at wizard time with no tools — it reasons purely from the sampled field statistics to propose a dictionary.

Note

The data dictionary is **per-tracker**, not per-entity — a dictionary change affects every entity sharing the tracker. Bulk dictionary updates are atomic (all-or-nothing), and operator review of a generated dictionary is always required regardless of the confidence score.

Example 1 — a CIM tracker with a generated dictionary

The FQM Advisor's dictionary generation is integrated directly into the **Fields Quality Monitoring** tracker-creation wizard. When creating a collect job for a CIM datamodel, the wizard steps you through selecting the tracker type, defining the search, sampling fields, and previewing a generated data dictionary. The embedded **Wizard Assistant** offers to *"generate the data dictionary based on the sampled fields"* and explains the validation options (e.g. `allow_unknown` vs `allow_empty_or_missing`).

AI Assistant
claude_haiku (claude-haiku-4-5)
Context: Wizard Assistant
You
Can you generate the data dictionary based on the sampled fields?
AI Assistant
Absolutely! I'll run the FQM Advisor in dictionary_generate mode to propose a starter data dictionary based on the fields you've already sampled in the wizard.
This will analyze the field distributions (cardinality, value patterns, data types) and recommend appropriate validation rules for each field — things like:
regex patterns (for structured fields like IPs, timestamps, etc.)
allow_unknown (whether to accept values outside the sampled set)
allow_empty_or_missing (whether nulls/blanks are valid)
The wizard will inject your sampled-fields payload automatically, so you'll get recommendations tailored to your actual data.
FQM ADVISOR — PROPOSED ACTION
Generate a starter data dictionary with field validation rules based on your sampled field distributions.

Example 2 — a non-CIM tracker with a brand-new dictionary

The same flow applies to a **non-CIM** tracker, where there is no datamodel to align against. The advisor proposes a brand-new dictionary purely from the observed field types and value distributions — proposing presence-only validation where a field has no clear pattern rather than inventing a regex. The proposed dictionary is rendered as an editable table for operator review before it is applied.

Threshold tuning and dictionary review

Beyond the wizard, the **AI FQM Advisor** tab on FQM entity overviews runs the standard inspect/act flow for existing trackers — validating thresholds against observed quality history, inspecting failing samples, testing candidate regexes, and proposing dictionary updates (which can also be proposed by the *AI Assistant* as a consent card). It participates in the nightly automated batch for threshold tuning and dictionary maintenance; dictionary *generation* is wizard-only by design. See *AI Agents automation*.

AI Component Health Advisor

Overview

The **AI Component Health Advisor** handles two components in a single advisor with dynamic per-component tool selection:

- **WLK (Workload Monitoring)** — the execution health of Splunk scheduled saved searches: skip rate, error count, execution delay, versioning drift.
- **MHM (Metric Host Monitoring)** — the lag of hosts reporting metric data (the metric-equivalent of DHM), including per-class lagging thresholds.

The same advisor code drives both because the threshold-management surface is structurally identical and the decision-making pattern is the same (read history → compare peers → recommend). At launch the advisor selects only the tools for the component in scope, so a WLK run never sees MHM tools and vice versa.

See *The AI Advisors* for the shared inspect/act model, the consent-card bridge, and the structured output contract.

When to use it

WLK

- A WLK entity is RED because the skip rate exceeded its threshold and you want to know if the threshold is realistic for this saved search's load profile.
- An app deployment introduced new scheduled searches with default thresholds and you want them validated after a week.
- A saved search's error count is bursting and you want to inspect peer thresholds across the app.

MHM

- A metric host is RED because of excessive lag and you want to check whether the lag is genuinely problematic or the threshold is too tight.
- The tenant's lagging classes (platinum / gold / silver) have stale threshold values and you want them reviewed.

What it reads and writes

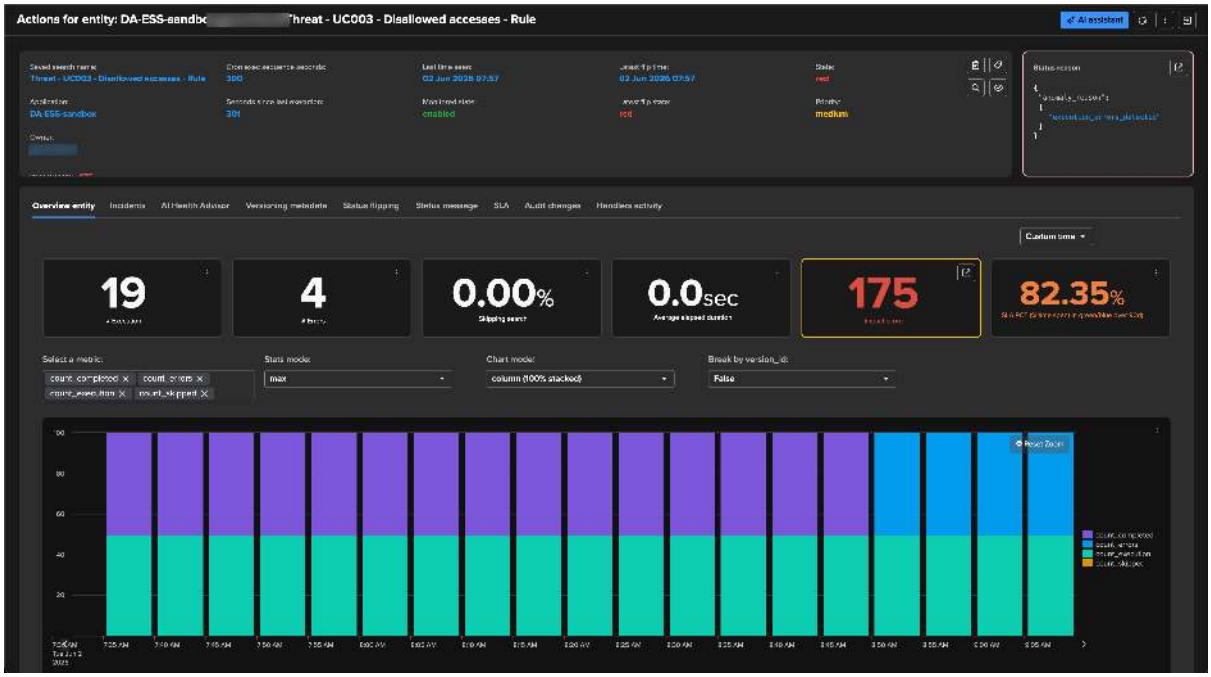
For **WLK**, inspect reads the full entity context, the execution history (skip rate, error rate, execution time per day), the breach history, and peer thresholds in the same app. In act mode it can add / update / delete execution-metric thresholds and update the entity's monitoring state or priority (decommission-gated).

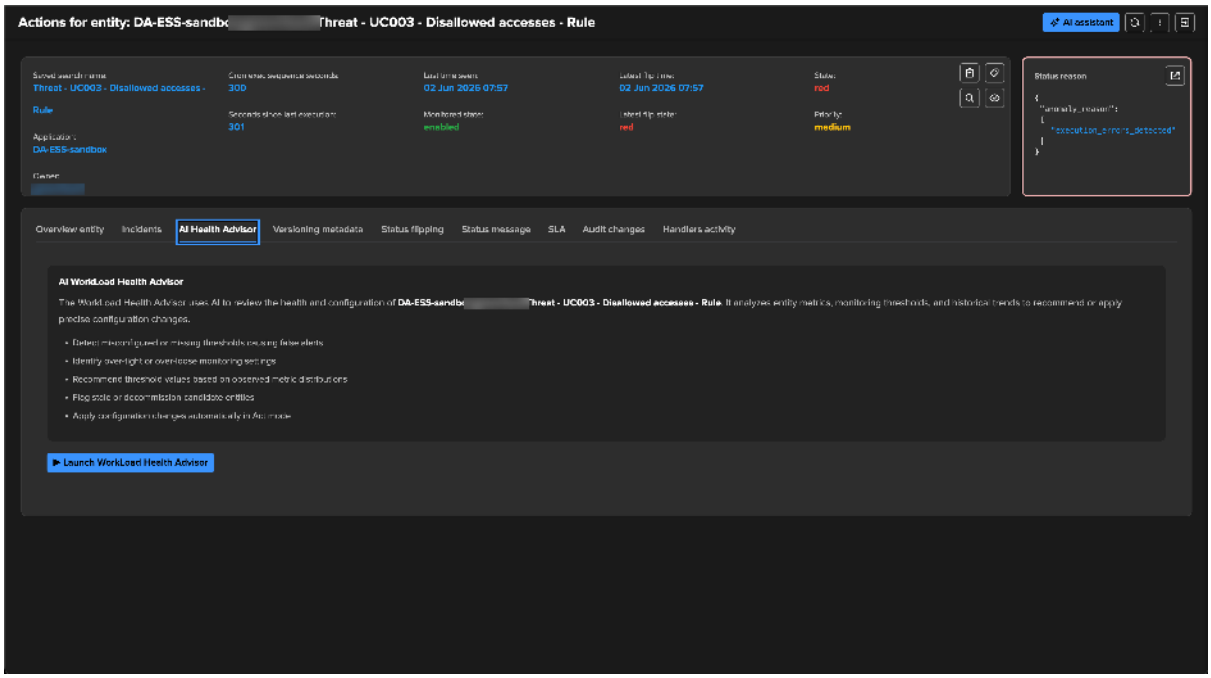
For **MHM**, inspect reads the entity context, the metric-lag history, the breach history, and the tenant's lagging-class definitions. In act mode it can update the per-entity metric-lag threshold and the entity's monitoring state or priority.

> **Note**
>
> The advisor can *recommend* a lagging-class-level change for MHM but cannot apply one — class-level changes are tenant-level and go through the admin UI or the *AI Concierge*. For WLK, if the error count is consistently non-zero with no deployment change, the advisor recommends investigating the saved search itself rather than raising the threshold to mask a broken search.

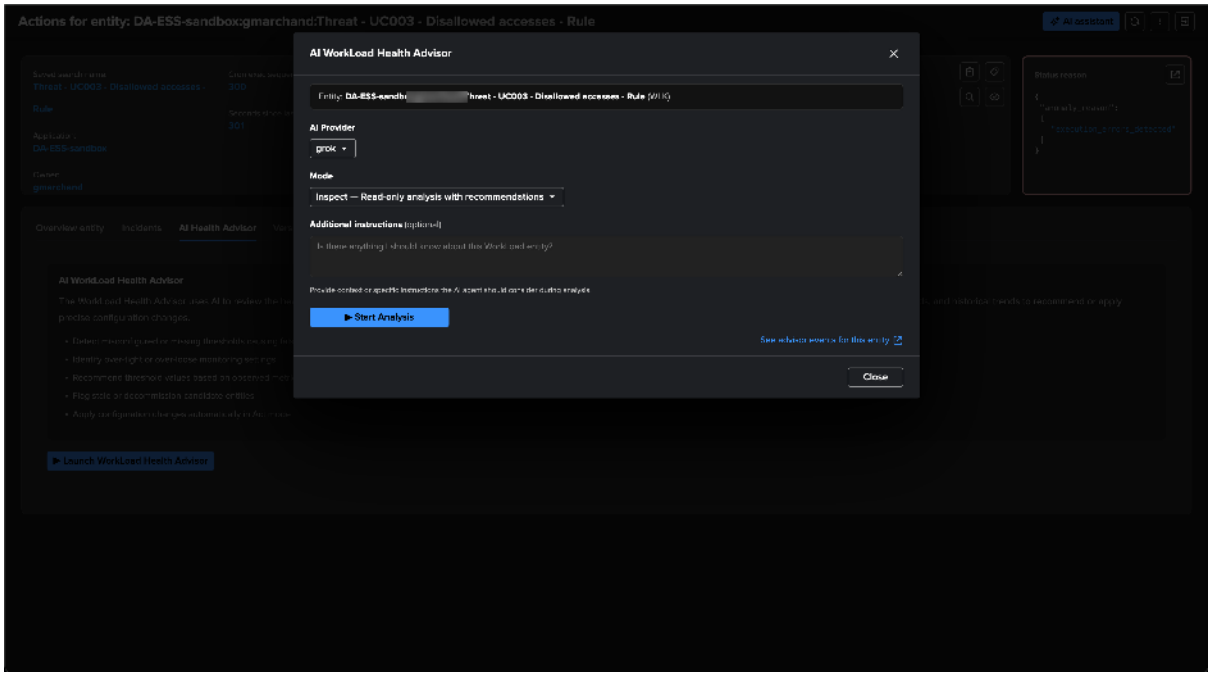
Example — a WLK schedule in error

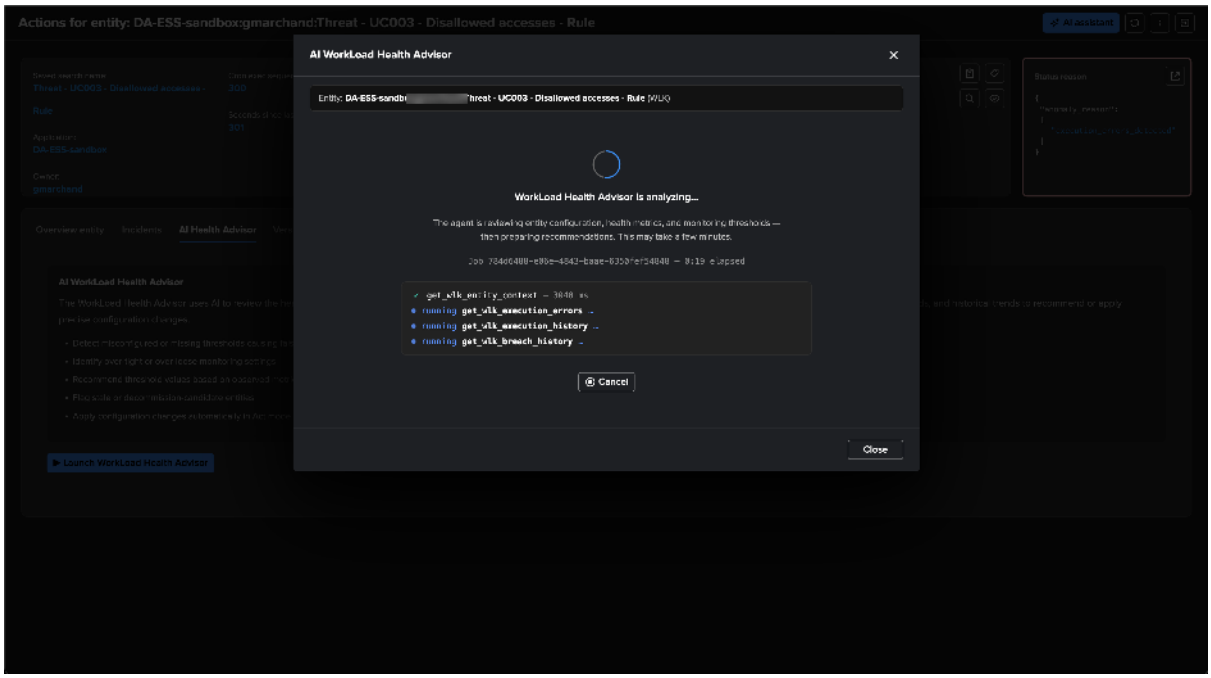
The Component Health Advisor is launched from a WLK entity's **AI Health Advisor** tab via the **Launch Workload Health Advisor** button. In this example the saved search `DA-ESS-sandbox:...:Threat - UC003 - Disallowed accesses - Rule` is RED with `execution_errors_detected` — the schedule is failing, not merely slow.



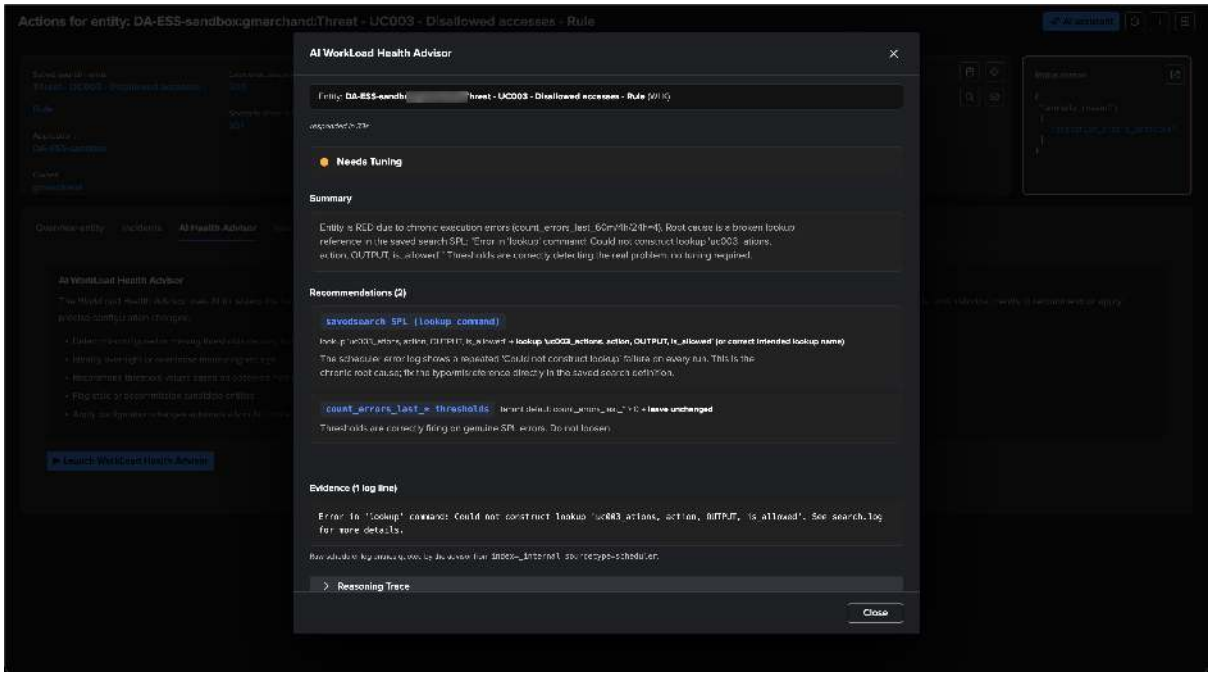


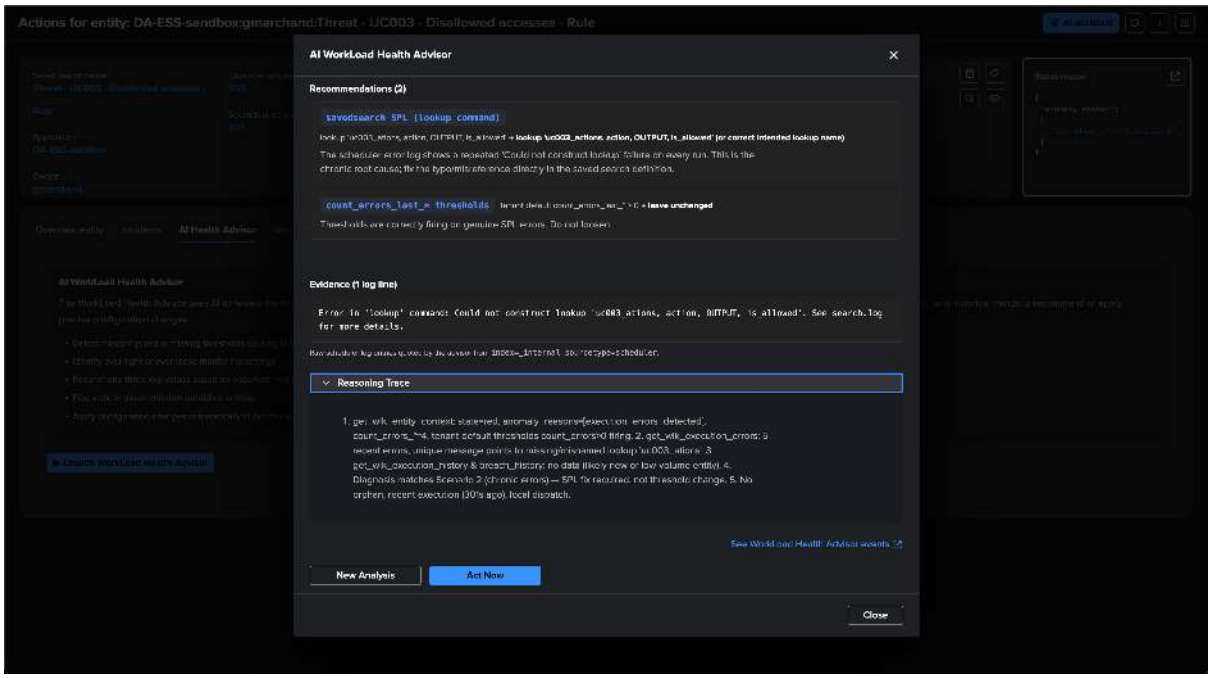
The advisor inspects the entity, reading the execution context, the execution-error history, the execution history, and the breach history via its live tool feed.





It then returns a structured verdict and recommendations — here correctly diagnosing that the search itself is failing and that the fix is to investigate the SPL rather than relax the threshold.





Where to find it

The advisor appears as the **AI Health Advisor** (WLK) tab on WLK entity overviews and as the **AI MHM Advisor** tab on MHM entity overviews — both run the same backend with the appropriate component selected. It can also be proposed by the *AI Assistant* as a consent card, and it participates in the nightly automated batch (one batch per component). See *AI Agents automation*.

3.5 AI Agents for findings

3.5.1 Overview

TrackMe 2.4.19 introduces the **AI Agent**: an agentic operator for the dedicated findings tenants. Where the *AI Advisors* tune the configuration of monitored entities, the AI Agent works on **findings**. It triages them the way an operator would: it reads the evidence TrackMe holds, assesses each finding, recommends a decision and, when the tenant allows it, applies that decision itself, for example marking a Finding group investigating, dismissing it for a bounded time or resolving it once a recovery is proven. It keeps one current `[AI Agent]` note on every finding it reviewed and records every decision in a decision log.

Tenant type	AI Agent
User Activity Monitoring	**UAM AI Agent**. It replaces the UAM Findings Advisor of TrackMe 2.4.18; on upgrade, an enabled advisor's settings are carried over to the agent.
Cribl Stream	**Cribl Stream AI Agent**
Cribl Edge	**Cribl Edge AI Agent**

The three agents run on **one shared framework**: the same identity, the same inspect / act contract, the same settings, the same scheduling, the same decision log and the same user interface. Each tenant type brings what is specific to it: its evidence, its assessments and the decisions it may take.

Note

The AI Agent is part of the *findings model* shared by User Activity Monitoring, Cribl Stream and Cribl Edge. The product guide covers it from the tenant's point of view in *Findings AI Agents*; this page is the reference from the AI side.

How the AI Agent differs from the other AI features

	AI Advisors and AI Agents automation	AI Agent
Works on	Entities of the monitoring components (DSM, DHM, FLX, FQM, WLK, MHM, VOL) and their configuration: models, thresholds, delays, dictionaries	Findings and Finding groups of a User Activity Monitoring, Cribl Stream or Cribl Edge tenant
Decides	Configuration changes, with your consent or within the automation policy	Triage decisions on findings, within the decisions the tenant allows
Acts as	The user who launched it (interactive) or the tenant owner (scheduled)	Its own actor, **AI Agent**, shown in the finding history; the decision log also records who asked
Schedule	Nightly batch (*AI Agents automation*)	Hourly scheduled triage, per tenant
Where to follow it	The entity's audit changes, the AI Advisor audit dashboards	The **AI Agent** tab of the workspace, the finding history and notes, the same audit dashboards

3.5.2 How it works

Every review follows the same five steps, whether you ask the agent about one finding or the hourly triage reviews the open findings of the tenant.

1. **Select.** One finding per Finding group, the most severe first. A scheduled run skips the findings it reviewed recently, unless something changed since.
2. **Gather the evidence.** TrackMe computes the facts about the finding on the server, from what it already holds, and gives them to the agent: the finding, its episodes and its history, the policy, and the object it names. For UAM, that is the account, its class and where the class comes from, and its activity. For Cribl Stream, that is

when the object was first seen, whether it is disabled in Cribl or gone from the Inventory, which Routes reference it, its traffic and its traffic ML model. For Cribl Edge, that is the node or the Fleet as the node directory last published it: connected and disconnected nodes, versions and configuration drift, the node's state, version, disk and the health of its Sources and Destinations, and whether the node or Fleet is still in the directory.

3. **Assess.** The agent classifies the finding and gives its confidence (high, medium or low).
4. **Decide.** It recommends one decision. In act mode it applies it, and the server checks again, at that moment, that the decision is allowed and that its preconditions hold, whatever the model wrote. A decision that fails these checks is refused and recorded as such.
5. **Record.** It writes or refreshes its `[AI Agent]` note on the finding, the decision appears under the actor **AI Agent** in the history, and the review lands in the decision log and the audit trail.

Deterministic evidence first, the LLM second. The agent reasons on facts TrackMe checked, not on guesses, and it cannot dispatch searches of its own: the Cribl Stream agent reads the newest certified interval, the traffic models and the incident's own record; the Cribl Edge agent reads the newest publication of the node directory; the UAM agent reads bounded activity records (at most 50 events per read). Proofs such as "this object has had no traffic for 7 days" are computed by TrackMe, never inferred by the model.

Assessments

Assessment	Meaning
True positive	The condition is real and needs an operator.
Likely false positive	The evidence points to a detection that does not reflect a real problem.
Expected behaviour	The condition is real but expected, for example a seasonal or planned pattern.
Needs investigation	The evidence is not enough to conclude.
Object not in use *(Cribl Stream)*	The object is disabled, removed or never carried traffic.
Node or Fleet not in use *(Cribl Edge)*	The node or Fleet is retired: gone from the node directory, or a Fleet the tenant no longer collects.
Misclassified account *(UAM)*	The finding comes from an account classified as the wrong type (human or service).

3.5.3 Inspect and act

Mode	What it does
Inspect	Assesses and recommends. It writes one current `[AI Agent]` note per finding and changes nothing else. This is the default, for asked reviews and scheduled ones.
Act	Inspects, then applies the decisions the evidence supports **and** the tenant settings allow. Act must be chosen explicitly.

The decisions act may take, each with its own setting:

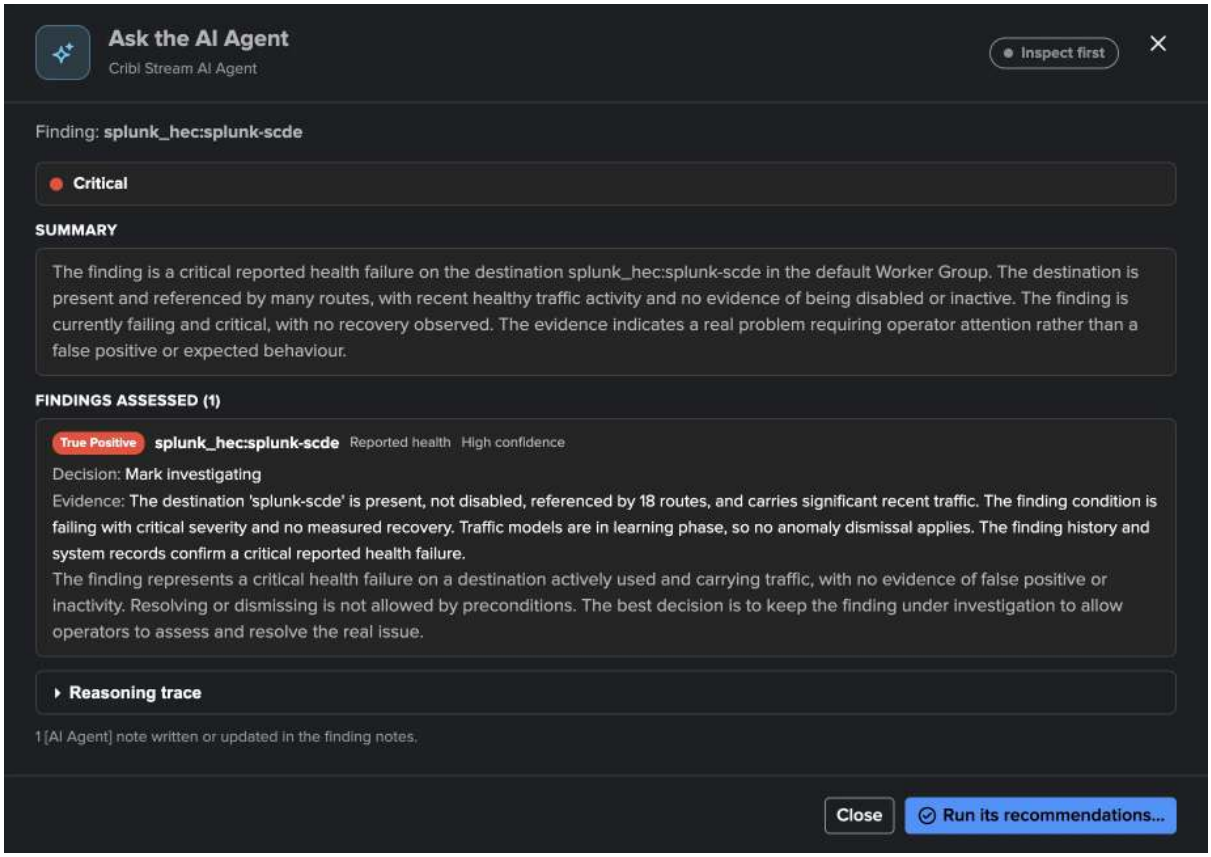
Decision	Default	UAM	Cribl Stream	Cribl Edge
Mark investigating	On	Yes	Yes	Yes
Dismiss for a time (7 days at most by default, up to 90)	On	Never a critical or high finding still observed	A critical failing finding only with proof that the object is disabled, missing or inactive	A critical or high finding still failing only when its node or Fleet is gone from the node directory, and never across the nodes of a Finding group
Not an anomaly (a traffic outlier)	On	—	Yes	—
Resolve	Off	Only a finding its policy no longer observes	Only after a measured recovery	Only after a measured recovery
Classify an account (human or service)	Off	Only an account without a class set by an operator	—	—
Stop monitoring an object	Off	—	Only with proof of inactivity (7 days by default)	—

The agent **never** dismisses permanently, assigns or unassigns, changes a severity, or changes a policy, a model or a setting (on Cribl Edge, the node selection or the collected Fleets): these decisions do not exist in its vocabulary. On Cribl Stream it may **recommend** *Forget this object* for an object removed from Cribl, but only a TrackMe administrator of the tenant can do it.

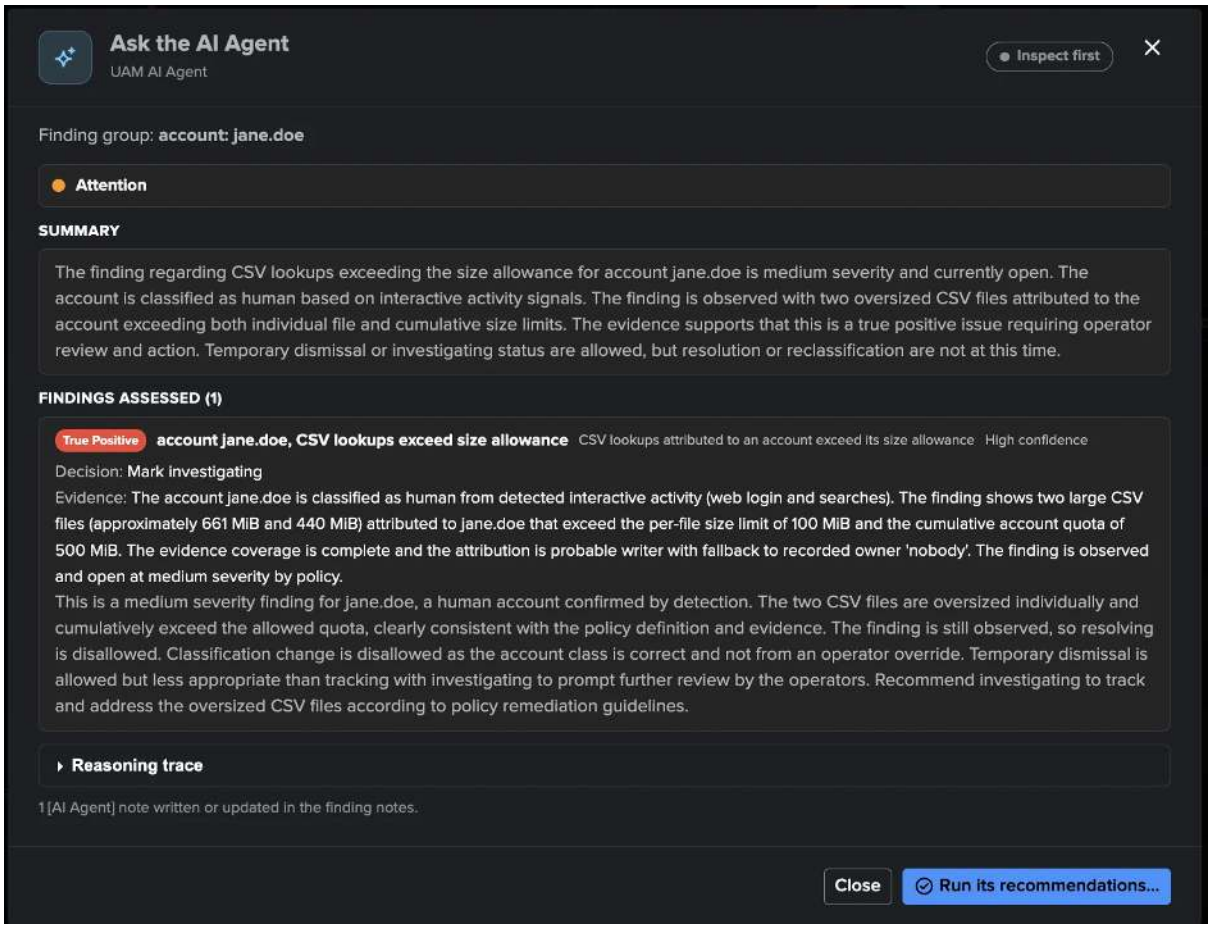
3.5.4 Asking the AI Agent

Ask the AI Agent… is in the finding and Finding group menus, the investigation view and the **AI Agent** tab of the workspace, with optional instructions for the review. The agent always inspects first: you read its assessment, its evidence and its rationale, then choose **Run its recommendations…** to let it act on that inspection, with optional instructions, within 30 minutes.

The **AI Assistant** of the workspace can also propose an AI Agent review in the chat, as a consent card you confirm, the same way it proposes an AI Advisor (see *AI Assistant*).



Ask the AI Agent
Cribl Stream AI Agent
Inspect first
Finding: splunk_hec:splunk-scde
Critical
SUMMARY
The finding is a critical reported health failure on the destination splunk_hec:splunk-scde in the default Worker Group. The destination is present and referenced by many routes, with recent healthy traffic activity and no evidence of being disabled or inactive. The finding is currently failing and critical, with no recovery observed. The evidence indicates a real problem requiring operator attention rather than a false positive or expected behaviour.
FINDINGS ASSESSED (1)
True Positive splunk_hec:splunk-scde Reported health High confidence
Decision: Mark investigating
Evidence: The destination 'splunk-scde' is present, not disabled, referenced by 18 routes, and carries significant recent traffic. The finding condition is failing with critical severity and no measured recovery. Traffic models are in learning phase, so no anomaly dismissal applies. The finding history and system records confirm a critical reported health failure.
The finding represents a critical health failure on a destination actively used and carrying traffic, with no evidence of false positive or inactivity. Resolving or dismissing is not allowed by preconditions. The best decision is to keep the finding under investigation to allow operators to assess and resolve the real issue.
Reasoning trace
1 [AI Agent] note written or updated in the finding notes.
Close
Run its recommendations...



Ask the AI Agent
UAM AI Agent
Inspect first
Finding group: account: jane.doe
Attention
SUMMARY
The finding regarding CSV lookups exceeding the size allowance for account jane.doe is medium severity and currently open. The account is classified as human based on interactive activity signals. The finding is observed with two oversized CSV files attributed to the account exceeding both individual file and cumulative size limits. The evidence supports that this is a true positive issue requiring operator review and action. Temporary dismissal or investigating status are allowed, but resolution or reclassification are not at this time.
FINDINGS ASSESSED (1)
True Positive account jane.doe, CSV lookups exceed size allowance CSV lookups attributed to an account exceed its size allowance High confidence
Decision: Mark investigating
Evidence: The account jane.doe is classified as human from detected interactive activity (web login and searches). The finding shows two large CSV files (approximately 661 MiB and 440 MiB) attributed to jane.doe that exceed the per-file size limit of 100 MiB and the cumulative account quota of 500 MiB. The evidence coverage is complete and the attribution is probable writer with fallback to recorded owner 'nobody'. The finding is observed and open at medium severity by policy.
This is a medium severity finding for jane.doe, a human account confirmed by detection. The two CSV files are oversized individually and cumulatively exceed the allowed quota, clearly consistent with the policy definition and evidence. The finding is still observed, so resolving is disallowed. Classification change is disallowed as the account class is correct and not from an operator override. Temporary dismissal is allowed but less appropriate than tracking with investigating to prompt further review by the operators. Recommend investigating to track and address the oversized CSV files according to policy remediation guidelines.
Reasoning trace
1 [AI Agent] note written or updated in the finding notes.
Close
Run its recommendations...

Who can ask:

- **User Activity Monitoring**: the TrackMe administrators of the tenant ask the agent and let it act; the tenant's power roles can read its settings and decision log.
- **Cribl Stream** and **Cribl Edge**: the tenant's power and admin roles, the roles that can triage, ask the agent and let it act; the settings belong to a TrackMe administrator of the tenant.

Asking needs the AI Assistant to be enabled and at least one *AI provider* configured, on Splunk 10.2.x or later (the AI Agent is built on the Splunk Agent SDK, like the AI Advisors).

3.5.5 Scheduled triage

The AI Agent can review the open and investigating findings of its tenant **every hour** on its own. Scheduled triage is **off by default**. Its report only runs when all of the following hold:

- the AI Assistant is enabled and at least one AI provider is configured;
- the tenant is enabled and its AI Agent is enabled (workspace **Settings → AI Agent**);
- the tenant owner is a real account, not `nobody` or `splunk-system-user`. The Guardian check `ai_automation_owner_is_system_user` warns otherwise. On Cribl Stream and Cribl Edge the owner must also be a Splunk administrator.

Saving the AI Agent settings schedules or unschedules the report at once; the tenant health tracker checks these conditions every five minutes and follows any other change, such as a provider added or removed.

Each run:

- reviews up to 10 findings (1 to 50), one per Finding group, the most severe first, within a time budget that fits the hourly cadence;
- skips a finding reviewed within the review interval (1 day by default), unless a new episode started or the Finding group changed;
- **never overrides a person**: a finding or Finding group that an operator decided on, or that has an assignee, is left to the operators;
- applies the shared filters of the automated AI reviews, with the finding severity as the priority: by default only **critical and high** findings are selected. The filter expression applies too, and so do the shared custom instructions of the tenant, which apply to scheduled runs only (see *AI Agents automation*); the agent's own custom instructions apply to every run (see *Custom instructions and Evaluate*).

A run never makes more than one decision per finding and Finding group, and every decision belongs to its run, its tenant and its scope.

3.5.6 Settings

In the workspace **Settings → AI Agent**. Every findings AI Agent also appears in **Manage AI Agents automation** (*AI Agents automation*), with its tenant's row: enabling, mode, provider, review interval, runtime and custom instructions; the allowed decisions stay in the workspace.

Setting	Default	Notes
Enabled	Off	Scheduled triage only; asking the agent needs only AI to be available.
Mode	Inspect	Inspect or act, for scheduled runs.
AI provider	First available	
Review interval (days)	1	A finding is not reviewed again within this interval unless it changed.
Maximum runtime (seconds)	3000	Fits the hourly cadence.
Findings per run	10	1 to 50.
Custom instructions	Empty	At most 4000 characters; see *Custom instructions and Evaluate*.
Allowed decisions and longest dismissal	See *Inspect and act*	Per decision; Cribl Stream adds the days of proven inactivity before stop monitoring.

Allowing more (enabling the agent, act mode, a decision, a longer dismissal) needs a licence that allows changes; restricting it never does.

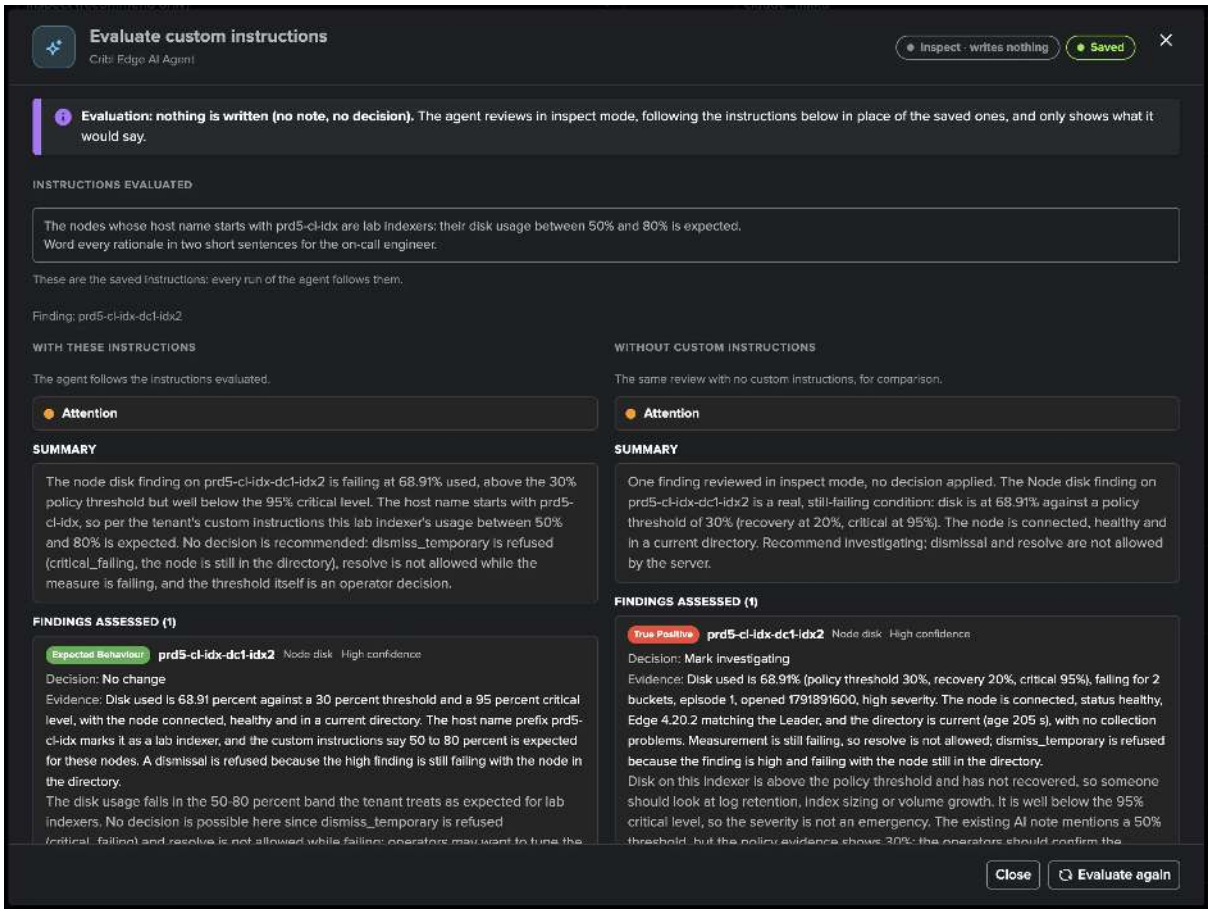
3.5.7 Custom instructions and Evaluate

Custom instructions are plain English that the tenant's administrators write for their agent, in **Settings → AI Agent → Custom instructions** (also in Manage AI Agents automation and in the Configure tenant dialog). The agent follows them on **every run**, asked or scheduled: what to treat as expected, what to look at first, how to word its recommendations. For example: "The accounts named `svc_*` are service accounts." or "The nodes named `lab-*` are lab machines: their disk usage up to 80% is expected."

- At most 4000 characters; line breaks are kept.
- They **never widen what the agent may do**. The allowed decisions of the tenant and the checks TrackMe makes before every decision still decide: an instruction to dismiss a critical finding that is still failing is refused by TrackMe like any other.
- They come after the provider's custom prompt and, for scheduled runs, after the tenant's shared custom instructions of *AI Agents automation* (which apply to scheduled runs only): the agent's own instructions are the most specific.

Evaluate…, next to the field, tries a draft before you save it. It runs the agent in **inspect** mode with the draft in place of the saved instructions, on one open finding or on a review of the open findings (at most 10, the most severe first), and can run the same review **without** custom instructions side by side, so you see what the instructions change.

An evaluation **writes nothing**: no `[AI Agent]` note, no decision, no entry in the decision log. It is recorded in the audit with the status `evaluation`, and TrackMe refuses any decision or review from an evaluation run, whatever the model writes.

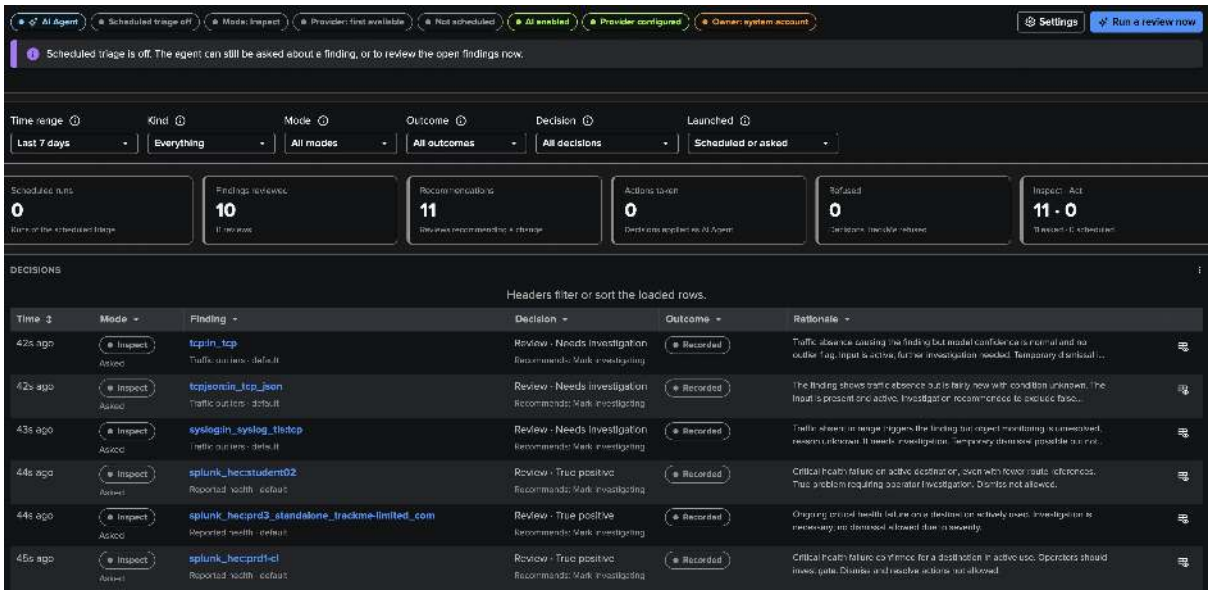


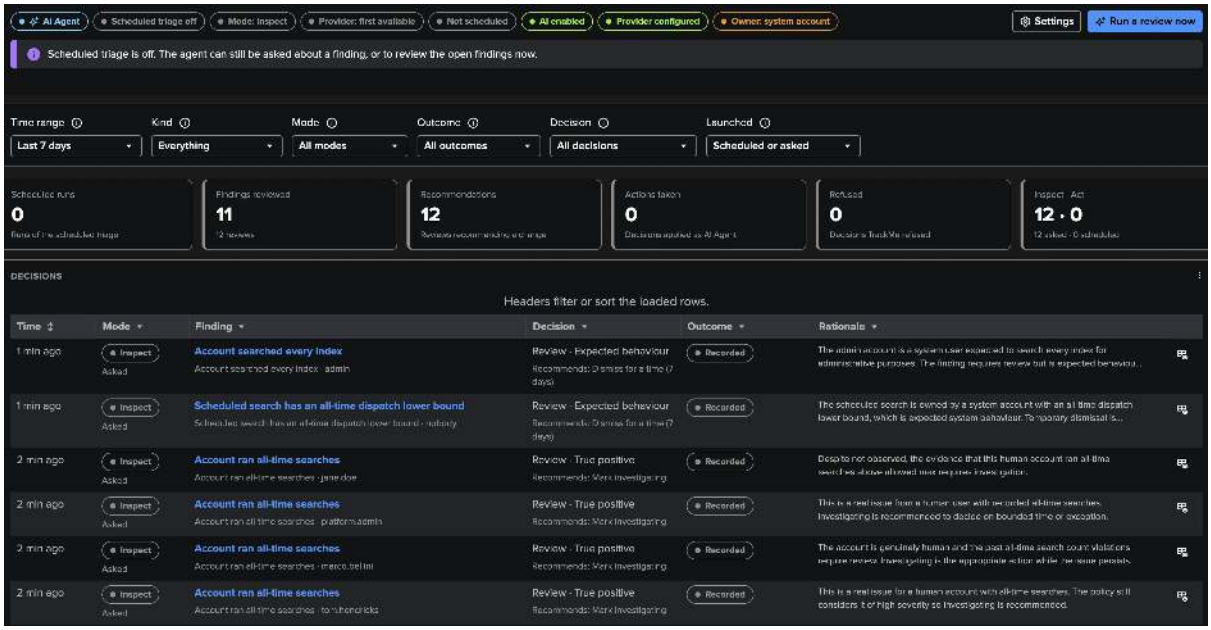
3.5.8 What the AI Agent did

Everything the agent does can be followed from four places:

- **The AI Agent tab** of the workspace: whether it can run and why, its totals (scheduled runs, findings reviewed, recommendations, actions taken, decisions TrackMe refused, inspect and act), **Run a review now**, and the decision log with its filters. Each row opens the investigation of that decision: the facts the agent read and its rationale.
- **The finding** itself: its history shows each decision under the actor **AI Agent**, and its notes hold the current `[AI Agent]` assessment.
- **The audit dashboards** of *Auditing AI activity*: *Review AI Advisor activity* and *Review Scheduled AI Advisor activity* include the three agents, labelled **UAM AI Agent**, **Cribl Stream AI Agent** and **Cribl Edge AI Agent**.
- **SPL**: every run is indexed to the tenant summary index with the sourcetype `trackme:ai_agent:uam_agent:<inspect|act>`, `trackme:ai_agent:cribl_agent:<inspect|act>` or `trackme:ai_agent:cribl_edge_agent:<inspect|act>`, with `launched_by` (UI, AI Assistant or automation), `automated` and the chat session that triggered it, next to the per-tool events of `trackme:ai_agent:tool_call`.

```
index=trackme_summary sourcetype="trackme:ai_agent:*_agent:*"
| table _time, sourcetype, tenant_id, launched_by, automated, status
```





3.5.9 Data and privacy

The AI Agent follows the same rules as the rest of the AI layer (see *AI Compliance, Privacy and Data Governance*): nothing is sent to an LLM until an administrator configures a provider, and the agent sees only what its tools return, pinned to its tenant and its run.

- The evidence is computed by TrackMe from what the tenant already holds. No credentials, connection details or secrets are part of it.
- **Cribl Stream**: the agent cannot run searches and never calls Cribl; its facts come from the inventory, the traffic snapshots and the traffic models TrackMe already collected.
- **Cribl Edge**: the agent cannot run searches and never calls Cribl; its facts come from the node directory and the findings TrackMe already holds.
- **User Activity Monitoring**: the evidence never carries the text of a search. The agent may read a search text only when it needs it to conclude, and only for searches collected while the tenant's *Store SPL search* setting was on.
- The anonymisation of entity and index names in the AI settings does not apply to the AI Agent: account and object names are part of its evidence, so choose your AI provider accordingly.

3.6 AI Routines & Automation

Scheduled and agentic automation: user-authored **AI Routines**, the broader **AI Agents automation** surface, and **natural-language FLX** tracker generation.

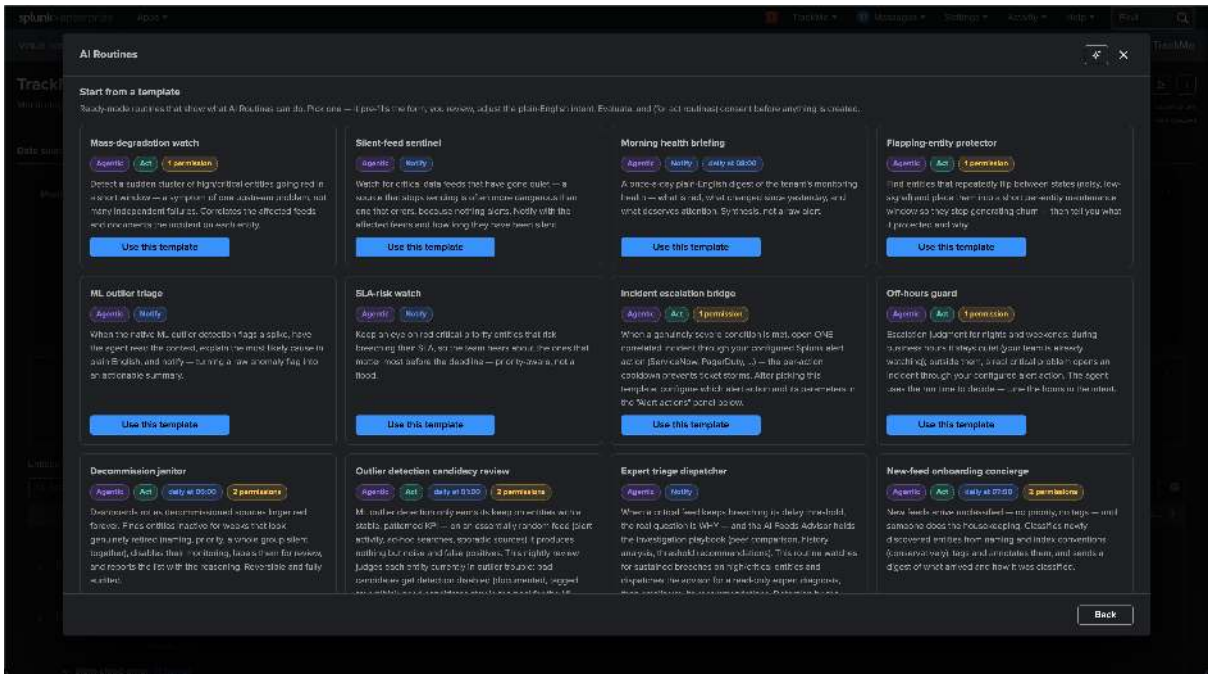
3.6.1 AI Routines

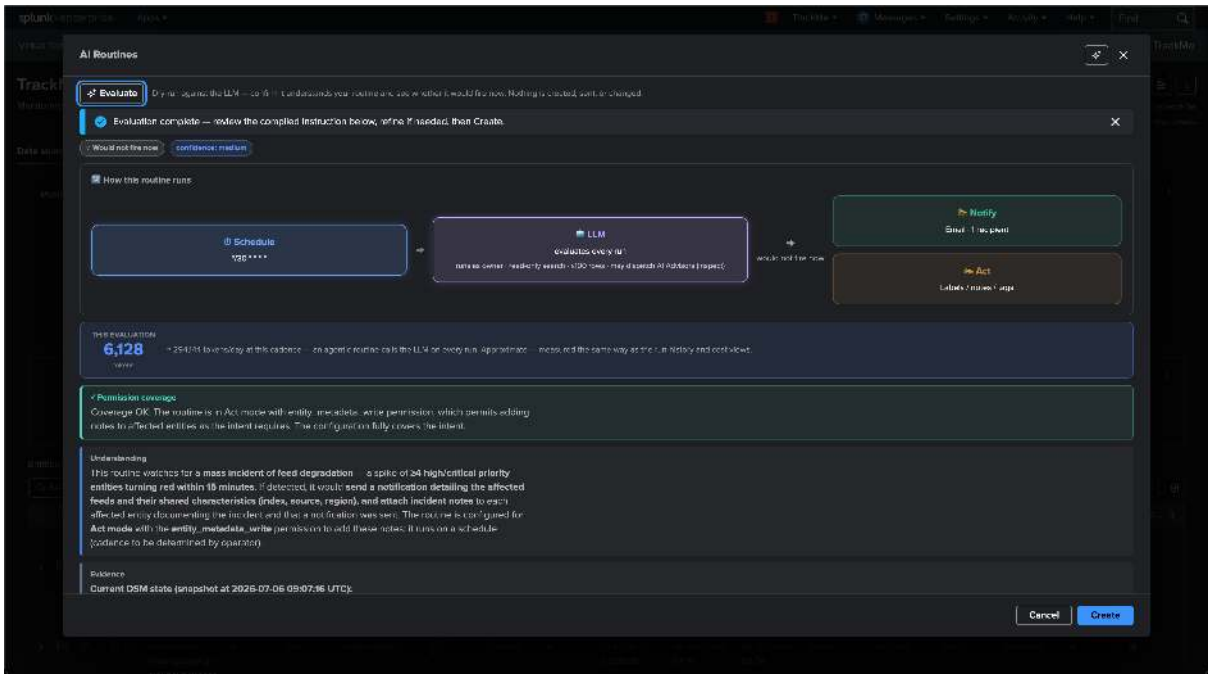
Overview

AI Routines let you describe a monitoring task in plain English — and TrackMe watches for it on a schedule, then **notifies you or acts**, autonomously and under your explicit consent.

Where the *AI Assistant* answers when you ask, and the *AI Advisors* investigate when you (or the automation) dispatch them, an AI Routine is **your own standing instruction**: *"Tell me if 4 or more high priority feeds turn red within 15 minutes, correlate what they have in common, and add a note to each entity documenting the incident."* You write that sentence once; TrackMe compiles it into a structured instruction, runs it on a cron schedule of your choice, and delivers the outcome — an email or a Splunk event, and (if you granted it) real, audited actions.

Start from a template or from a blank intent — either way, TrackMe shows you exactly how your routine will run before anything is created:



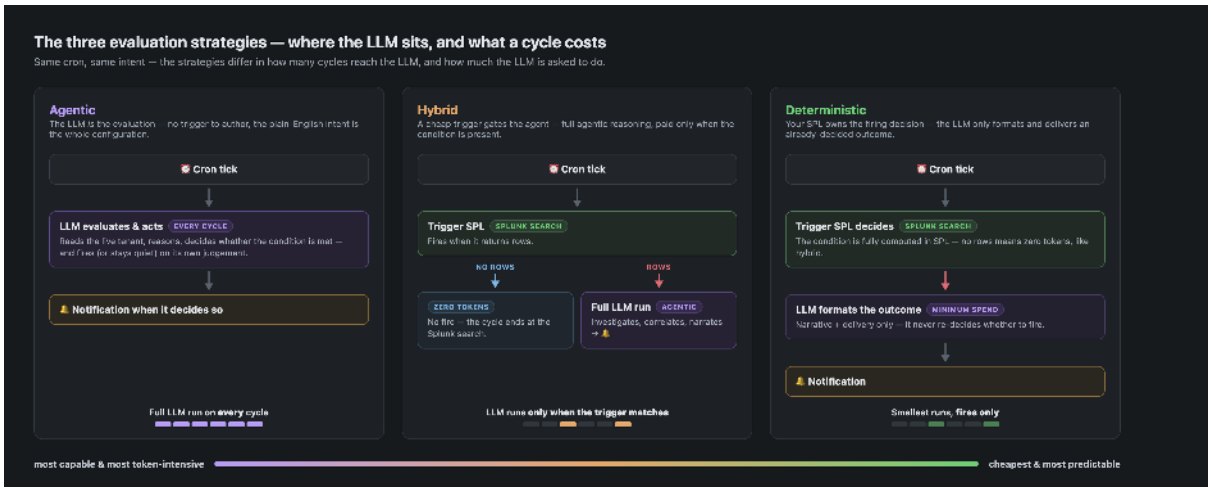


Important

AI Routines share the AI Advisors' platform requirements: **Python 3.13.x** (Splunk 10.2.x and later) and at least one configured *AI provider*. The feature is **opt-in by construction** — it is completely inert until the AI Assistant is enabled and a provider is configured — and ships with its own kill switch (`enable_ai_routines`) and a creator-roles policy (administrators only, or administrators and power users) in the system settings.

The three evaluation strategies

Every routine picks how its condition gets evaluated — this is the main cost dial:

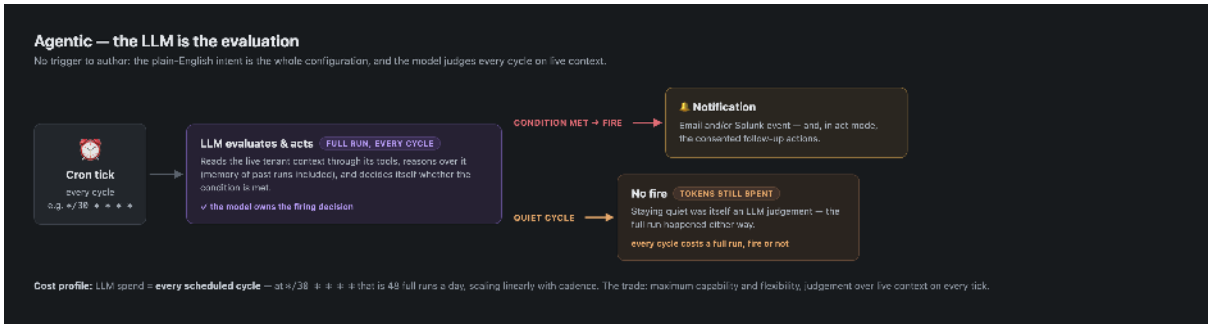


- **Agentic** — the LLM runs on every scheduled cycle and does everything: it reads the tenant, decides whether the condition is met, and acts. The most capable and flexible option (it reasons over live context each run), and the most token-intensive.
- **Hybrid** — a cheap, compiled **SPL trigger** runs first on each cycle; the LLM is only invoked when the trigger matches. When nothing is happening, a cycle costs **zero LLM tokens**. This is the recommended shape for tight schedules at scale.
- **Deterministic** — the trigger fully computes the condition; the LLM formats and delivers the outcome. The cheapest option for conditions that are precisely expressible in SPL.

The trigger is a **cost gate in front of the agent, never a replacement for it** — the LLM remains central to understanding, correlating, and explaining.

The strategy is chosen at creation time, and the form adapts to it — the inline explainer states the behaviour and the cost consequence, and the cadence hint under the cron field translates your schedule into runs per day so the cost implication is explicit before you save.

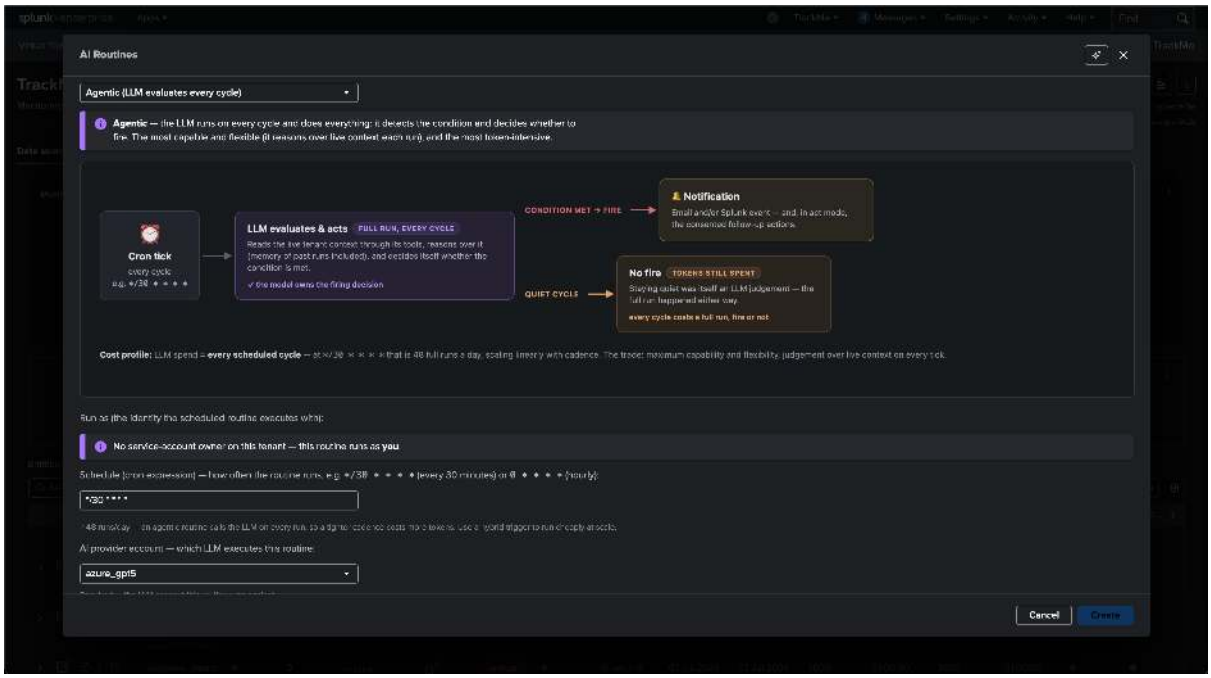
Agentic — the LLM evaluates every cycle



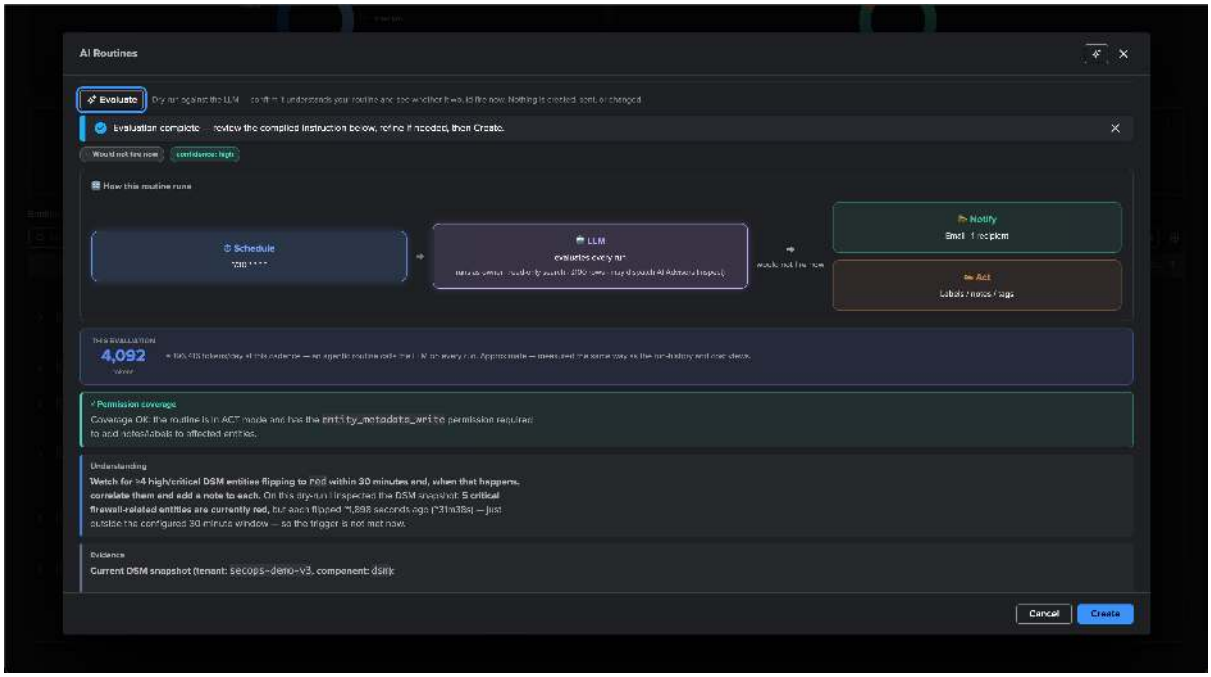
The LLM is the evaluation: on every cron tick it reads the live tenant context, reasons over it, and decides itself whether the condition is met. There is no trigger to author — the plain-English intent is the whole configuration. This

is the right choice when the condition is fuzzy or judgement-based (*"anything unusual compared to the last runs"*), when it needs correlation that is hard to express in SPL, or while you are still shaping what "abnormal" means.

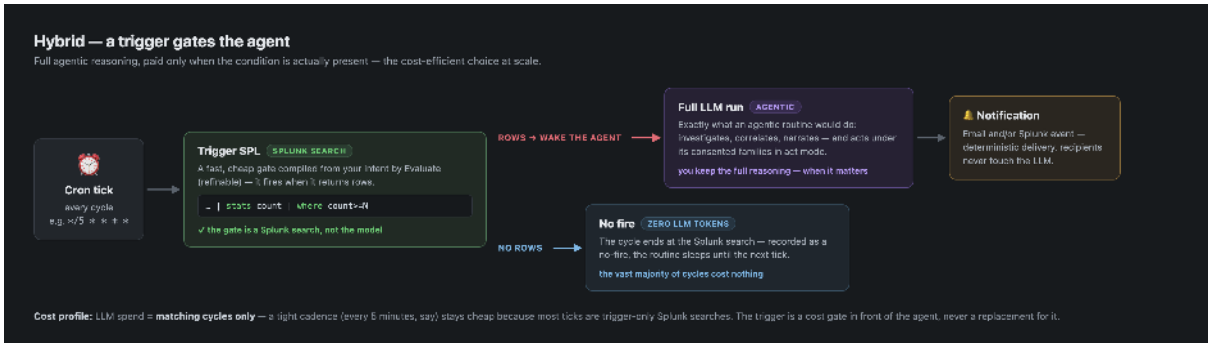
The cost consequence is structural: **every scheduled cycle is a full LLM run**, whether or not anything is happening. At `*/30 * * * *` that is 48 LLM runs a day — the form says so under the cron field. Tighten the cadence and the cost scales linearly with it.



An Evaluate dry-run makes the mode's behaviour concrete before you save: the *How this routine runs* pipeline shows the LLM in the evaluation seat, and the token callout extrapolates the measured per-run cost to your cadence (here ~4K tokens per run ≈ 196K tokens/day at every 30 minutes) — the honest verdict below (*Would not fire now*, with the reasoning) is the same judgement the model will make on schedule:



Hybrid — a trigger gates the agent

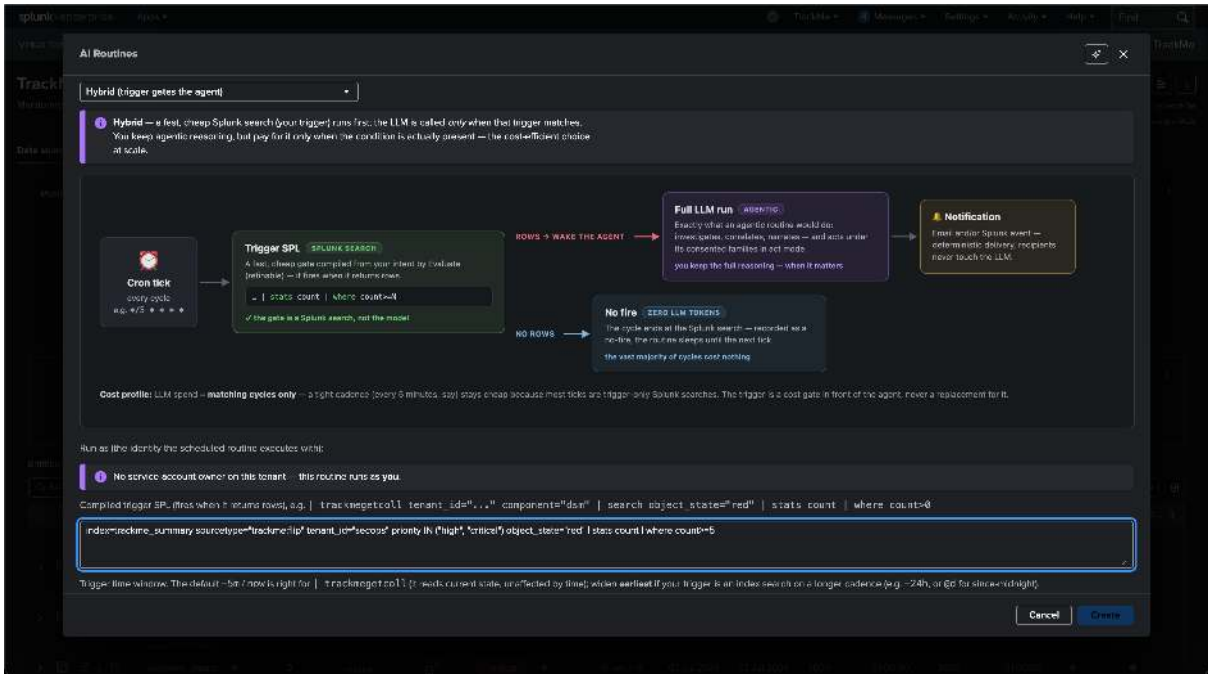


A fast, cheap Splunk search — the **compiled trigger SPL** — runs first on each cycle; the LLM is called *only* when that trigger returns rows. You keep the full agentic reasoning (once invoked, the agent investigates, correlates and narrates exactly as an agentic routine would), but you pay for it only when the condition is actually present. A quiet cycle costs **zero LLM tokens** — the run is recorded as a no-fire and the routine goes back to sleep.

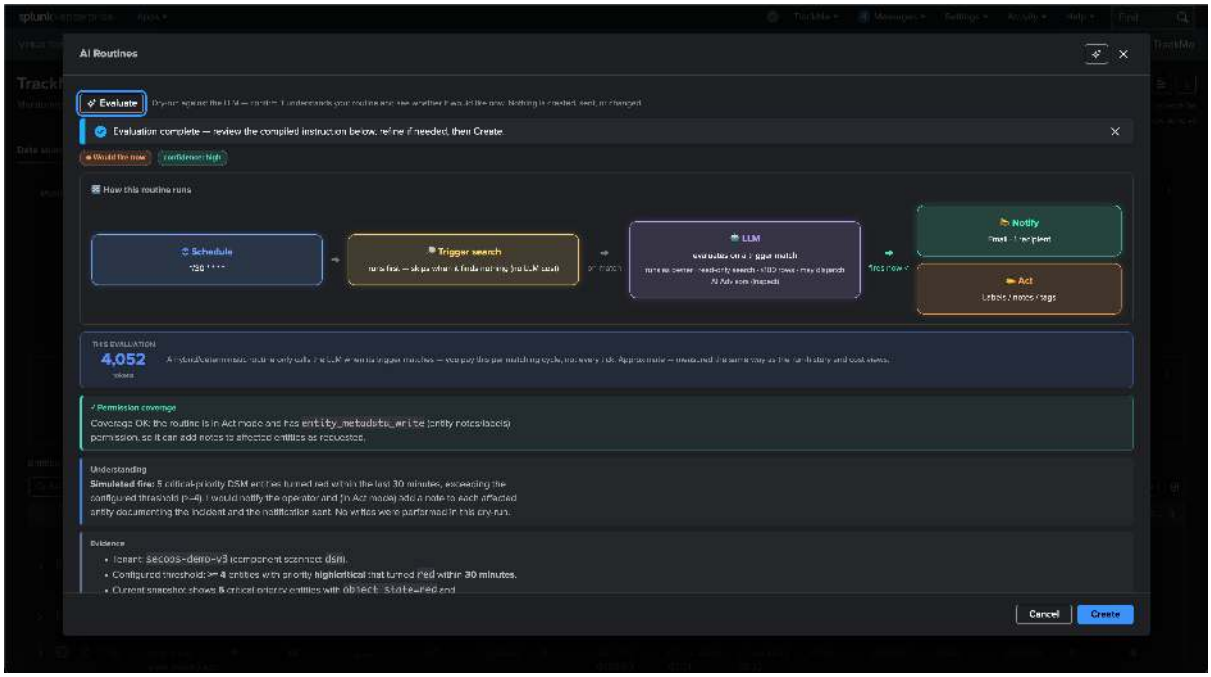
Selecting hybrid reveals two extra fields:

- **Compiled trigger SPL** — authored by the Evaluate step from your intent (you can refine it); it fires when it returns rows, so the canonical shape ends in something like `| stats count | where count>=N`.
- **Trigger time window** — the default `-5m / now` is right for `| trackmegetcoll` (it reads current state, unaffected by time); widen `earliest` if your trigger is an index search on a longer cadence (e.g. `-24h`, or `@d` for since-midnight).

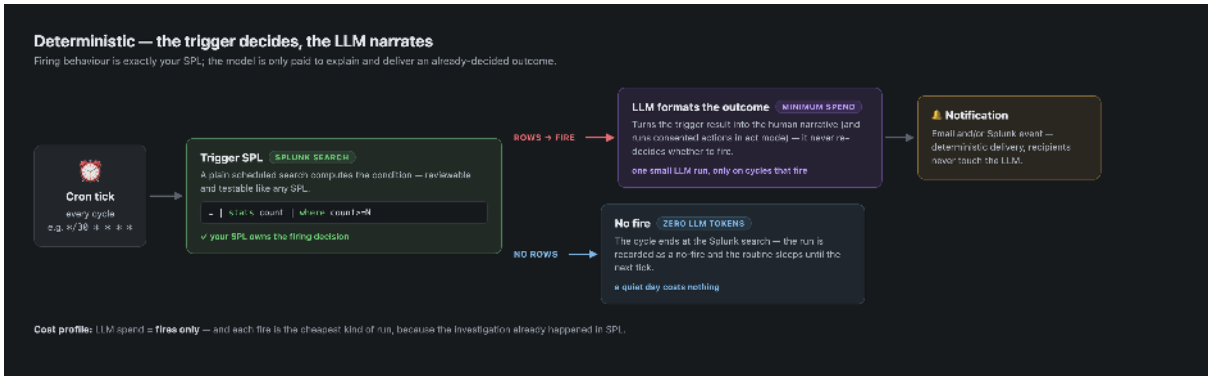
This is the cost-efficient choice at scale: a tight cadence (every 5 minutes, say) stays cheap because the vast majority of cycles are trigger-only Splunk searches.



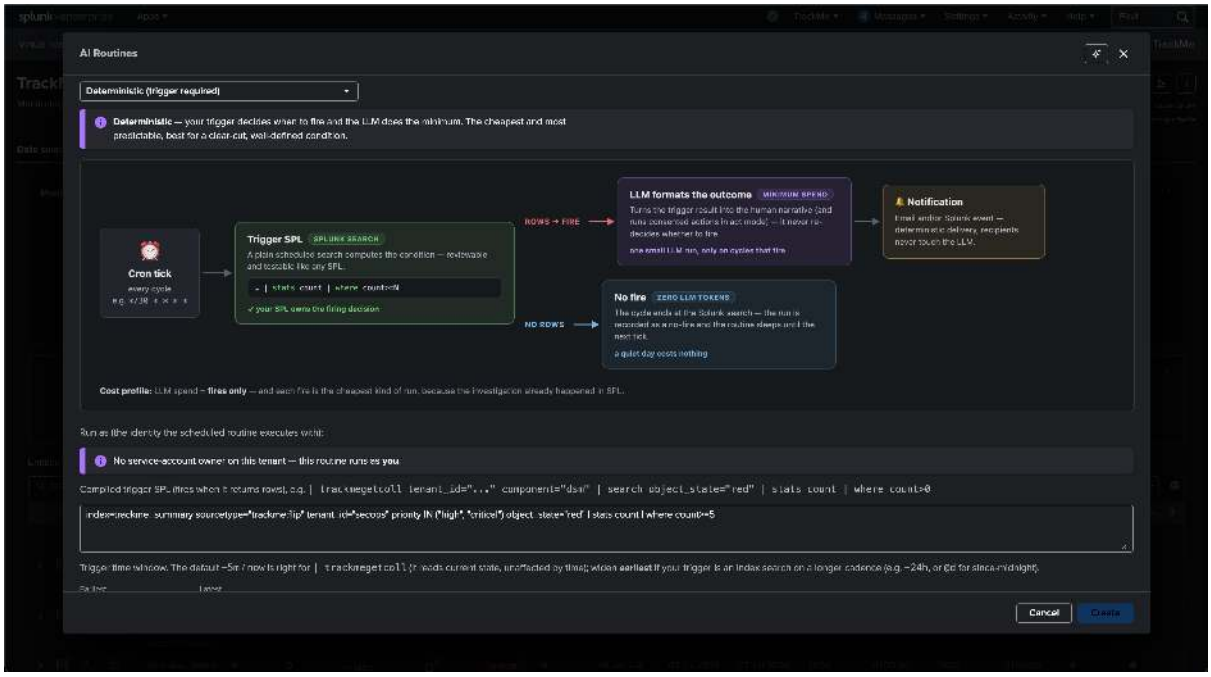
On Evaluate, the pipeline gains the **Trigger search** stage in front of the LLM (*"runs first — skips when it finds nothing (no LLM cost)"*), and the token callout switches to the hybrid cost model: you pay the per-run cost **per matching cycle, not every tick**. In this dry-run the trigger matched, so the evaluation simulated the fire end-to-end (verdict *Would fire now*, with the would-be notification and act-mode writes described — nothing is actually sent or changed):



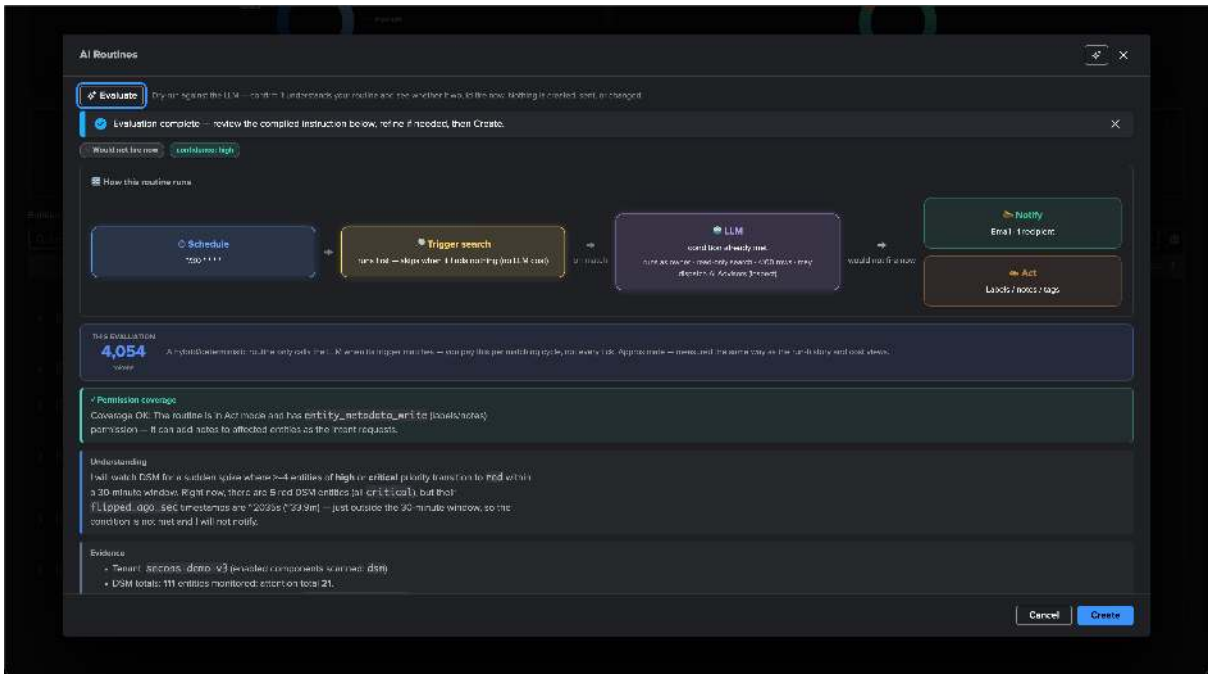
Deterministic — the trigger decides



Your trigger fully computes the condition; when it matches, the LLM does the minimum — it turns the trigger's result into the human-readable notification (and, in act mode, the consented follow-up actions) rather than re-deciding whether to fire. The same trigger SPL and time-window fields apply as in hybrid. The cheapest and most predictable strategy: firing behaviour is exactly your SPL, reviewable and testable like any Splunk search, with the LLM spend limited to the cycles that fire — best for a clear-cut, well-defined condition (*"any critical entity red for more than an hour"*).



The Evaluate dry-run shows the same gated pipeline — but here the trigger owns the decision outright, and the verdict follows your SPL, not the model's judgement (in this example the condition window had just lapsed, so the honest answer is *Would not fire now* even though the entities are still red — exactly what the configured 30-minute window dictates):



Choosing, in cost terms

At the same `*/30 * * * *` cadence (48 cycles/day), the three strategies diverge only in **how many of those cycles reach the LLM**: all 48 for agentic; only the matching ones for hybrid and deterministic (a quiet day costs zero tokens, a noisy day costs one LLM run per matching cycle — with deterministic runs staying individually smaller, since the agent formats an already-decided outcome instead of investigating). A practical path: start **agentic** while you shape the intent, then let Evaluate compile the trigger and switch to **hybrid** when the routine earns a tight schedule — and use **deterministic** when the condition is precise enough that you want SPL, not the model, to own the firing decision. See *Cost transparency* for how consumption is surfaced per routine and per run.

Notify or Act

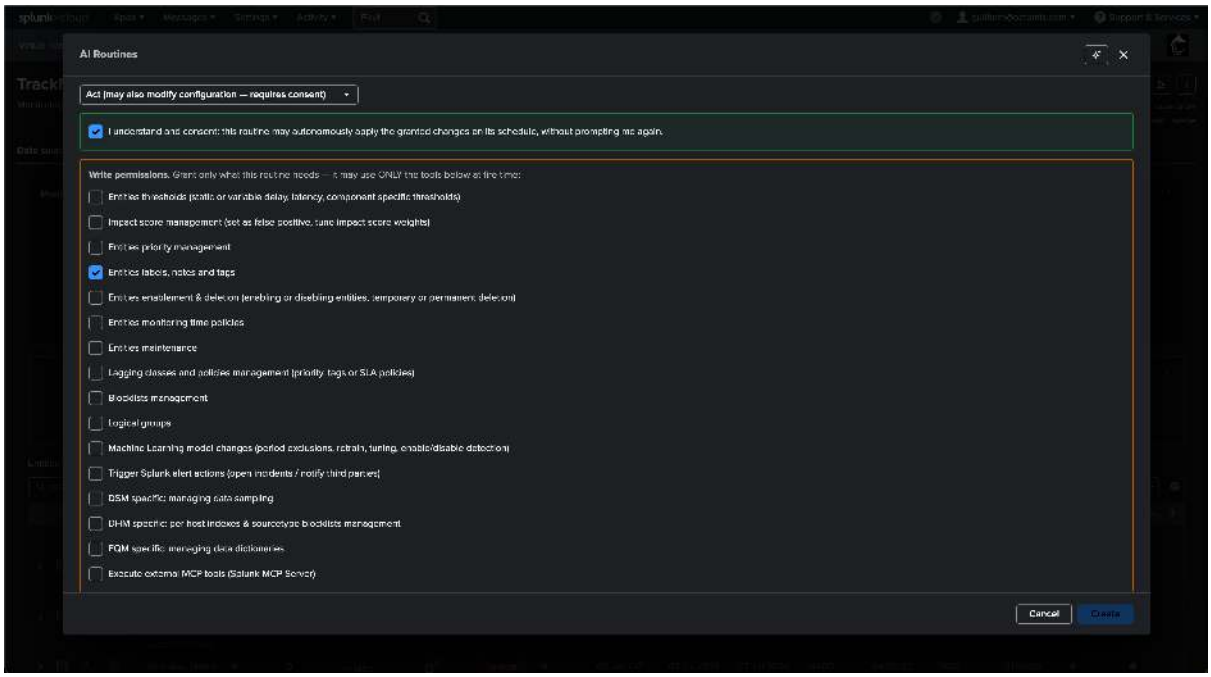
A routine runs in one of two action modes:

- **Notify** (read-only) — the routine observes and delivers: an email, a structured Splunk event indexed to your summary index, or both at once. Recipients and targets are configured on the routine and delivered deterministically — they never depend on the LLM.
- **Act** — the routine may also **change things**: tune thresholds, update priorities, attach notes and labels, manage maintenance windows, retrain ML models, trigger Splunk alert actions (open incidents in your ITSM, notify Slack or PagerDuty), and more.

Act mode is governed by **explicit, granular consent**:

- You grant **permission families** — capability-oriented checkboxes such as *entities thresholds*, *entities priority*, *labels/notes/tags*, *ML model changes*, *trigger Splunk alert actions*, or *execute external MCP tools*. Each family exposes exactly its tools to the routine at fire time — nothing more.
- Consent is **pinned to what you approved**: the exact intent text, the exact set of granted families, and (where applicable) the exact alert-action and external-MCP contracts. Editing any of them invalidates the consent and the routine cannot act again until you re-affirm.
- Every write lands in the entity audit trail with an `[AI Agent]` stamp, exactly like the *AI Advisors*.

Switching the mode to **Act** reveals the consent checkbox and the write-permission families — sixteen capability-oriented grants, each exposing exactly its own tools. Tick only what the routine genuinely needs (least privilege), then affirm the consent:



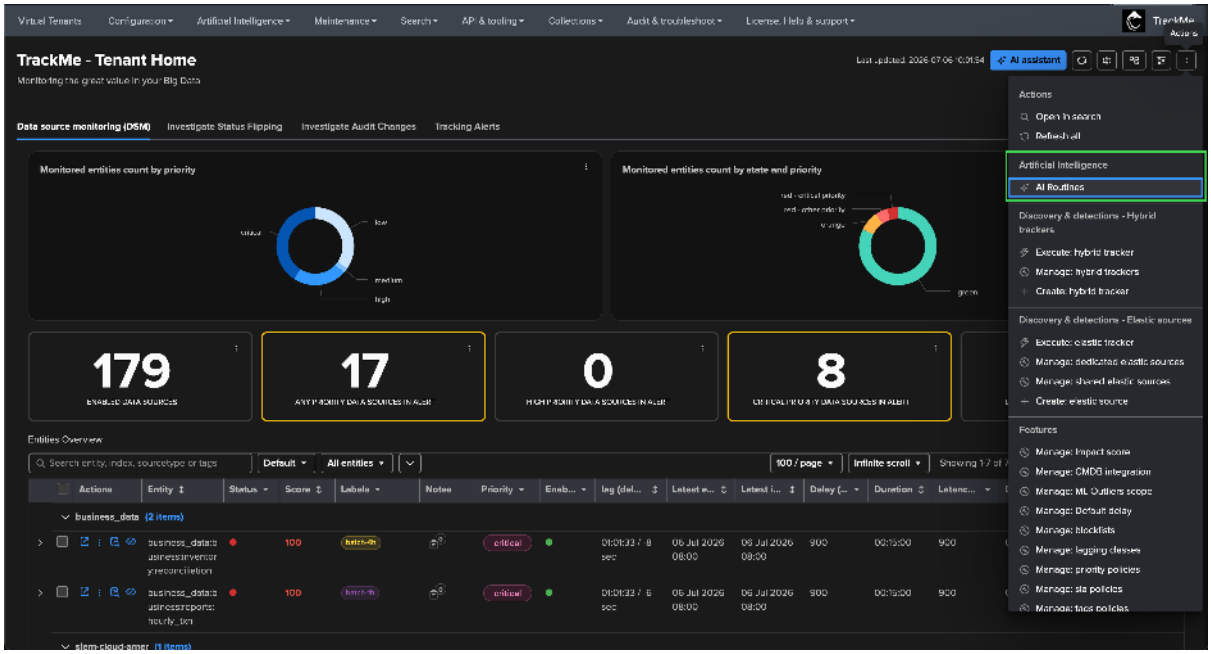
Note

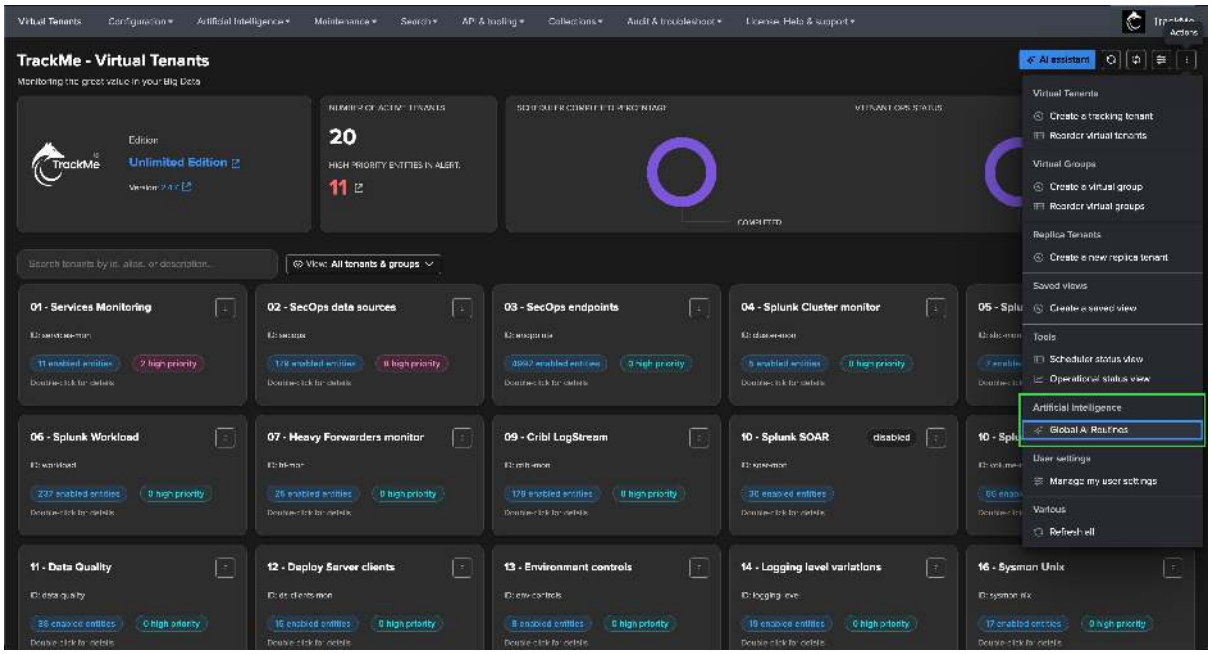
Two read capabilities are independent of the action mode and enabled by default: **read-only Splunk searches** (a bounded correlation search the routine can use to investigate) and **AI Advisor dispatch** (the routine can commission up to two inspect-only *AI Advisor* investigations per run when a deeper expert diagnosis is warranted). Both are reads — they never require consent, and both can be switched off per routine.

Where to find AI Routines

AI Routines live in two places, matching their scope:

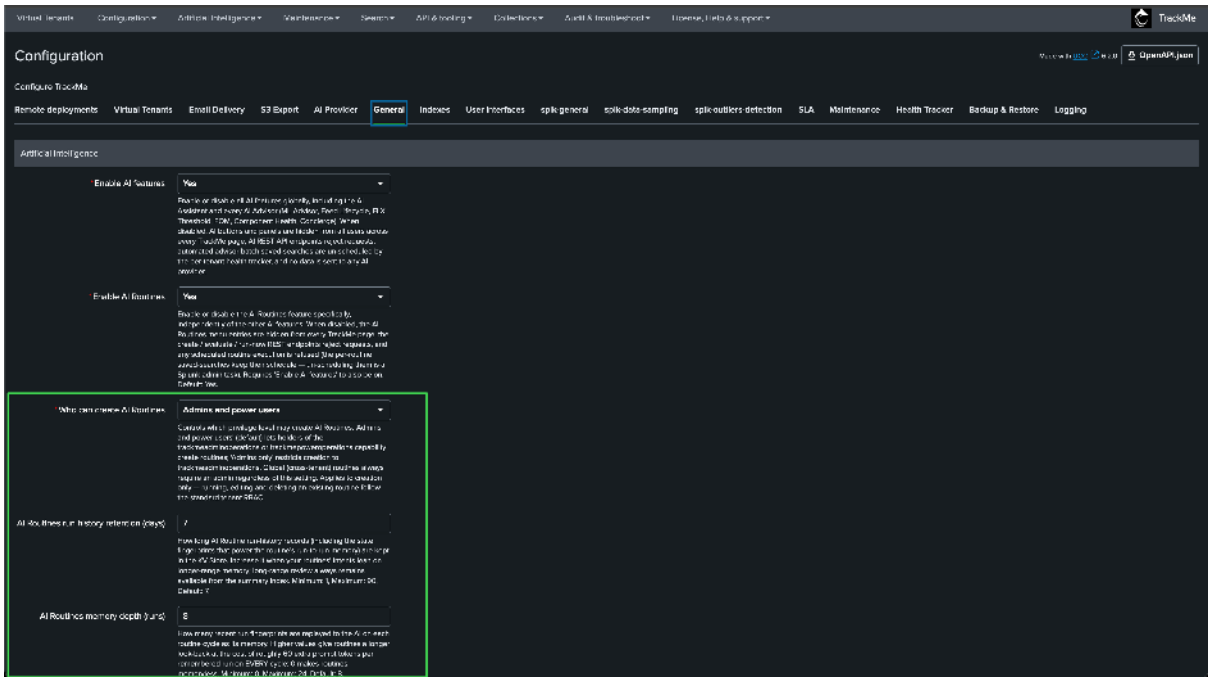
- **Tenant Home** — routines scoped to that tenant (they read and act on this tenant only).
- **Virtual Tenants — global** routines that correlate **across tenants** of your choice.





Global configuration

The feature's deployment-wide switches live in *Configuration → General → Artificial Intelligence*:

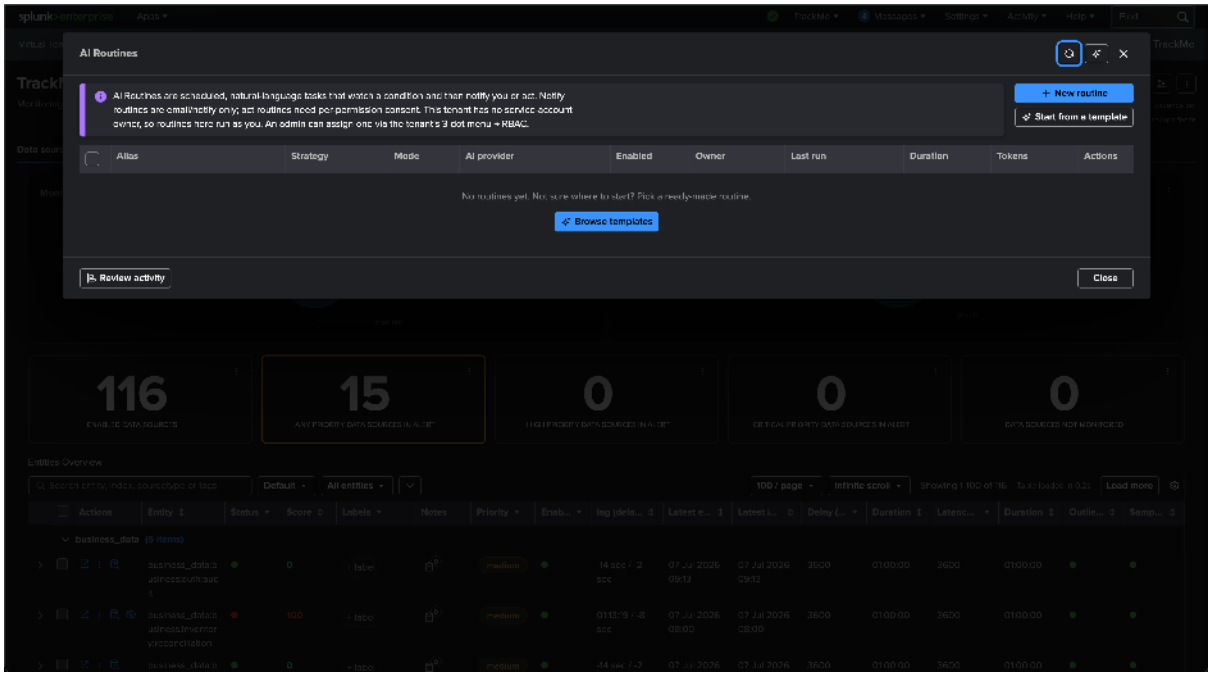


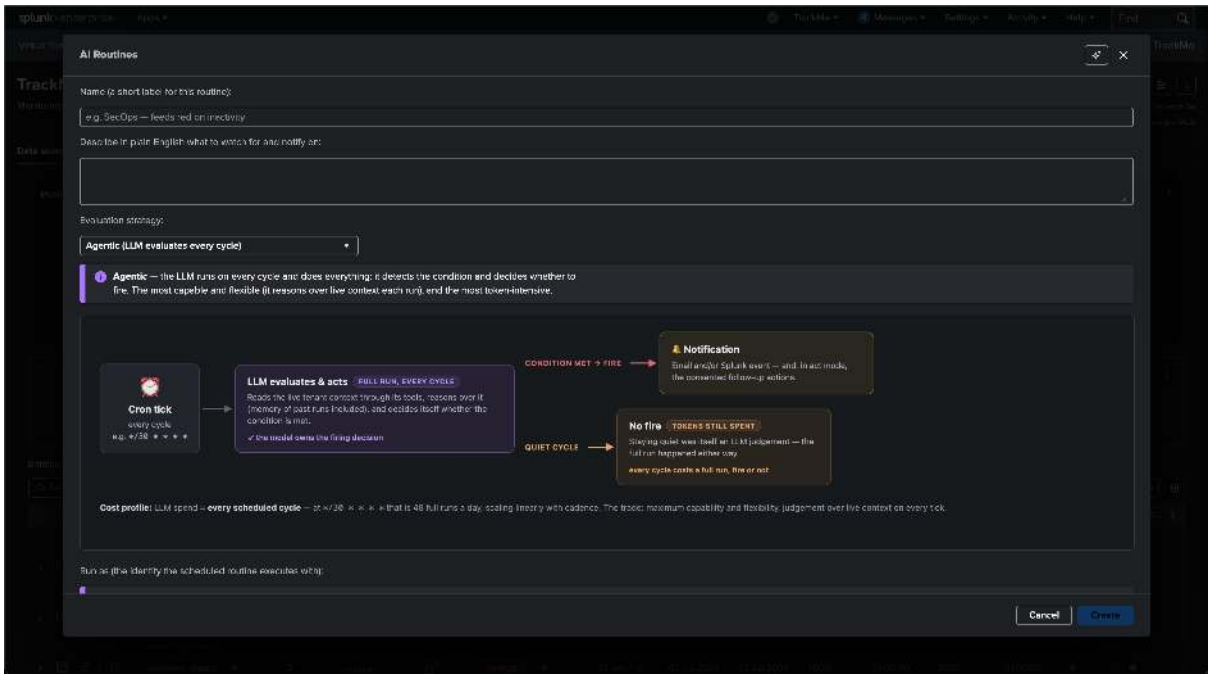
- **Enable AI features** — the master switch for everything AI in TrackMe (AI Assistant, every AI Advisor, and AI Routines). AI Routines require it to be on.
- **Enable AI Routines** — switches the AI Routines feature specifically, independently of the other AI features. When disabled, the AI Routines menu entries are hidden from every TrackMe page, the create / evaluate / run-now REST endpoints reject requests, and any scheduled routine execution is refused. Default: Yes.
- **Who can create AI Routines** — controls the privilege level required to *create* routines. The default (**Admins and power users**) lets holders of the `trackmeadminoperations` or `trackmepoweroperations` capability create routines; **Admins only** restricts creation to `trackmeadminoperations`. Global (cross-tenant) routines always require an admin regardless of this setting. This applies to creation only — running, editing and deleting an existing routine follow the standard tenant RBAC.
- **AI Routines run history retention (days)** and **AI Routines memory depth (runs)** — the two memory levers, covered in *Memory between runs* below. Defaults: 7 days and 8 runs.

Creating a routine

Creation is a single form — with an important twist: **you cannot create a routine blind**. The **Evaluate** step is a mandatory dry-run gate for the LLM-driven strategies.

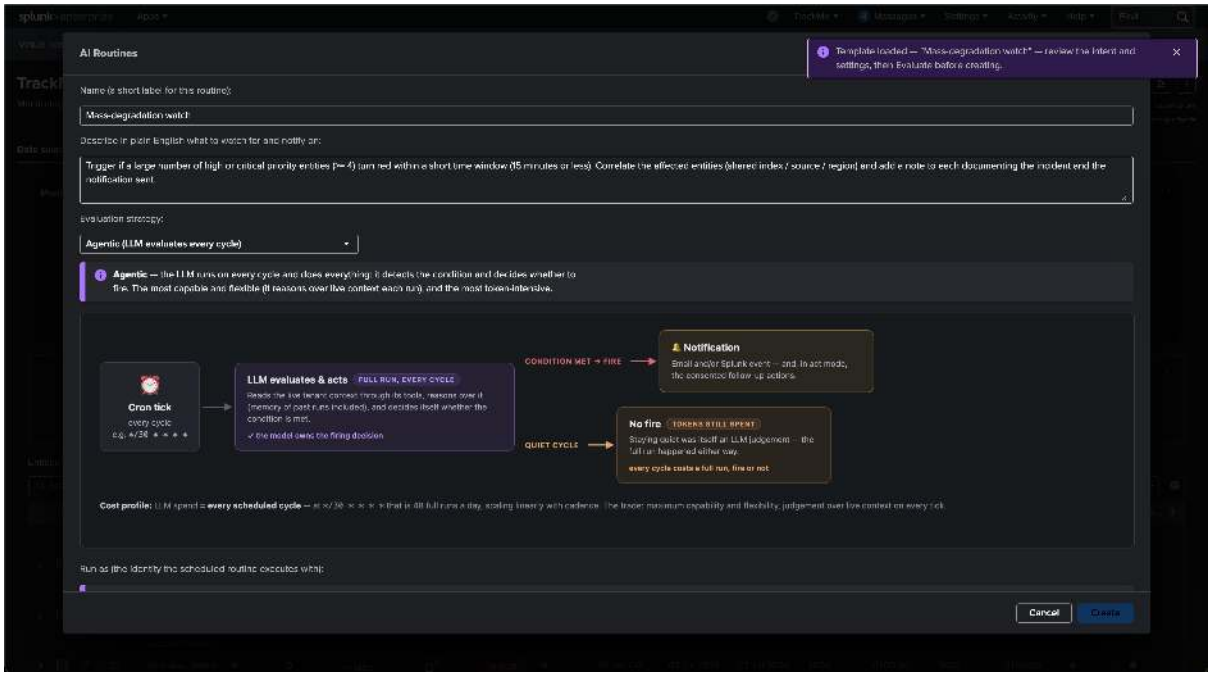
1. **Describe your intent** in plain English. Be as specific as you naturally would with a colleague: thresholds, time windows, priorities, what to do when it happens.
2. **Pick the evaluation strategy**, the cron schedule, the AI provider, and the notification channel (email or Splunk event).
3. For **act** routines: tick the permission families the routine may use, and affirm the consent.
4. **Evaluate** — TrackMe runs the routine against your live environment as a **read-only dry-run**: nothing is created, sent, or changed.

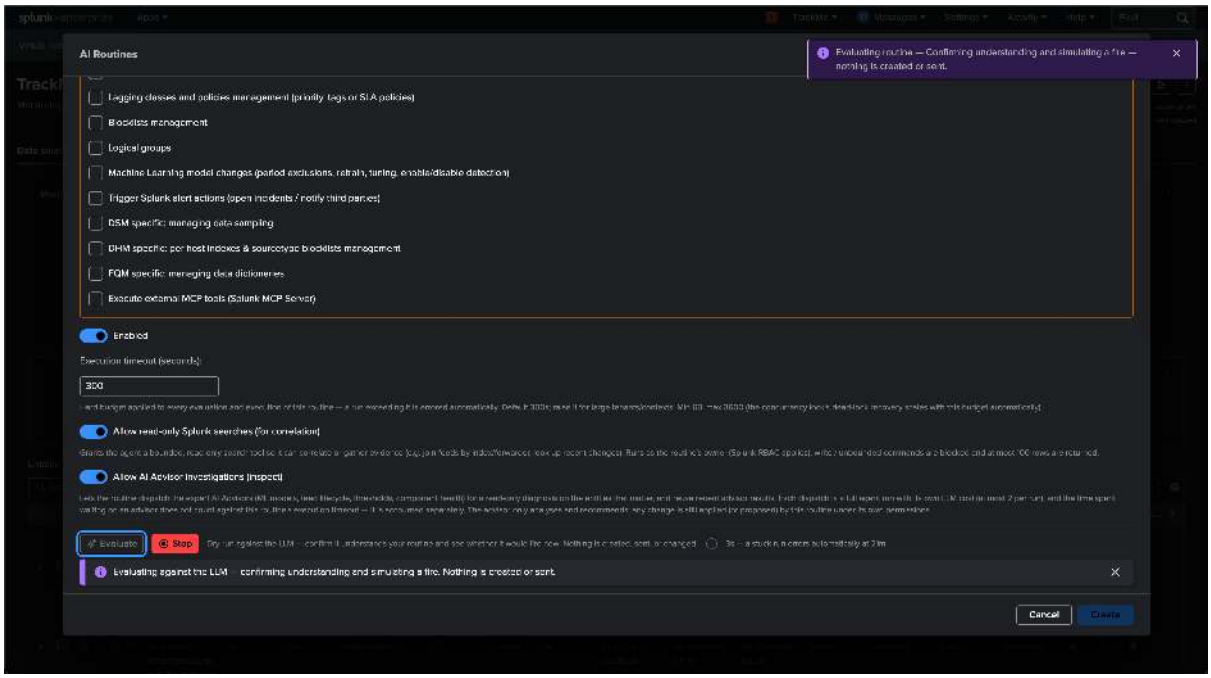




The Evaluate result is where the feature earns your trust before it earns its schedule:

- A **compiled instruction** — the structured spec the routine will run against (objective, watch condition, signals, notify policy, act policy, assumptions). This is what gets persisted and replayed on every run, so what you approve is exactly what executes.
- A **verdict** — would the routine fire *right now*, against your real data, and why.
- A **permission-coverage check** — if your intent implies an action the granted permissions cannot perform (say, the intent wants notes added but the notes family is not ticked), Evaluate tells you before you create it.
- A **cost preview** — the tokens this evaluation consumed, extrapolated to your chosen cadence, plus an expandable *Raw LLM input* panel showing byte-for-byte what is sent to the model.
- A **refine loop** — reply to the evaluation in plain English (*"use a threshold of 20 red entities; ignore orange"*) and re-evaluate until the compiled instruction says exactly what you mean.





Tip

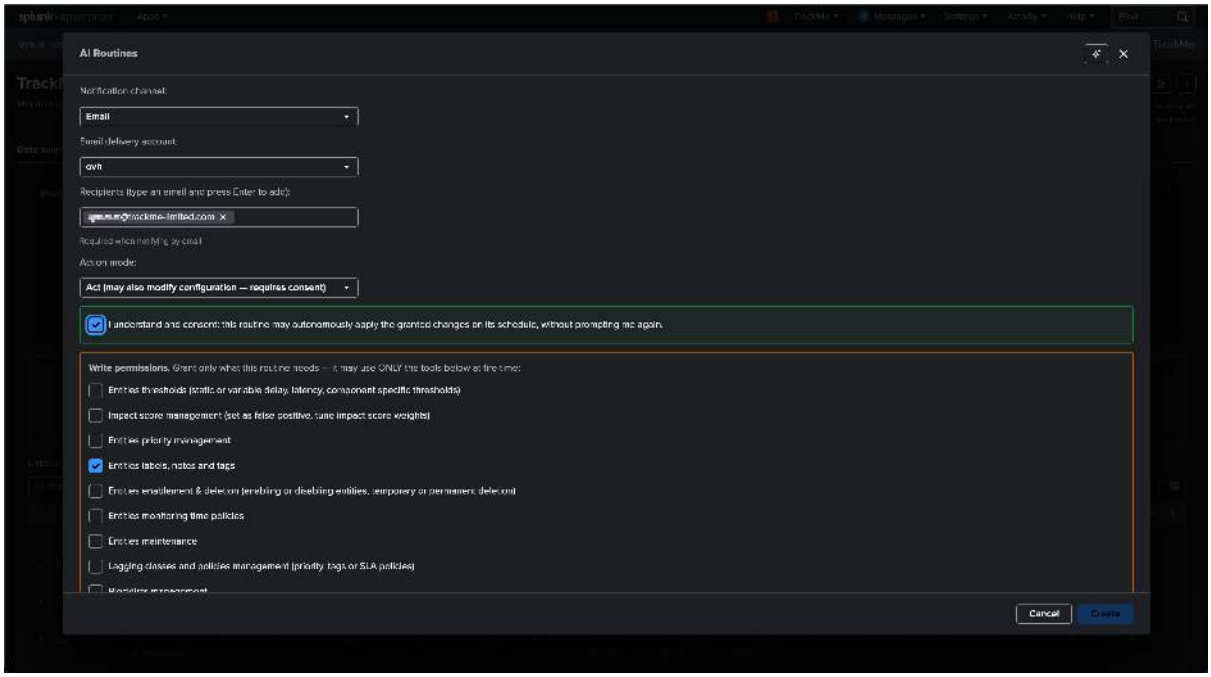
Routines understand **movement**, not just current state. The tenant snapshot the agent reads carries each degraded entity's *time since last state change*, and a dedicated tool lets the routine list the exact **state transitions** (flips) since its previous run — including entities that turned red and recovered in between. Conditions like *"N entities turn red within M minutes"* are evaluated from the real flip history of your tenant, not guessed.

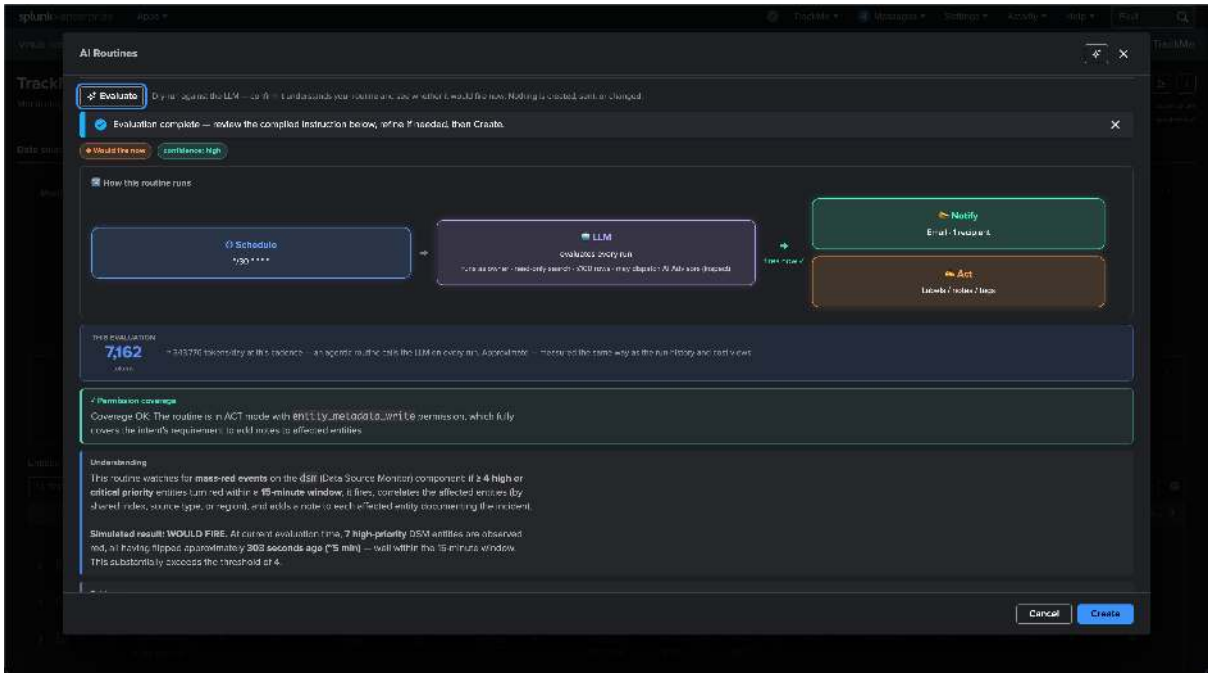
Email notifications

When a routine's notification channel is **Email** (or **Email & Splunk event**), every fire delivers a formatted email to the recipients configured on the routine. Two principles govern the delivery:

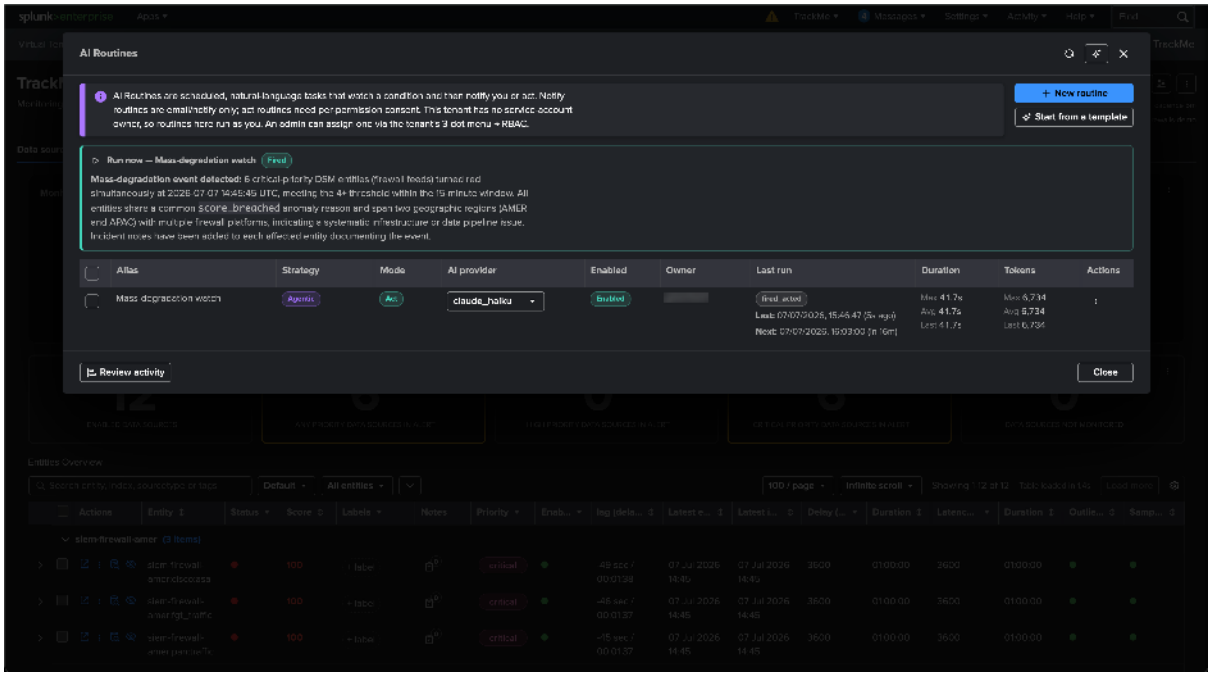
- **Recipients are configuration, not AI output.** The recipient list and the delivery account are set on the routine and used deterministically — the AI authors the *content*, never the audience.

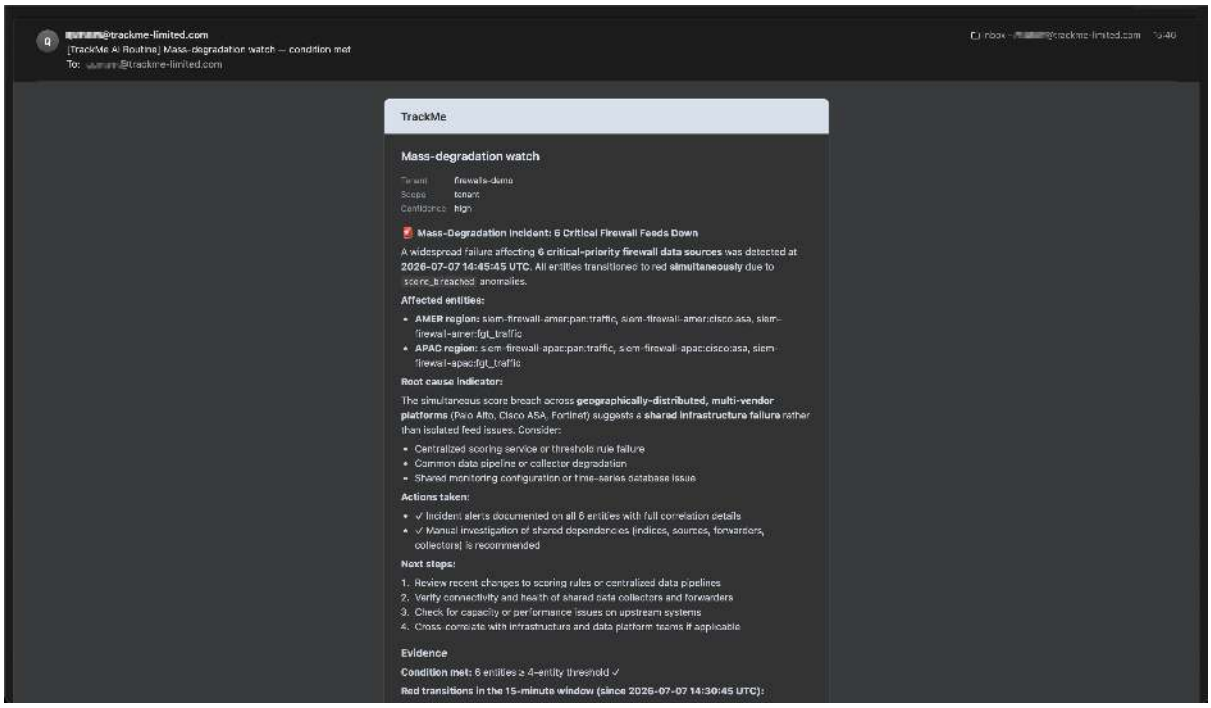
- **Your email delivery accounts are honoured end to end** — the same accounts used by TrackMe's stateful alerting (transport and security settings, allowed recipient domains with out-of-domain recipients skipped, HTML vs text format preference, custom footer). The form pre-selects your first configured delivery account; the local MTA remains available as the default fallback.





The email arrives as **multipart**: a branded HTML rendering for modern clients and a plain-text fallback carrying the same content. The HTML shell shows the routine name with the tenant, scope and the AI's confidence as header rows, followed by the AI-authored summary and evidence rendered from Markdown — headings, bullet and numbered lists, tables, inline code, and section rules all render properly, and the LLM output is HTML-escaped before rendering as a security measure. The subject line is stable and filter-friendly: `[TrackMe AI Routine] <routine name> — condition met`.





In the example above, the mass-degradation routine fired and the email carries the full incident narrative — the affected feeds grouped by root-cause cluster, per-cluster status and likely root cause, and concrete check-lists for the operator — exactly as the agent wrote it.

Splunk event notifications

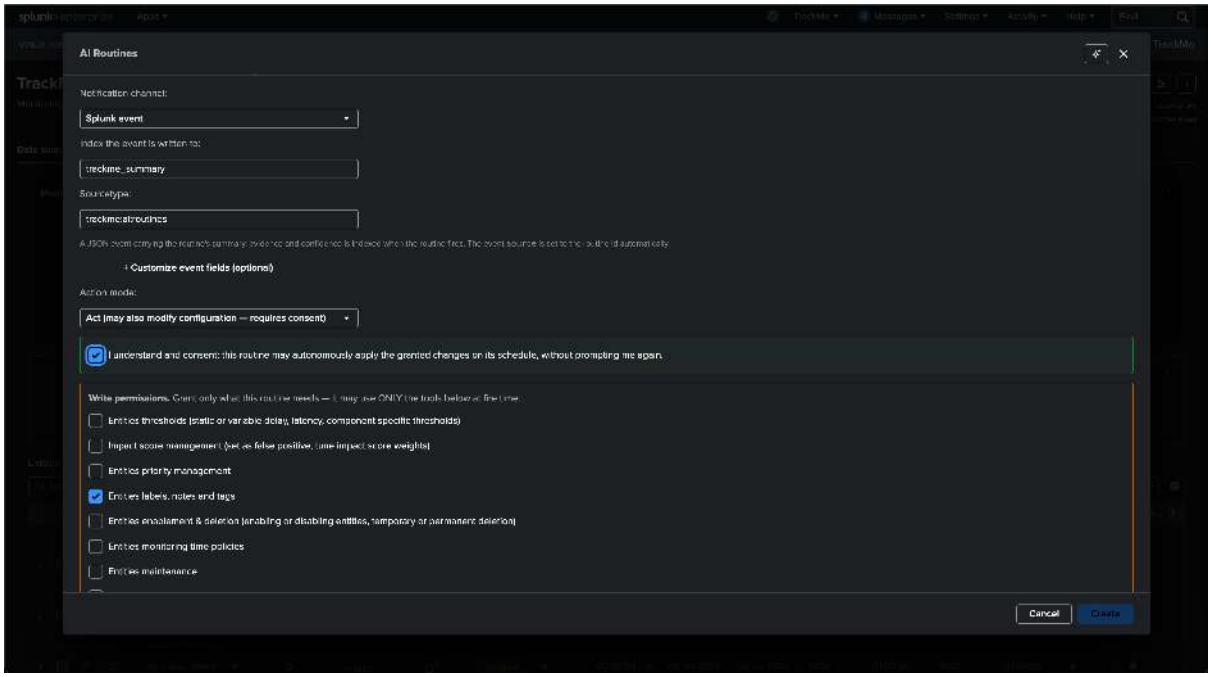
When a routine's notification channel is **Splunk event** (or **Email & Splunk event** — both channels at once, each delivered independently), every fire indexes **one structured JSON event** to the index and sourcetype you configure (defaults: `trackme_summary` / `trackme:ai:routines`), with the event `source` set to the routine id so per-routine searches are trivial.

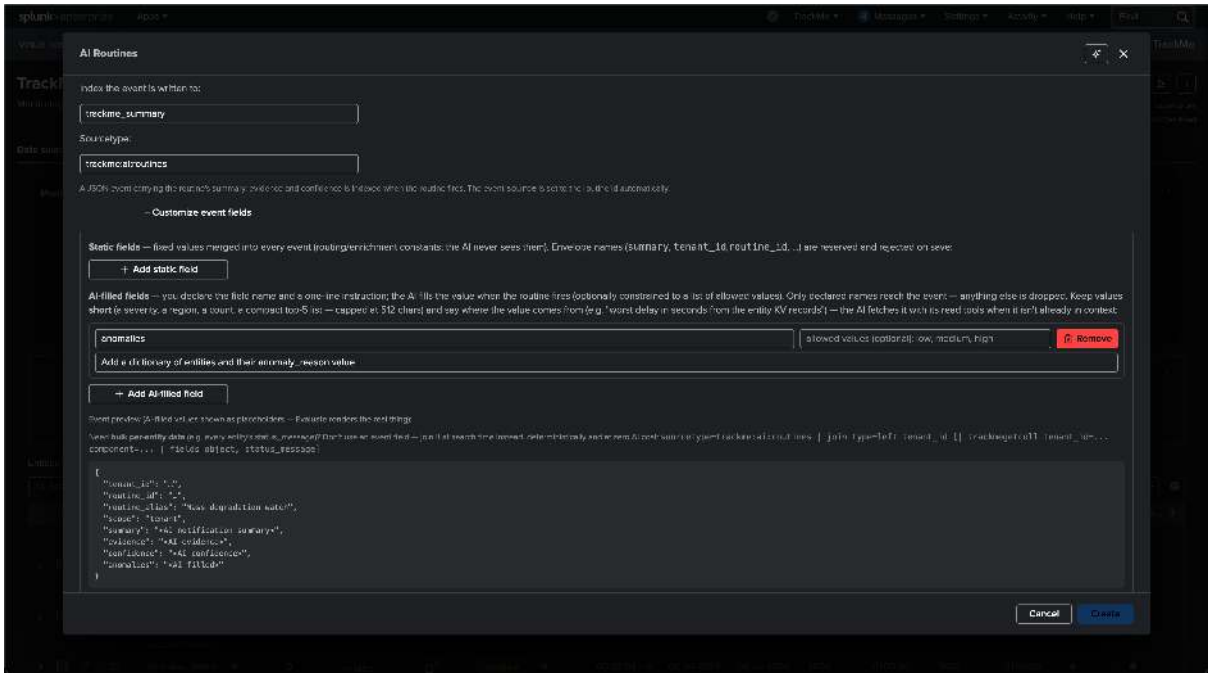
The event always carries a **deterministic envelope** — `tenant_id`, `routine_id`, `routine_alias`, `scope`, plus the AI-authored `summary`, `evidence` and `confidence` — and the targets come from the routine's configuration, never from the AI. Your SPL, alerts and dashboards built on these events never break because a model phrased something differently.

Custom event fields

The optional **Customize event fields** panel extends that envelope under a strict contract — *you own the schema, the AI only supplies values*:

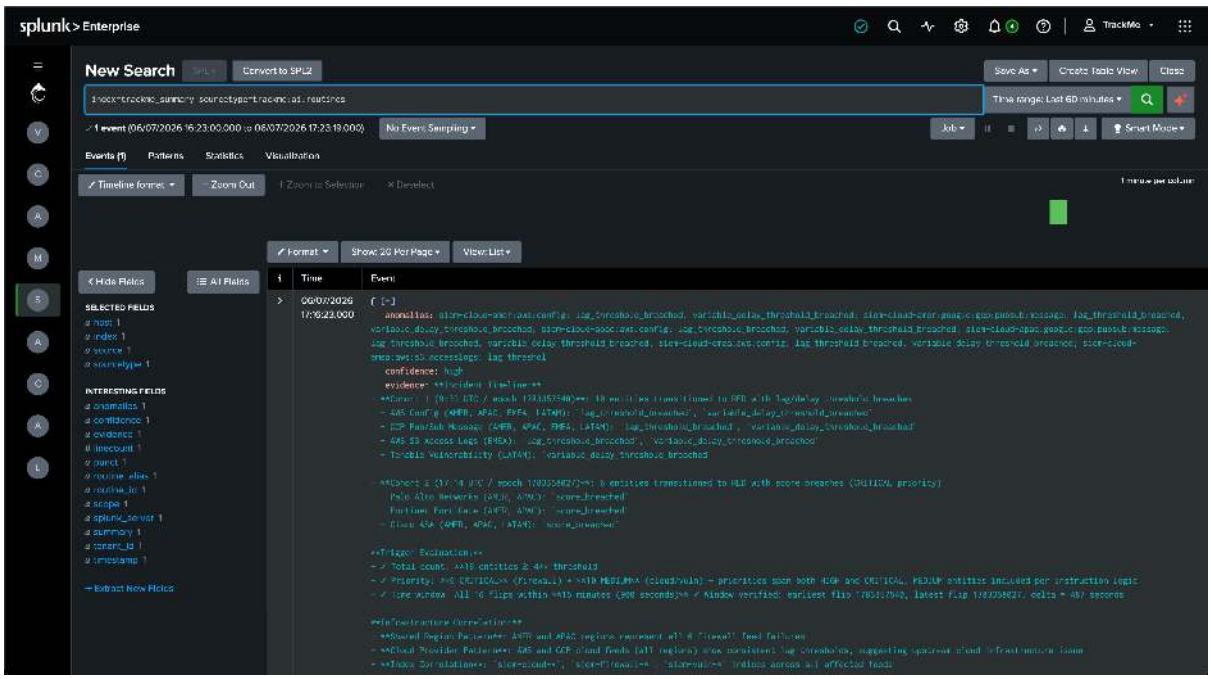
- **Static fields** — fixed values merged into every event (routing and enrichment constants such as `team=siem` or `env=prod`). The AI never sees them.
- **AI-filled fields** — you declare the field name, a one-line instruction, and optionally a list of allowed values; the AI fills the value when the routine fires. Only the declared names ever reach the event: anything else the model produces is dropped, values are length-capped, and a value outside your allowed list is blanked rather than passed through.





The panel shows a **live preview** of the event shape as you type (AI-filled values as placeholders), and the **Evaluate** dry-run renders the real thing — an *"Event it would index"* block built by the exact same code as production delivery, so what you approve is byte-identical to what a fire indexes.

In the example below, the operator declared an `anomalies` field with the instruction *"Add a dictionary of entities and their anomaly_reason value"* — the fired event carries a compact `entity: reason; entity: reason` digest alongside the envelope, ready for downstream parsing:



Tip

Keep AI-filled values **short and typed** — a severity, a region, a count, a compact top-5 list. For **bulk per-entity data** (say, every entity's full `status_message`), don't use an event field: join it at search time instead, deterministically and at zero AI cost:

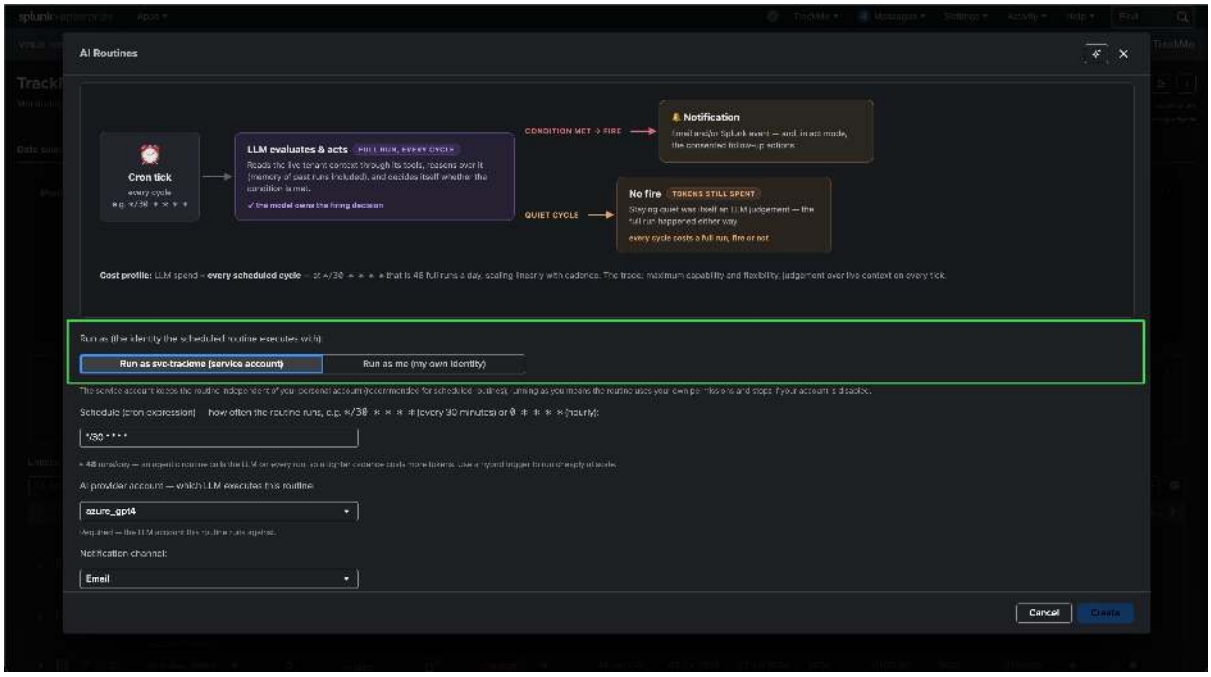
```
index=trackme_summary sourcetype=trackme:ai:routines
| join type=left tenant_id [ | trackmegetcoll tenant_id=... component=... |␣
↪fields object, status_message ]
```

What runs, as who

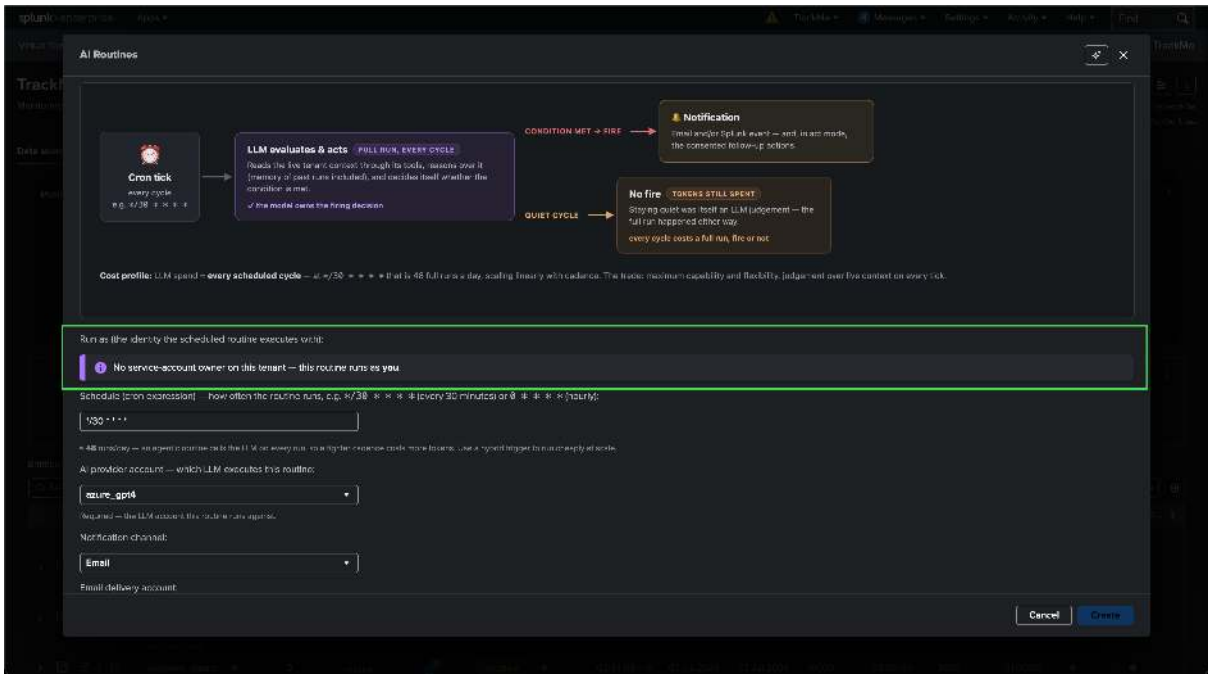
Each routine is materialised as **its own Splunk scheduled search** running on the routine's cron — no shared orchestrator, full failure isolation, and everything is visible with standard Splunk tooling. Splunk RBAC applies to everything the routine reads and does: the execution identity decides which data the routine can search, which entities it can touch in act mode, and whether the routine survives personnel changes.

Ownership is an **explicit choice at creation time**. When the tenant has a real service-account owner assigned (Virtual Tenants → three-dot menu → RBAC), the wizard presents the identity as a two-option selector:

- **Run as the service account** (default, recommended for scheduled routines) — the routine is independent of any personal account: it keeps running if you leave, change roles, or your account is disabled.
- **Run as me** — the routine uses your own permissions; it stops working if your account is disabled.

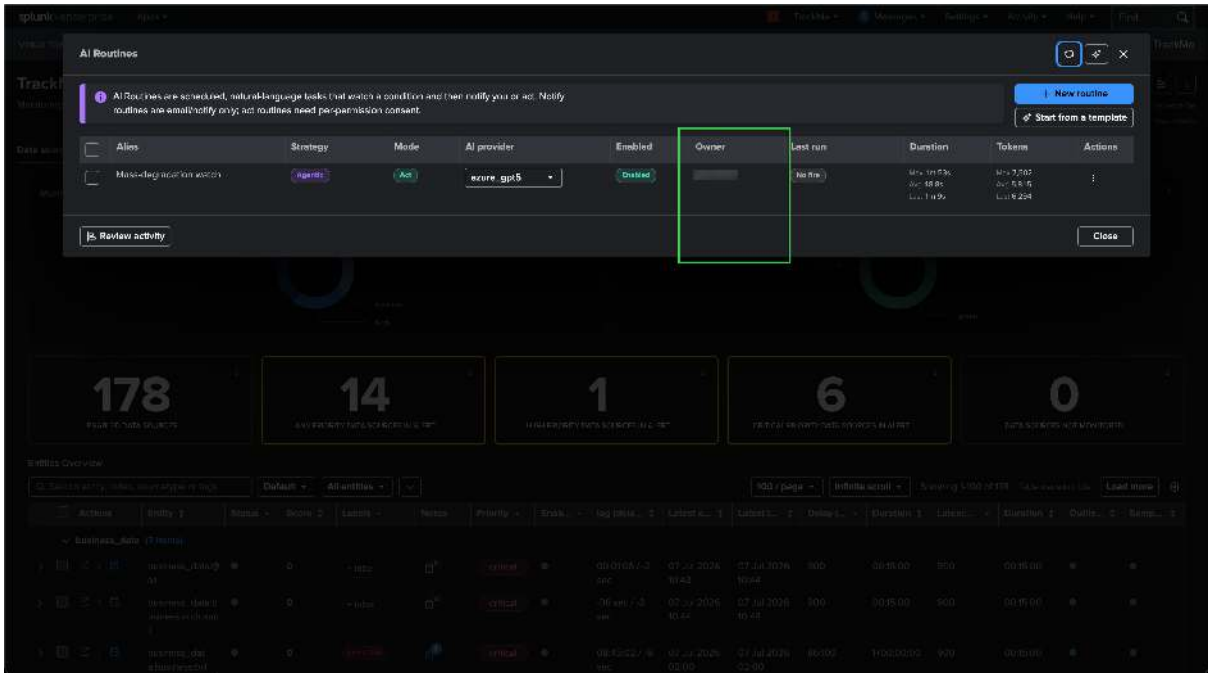


When the tenant has **no service-account owner** (owned by `nobody` / a system user — good Splunk hygiene for knowledge objects, but a Splunk AI agent cannot execute as the system user), there is no choice to offer: the wizard states it plainly and the routine runs as its creator. Assigning a service account to the tenant later and re-saving the routine moves it over:



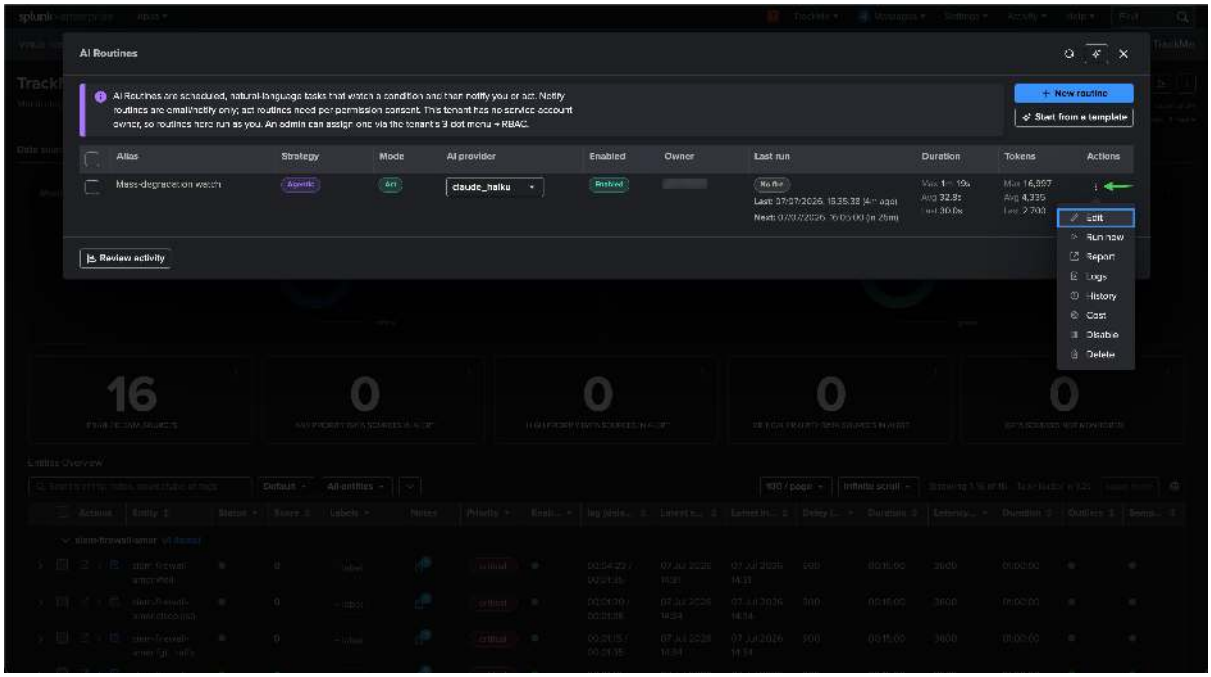
Global (cross-tenant) routines always run as their creator — there is no single tenant whose service account could span the scope.

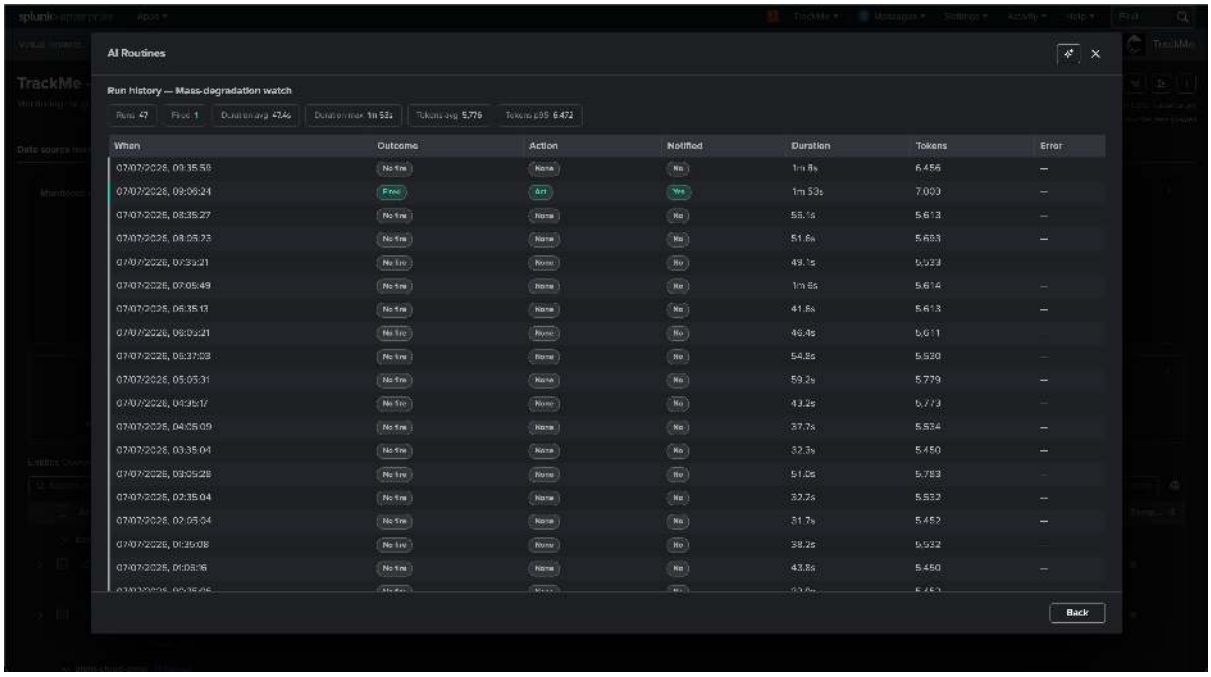
The resolved identity is never hidden: the management view carries an **Owner** column per routine, so an admin can audit at a glance which identity each routine executes with:



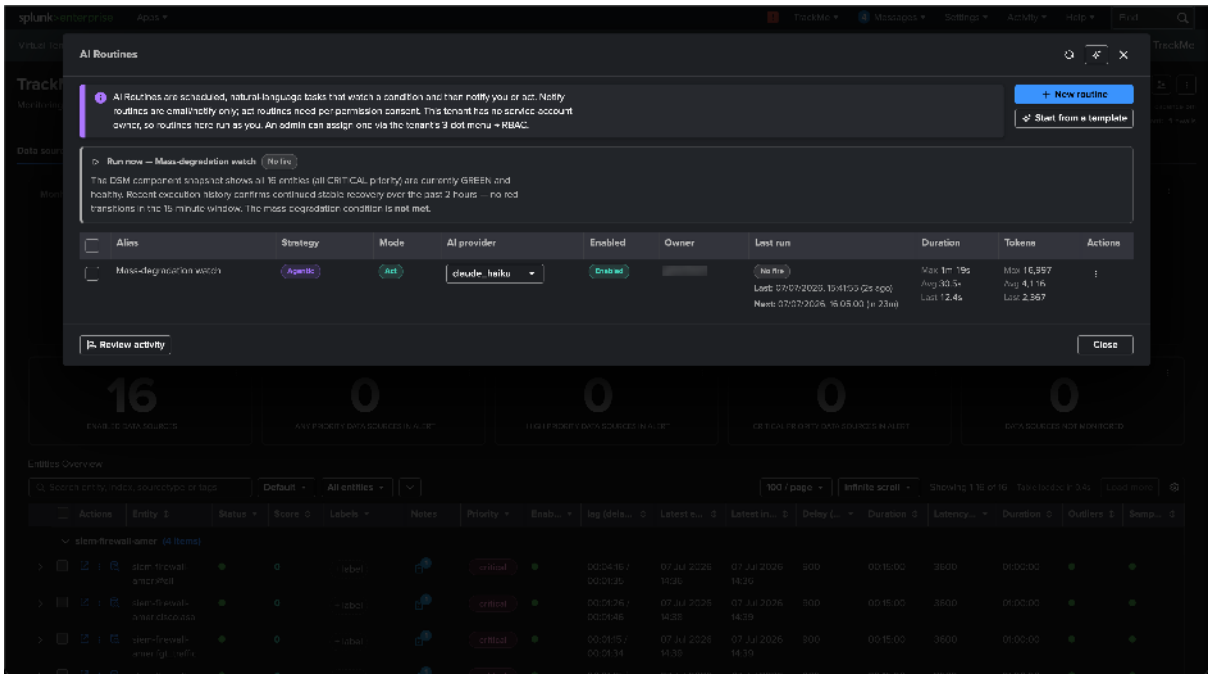
Managing routines

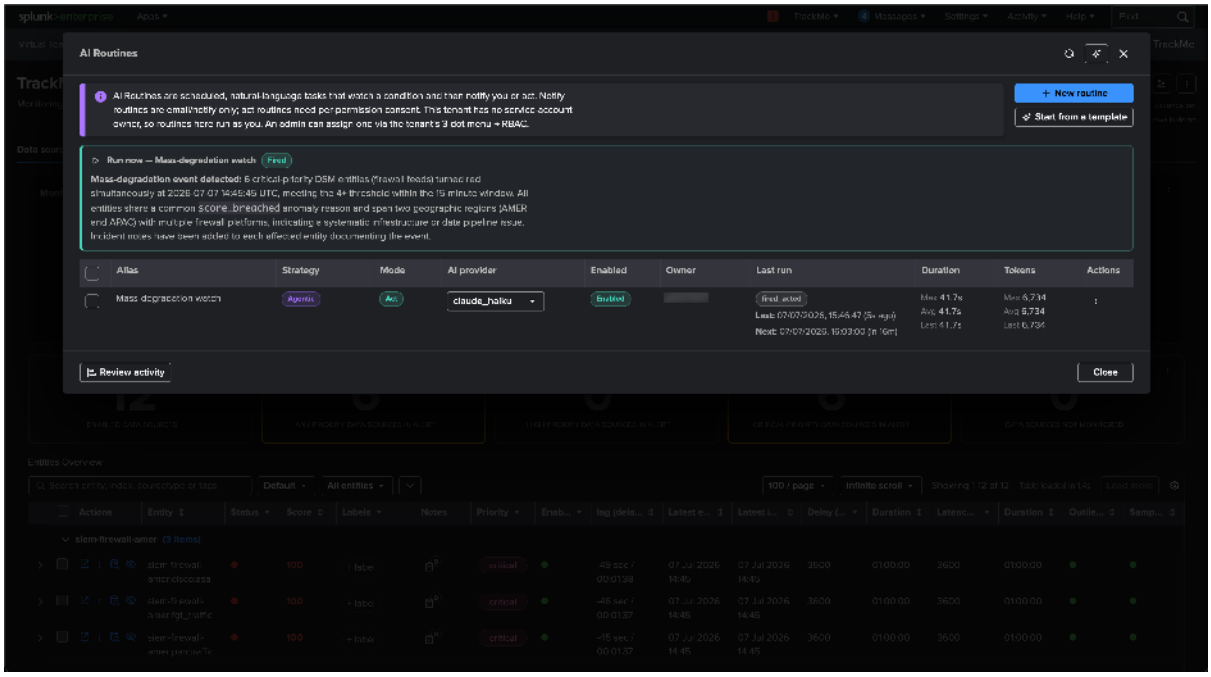
The management view lists your routines with their strategy, mode, provider (switchable in place), schedule state, and last-run outcome. From the row menu you can edit, enable/disable, delete, review the run history, or **run now** — a fire on demand with live progress:





A run ends in one of two honest outcomes — **No fire** (the condition is not met; the routine stays quiet, no notification noise) or **Fired** (with the action taken and the notification status). The run history keeps both, along with per-run duration and token counts:

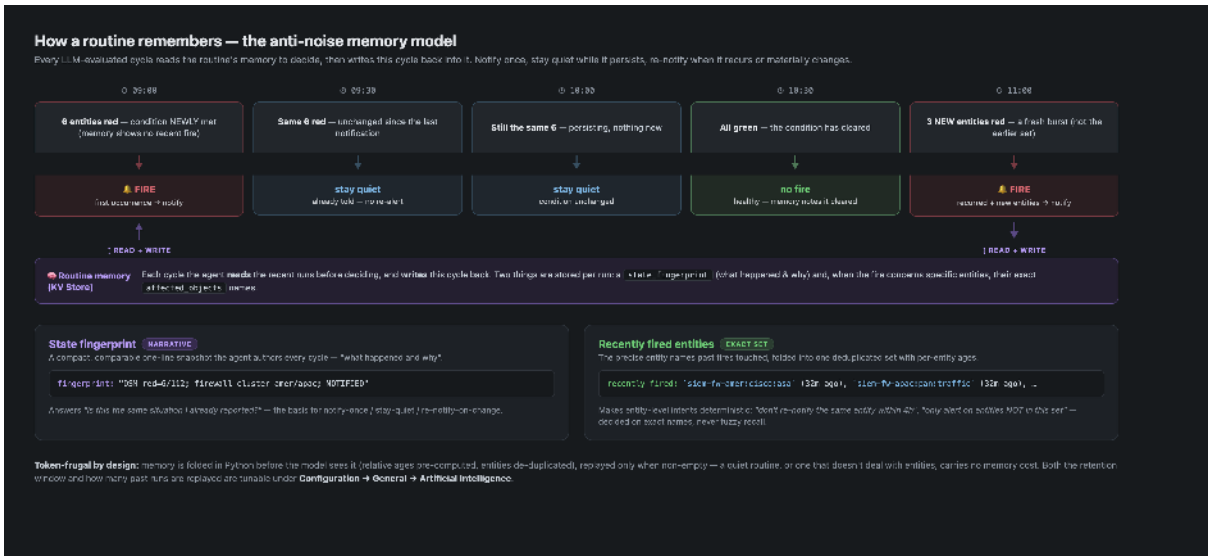




Note

The run history is a lightweight operational view retained for **7 days**. For long-range review, use the *Review AI Routines activity* dashboard below — the underlying events are indexed to your summary index and follow your own retention policy.

Memory between runs



Routines remember. Every LLM-evaluated cycle ends with the agent writing a **state fingerprint** — a compact, comparable snapshot it authors itself (for example *"DSM red=12/112; firewall cluster amer/apac; NOTIFIED"*). On the next cycle, the most recent fingerprints are replayed to the agent as the routine's memory. This is what powers the anti-noise behaviour you see in practice: *notify once when the condition is newly met, stay quiet while the same entities remain red, re-notify when it clears and recurs or when the affected set changes materially.*

Because the fingerprint is the agent's own scratchpad, your intent can lean on it: *"track the worst-offending entity across runs and tell me when it changes"* works — the agent encodes what it needs to remember into the fingerprint. For **deeper history** than the recent fingerprints (say, *"compare this week's incident count with last week's"*), phrase it

in the intent: every fire's full narrative is indexed, and the agent can search it with its read-only correlation search like any other Splunk data.

Per-entity memory. The fingerprint is a narrative; entity-level intents are *set* questions — and those get their own dedicated memory. When a fire concerns specific TrackMe entities, the agent also records their **exact entity names** with the run (`affected_objects`). On later cycles, the recent fires are folded into a single deduplicated *recently fired entities* set with per-entity ages (*"entity X fired 32m ago"*) and handed back to the agent. This makes intents like *"do not re-notify for the same entity within 4 hours"* or *"only alert on entities that were not part of the last fire"* deterministic — decided on exact names, never on fuzzy recall from the fingerprint text. It is also token-frugal by design: quiet cycles and use cases that don't deal with entities carry no per-entity memory at all.

Two storage layers, should you want to investigate manually:

- **Run history (short-lived operational index)** — the KV Store collection `kv_trackme_ai_routine_runs`: one row per evaluated run with the outcome, fingerprint, affected entities, tokens, duration and error. Retained for **7 days by default**. This also answers *"which runs touched entity X?"* directly from SPL:

```
| inputlookup trackme_ai_routine_runs | search routine_id="<routine_id>" |␣
↪sort - cycle_at
```

- **Indexed run events (long-range, follows your index retention)** — every fire's full summary and evidence in the tenant's summary index:

```
index=trackme_summary sourcetype=trackme:ai_agent:ai_routine:*
```

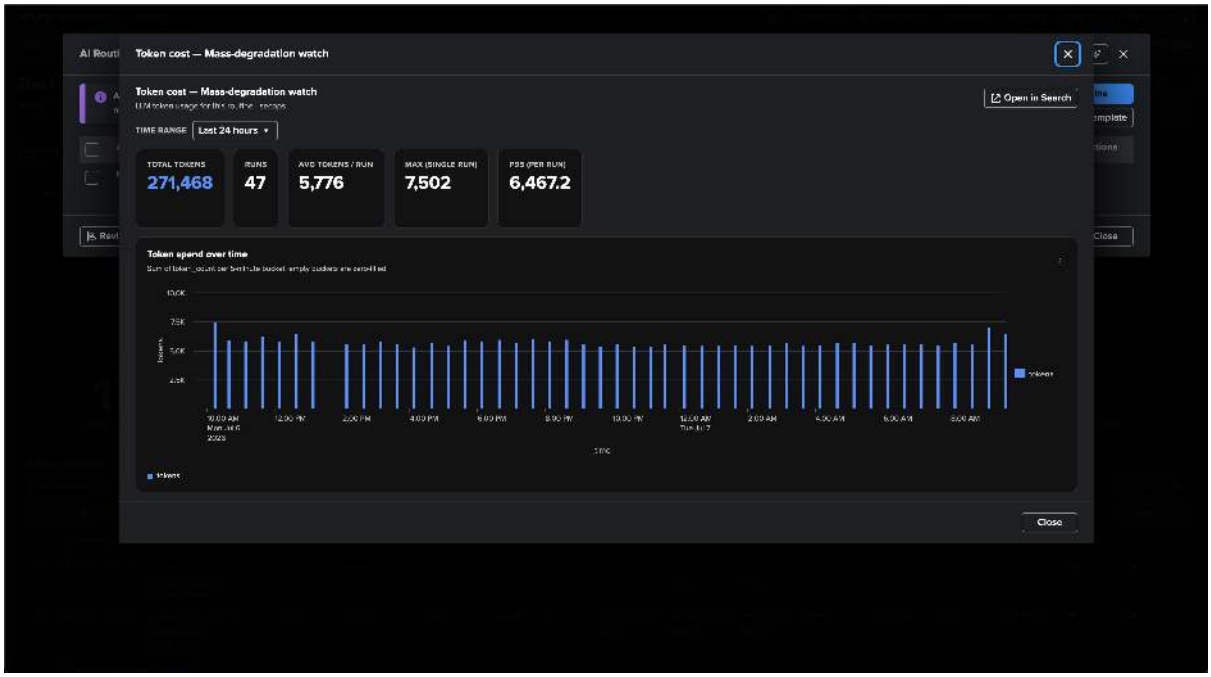
Both memory levers are **tunable** under *Configuration → General → Artificial Intelligence* for deployments whose intents lean intensively on memory: ai_routines_run_retention_days (default 7, 1–90) controls how long the run rows above are kept, and ai_routines_memory_depth (default 8, 0–24) controls how many recent fingerprints are replayed to the AI on each cycle — each remembered run costs roughly 60 extra prompt tokens on every cycle.

Note

The memory has honest bounds: it is **per-routine** (routines do not read each other's fingerprints), it replays the most recent runs only, and **hybrid quiet cycles leave no memory** — when the trigger does not match, no LLM run happens at all (that is the cost model working as intended), so the memory timeline is "every LLM-evaluated cycle", not "every cron tick".

Cost transparency

Token consumption is a first-class citizen throughout: the routine list shows max/avg/last tokens per routine, the run history carries per-run counts, Evaluate extrapolates a daily cost for your cadence, and the dedicated **cost view** breaks consumption down over time:

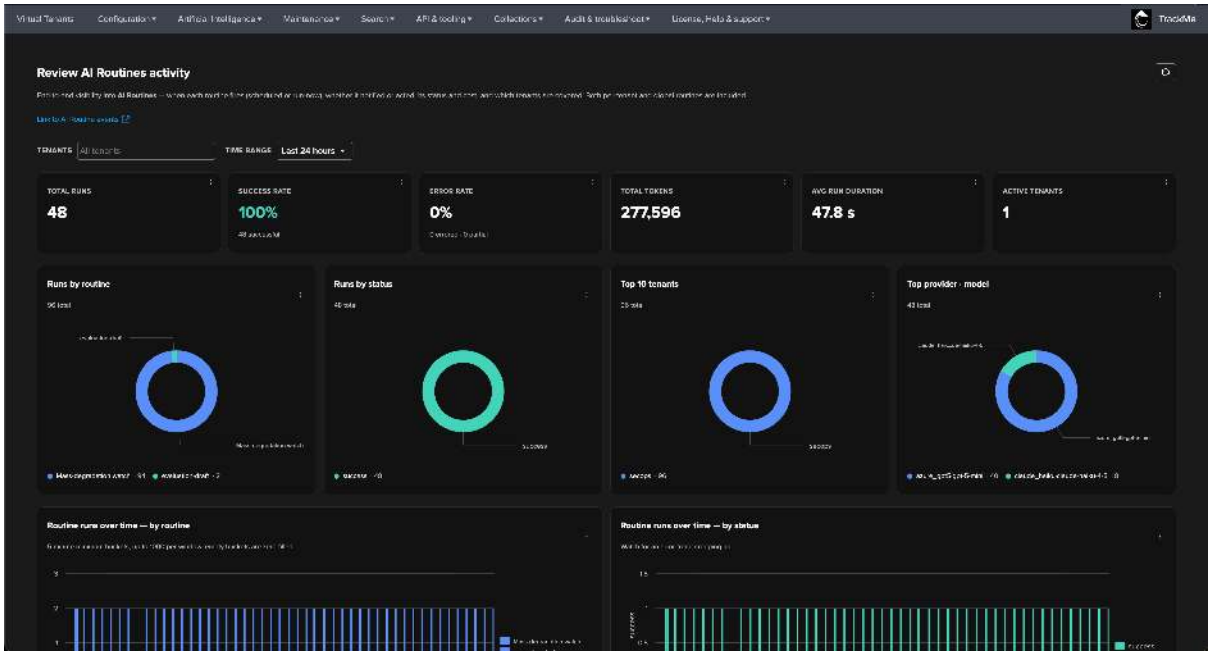


A few cost habits that pay off:

- Prefer **hybrid** for tight schedules — quiet cycles cost zero LLM tokens.
- Right-size the cadence: an agentic routine at `*/30` runs the LLM 48 times a day whether or not anything happened.
- Use the **Raw LLM input** panel (Evaluate) to see exactly what your routine sends — and keep the intent focused; it is replayed verbatim on every run.

Auditing routine activity

Everything a routine does is observable. The **Review AI Routines activity** dashboard (Artificial Intelligence menu) charts runs by routine, outcome, and cadence, and lets you drill into each run — alongside the structured events in the summary index and the per-routine execution logs:



See also *Auditing AI activity* for the AI-wide audit surfaces, and *AI Agents automation* for the scheduled advisor batches — AI Routines are user-authored and complementary to those product-defined automations.

3.6.2 AI Agents automation

Overview

Every specialised *AI Advisor* can run **unattended** on a nightly schedule, in addition to the interactive on-demand path. The automated batch selects eligible entities for a tenant, invokes the relevant advisor (typically in **act** mode) against each, and records the outcome — all scoped by per-tenant policy that you control.

Automation is configured from **Artificial Intelligence > Manage AI Agents automation** and observed from **Artificial Intelligence > Review Scheduled AI Advisor activity**.

Important

Automation is **disabled by default** for every tenant. Nothing runs unattended until you explicitly enable the ML Advisor and/or the Components Advisor for a tenant and pin them to a provider. The decommission guard (the ability to disable entities automatically) is **also off by default**.

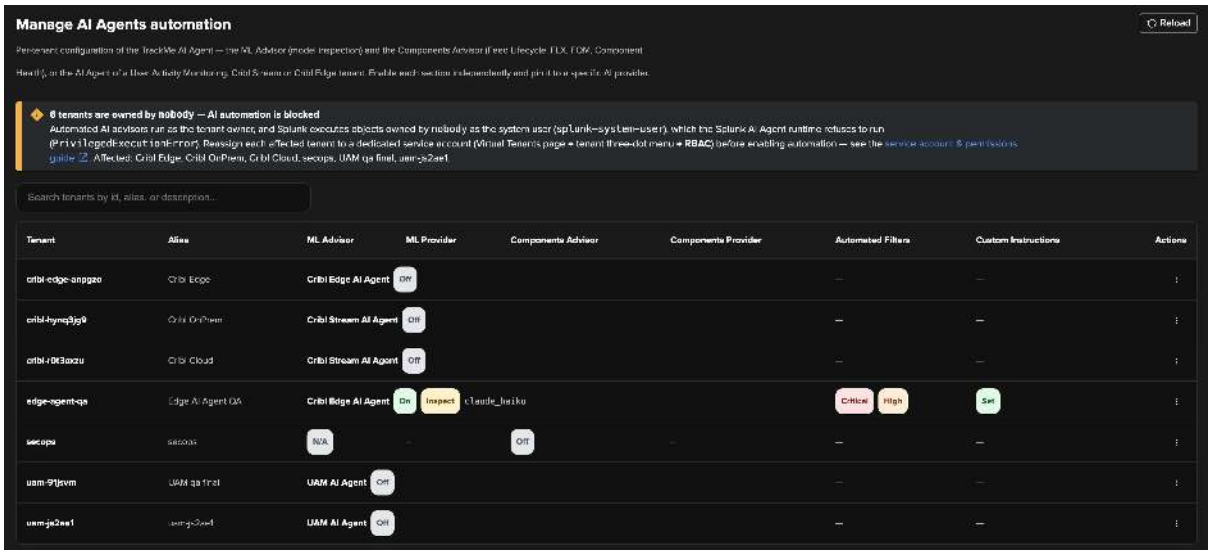
Note

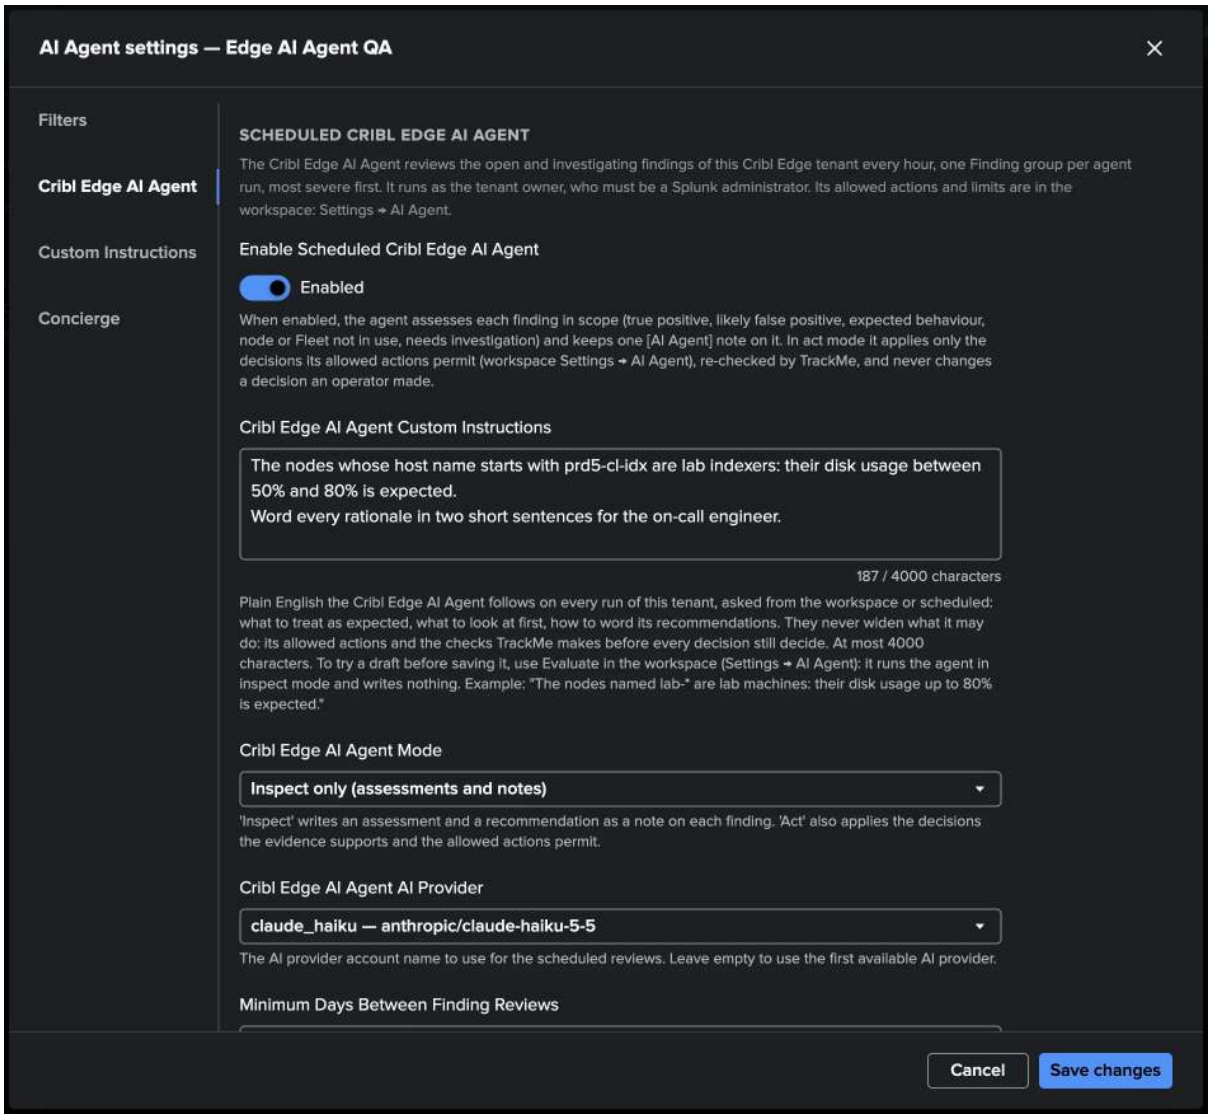
The *AI Concierge* has **no** automated path — it is interactive-only by design. Automation applies to the five specialised advisors only.

Note

The *AI Agents for findings* of User Activity Monitoring, Cribl Stream and Cribl Edge have their own **hourly scheduled triage**, configured in the workspace of each tenant (*Settings → AI Agent*). They also appear on the **Manage AI Agents automation** page: a findings tenant shows its own agent (UAM AI Agent, Cribl Stream AI Agent or Cribl Edge AI Agent) in place of the ML and Components advisors, with its enable toggle and a tab for its core settings (mode, provider, review interval, runtime and the agent's own custom instructions); the decisions the agent may take stay in the workspace. The shared scope filters of this page (priority filter, filter expression)

apply to them too, with the finding severity as the priority; the shared **Custom Instructions** of this page apply to their scheduled runs only, while the agent's own custom instructions apply to every run.



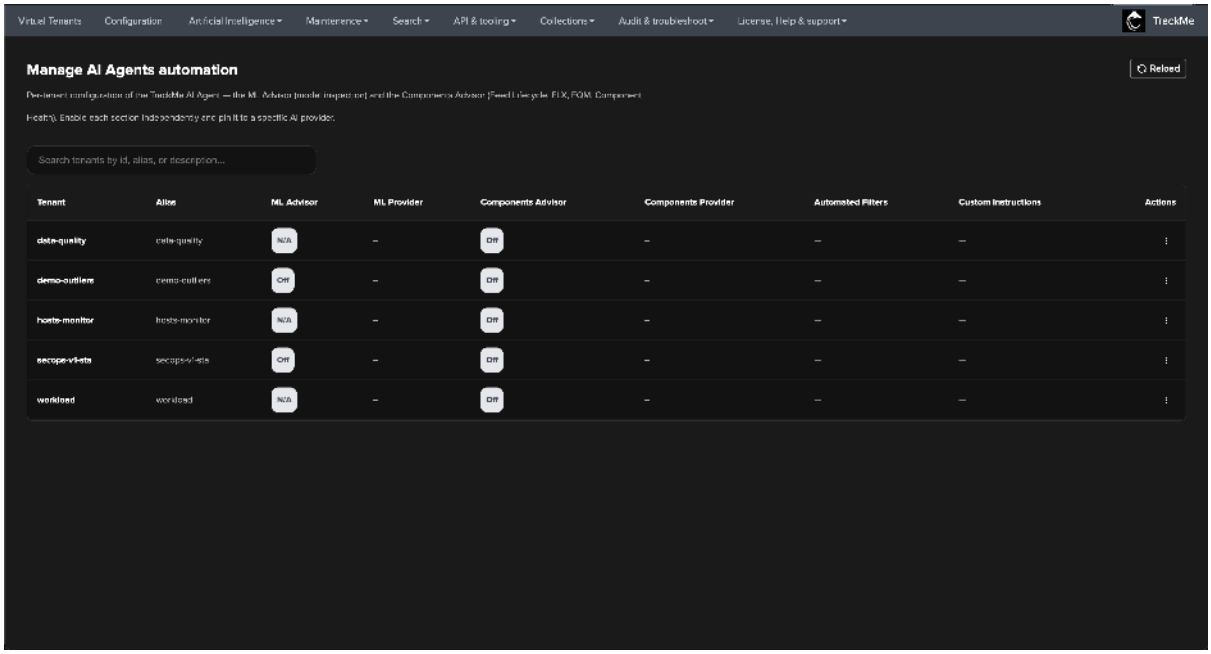


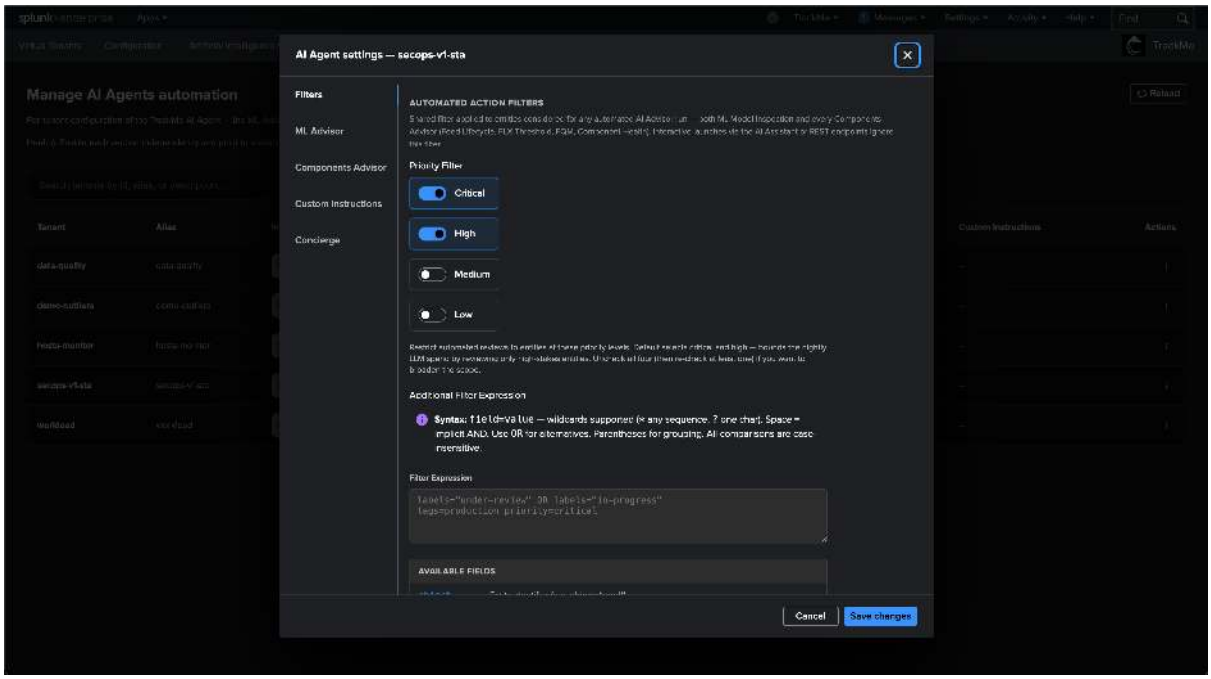
Managing automation per tenant

The **Manage AI Agents automation** page lists every tenant with its automation state. Two families of automation are configured independently:

- **ML Advisor —** the model-inspection advisor, with its own enable toggle and pinned provider. It reviews the ML outlier models of every component that has them (DSM, DHM, VOL, FLX, FQM, WLK).
- **Components Advisor —** the unified configuration advisor covering **Feed Lifecycle** (DSM/DHM), **FLX Threshold** (FLX), **FQM Advisor** (FQM), and **Component Health** (WLK/MHM), with its own enable toggle and pinned provider.

Each row also shows the **Automated Filters** (the scope of eligible entities) and any **Custom Instructions** in effect.





Opening a tenant's **AI Agent settings** reveals the per-section configuration across tabs **— Filters**, **ML Advisor**, **Components Advisor**, **Custom Instructions**, and **Concierge**. The Components Advisor tab, for example, enables the automated review and lets you scope which components are eligible.

Scoping and cost control

The batch honours a set of per-tenant gates — the same gates are the primary cost-control knobs for billed providers:

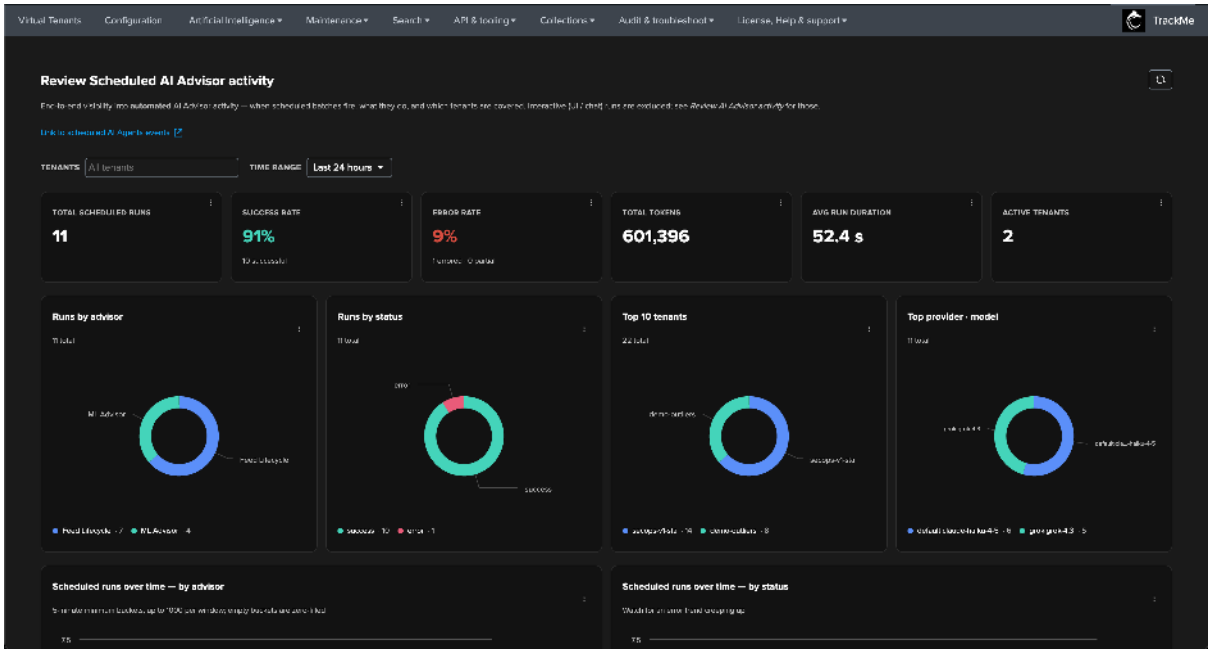
Gate	What it does
Master switches	`ai_mladvisor_enabled` (ML) and `ai_components_advisor_enabled` (Components). When off, the scheduled search scans and exits — no entities selected, no tokens consumed.
Eligible components list	`ai_components_advisor_list` — restrict the Components Advisor to specific components (dsm, dhm, mhm, flx, fqm, wlk).
Priority filter	`ai_automated_priority_filter` (default `critical,high`) — only entities in the listed priorities are reviewed. An optional `ai_automated_filter_expression` narrows further.
Freshness window	`*_min_days_between_reviews` (default 30) — an entity reviewed within the window is skipped, so the same entity is not re-processed every night.
Per-entity opt-out	`ai_mladvisor_disabled=1` on an entity excludes it from the batch (useful after manual tuning).
Decommission guard	`ai_components_advisor_allow_decommission` / `ai_mladvisor_allow_model_disable` (both off by default) — block automatic disabling of entities / models even when act mode is on.
Runtime cap	`*_max_runtime_sec` (default 14400s = 4h) — a per-batch wall-clock ceiling.

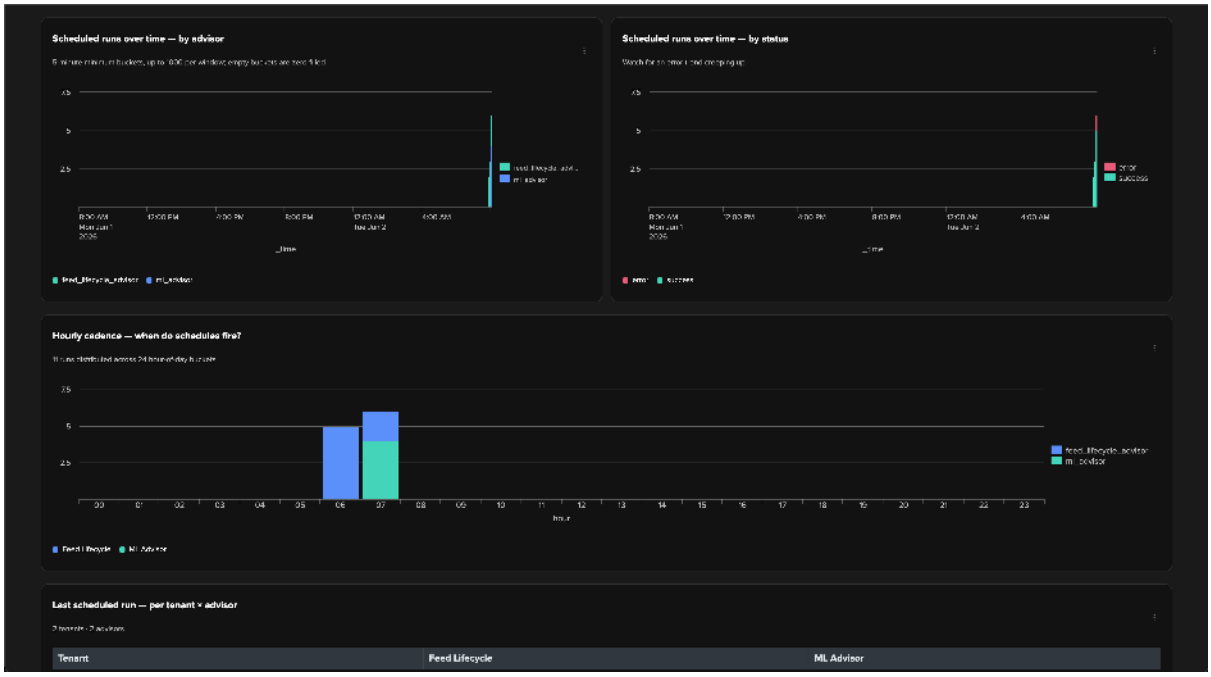
Tip

The priority filter and the freshness window compound multiplicatively. Tightening from `critical,high` + 30 days to `critical` + 60 days typically cuts the token bill by 6–10×. Schedules are staggered across advisors so a tenant does not fire every batch at once and exhaust provider rate limits.

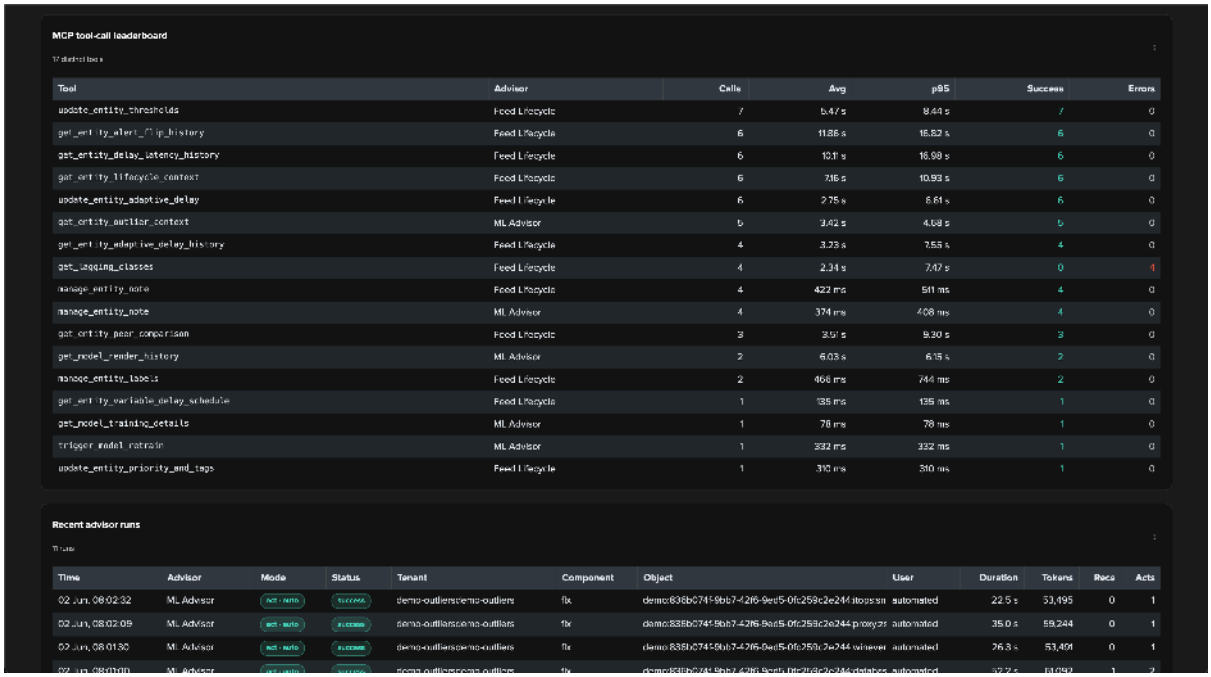
Reviewing scheduled activity

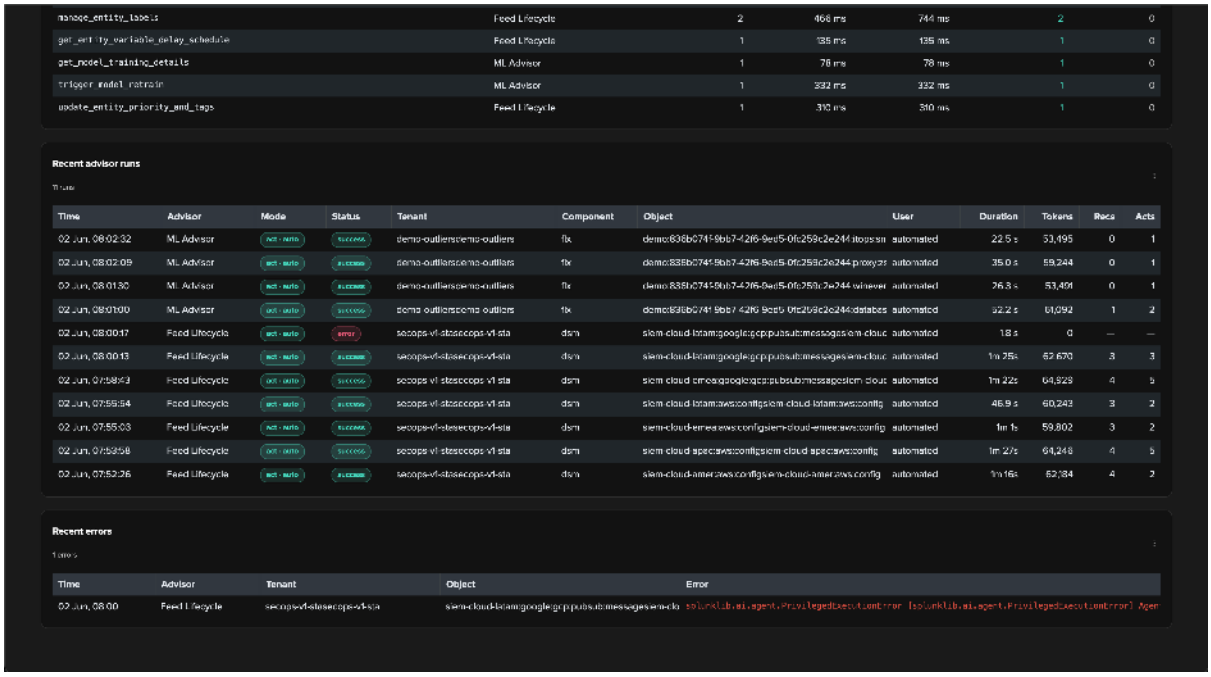
The **Review Scheduled AI Advisor activity** dashboard answers one operational question: *is the automation actually firing for every tenant?* Every panel filters to scheduled (`automated=true`) runs only — interactive runs appear in the *Review AI Advisor activity* dashboard instead.





It surfaces KPI cards (total scheduled runs, success / error rate, total tokens, average run duration, active tenants), breakdowns by advisor / status / tenant / provider-model, runs-over-time charts, an MCP tool-call leaderboard, and the recent scheduled runs — so you can confirm, for example, that the ML Advisor's nightly cron is firing in the expected hours and that no tenant's automation has gone silent.





Each nightly batch produces a per-entity terminal audit event per advisor run, all the per-tool-call events, one `[AI Agent]` audit comment per write, and a batch summary — exactly the same audit surface as interactive runs, marked with `automated=true`. See *Auditing AI activity*.

3.6.3 Natural-language FLX tracker generation

Overview

Flex Objects (FLX) is the most powerful TrackMe component — it turns *any* Splunk search into a set of tracked entities with custom KPIs, thresholds and anomaly detection. It is also the one with the steepest learning curve, because you have to author SPL that satisfies the FLX *search contract*.

Natural-language FLX tracker generation collapses that curve. From the Flex Objects tracker-creation wizard you describe *what you want to monitor in plain language*, and the *AI FLX Threshold Advisor* drafts the tracker for you: it grounds the SPL on the closest of the *60+ Flex Objects use-case templates*, proposes scheduling and starter thresholds, **dry-runs the search against your live data**, and fills the wizard with a validated proposal you review before anything is created.

This is the showcase of TrackMe's AI layer: it does not just *detect* problems, it now helps you *build* the monitoring in the first place — grounded in real data, with the operator firmly in the loop.

Note

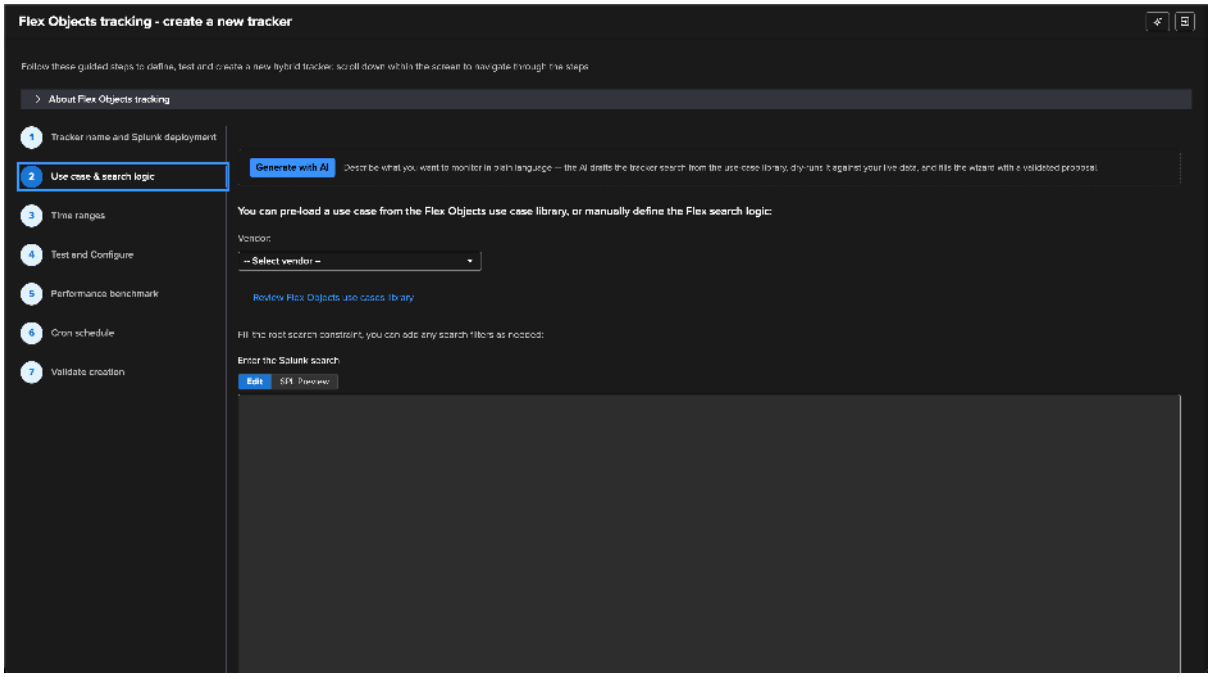
Trust by design. The AI never silently creates anything. SPL hallucination is structurally mitigated by two rules: every proposal is **grounded on the use-case template library** rather than written from scratch, and the candidate search is **dry-run against your live data before you ever see it** — you always review real entity counts and sample results first. The advisor only *proposes*; the tracker is created through the wizard's own create step, with your credentials, on your explicit click.

Requirements

- An **AI provider** must be configured — the feature (like the whole AI layer) is opt-in and inert until then. See *Configuring AI Provider accounts*. The **Generate with AI** button only appears once at least one provider is available.
- The advisor runs on the same **Splunk 10.2.x+ / Python 3.13.x** requirement as the rest of the *AI Advisors*. See *Artificial Intelligence in TrackMe* for compatibility.
- Your role must be allowed to create Flex Objects trackers in the tenant (the create step uses your own credentials, exactly as the manual flow does).

Where to find it

Open the **Flex Objects tracking — create a new tracker** wizard (Tenant Home → Flex Objects → create a new tracker) and go to step **2 — Use case & search logic**. Alongside the manual options (pre-load a use case from the library, or write the search by hand) you will find the **Generate with AI** button.

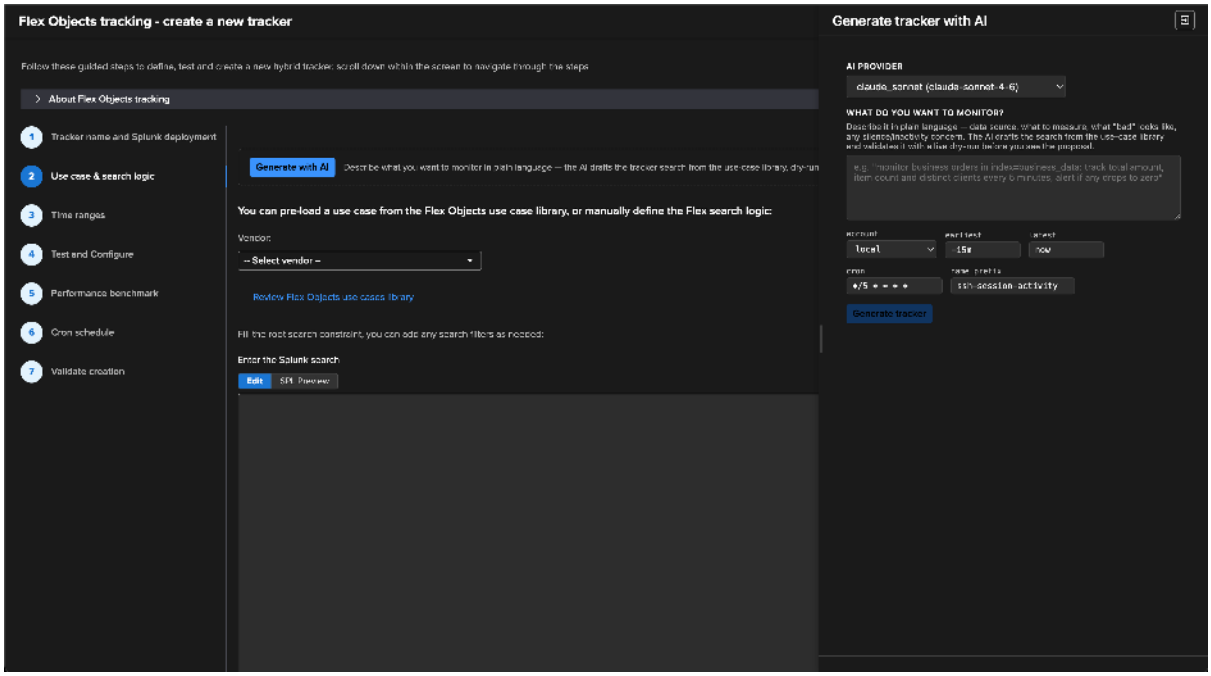


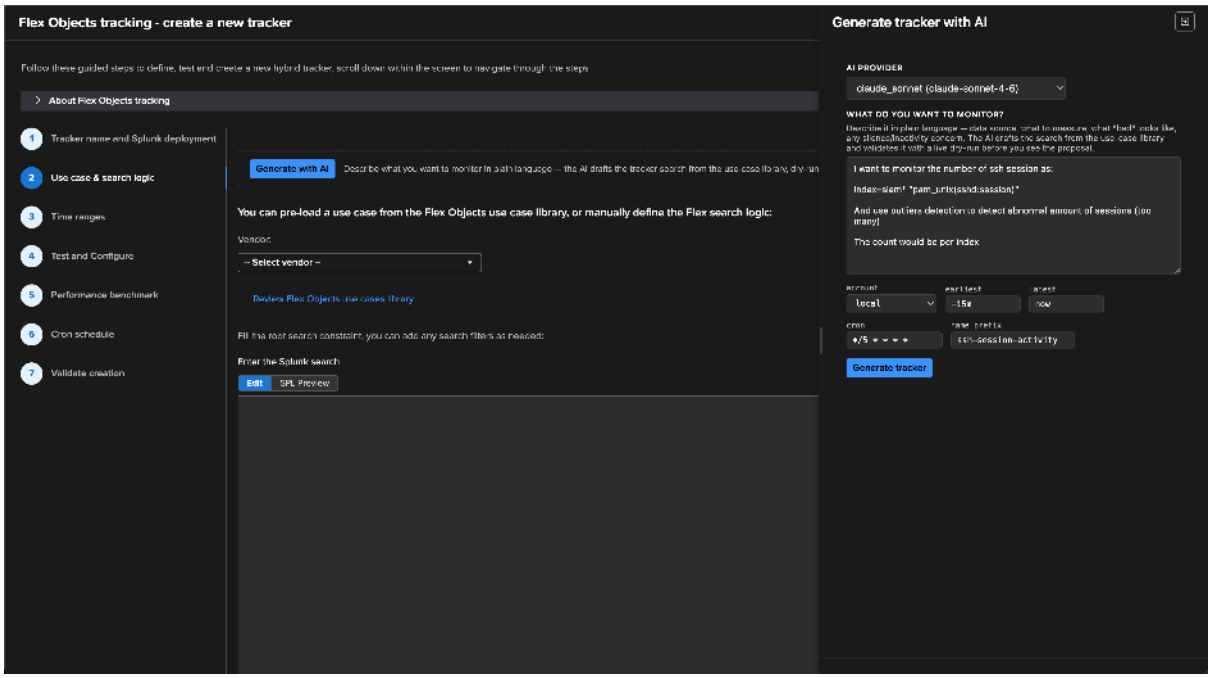
Walkthrough

1. Choose a provider and describe what to monitor

Clicking **Generate with AI** opens the generation panel as a side drawer, so the wizard stays visible underneath. At the top, pick the **AI provider / model** to use for this run — a deliberate choice, because drafting and dry-running SPL is a token-heavy operation and different models trade off cost against quality.

Then describe, in plain language, **what you want to monitor**: the data source, the metric(s) that matter, what "bad" looks like, and any silence/inactivity concern. The tracker settings shown as controls below the description (**account**, **earliest**, **latest**, **cron**, **name prefix**) are the starting constraints the dry-run will use — they are fully editable here, exactly as if you set them on the wizard's own steps.

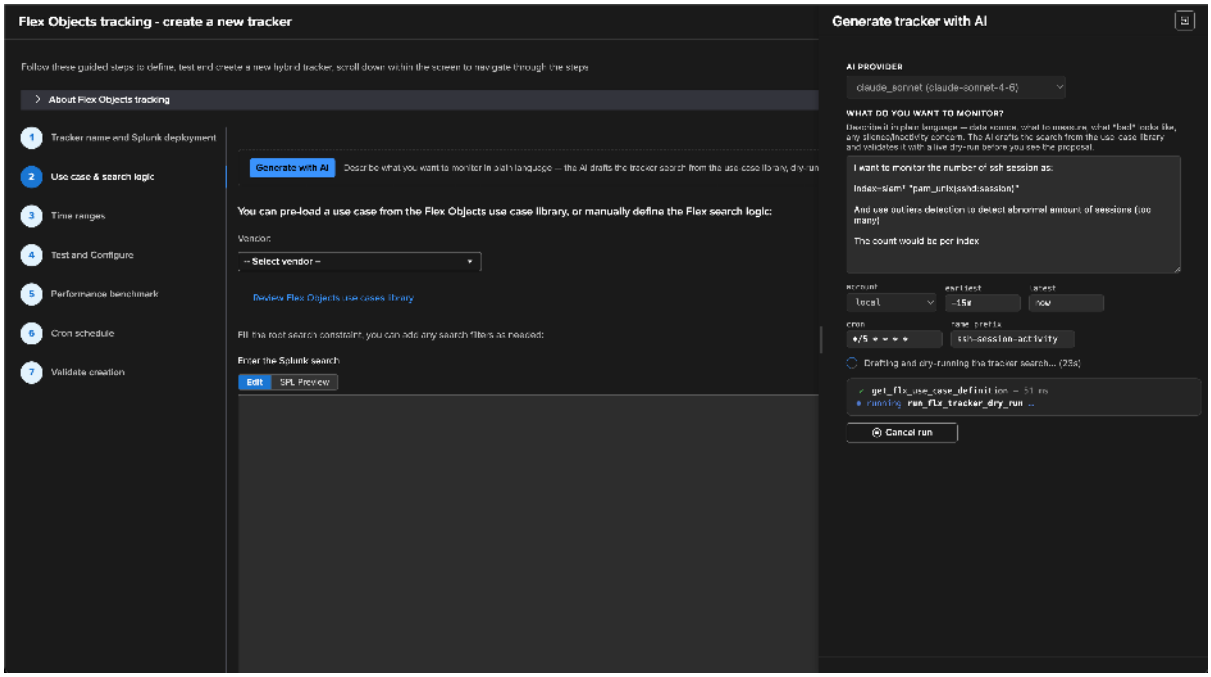




In this example the operator asks to *monitor the number of SSH sessions* from a sourcetype, **per index**, and to **use outlier detection to flag an abnormal number of sessions**.

2. Generate

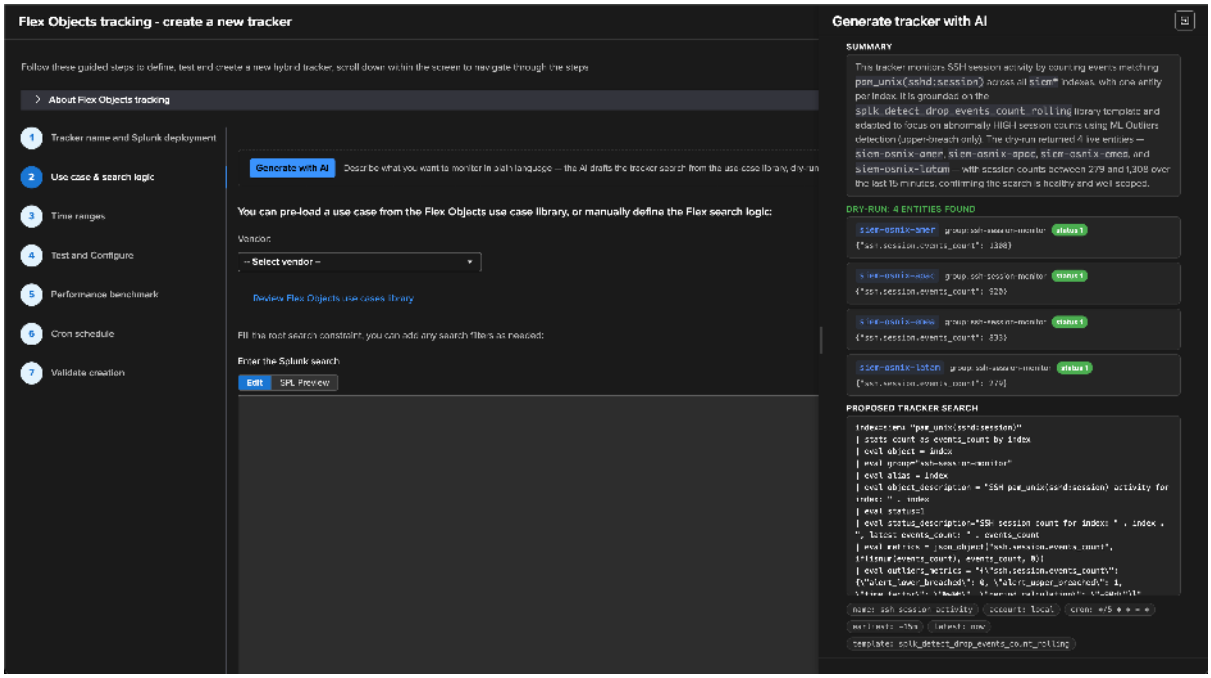
Click **Generate tracker**. The agent works in front of you: a live tool-call feed shows it pulling the closest use-case template (`get_flx_use_case_definition`) and then **dry-running** the candidate search (`run_flx_tracker_dry_run`). Each dry-run is capped and read-only — you can **Cancel run** at any time.



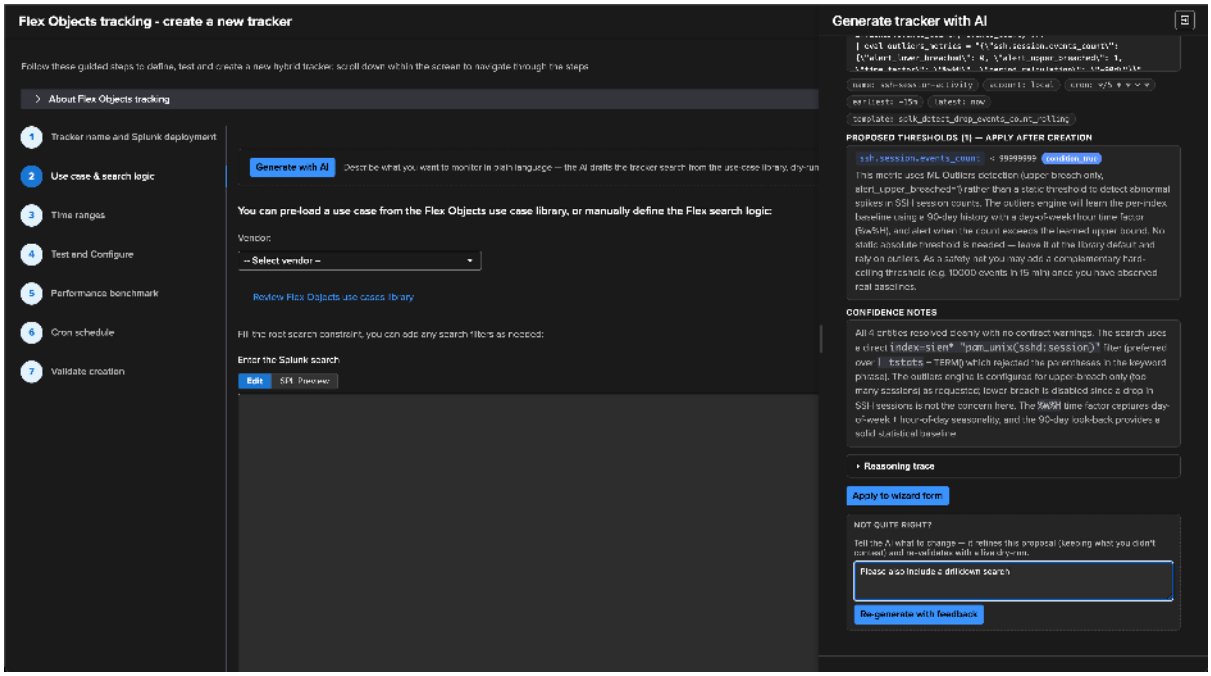
3. Review the validated proposal

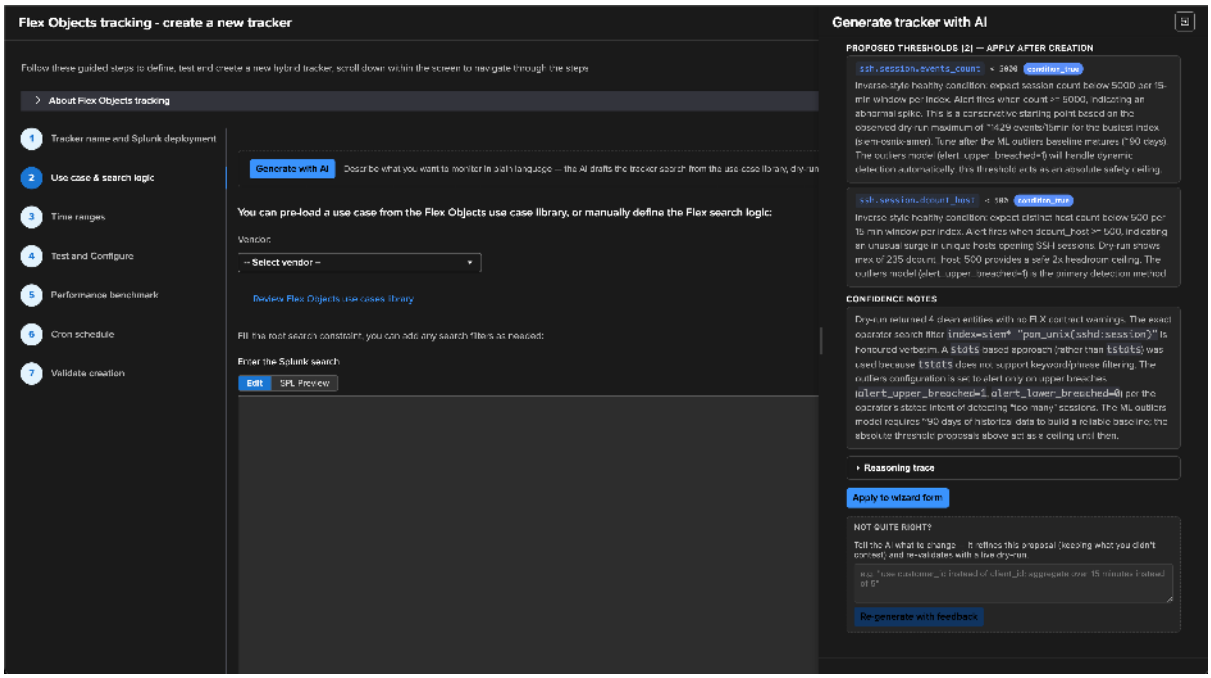
When the agent finishes you get a complete proposal whose evidence comes from the **last successful dry-run of the exact SPL being proposed** — never a proposal without live results. It includes:

- a **summary** of what the tracker monitors and which template it was grounded on;
- the **dry-run evidence** — the number of entities found and a sample of them (object / group / status / metrics), so you can confirm the search behaves as intended *before* creating it;
- the **proposed tracker search** (the SPL), and grounding/schedule chips (template used, account, cron, earliest, latest, name).



Scrolling down, the proposal also surfaces **starter threshold recommendations** and **confidence notes** (what was assumed, what could not be verified — e.g. a field name that may need adjusting), and a collapsible **reasoning trace**.





Note

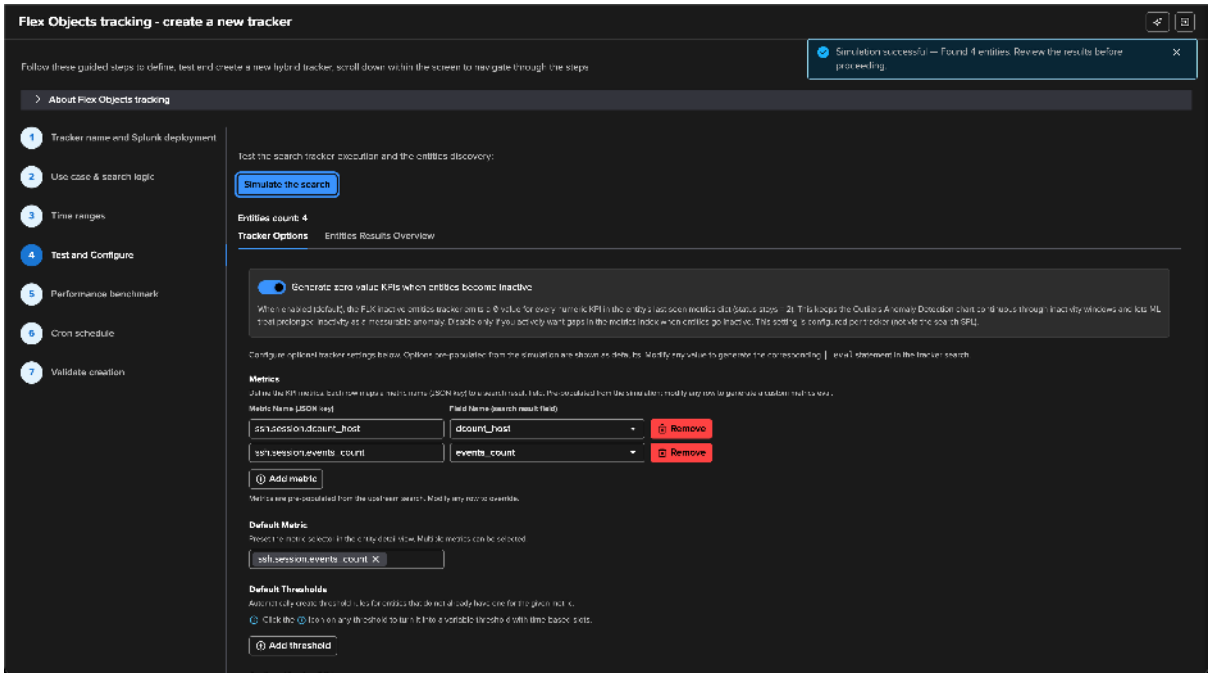
The **proposed thresholds are recommendations to apply after creation —** the Flex Objects create step does not take thresholds directly. They give you a calibrated starting point you (or the *AI FLX Threshold Advisor* later) can apply on the new entities.

4. Refine (optional, repeatable)

If the proposal is close but not quite right, you do not start over. Use **Not quite right?** at the bottom of the result: type what should change (for example *"use a different field for the distinct count"* or *"aggregate over 15 minutes instead of 5"*) and click **Re-generate with feedback**. The agent **iterates on the previous proposal —** keeping everything you did not contest, applying your feedback, and re-validating with a fresh dry-run. Repeat until you are happy.

5. Apply to the wizard

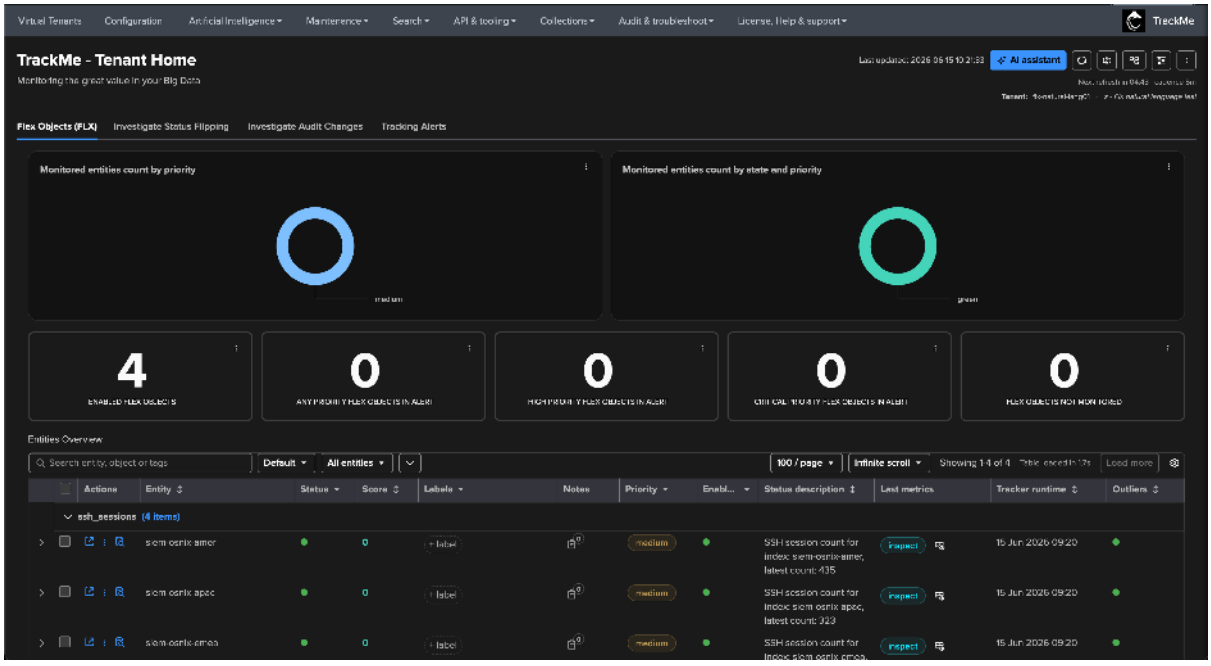
When the proposal is right, click **Apply to wizard form**. The drawer closes and the wizard jumps to **step 4 — Test and Configure**, pre-filled with the proposed search, metrics, default metric and schedule, and it **re-runs the wizard's own simulation** so you immediately see the live entities in the wizard's own panel.



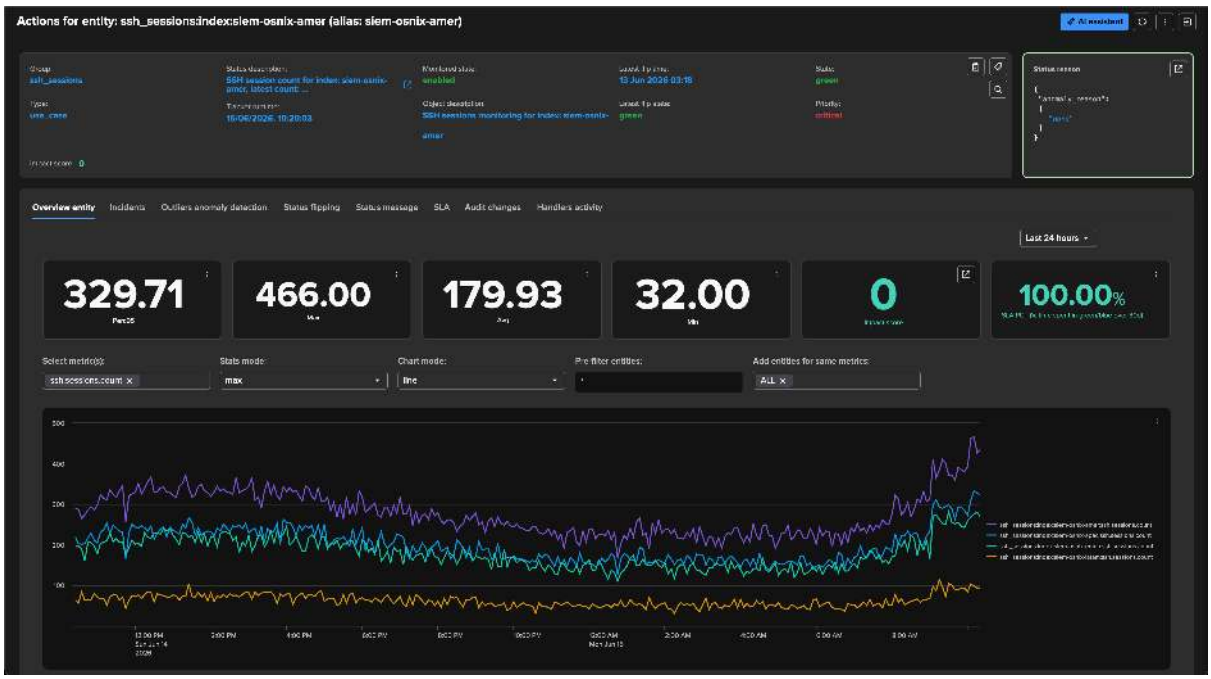
From here it is the **standard Flex Objects creation flow** — review the metrics and thresholds, adjust anything you want, set the cron schedule, and create the tracker. Nothing about creation is AI-driven; you are simply finishing the wizard you would have used manually, with the hard part already done. See *Creating a Flex Tracker* for the manual steps.

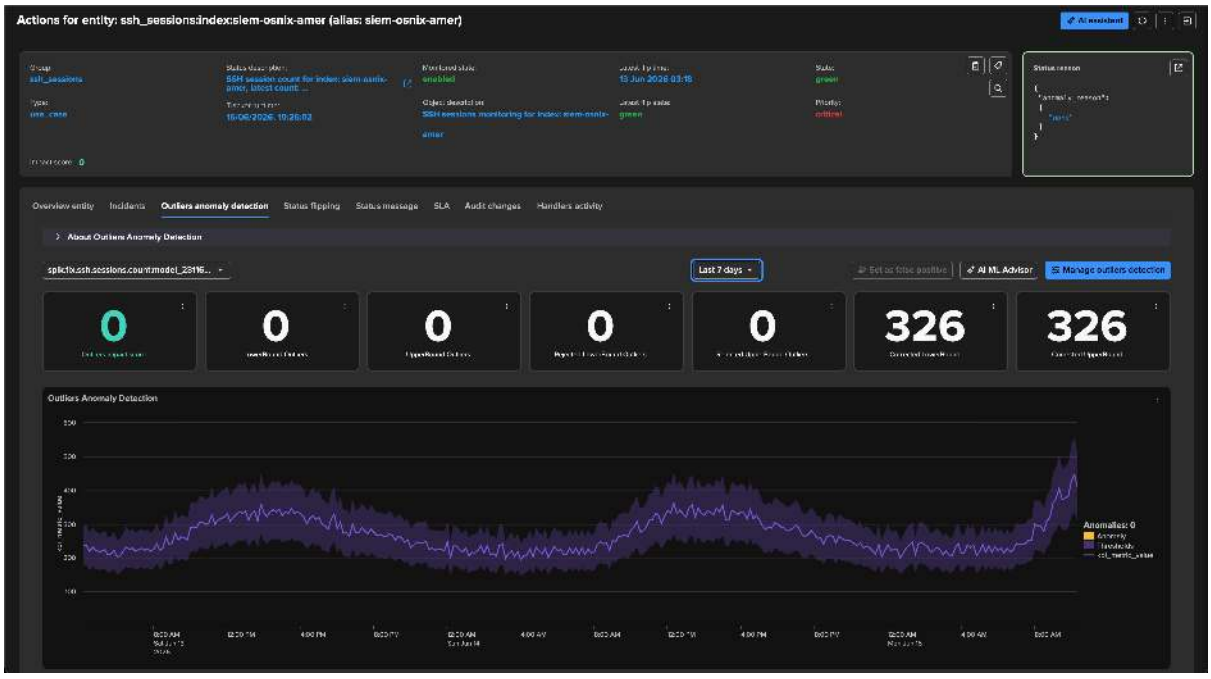
6. The tracker is live

Once created, the new Flex Objects tracker behaves like any other — its entities appear on Tenant Home, are scored and alertable, and participate in the full TrackMe feature set.



Because the description in this example asked for **outlier detection**, the generated tracker is configured for it: the entity overview shows the live KPI, and the **Outliers anomaly detection** tab shows the native ML model already tracking the per-index session counts.





Good to know

- **The AI proposes, you create.** The advisor never calls the tracker-create endpoint. Creation always happens through the wizard's own create step, with your credentials — so license limits, name sanitisation and the audit trail all flow through the proven path.
- **Always dry-run-validated.** A proposal's entity counts and samples always come from a real dry-run of the exact SPL being proposed. If the data is sparse or a field name is uncertain, the agent says so in the confidence notes rather than hiding it.
- **Editable settings.** Account, time window, cron and name prefix are editable in the panel and mirror straight into the wizard form. The AI may still adjust the schedule/window to fit the chosen use case; whatever the final

proposal returns is what **Apply** writes.

- **Provider choice matters.** Generation is token-heavy and iterative — pick the model that fits your cost/quality preference at the top of the panel.
- **Interactive only.** Tracker generation is a wizard-time, human-in-the-loop capability — there is no unattended/automated generation path. (The *AI Advisors automation* schedule covers inspect/act remediation, not creation.)
- **Audited.** Like every AI action, generation runs are recorded. In the **Review AI Advisor activity** dashboard they appear under their own **FLX Generation** category (distinct from FLX threshold tuning). See *Auditing AI activity*.

3.7 Governance

How to audit what TrackMe's AI did, the privacy, data-governance and compliance posture of the AI features, and how TrackMe positions against the EU AI Act.

3.7.1 Auditing AI activity

Overview

Auditability and traceability are first-class principles of the TrackMe AI layer. Every AI Assistant chat, every AI Advisor run, and every Concierge action is indexed to the tenant summary index and surfaced in dedicated audit dashboards — so you can always answer *who launched what, which provider and model were used, what was proposed or changed, and how long it took*.

There are four audit dashboards under the **Artificial Intelligence** menu:

- **Review AI Advisor activity** — interactive (UI- or chat-launched) advisor runs, and the runs of the *AI Agents for findings* (UAM AI Agent, Cribl Stream AI Agent, Cribl Edge AI Agent).
- **Review Scheduled AI Advisor activity** — the automated nightly batch (covered in *AI Agents automation*) and the hourly scheduled triage of the findings AI Agents.
- **Review AI Routines activity** — user-authored scheduled routines, interactive and scheduled.
- **Review AI Assistant activity** — chat conversations and stateful-alert AI status reports.

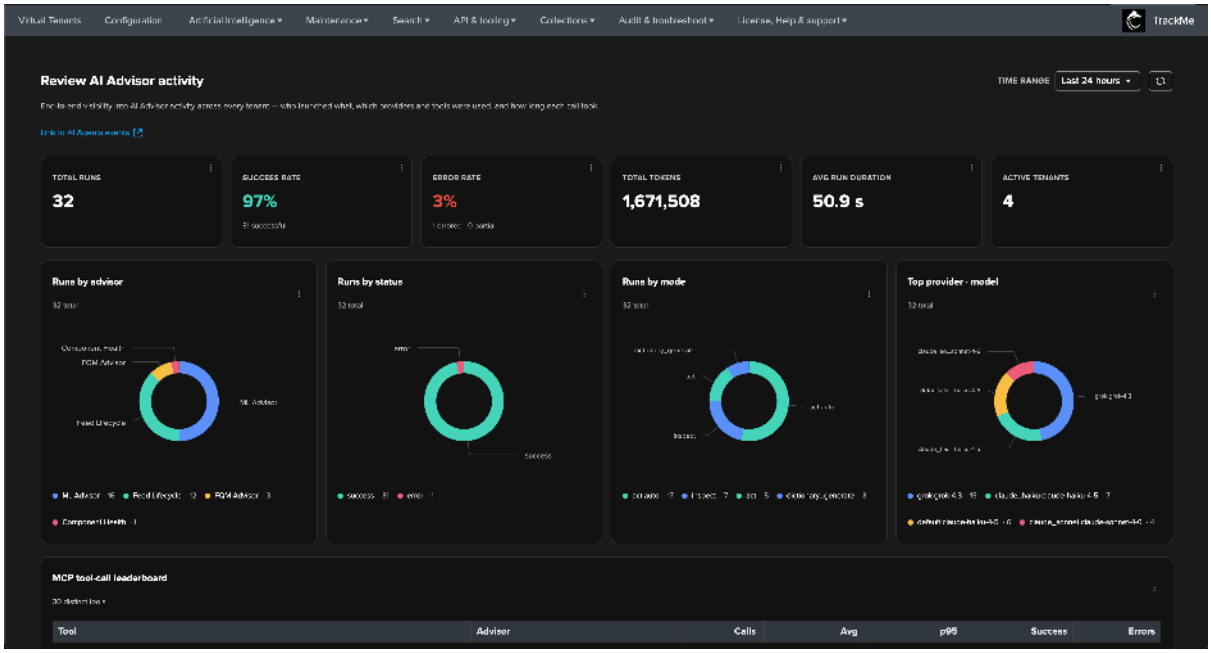
Note

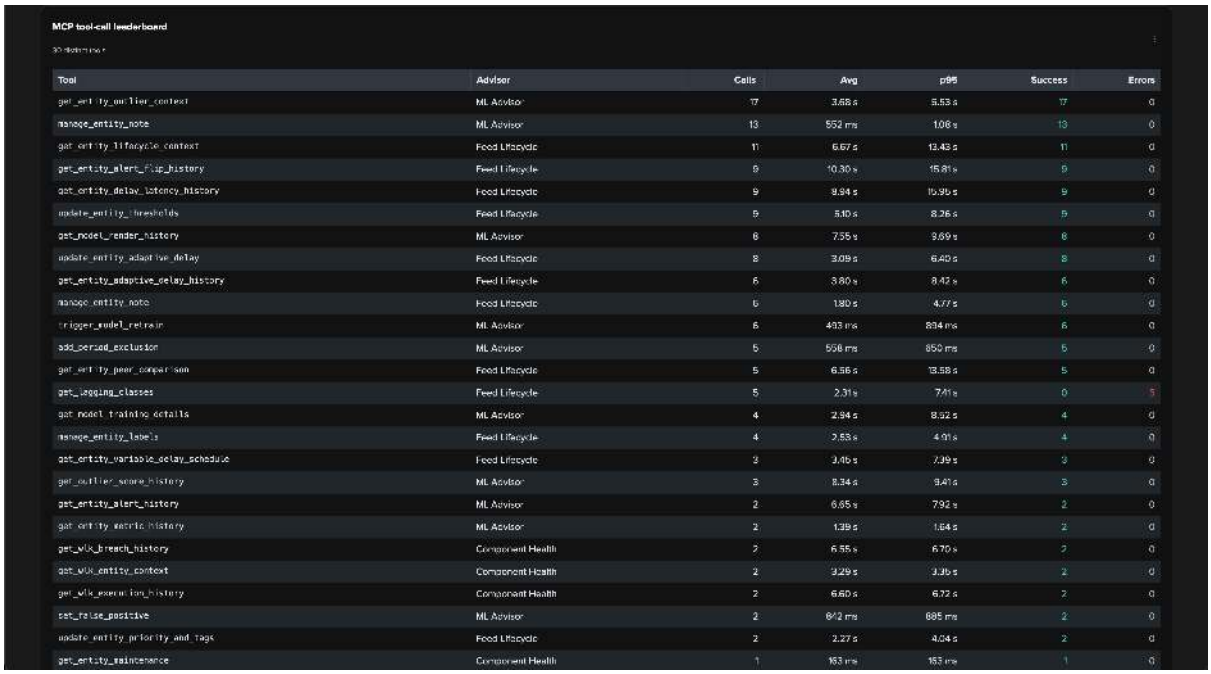
In addition to the dashboards, every advisor or Concierge **write** is stamped with an `[AI Agent] <reason>` prefix in the affected entity's *Audit changes* panel, so the per-entity history shows exactly what the AI changed and why — independently of the dashboards. The findings AI Agents record their decisions in the finding history under the actor **AI Agent** and in the **AI Agent** tab of the workspace (see *AI Agents for findings*).

Review AI Advisor activity

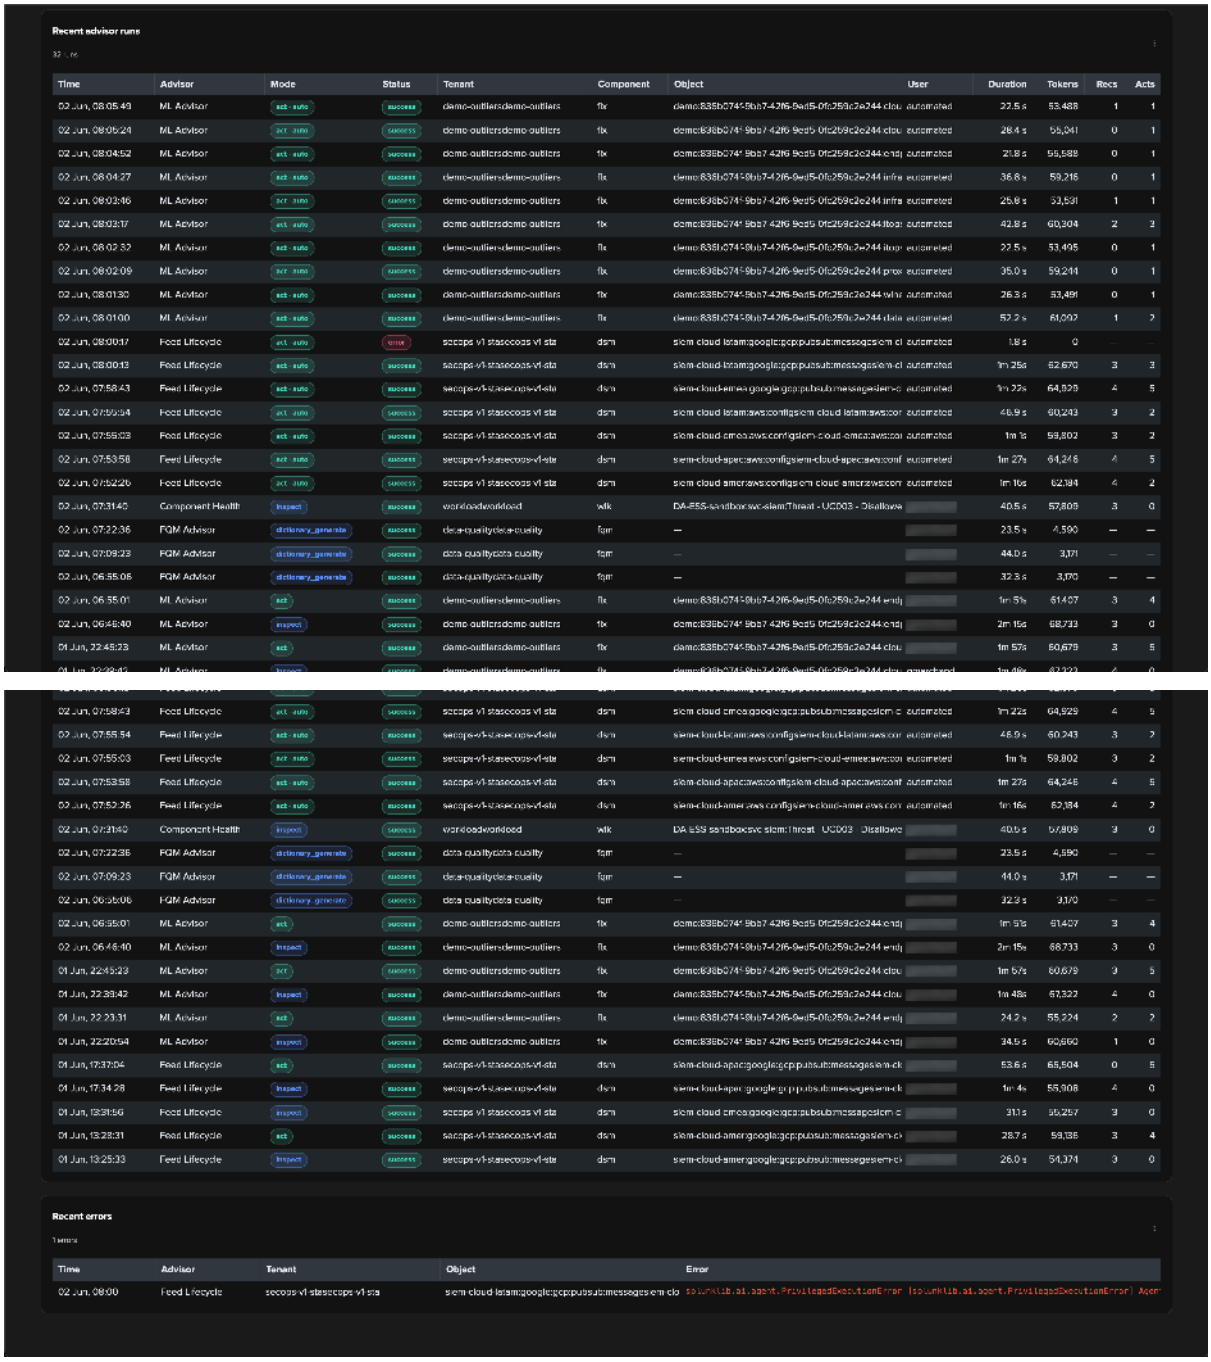
This dashboard gives end-to-end visibility into AI Advisor activity across every tenant — who launched what, which providers and tools were used, and how long each call took. It covers the **interactive** path; scheduled runs live in the *Review Scheduled AI Advisor activity* dashboard.

The KPI strip shows total runs, success / error rate, total tokens, average run duration, and active tenants. Donut charts break activity down by advisor, by status, by mode (inspect / act / dictionary_generate), and by top provider-model. A tool-call leaderboard and a recent-runs table complete the picture.





The **MCP tool-call leaderboard** shows every tool the advisors invoked, with call counts, average and p95 durations, and success / error counts — useful for spotting a slow or failing tool. The **recent advisor runs** table lists each run with its advisor, mode, status, tenant, component, object, user (or `automated`), duration, tokens, and the number of recommendations and actions taken.



Tip

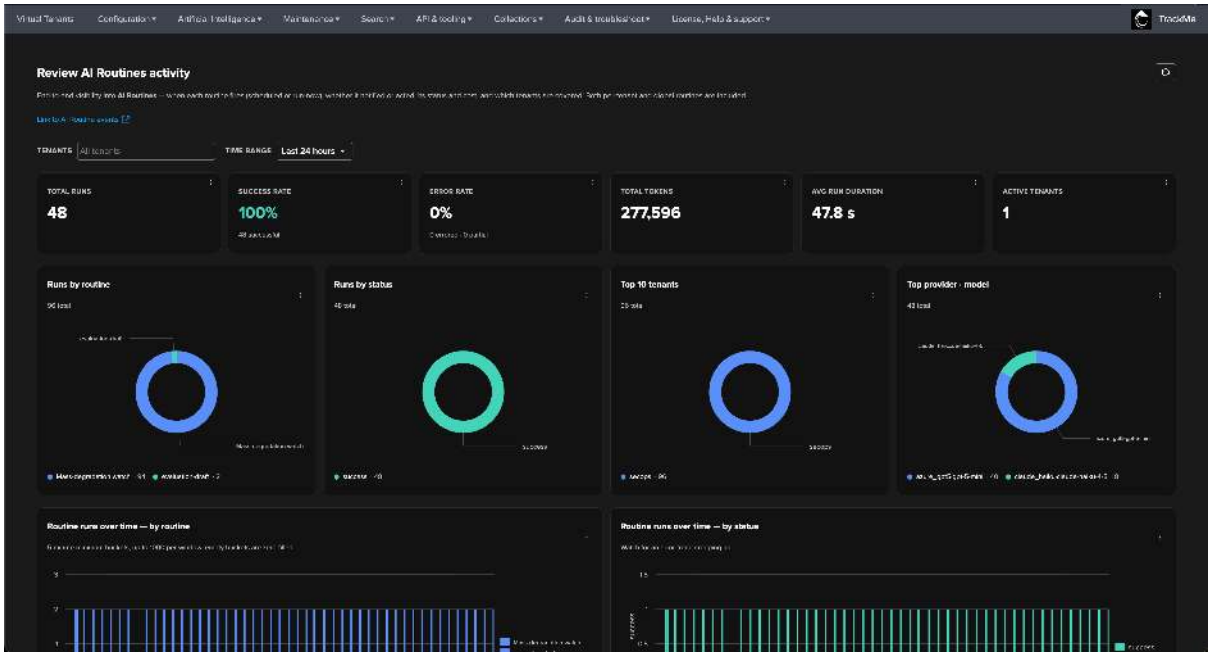
Every panel has a 3-dot menu with **Open in Search** that deep-links into the Splunk Search app with the panel's SPL pre-loaded. The underlying events use the sourcetype pattern `trackme:ai_agent:*advisor*` — and `trackme:ai_agent:*_agent:*` for the findings AI Agents (plus `trackme:ai_agent:tool_call` for per-tool events), so you can pivot AI activity in plain SPL.

Review AI Routines activity

This dashboard gives end-to-end visibility into *AI Routines* — the user-authored, scheduled natural-language tasks that watch a condition and then notify or act. It combines **interactive** runs (Evaluate dry-runs and Run-now) with the **scheduled** fires, so you can see how often each routine ran, whether it fired, what it cost, and how it was launched.

The KPI strip shows total runs, success / error rate, total tokens, average run duration, and active tenants. Donut charts

break activity down by routine, by status (fired / no-fire / error), by top tenants, and by top provider-model. Runs-over-time column charts (by routine and by status) and an hour-of-day cadence histogram make it easy to confirm a routine's schedule is actually firing in its window, and a per-tenant × routine last-run matrix highlights any routine that has gone silent.

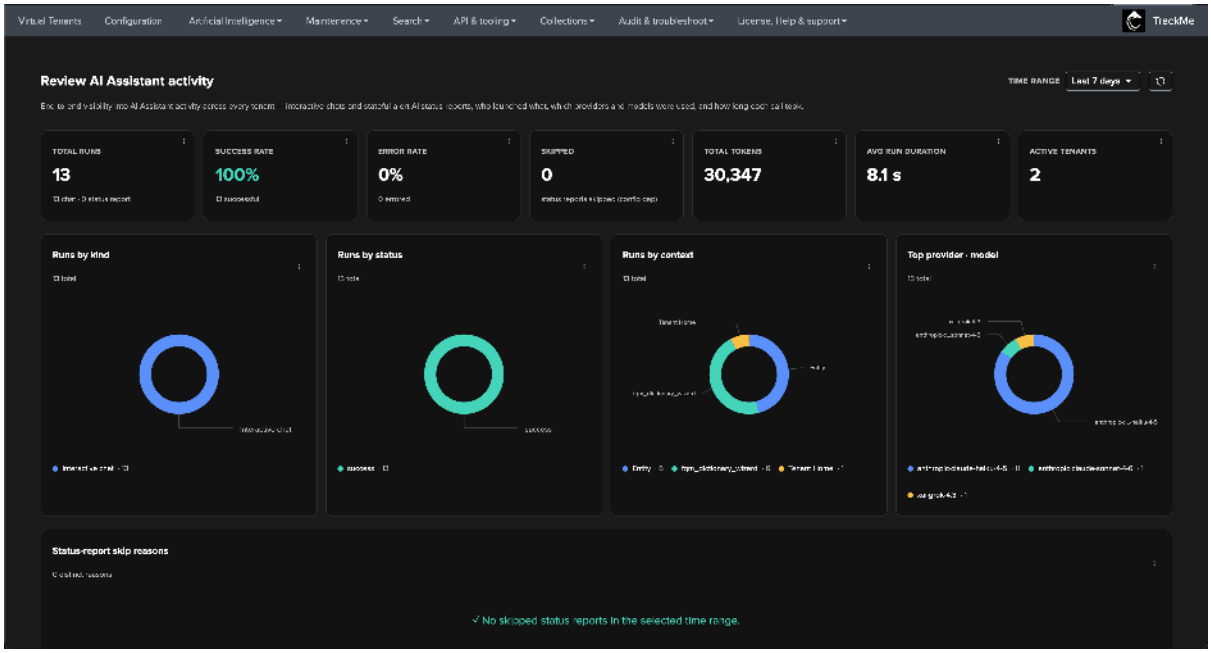


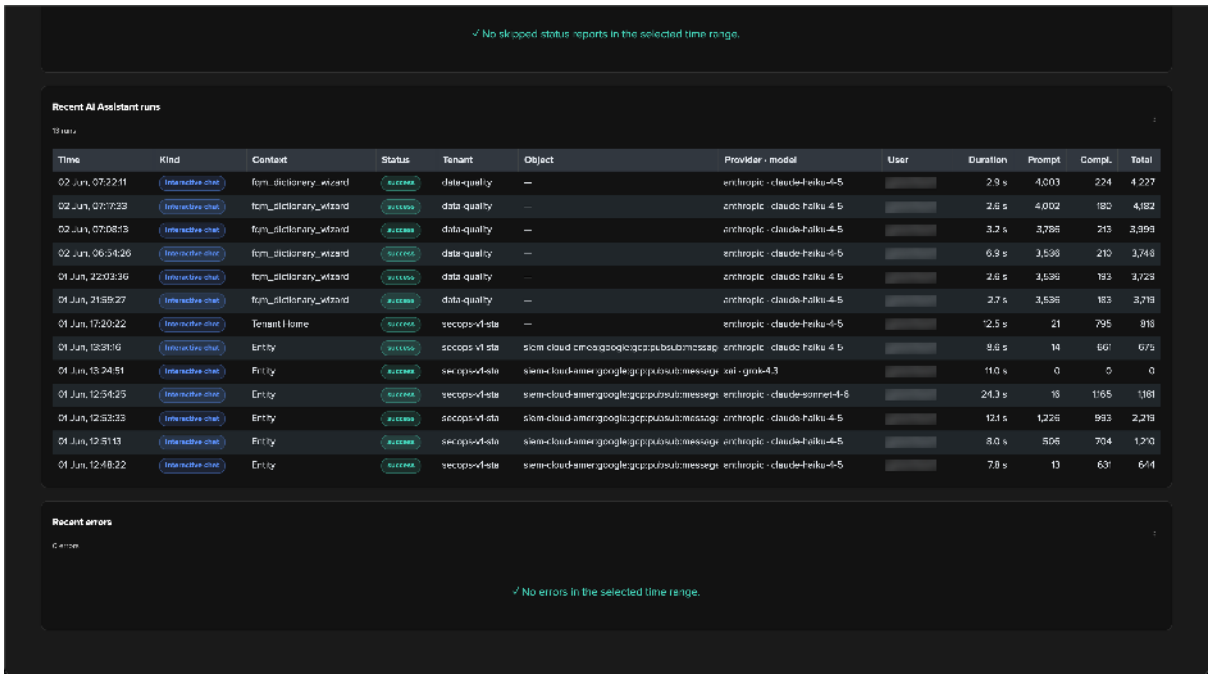
Each routine fire is indexed to the tenant summary index with the sourcetype pattern `trackme:ai_agent:ai_routine:*` (carrying `advisor="ai_routine"`), alongside the same per-tool `trackme:ai_agent:tool_call` events the advisors emit — so the routine's reads and writes are auditable in plain SPL, and each act-mode write is additionally stamped `[AI Agent] <reason>` in the affected entity's *Audit changes* panel. See *AI Routines* for the routine model itself and its per-routine execution logs.

Review AI Assistant activity

This dashboard covers the conversational AI Assistant — both interactive chats and the AI status reports embedded in stateful-alert emails. It records who launched each chat, which provider and model answered, the context it ran in, and how long it took.

The KPI strip shows total runs, success / error rate, skipped status reports, total tokens, average duration, and active tenants. Donut charts break activity down by kind (interactive chat vs status report), by status, by context (entity / Tenant Home / wizard / feature pages), and by top provider-model. A status-report skip-reasons panel explains any skipped email reports.





The **recent runs** table lists each chat or status report with its kind, context, status, tenant, object, provider-model, user, duration and token usage; a **recent errors** table isolates failures. The underlying events use the sourcetype pattern `trackme:ai_assistant:*`.

Note

Cancelled chats are deliberately **not** indexed (the user walked away — counting them would distort the error rate). Non-entity chat contexts (e.g. Virtual Tenants) are bucketed under a synthetic `system` tenant so the by-tenant breakdown stays stable.

The audit envelope

All AI audit events share a common envelope so the dashboards can aggregate without parsing JSON. Useful fields include:

Field	Meaning
`tenant_id`	The tenant the event belongs to (`system` for non-entity contexts).
`advisor` / `kind`	The advisor name (Advisor events), `ai_routine` (Routine events), or `chat` / `status_report` (Assistant events).
`mode`	`inspect` / `act` / `dictionary_generate` for advisors; `inspect` (notify) / `act` for routines.
`status`	`success` / `error` / `skipped`.
`launched_by`	`ui` / `ai_assistant` / `automation` — who triggered the run (routine fires on a schedule report `automation`).
`automated`	`true` for scheduled batch runs, `false` for interactive.
`provider` / `model`	The resolved provider account and model.
`duration_ms` / `*_tokens`	Wall-clock time and token usage.
`chat_session_id`	Correlates a bridge-launched advisor run with the chat conversation that triggered it.

Tip

To find which conversation triggered a given advisor run:

```
index=trackme_summary sourcetype="trackme:ai_agent:*advisor*"
  launched_by="ai_assistant" chat_session_id="chat-XXX-yyy"
```

3.7.2 AI Compliance, Privacy and Data Governance

Overview

This page is written for **compliance, security, privacy and risk teams** evaluating the use of TrackMe's AI capabilities in regulated or data-sensitive environments. It answers, in one place, the questions that matter for an AI risk assessment:

- *Where does the AI processing happen, and who is in the data path?*
- *Exactly what data is exchanged with the LLM provider — and what is never sent?*
- *What can the AI actually do — which tools does it have, and which are read-only?*
- *How are write actions controlled, audited and reversed?*

- *How do we restrict, monitor, or completely disable the AI layer?*

Every statement on this page reflects how the product is implemented. For the functional walkthroughs of each AI capability, see *Artificial Intelligence in TrackMe* and the dedicated pages of this section; for provider configuration, see *Configuring AI Provider accounts*. For the mapping of these capabilities to the **EU AI Act**'s roles, risk categories and Article 50 transparency obligations, see *EU AI Act compliance*.

Important

The short version — TrackMe's AI layer is **opt-in and inert by default**: no LLM call is ever made until an administrator explicitly configures an AI provider account. When enabled, LLM calls go **directly from your Splunk search head to the provider you chose —** including fully air-gapped self-hosted models — using **your own credentials**. TrackMe Limited (the vendor) operates **no AI cloud service, no proxy, and no telemetry collection** in the AI data path and never receives your data. The AI works on **monitoring metadata and telemetry**, not on your raw indexed events, and every interaction is **recorded in an audit trail you control**.

Compliance at a glance

Question	Answer
Is AI enabled by default?	**No.** The AI layer is completely inert until an administrator creates at least one AI provider account. Until then, no data leaves Splunk and no LLM call is made.
Is the vendor (TrackMe Limited) in the data path?	**No.** TrackMe is a Splunk application running entirely inside your Splunk deployment. LLM requests are sent directly from your search head to the provider endpoint you configured. There is no intermediate TrackMe-operated service, and TrackMe Limited never receives any of your data, prompts, or responses.
Can we keep all AI processing on-premises?	**Yes.** TrackMe supports fully self-hosted inference via Ollama and any private OpenAI-compatible endpoint (e.g. NVIDIA NIM, LM Studio, corporate LLM gateways) — zero external API calls. On Splunk Cloud, the **Splunk Hosted (SLIM API)** provider keeps processing inside the Splunk platform. See *Configuring AI Provider accounts*.
Is our data used to train models?	TrackMe sends requests to **API endpoints** using **your own API keys**, under the data-use terms of your agreement with the provider. Major providers (OpenAI, Anthropic, Azure OpenAI, Google, Mistral) contractually do not train on API traffic by default. TrackMe itself never stores or reuses your prompts for any training purpose. See *Provider choice, data residency and model training*.
Are raw Splunk events sent to the LLM?	**No, with one narrow, documented exception.** AI context is built from TrackMe's own monitoring metadata and telemetry (entity state, thresholds, metric histories, audit records). The only feature that can expose event samples is the FQM Advisor's sampled-failure inspection, scoped to field-quality diagnosis. See *What is sent to the LLM — and what is not*.
Are credentials or secrets ever sent to the LLM?	**No.** API keys, Splunk credentials, session tokens and stored passwords are never part of any prompt or context payload. Provider API keys are stored encrypted in Splunk's `storage_passwords` and are write-only once saved.
Can the LLM run arbitrary searches in our environment?	**No.** The LLM never generates raw SPL for execution. All data access goes through a fixed registry of typed tools whose SPL and REST calls are pre-built and parameter-validated by TrackMe. See *The complete tool inventory*.
Can the AI change things without a human?	**Not unless you explicitly opt in.** Interactive advisor/Concierge writes always require an explicit user consent click (executed under the user's own credentials and RBAC). Unattended advisor automation is **disabled by default**, per-tenant, and protected by additional guards (e.g. the agent can never decommission an entity or disable a model unless you enable a dedicated flag). **AI Routines** — user-authored scheduled tasks — are notify-only unless the author selects *act* mode and grants explicit capability-scoped permissions under a **hash-pinned consent** captured at creation; editing the intent or the grants invalidates the consent and the routine cannot act again until re-affirmed. See *AI Routines: user-authored automation, explicitly consented*.
Is AI activity audited?	**Yes, comprehensively.** Every chat, every advisor run, and every individual tool call is indexed to your Splunk environment with user, provider, model, token usage, duration and outcome. Every write is additionally stamped in the per-entity audit trail with an `[AI Agent] <reason>` justification. See *Auditing AI activity*.
Can we restrict who uses AI?	**Yes.** AI endpoints are gated by TrackMe's standard role model (read / power / admin capabilities, per-tenant role scoping), enforced at the REST boundary. See *Access control (RBAC)*.
Who controls retention of AI audit data?	**You do.** AI audit events are indexed to your tenant summary index and follow your Splunk index retention policies; no AI data is retained outside your Splunk deployment by TrackMe.

Architecture and data flow

Where the AI runs

TrackMe's AI layer runs **entirely inside your Splunk deployment**:

1. A user (or a scheduled automation you enabled) triggers an AI interaction in TrackMe.
2. The TrackMe backend, running on your **search head**, builds the request: a system prompt, the relevant monitoring context, and — for agentic features — the typed tool registry.
3. The search head makes a **direct HTTPS call** to the AI provider endpoint configured in *Configuring AI Provider accounts*, authenticated with **your** API key (or no key at all for self-hosted Ollama and Splunk Hosted).
4. The response is rendered to the user, and the interaction is **audited** to your tenant summary index.

There is **no third-party relay**: the only parties in the data path are your Splunk platform and the AI provider **you** selected. If you select a self-hosted provider, no data leaves your network at all.

Note

TrackMe Limited never receives your data. The vendor operates no AI backend, collects no AI telemetry, and has no technical ability to observe your prompts, your monitoring data, or the provider responses. The AI provider relationship — endpoint, credentials, region, data-use terms — is entirely between your organisation and the provider you configure.

Agentic execution model

The conversational **AI Assistant** is a single-call interface: TrackMe builds a context payload (see below), sends one request, and renders the answer. The assistant **executes no tools and performs no writes** — when an action would help, it can only *propose* one via a consent card that the user must explicitly approve.

The **AI Advisors** and the **AI Concierge** are agentic: they run a bounded reasoning loop (built on the Splunk Agent SDK, `splunklib.ai`) in which the LLM may call tools from a **fixed, tag-filtered registry**. The tools — not the LLM — perform all data access, through TrackMe's own REST API and pre-built searches, under Splunk authentication. Every tool invocation is individually audited.

The **AI Routines** are agentic on the same SDK and tool registry, but are **user-authored and scheduled** rather than product-defined: an operator describes a monitoring task in plain English and TrackMe runs it on a cron schedule. They are the one surface where a write can occur **on a schedule without a per-action click** — so their governance is described in full below.

AI Routines: user-authored automation, explicitly consented

AI Routines let an operator schedule a natural-language task that watches a condition and then **notifies or acts**. Because a routine can act autonomously on its schedule, it is governed by a distinct, stricter consent model than the interactive advisors:

- **Notify by default, act only on opt-in.** A routine in **notify** mode has **no write tools** — it can only deliver a message. Writing requires the author to switch it to **act** mode and grant specific permissions; a notify routine can never change configuration.
- **Capability-scoped permission families.** Act permissions are granted as **16 capability-oriented families** (e.g. entity thresholds, priority, labels/notes, ML models, alert actions). Ticking a family exposes **exactly** its tools at fire time and nothing more — there are no implied grants.
- **Hash-pinned, perishable consent.** At creation the author affirms an explicit consent that is **cryptographically pinned** to the verbatim intent, the exact set of granted families, and — where applicable — the exact alert-action contract and the external-MCP tool-name list. **Any edit to those invalidates the consent**, and the routine cannot act again until the author re-affirms. The consent is checked on every fire.

- **Deterministic, non-LLM delivery.** Recipients (email) and event targets (index/sourcetype) are configuration, never model output — the LLM authors the *content*, never the *audience*. Alerts and SPL built on routine events cannot be redirected by a model phrasing something differently.
- **Off-box side effects are gated.** Two families reach outside TrackMe's own KV Store — *trigger Splunk alert actions* (open incidents / notify ITSM, Slack, PagerDuty) and *execute external MCP tools* (the Splunk MCP Server). Both are act-only, part of the pinned consent, and enforced at the Splunk boundary: the MCP token is minted for the routine's **owner** under Splunk RBAC, exposing only the explicitly allow-listed tool names.
- **Identities and tenant scope are never model-authored.** A routine runs as a resolved **owner** (the tenant's service account, or the creator) recorded on every event; the tenant it may touch is fixed from the routine's own scope, not the LLM — a tool call targeting any other tenant is refused before it executes.
- **Who may create routines is policy-controlled.** A deployment-wide creator-roles setting restricts routine creation to administrators, or to administrators and power users; global (cross-tenant) routines always require an administrator. The whole feature has its own kill switch (`enable_ai_routines`) and is inert until the AI layer is enabled and a provider configured.

Every routine fire — reads, writes and the fire/no-fire decision — is audited exactly like an advisor run (see *Auditing AI activity*), with act-mode writes additionally stamped `[AI Agent] <reason>` in the per-entity trail.

What is sent to the LLM — and what is not

Data sent, per feature

All AI context is built server-side by TrackMe from its own collections and summary telemetry. The table below describes the **maximum** content each feature can include in a request to the LLM:

Feature	Data included in LLM requests
AI Assistant (chat)	The TrackMe system prompt for the current page context; the user's typed message and the conversation history of the current chat; and a structured context payload built from TrackMe's *describe* endpoints — entity identity and configuration (names, identifiers, state, thresholds, schedules), monitoring telemetry (lag/latency/volume KPIs, outlier scores), active alerts and Guardian configuration findings, tenant/component summaries, and license state on the relevant pages. Context is rebuilt fresh on every request.
AI status reports (stateful alert emails)	The same class of entity context as the AI Assistant, for the alerting entity, used to generate the short AI investigation summary embedded in the alert email.
AI Advisors (ML, Feed Lifecycle, FLX Threshold, FQM, Component Health)	Entity configuration and state; metric and quality **histories** (e.g. 7–30 day delay, latency, outlier-score or quality-percentage series, aggregated via `mstats`/summary searches); peer-entity threshold comparisons; ML model training metadata (distributions, boundaries, confidence); per-entity audit/state-transition history; and the optional free-text instruction the operator provides when launching the run.
AI Concierge	The TrackMe REST API **catalog metadata** (endpoint paths, schemas, descriptions, danger levels — product documentation, not customer data); the user's request; and the responses of read-only catalog-validated endpoint calls the agent performs to verify state.
AI Agents automation (scheduled)	The same per-entity context as the corresponding advisor, for the entities selected by your per-tenant scope filters (priority filter and optional filter expression).
AI Agents for findings (UAM, Cribl Stream, Cribl Edge)	The evidence TrackMe computes for the finding under review: the finding, its episodes and history, the policy, and the object it names — for UAM the account (its name, class and open findings) and bounded activity records, for Cribl Stream the inventory, traffic and traffic-model facts of the object, for Cribl Edge the node or Fleet as the node directory published it. Every run adds the agent's own custom instructions (written by the tenant administrators); interactive runs add the operator's optional instructions; scheduled runs add the tenant's shared custom instructions. See *AI Agents for findings*.
AI Routines	The operator's plain-English intent and its compiled instruction; a slimmed per-tenant entity summary (state, priority, recency of state changes) for the routine's scope; the trigger-match rows for hybrid/deterministic routines; and the routine's own **memory** — compact fingerprints of its recent runs and, for entity-level intents, the exact entity names it acted on last (see *AI Routines*). No credentials, no user directory data, no raw indexed events. Anonymisation toggles apply to routine context as they do elsewhere.

What is never sent

The following are structurally excluded from every AI request:

- **Raw indexed events** from your Splunk indexes — with the two exceptions documented below. TrackMe's AI reasons over monitoring metadata and aggregated telemetry, not over your log data.
- **Credentials and secrets** — Splunk passwords, session keys, API keys (including the AI provider keys themselves), and tokens are never included in prompts, context payloads, or tool results.
- **User directory data** — usernames and email addresses of your Splunk users are not part of context payloads (the *operator's* identity is recorded in the local audit trail, but not sent to the LLM). The exception is the account a User Activity Monitoring finding is about, documented below; email addresses are never sent.
- **Data from other configured providers** — provider accounts are isolated; no data is ever shared between providers.

Important

The FQM exception — the *AI FQM Advisor* includes a `get_fqm_sampled_failures` tool that lets the agent inspect **samples of failing events** already collected by the FQM collect job, strictly to diagnose field-quality

issues (e.g. test a regex against real values). If your FQM-monitored sourcetypes contain sensitive payloads and your policy prohibits sending event samples to your chosen provider, either run the FQM Advisor against a self-hosted provider, or do not enable the FQM Advisor. All other advisors and the assistant operate on metadata and aggregated telemetry only.

Important

The User Activity Monitoring exception — the subject of a User Activity Monitoring finding is a Splunk account, so the *UAM AI Agent* sees account names, their class, their roles and bounded records of their activity (at most 50 per read). It sees the text of a search only when it asks for it, and only for searches collected while the tenant's *Store SPL search* setting was on (off by default). The name anonymisation options do not apply to the findings AI Agents. If your policy prohibits sending account names to your provider, use a self-hosted provider or do not use the UAM AI Agent.

Anonymisation options

For organisations whose *infrastructure metadata itself* is sensitive (hostnames, IPs, index names), TrackMe provides global anonymisation toggles (**Configuration > General > Artificial Intelligence**, see *Configuring AI Provider accounts*):

Setting	Effect
Anonymize entity names for AI	Entity names (object and alias fields) are replaced by SHA256 hashes in every payload sent to the AI provider. The AI is guided to reason on opaque `object_id` references instead; when an action is approved, the real identifiers are resolved locally by TrackMe — the LLM never constructs primary keys.
Anonymize index names for AI	Splunk index names are replaced by SHA256 hashes in entity information, investigation searches and metric details sent to the provider.

Both options trade some answer readability for confidentiality and can be combined with a self-hosted provider for defence in depth.

Provider choice, data residency and model training

You decide where data is processed

TrackMe is **provider-agnostic** — the same AI code runs against every supported backend, so the choice of jurisdiction, deployment model and data-use terms stays with you:

Requirement	Option
Air-gapped / fully on-premises	Ollama (self-hosted open-source models) or any internal OpenAI-compatible endpoint (NVIDIA NIM, LM Studio, corporate gateways). Zero external calls.
Keep data inside the Splunk platform (Splunk Cloud)	**Splunk Hosted (SLIM API)** — models operated by Splunk within the Splunk Cloud platform; no external API key, short-lived platform tokens, no third-party egress.
Specific geography / sovereign cloud	**Azure OpenAI** deployed in your chosen region, or region-pinned deployments from other providers via the Custom provider type.
Managed frontier models	OpenAI, Anthropic (Claude), Google Gemini, Mistral AI, xAI (Grok) — via their public API endpoints with your own account.

See *Configuring AI Provider accounts* for the full configuration reference of each provider type.

Model training and provider-side retention

Three facts frame the training question:

1. **TrackMe never trains on, stores, or reuses your AI traffic.** Prompts and responses transit the search head and are rendered to the user; what TrackMe persists is the audit metadata and the structured advisor results, in **your** Splunk indexes.
2. **All cloud providers are consumed through their API tier**, authenticated with **your** organisation's API key. The applicable data-use and retention terms are those of *your* agreement with the provider — not consumer-product terms. As of this writing, the major supported providers (OpenAI, Azure OpenAI, Anthropic, Google, Mistral) state that API/business traffic is **not used to train their models by default**, and several offer zero-data-retention or regional-processing agreements on request.
3. **Self-hosted options remove the question entirely** — with Ollama or a private endpoint, no third party ever sees the data.

Note

Provider terms evolve. For a formal assessment, verify the current data-usage commitments directly with your provider — e.g. OpenAI's *API data usage policies*, Anthropic's *commercial terms*, Microsoft's *Data, privacy, and security for Azure OpenAI*, Google's *Gemini API terms*, Mistral's *privacy policy* — and attach them to your AI risk file alongside this page.

Credential management

- AI provider API keys are entered once in **Artificial Intelligence > Manage AI Provider accounts** and stored **encrypted** in Splunk's secure credential store (`storage_passwords`). They are write-only: the UI and REST API never return a stored key.
- Decryption is performed server-side, only at the moment an LLM request is made, by TrackMe's backend under Splunk's access controls. Keys are never logged, never included in audit events, and never part of any prompt.
- Self-hosted (Ollama, custom internal endpoints) and Splunk Hosted providers require no stored API key at all.

The complete tool inventory

The compliance-critical property of TrackMe's agentic features is that the LLM can only interact with your environment through a **fixed registry of typed tools**. There is no generic "run a search" or "call an API" capability exposed to the model:

- **The LLM never writes SPL.** Every search a tool performs is pre-built by TrackMe (`mstats` on TrackMe metric indexes, bounded searches on TrackMe summary/audit indexes); the model only supplies validated, typed parameters.
- **Tool sets are mode-filtered at runtime.** In **inspect** mode, write tools are *absent from the registry* — not merely discouraged. **Act** mode adds the write tools and is gated by RBAC.
- **Every write tool requires a ``reason``** that is stamped into the per-entity audit trail as `[AI Agent] <reason>`, and every tool invocation (read or write) emits its own audit event.

The tables below enumerate every tool, per advisor.

AI Assistant (chat)

The assistant has **no tools and no write path**. It receives context built server-side and can only *propose* advisor or Concierge invocations as consent cards; nothing executes without the user's explicit click, which runs under the user's own credentials.

AI Concierge

Catalog-driven generalist with **six read tools and zero write tools by design** — mutations are proposed as action contracts and executed only by the user's consent click, through the user's own RBAC-checked credentials. Destructive actions additionally require the user to **type the action name** to confirm.

Tool	Purpose / data accessed	Access
`discover_endpoints`	Search the TrackMe REST API catalog by intent (endpoint metadata only).	Read
`list_resource_groups`	List the curated resource groups of the API catalog.	Read
`list_endpoints_in_group`	Enumerate the endpoints of one group with their schemas.	Read
`describe_endpoint`	Full self-documentation of a single endpoint (parameters, examples, danger level, RBAC).	Read
`read_via_endpoint`	Execute a **read-classified** endpoint to verify live state. Refuses any path not present in the catalog or not marked read-only.	Read
`propose_action`	Validate and record a proposed action contract — **does not execute**. The consent card click is what fires the actual REST call.	Read (proposal only)

AI ML Advisor

Scope: ML outlier model integrity. See *AI ML Advisor*.

Tool	Purpose / data accessed	Access
`get_entity_outlier_conte`	Entity description and ML model state (config, boundaries, confidence).	Read
`get_entity_metric_histor`	Metric time series from TrackMe metric indexes (`mstats`).	Read
`get_model_training_detai`	Fitted distributions, boundaries, fit-quality indicators.	Read
`get_outlier_score_histor`	Historical outlier scoring timeline.	Read
`get_entity_alert_history`	Entity state-transition / alert history from the audit trail.	Read
`get_model_render_history`	Training-window rendering with boundaries and outlier flags.	Read
`add_period_exclusion`	Exclude an anomalous window from model training. Reversible.	Write
`trigger_model_retrain`	Retrain the model (live or simulation).	Write
`set_false_positive`	Neutralise the current outlier score as a false positive.	Write
`update_model_rules`	Tune model parameters; refuses empty/no-op updates.	Write
`manage_outlier_detection`	Enable / disable / reset outlier detection. Disabling in automated mode is blocked unless the dedicated tenant flag is set.	Write (guarded)

AI Feeds Advisor (Feed Lifecycle — DSM/DHM)

Scope: data source / data host thresholds and lifecycle. See *AI Feeds Advisor*.

Tool	Purpose / data accessed	Access
get_entity_lifecycle_con	Full entity lifecycle context (config, thresholds, state, alerts).	Read
get_entity_delay_latency	30-day delay/latency history from the summary index.	Read
get_entity_alert_flip_hi	State-transition (flip) history from the audit index.	Read
get_entity_peer_comparis	Threshold comparison against peer entities of the same tenant.	Read
get_entity_variable_dela	Current variable-delay schedule, if any.	Read
get_entity_adaptive_dela	Adaptive-delay change history from the audit trail.	Read
update_entity_thresholds	Update delay / latency thresholds.	Write
update_entity_monitoring_s	Enable or disable monitoring of the entity. Disabling in automated mode is blocked unless the decommission flag is set.	Write (guarded)
update_entity_adaptive_del	Lock or unlock adaptive delay.	Write
update_entity_variable_del	Create or update a variable-delay schedule.	Write
update_entity_priority_and	Update entity priority and/or manual tags.	Write
update_entity_impact_score	Adjust per-entity impact-score weights.	Write

AI FQM Advisor

Scope: field-quality thresholds and the data dictionary. See *AI FQM Advisor*.

Tool	Purpose / data accessed	Access
get_fqm_entity_context	Full FQM entity context.	Read
get_fqm_dictionary	Data dictionary and the trackers using it.	Read
get_fqm_field_dictionary	A single field's dictionary entry.	Read
get_fqm_quality_history	Success / coverage percentage history with day-of-week breakdown.	Read
get_fqm_sampled_failures	**Sampled failing events** collected by the FQM collect job (see the FQM exception above).	Read
get_fqm_collect_job_cont	Health of the collect-job and monitor saved searches.	Read
get_fqm_peer_entity_thre	Peer FQM entities' thresholds on the same tracker.	Read
get_fqm_datamodel_contex	CIM datamodel context and diff versus expected fields.	Read
test_fqm_regex	Test a candidate regex against real sampled values.	Read
add_fqm_threshold / update_fqm_threshold / delete_fqm_threshold	Manage field-quality thresholds.	Write
update_fqm_field_dictionar / update_fqm_dictionary_bulk	Update data-dictionary validation configuration (single field or bulk).	Write
update_fqm_entity_state_pr	Update monitoring state or priority.	Write (guarded)

AI FLX Threshold Advisor

Scope: Flex Object dynamic thresholds. See *The AI Advisors*.

Tool	Purpose / data accessed	Access
`get_flx_entity_context`	Full FLX entity context.	Read
`get_flx_metric_history`	30-day metric value history (`mstats`).	Read
`get_flx_threshold_breach`	State-transition and threshold-breach history.	Read
`get_flx_use_case_definit`	The use-case definition of the entity's tracker.	Read
`get_flx_peer_entity_thre`	Peer FLX entities' thresholds on the same tracker.	Read
`add_flx_threshold` / `update_flx_threshold` / `delete_flx_threshold`	Manage dynamic thresholds.	Write
`set_flx_variable_thresho`	Configure time-slot-based variable threshold values.	Write
`update_flx_entity_state_pr`	Update monitoring state or priority.	Write (guarded)

AI Component Health Advisor (WLK / MHM)

Scope: workload (WLK) and metric-host (MHM) health. See *AI Component Health Advisor*. The tool registry is component-filtered at runtime — a WLK run only sees WLK tools, an MHM run only MHM tools.

Tool	Purpose / data accessed	Access
`get_wlk_entity_context`	Full WLK entity context.	Read
`get_wlk_execution_histor`	Execution history with day-of-week breakdown.	Read
`get_wlk_breach_history`	State-transition and threshold-breach history.	Read
`get_wlk_peer_thresholds`	Peer WLK entities in the same Splunk app.	Read
`add_wlk_threshold` / `update_wlk_threshold` / `delete_wlk_threshold`	Manage execution-metric thresholds.	Write
`update_wlk_entity_state_pr`	Update monitoring state or priority.	Write (guarded)
`get_mhm_entity_context`	Full MHM entity context.	Read
`get_mhm_metric_lag_histo`	Metric-lag history with day-of-week breakdown.	Read
`get_mhm_breach_history`	State-transition and lag-breach history.	Read
`get_mhm_lagging_classes`	Lagging-class definitions for the tenant.	Read
`update_mhm_metric_max_lag`	Update the metric-lag threshold.	Write
`update_mhm_entity_state_pr`	Update monitoring state or priority.	Write (guarded)

Shared metadata tools (all specialised advisors, act mode only)

Tool	Purpose / data accessed	Access
`manage_entity_labels`	Assign or remove labels from the tenant's curated catalog. Does not auto-create labels.	Write
`manage_entity_note`	Create or delete free-form entity notes (append-only; notes are immutable once created).	Write

AI Routines (act mode)

A routine draws from the **same fixed, typed tool registry** as the advisors — there is no routine-specific "run anything" capability. Read tools (the tenant/scope summary, a bounded read-only correlation search, inspect-only advisor dispatch, and the flip-history reader) are always available; write tools are exposed **only** for the capability families the author consented to, one coherent capability per family (the 16 families are enumerated in *AI Routines*). Two families reach off-box under the pinned consent and Splunk RBAC — *trigger Splunk alert actions* and *execute external MCP tools* — as described in *AI Routines: user-authored automation, explicitly consented*. Notify-mode routines receive **no write tools at all**.

AI Agents for findings

Each findings AI Agent has its own small registry, pinned to the tenant and the run that started it: a tool can neither reach another tenant nor decide outside its run. Write tools are absent in inspect mode. The write tool reads the finding again and the server re-checks every precondition before applying anything; the model never supplies the version fences.

Tool	Purpose / data accessed	Access
`list_uam_findings` / `list_cribl_findings`	The open findings of the tenant, one row per Finding group (at most 50), with the settings and the decisions the tenant allows.	Read
`get_uam_finding_evidence` / `get_cribl_finding_eviden`	The evidence of one finding, computed by TrackMe, and the preconditions of each decision.	Read
`get_uam_policy_evaluatio`	How a UAM policy is configured and evaluated in the tenant.	Read
`get_uam_account`	A UAM account: its class, where the class comes from, and its findings.	Read
`get_uam_activity`	Bounded activity records of an account (at most 50 events); search text only on request and only when the tenant stored it.	Read
`apply_uam_finding_decision` / `apply_cribl_finding_decisi`	Apply one decision the tenant allows, with its rationale, under the actor **AI Agent**; refused when a precondition does not hold.	Write

Guardrails and safety controls

Defence in depth, by layer:

Layer	Control
Structural	The chat assistant has no tools and no write path. Write tools are physically absent from the registry in inspect mode. The Concierge has zero static write tools. The LLM never constructs primary keys (tenant and entity identifiers come from session state, not model output) and never emits raw SPL.
Human-in-the-loop	Every interactive mutation goes through a **consent card**: the user reviews the exact proposed action (and can edit the request body for Concierge actions) before clicking. The click executes through the **user's own credentials**. Destructive Concierge actions require typed confirmation of the action name.
RBAC	Enforced at the REST boundary, not in the prompt: inspect requires TrackMe read capability, act requires power-level capability, provider administration requires admin capability — all additionally scoped by per-tenant roles. An unauthorized write returns HTTP 403 regardless of what the agent attempts. See *Access control (RBAC)*.
Automation gates	Unattended runs are **disabled by default** per tenant and per advisor family. Even when enabled, dedicated flags (both **disabled by default**) are required before an automated agent may decommission an entity (`allow_decommission`) or disable an ML model (`allow_model_disable`). Entity selection is scoped by priority filters and an optional filter expression; an unparseable expression **fails closed** (no entity processed).
Runtime budgets	Hard token, step and wall-clock budgets per run, enforced by SDK middleware plus an independent watchdog thread; per-search-head concurrency caps; per-tenant Concierge rate limits and per-proposal action caps. A misbehaving run hits a real wall, not a soft prompt.
Validation	Advisor outputs are typed (Pydantic schemas) — invalid completions are retried or rejected. Concierge action paths are validated byte-for-byte against the live REST catalog at proposal time and re-validated at execution time; write tools refuse no-op updates.
Fail-safe semantics	AI failures never block operations: a failed chat degrades to an error message, a failed AI status report is replaced by "AI investigation unavailable" while the alert email still sends, and an unavailable provider simply disables the feature with a clear message.

Access control (RBAC)

AI features inherit TrackMe's standard three-tier role model (see *Roles & access control*), enforced at every REST endpoint:

Operation	Required capability	Notes
Use the AI Assistant; launch advisors in **inspect** mode; view audit dashboards	`trackmeuseroperations`	Read-only surface. Audit views and advisor context are additionally filtered to the tenants visible to the caller.
Launch advisors in **act** mode; approve consent-card actions	`trackmepoweroperations`	Writes execute under the approving user's credentials and are tenant-scope checked.
Ask a findings AI Agent and let it act	UAM: a TrackMe administrator of the tenant; Cribl Stream: the tenant's power and admin roles	The settings of the AI Agent belong to a TrackMe administrator of the tenant. Decisions are recorded under the actor **AI Agent**, with the requesting user in the decision log.
Manage AI provider accounts and global AI settings	`trackmeadminoperations`	Provider CRUD, connectivity tests, anonymisation and feature toggles.

Per-tenant role instances (`trackme_user|power|admin_<tenant_id>`) apply on top of the global capabilities — holding a global capability is not sufficient without the per-tenant role. Scheduled automation runs under the Splunk system user within the per-tenant gates described above.

Audit and traceability

Every AI interaction leaves a queryable trace in **your** Splunk environment — see *Auditing AI activity* for the dashboards. Three layers of records are emitted:

Record	Content
Per tool call (`trackme:ai_agent:tool_ca`	One event per tool invocation: timestamp, advisor, tool name, status, duration, tenant, component, entity, mode (inspect/act), interactive vs automated, job correlation ID, result size, error details.
Per run (`trackme:ai_agent:<advisc` `trackme:ai_agent:ai_rout` `trackme:ai_assistant:cha` `trackme:ai_assistant:sta`	One terminal event per advisor run, routine fire or chat: user (or resolved owner) identity, provider and model used, token usage, steps taken, duration, status, how it was launched (UI / chat / automation), the chat session correlation ID, and — for advisors and routines — the full structured result (recommendations and actions taken).
Per finding decision (findings AI Agents)	Every decision is recorded in the finding history under the actor **AI Agent**, in the tenant's decision log (with the requesting user, the provider and whether the run was scheduled), and in the current `[AI Agent]` note of the finding. Refused decisions are recorded too.
Per entity write (per-entity audit trail)	Every write is stamped `[AI Agent] <reason>` in the affected entity's *Audit changes* panel, with the agent required to cite the field changed, the before/after values and the operational trigger.

Properties relevant to compliance review:

- **Attribution** — every event carries the operator's identity (or `automated` for scheduled runs), the tenant, the provider account and the exact model. The `chat_session_id` field lets you answer "which conversation triggered this change?" with one SPL query.
- **Chat content is not indexed** — audit events for chats record metadata and token counts, not the conversation text. Chat exchanges transit a KV Store collection only for asynchronous delivery to the browser and are automatically purged within minutes; they are never written to a Splunk index. Advisor events do persist the structured result, which is the operational record of what was recommended and done.
- **Retention is yours** — all audit events land in your tenant summary index and follow your Splunk retention policies; nothing is retained outside your deployment.
- **Cost observability** — token usage is recorded per run and aggregated in the audit dashboards, per provider and model.

Enablement controls and defaults

The complete switchboard, from most global to most granular:

Control	Default	Effect
AI provider account configured	**None**	The root opt-in. With no provider account, the entire AI layer is inert — no UI surface, no LLM call, no egress.
Enable AI assistant (global, Configuration > General)	Enabled	Master feature switch. When off, every AI endpoint returns HTTP 403 and all AI UI is hidden. Enabled by default for discoverability, but functionally inert until a provider exists.
Anonymize entity / index names for AI (global)	Off	SHA256-hash entity and/or index names in all payloads sent to providers.
Max concurrent AI chats (global)	10	Concurrency cap; excess requests are rejected with HTTP 429.
ML Advisor automation (per tenant)	**Disabled**	Opt-in scheduled runs; mode, provider, review-frequency and runtime caps per tenant.
Components Advisor automation (per tenant)	**Disabled**	Opt-in scheduled runs for Feed Lifecycle / FLX / FQM / Component Health; component list, mode and caps per tenant.
Enable AI Routines (global, Configuration > General)	Enabled	Feature switch for AI Routines specifically (on top of *Enable AI assistant*). When off, routine menus are hidden, the create / evaluate / run-now endpoints return 403, and scheduled routine execution is refused.
Who can create AI Routines (global)	Admins & power users	Restricts routine creation to administrators, or administrators and power users; global (cross-tenant) routines always require an administrator.
Routine act mode + permission families (per routine)	**Notify / none**	A routine is notify-only unless the author selects *act* and grants specific capability families, under a hash-pinned consent that any later edit invalidates.
Automation scope filters (per tenant)	`critical, high`	Priority filter plus optional filter expression restricting which entities automation may touch. Invalid expressions fail closed.
Allow decommission / allow model disable (per tenant)	**Disabled**	Without these flags, automated agents can never disable an entity or an ML model.
AI Agent scheduled triage (per UAM, Cribl Stream and Cribl Edge tenant)	**Disabled**	Opt-in hourly triage of findings; inspect mode by default. Act mode applies only the decisions allowed one by one in the tenant settings, never over an operator's decision.
Per-entity opt-out	—	Individual entities can be flagged to be skipped by automated advisor runs.
RBAC	—	Standard TrackMe roles gate every AI surface per user and per tenant (see above).

To **completely disable AI**: do not configure any provider account (or delete existing ones), and set **Enable AI assistant** to off. Both conditions are independently sufficient to stop all LLM calls.

Network egress and transport security

All LLM traffic is **outbound HTTPS from the search head(s)** to the single endpoint of each configured provider. For firewall/egress allow-listing:

Provider	Egress destination (TCP 443)
OpenAI	`api.openai.com`
Azure OpenAI	`<your-resource>.openai.azure.com` (your region)
Anthropic	`api.anthropic.com`
Google Gemini	`generativelanguage.googleapis.com`
Mistral AI	`api.mistral.ai`
xAI (Grok)	`api.x.ai`
Ollama / Custom (OpenAI-compatible)	Your own endpoint — typically internal; **no Internet egress required**.
Splunk Hosted (SLIM API)	Splunk Cloud platform-internal (auto-discovered); no customer-managed egress.

Transport properties:

- TLS certificate verification uses the system CA trust store and is **strict for all cloud providers**. For Ollama only, hostname/certificate verification is relaxed **exclusively for loopback addresses** (`127.0.0.1` / `localhost`); a remote Ollama or custom endpoint is verified strictly.
- No inbound connectivity is required by any AI feature; TrackMe never opens listening ports for AI.
- Requests are bounded by the per-provider request timeout (see *Configuring AI Provider accounts*).

Frequently asked compliance questions

Does TrackMe Limited (the vendor) see our prompts, data, or AI responses?
No. TrackMe is a Splunk app executing in your environment; there is no vendor-operated AI service, proxy, or telemetry in the data path. The only external party — if you choose a cloud provider — is that provider, under your own account and terms.

Is anything sent to an LLM before we configure a provider?
No. Without a provider account the AI layer is inert: no call, no egress, no background AI processing of any kind.

Which data crosses the boundary to the provider, in one sentence?
The system prompt, the user's question or operator instruction, and a TrackMe-built context of monitoring metadata and aggregated telemetry for the entity/tenant in scope — never credentials, never user directory data, and never raw indexed events (FQM sampled failures being the single documented, avoidable exception).

Can the AI exfiltrate data by running its own searches?
No. The LLM cannot emit SPL or arbitrary REST calls. It can only invoke the typed tools listed on this page, whose queries are pre-built, scoped to TrackMe's own collections and indexes, bounded in time range, and individually audited. The Concierge's only generic read path refuses any endpoint not present in the catalog and not classified read-only.

Can the AI delete data, entities, or tenants on its own?
No. Interactive writes require an explicit user consent click (RBAC-checked, user credentials); destructive Concierge actions additionally require typed confirmation. Automated runs are opt-in, disabled by default, and structurally prevented from decommissioning entities or disabling models unless you enable dedicated flags that are also disabled by default.

Under whose identity do AI actions run?
Interactive reads/writes execute under the launching/approving user's Splunk session and roles. Scheduled advisor automation runs under the Splunk system user, inside the per-tenant gates and filters you configured. An **AI Routine** runs as a resolved **owner** — the tenant's service account, or the routine's creator — recorded on every event. All paths are fully attributed in the audit trail.

Can an AI Routine act on its own, and how is that controlled?
Only if its author explicitly made it an *act* routine and granted specific capability families under a hash-pinned consent. A routine is notify-only by default; in act mode it may apply just the consented capabilities on its schedule, with no per-fire click — but any edit to the intent or the grants invalidates the consent and stops it acting until re-affirmed, delivery targets are fixed configuration (not model output), the tenant it can touch is

fixed from its scope, and every fire (including each write, stamped `[AI Agent] <reason>`) is audited. The whole feature has a global kill switch and a policy for who may create routines. See *AI Routines: user-authored automation, explicitly consented*.

Is the conversation history stored?
Chat conversations are ephemeral. Message exchanges pass through a KV Store collection solely for asynchronous delivery and are automatically purged within minutes; chat bodies are never indexed. Audit events record metadata only (user, model, tokens, duration, status). Advisor runs persist their structured results as the operational record.

How would we investigate an AI-made change six months later?
The per-entity *Audit changes* panel shows the `[AI Agent] <reason>` entry; the summary index holds the per-run and per-tool events with the user, provider, model, and `chat_session_id` correlation back to the conversation that proposed it — all queryable in plain SPL, retained per your index policies.

Can we run a different provider per sensitivity tier?
Yes. Multiple provider accounts can coexist (e.g. self-hosted Ollama for sensitive tenants, a cloud provider elsewhere), and the provider is selected per chat / per advisor run. No data is shared between providers.

Does using TrackMe AI change our Splunk data's exposure to Splunk (the company)?
No, with one explicit exception you control: selecting the **Splunk Hosted (SLIM API)** provider on Splunk Cloud sends AI requests to models operated by Splunk inside the Splunk Cloud platform. All other providers bypass Splunk entirely; self-hosted providers bypass everyone.

What should our DPIA / AI risk assessment reference?
This page (data flows, tool inventory, controls), *Configuring AI Provider accounts* (provider terms, residency), *Auditing AI activity* (evidence and monitoring), your chosen provider's API data-use terms, and your Splunk index retention configuration for the audit trail.

3.7.3 EU AI Act compliance

Overview

This page describes how TrackMe's AI capabilities position against **Regulation (EU) 2024/1689 — the EU Artificial Intelligence Act** ("AI Act"). It is written for compliance, risk and legal teams that need to answer one question quickly — *"can we use TrackMe's AI features in the EU, and what does the AI Act require from us if we do?"* — and for TrackMe administrators who want to understand what the product already does for them.

It complements *AI Compliance, Privacy and Data Governance* (privacy, data flows, tool inventory, guardrails) and *Auditing AI activity* (audit trail): those pages describe *how the product behaves*; this page maps that behaviour to the *AI Act's roles, risk categories and obligations*.

Note

This page reflects TrackMe Limited's good-faith self-assessment of the product as implemented, and is provided for information only — it is **not legal advice**. The AI Act's application always depends on *your* deployment context and use; organisations subject to the Act should perform their own assessment with qualified counsel.

Important

The short version — TrackMe Limited assesses TrackMe's AI layer, for its intended purpose, as performing none of the Act's prohibited practices and as falling outside both high-risk routes (the Annex III use-case list and the Annex I product-safety route). The operative obligations are therefore the **Article 50 transparency** duties — a formal AI Act category of its own, not an exemption: users must know when they interact with AI, and AI-generated content must be identifiable as such, by machines as well as humans. TrackMe implements both: every AI surface is explicitly labelled, and artefacts embedding LLM-generated content carry a **machine-readable marking** (see *Article 50 transparency — how TrackMe complies*).

Roles under the AI Act

The AI Act assigns obligations by **role**. A TrackMe deployment involves three:

AI Act role	Who	What it means
GPAI model provider	The entity that developed the model you configure and placed it on the market under its own name — OpenAI, Anthropic, Microsoft (Azure OpenAI), Google, Mistral, Splunk, or the upstream developer of a self-hosted model served via Ollama or a private OpenAI-compatible endpoint	The general-purpose AI model obligations of the Act (Articles 53/55 — model documentation, copyright policy, systemic-risk measures) sit with the **model provider**, not with TrackMe and not with you as a TrackMe user. Simply configuring — or self-hosting — a model does **not** make your organisation the model provider: you remain a deployer unless you develop or substantially modify a model, or place one on the market under your own name or trademark. Your agreement with the provider governs data use; see *AI Compliance, Privacy and Data Governance*.
AI system provider	**TrackMe Limited**	TrackMe integrates general-purpose models into an AI system with a defined intended purpose (Splunk data-monitoring assistance) and places it on the market. TrackMe Limited therefore treats itself as the *provider* of that AI system and owns the system-level transparency design described on this page.
Deployer	**Your organisation**, when you enable the AI layer	Deployers use an AI system under their own authority. Your obligations are limited in TrackMe's risk category — see *What you should do as a deployer* below.

Risk classification

The AI Act is risk-tiered. TrackMe's AI capabilities assess as follows:

AI Act category	Applies?	Rationale
Prohibited practices (Article 5)	**No**	TrackMe's AI performs none of the banned practices: no manipulation or exploitation of persons, no social scoring, no biometric identification or categorisation, no emotion recognition. Its intended purpose is Splunk data-monitoring assistance; the exact data exchanged with the LLM per feature — including user-typed chat messages and, for FQM, sampled event excerpts — is documented feature-by-feature in *AI Compliance, Privacy and Data Governance*.
High-risk systems (Article 6 — Annex I and Annex III routes)	**No**	Neither of the Act's two high-risk routes applies. **Annex I route (Article 6(1))**: TrackMe is not a product — nor a safety component of a product — covered by the Annex I Union product-safety legislation (machinery, medical devices, vehicles, etc.). **Annex III route (Article 6(2))**: IT observability is not an Annex III domain. The closest category — AI used as a *safety component in the management and operation of critical digital infrastructure* — does not apply: TrackMe **observes and alerts**, it does not operate or control infrastructure, and the AI layer is an *advisory* surface on top of TrackMe's deterministic monitoring engine (detection, scoring and alerting are conventional code and remain fully functional with AI disabled). AI write actions target TrackMe's own monitoring configuration and are RBAC-checked, consented and audited; AI Routines can additionally trigger operator-configured Splunk alert actions and external MCP tools — each individually and explicitly consented at routine creation — see *AI Compliance, Privacy and Data Governance*.
Transparency-risk systems (Article 50)	**Yes**	TrackMe's AI Assistant interacts directly with users, and several features generate synthetic text (status reports, advisor summaries, routine notifications). The Article 50 transparency obligations are the operative requirements — fully addressed below.
General-purpose AI models (Chapter V)	**Not TrackMe**	TrackMe does not provide, train, or fine-tune any model. Model-level obligations rest with the model provider you select.

Article 50 transparency — how TrackMe complies

Article 50 (applicable since **2 August 2026**) contains the two obligations relevant to TrackMe.

Disclosure of AI interaction — Article 50(1)

Persons interacting with an AI system must be informed they are interacting with AI, unless obvious from context. In TrackMe:

- Every conversational surface is explicitly and persistently branded **AI Assistant**; assistant messages are labelled as such in the chat transcript.
- Every agentic surface (AI Advisors, AI Concierge, AI Routines) is presented under an explicit **AI** name, launched from clearly-labelled entry points, and — for any write action — gated by an explicit consent flow (see *AI Compliance, Privacy and Data Governance*).
- The entire AI layer is **opt-in**: nothing AI-related is shown to end users until an administrator configures a provider, so no user can encounter AI output unknowingly.
- Disclosure is effective from the **first interaction**, as Article 50(5) requires: the AI Assistant panel is branded before any message is exchanged, the labelling is persistent (not a dismissible one-time notice), and it is rendered

as clear, distinguishable text within the standard Splunk UI (theme-aware, keyboard-accessible) rather than hidden in tooltips or fine print.

Machine-readable marking of AI-generated content — Article 50(2)

Providers of AI systems generating synthetic content must ensure outputs are marked as artificially generated **in a machine-readable format**, in addition to any human-readable labelling. TrackMe applies **machine-readable marking** to artefacts that leave the product with embedded LLM content (the email surfaces below), and **provenance labelling** to AI result records stored in your Splunk indexes:

AI output surface	Marking
Stateful alert emails with an AI status report (`ai_status_report=1`)	The message carries an `X-TrackMe-AI-Generated: true` MIME header; the HTML section holding the report carries a `data-ai-generated="true"` attribute; the plain-text alternative labels the section `--- AI Status Report (AI-generated content) ---` (TrackMe 2.4.13+). Emails without an AI report carry **no** marking — the signal is meaningful precisely because it is not blanket-applied.
AI Routine notification emails	The notification body *is* the LLM-generated run summary, so every routine email carries the same `X-TrackMe-AI-Generated: true` header and `data-ai-generated="true"` HTML attribute (TrackMe 2.4.13+).
AI Routine Splunk event notifications	Routine `splunk_event` deliveries index the AI-authored `summary` / `evidence` under the dedicated `trackme:ai:routines` sourcetype (event `source` = the routine id), so these records are identifiable as AI output in plain SPL — provenance labelling, like the advisor results below. The email variant of the same notification carries the full email marking above.
Advisor / agent results indexed in Splunk	Every automated or interactive agent run is indexed with a dedicated `trackme:ai_agent:<advisor>:<mode>` sourcetype, so stored agent results are identifiable — and filterable — as AI output in plain SPL. These sourcetypes are provenance labelling of the stored result records (they double as the audit trail, see *Auditing AI activity*); the artefact-level Article 50(2) marking for content that leaves the product is the email marking above.
Interactive chat responses	Rendered exclusively inside the persistently-labelled AI Assistant panel — an Article 50(1) interaction surface where the AI origin of every response is disclosed by construction. The product does not itself embed chat output into distributable artefacts; where TrackMe embeds LLM output into an artefact that leaves the product (the email surfaces above), it applies the machine-readable marking. TrackMe tracks the Commission's transparency guidelines and the Code of Practice on marking of AI-generated content as they mature, and will extend marking mechanisms accordingly.
Deterministic notifications (Configuration Guardian, topology alerts, connectivity test emails, standard alert emails without an AI report)	**Never marked** — these contain no LLM-generated content. TrackMe deliberately excludes them so the marking remains a reliable discriminator for downstream mail rules, DLP and compliance tooling.

Note

Article 50(2) expects markings to be *effective, interoperable, robust and reliable as far as technically feasible*, reflecting the state of the art. The `X-TrackMe-AI-Generated` header and `data-ai-generated` attribute are TrackMe's **current product marking**, aligned with Article 50(2)'s direction for email artefacts; as the Commission's guidelines and the Code of Practice on marking of AI-generated content converge on common mechanisms, TrackMe will evolve its markings accordingly (the same commitment stated for the chat surface above). Deployers should not assume the proprietary header alone survives every mail transformation — see the transparency-chain guidance in *What you should do as a deployer*.

Alignment with the Act's broader principles

Beyond its formal obligations, TrackMe's AI design already implements the practices the AI Act promotes for all AI systems:

AI Act principle	TrackMe implementation
Human oversight	Read-only *inspect* mode versus consented *act* mode on every advisor; explicit per-run consent cards; per-tenant enablement flags; per-model opt-outs; a global administrator kill switch (`enable_ai_assistant`). See *AI Compliance, Privacy and Data Governance*.
Transparency of operation	Structured results with reasoning traces; live tool-call progress feeds; every tool an agent may use is publicly documented in the complete tool inventory of *AI Compliance, Privacy and Data Governance*.
Traceability / record-keeping	Every AI interaction and every agent action is recorded in the per-entity audit trail and in dedicated audit dashboards, with structured audit events in your own Splunk indexes. See *Auditing AI activity*.
Robustness	The AI layer is fail-open by design: an AI failure never blocks monitoring, alerting or email delivery. LLM output is treated as untrusted input (sanitised and escaped before rendering).
Privacy and data governance	Direct search-head-to-provider data path with no vendor intermediary, self-hosted / air-gapped options, optional anonymisation of entity and index names, no training on your data by TrackMe. See *AI Compliance, Privacy and Data Governance*.

Applicability timeline

Date	Milestone
2 February 2025	The Act's original core prohibited-practices ban (Article 5) and the AI-literacy obligation (Article 4) apply. *(No impact: TrackMe performs no prohibited practice.)*
2 August 2025	General-purpose AI model obligations apply — to model providers, not TrackMe.
27 July 2026	The "digital omnibus on AI" amendment — Regulation (EU) 2026/1744 — enters into force: it adds a new Article 5 prohibition (non-consensual intimate imagery / CSAM generation, applicable 2 December 2026) *(not relevant to TrackMe)*, defers Annex III high-risk obligations to 2 December 2027 and Annex I embedded systems to 2 August 2028 *(TrackMe is neither)*, and keeps the 2 August 2026 Article 50 application date — while adding, via the new Article 111(4), the four-month transitional period for the Article 50(2) machine-readable marking on systems already on the market (next-but-one row).
2 August 2026	**Article 50 transparency obligations apply** — the operative requirements for TrackMe, addressed as described on this page.
2 December 2026	End of the transitional grace period for the machine-readable marking obligation for AI systems placed on the market before 2 August 2026. TrackMe ships the marking from 2.4.13, ahead of this deadline.

What you should do as a deployer

For a system in TrackMe's risk category, deployer obligations are narrower than for high-risk systems, but they are real. The following covers what applies (and what is good practice):

- **AI literacy (Article 4)** — ensure staff operating TrackMe's AI features have a sufficient understanding of what the AI does and its limits. The *Artificial Intelligence in TrackMe* and *AI Compliance, Privacy and Data Governance* pages are written to support exactly this.
- **Article 50(4) disclosure triggers** — deployers must clearly disclose (i) **deep fakes** (AI-generated or manipulated image, audio or video presented as authentic) and (ii) **AI-generated or manipulated text published to inform the public on matters of public interest** (unless the text underwent human review and a person holds editorial responsibility). TrackMe produces neither: its AI output is operational monitoring text delivered to

your own teams. The obligation would only be triggered by *your* downstream use — for example, publishing an AI-generated TrackMe report verbatim as public communication — in which case disclose accordingly.

- **Keep the transparency chain intact** — if you forward or re-publish AI-generated content (e.g. pasting an AI status report into a ticket or report), preserve its AI-generated labelling. Note that preservation is **conditional on the path**: forwarding as an attachment preserves the `X-TrackMe-AI-Generated` header, but inline forwards typically re-compose the message and may drop custom headers (the in-body `data-ai-generated` attribute and the plain-text section label are more likely to survive). When a republication path strips the marking, re-apply an equivalent AI-generated label yourself.
- **Review your model provider's terms** — data-use, residency and retention are governed by your agreement with the provider you configure; see *AI Compliance, Privacy and Data Governance* for provider-specific notes and self-hosted options.
- **Use the audit surfaces** — the audit dashboards and `trackme:ai_agent:*` events give you the record-keeping evidence an AI governance programme typically asks for; see *Auditing AI activity*.
- **Run your own assessment** — if your organisation uses TrackMe in an unusual context (for example, as part of a system that *does* fall under Annex III), assess that composed system yourself; TrackMe's classification above covers the product as shipped.

Version applicability

The Article 50(2) machine-readable email marking ships in the companion **TrackMe 2.4.13** application release; it will appear in the Version 2.4.13 entry of the *release notes* when that release is published. All other mechanisms referenced on this page (labelled AI surfaces, consent flows, audit trail, indexed `trackme:ai_agent:*` and `trackme:ai:routines` events, kill switch, anonymisation) are available from TrackMe 2.4.x as described in *AI Compliance, Privacy and Data Governance*.

CHAPTER

FOUR

LICENSE & SUPPORT:

4.1 EULA License

Download the EULA License as a text file

4.1.1 TrackMe Limited (TrackMe) EULA

End-User License Agreement ("Agreement")

Our EULA was last updated on 10 February 2025.

We provide the Application, also known as TrackMe. In this Agreement, you means the person or entity using the Application. If you are agreeing to this Agreement not as an individual but on behalf of your company, government, or other entity for which you are acting (for example, as an employee or governmental official), then you means your entity and you are binding your entity to this Agreement.

Please read this End-User License Agreement carefully before clicking the "I Agree" button, downloading or using TrackMe, Data Tracking system for Splunk.

Interpretation and Definitions

Interpretation

The words of which the initial letter is capitalized have meanings defined under the following conditions. The following definitions shall have the same meaning regardless of whether they appear in singular or in plural.

Definitions

For the purposes of this End-User License Agreement:

- "Agreement" means this End-User License Agreement that forms the entire agreement between you and the Company regarding the use of the Application.
- "Application" means the software program provided by the Company downloaded by You through an Application Store's account to a device, named TrackMe, Data Tracking system for Splunk.
- "Application Store" or "Splunk Base" means the digital distribution service operated and developed by Splunk Inc. ("Splunk") by which the Application can be downloaded to your Splunk Enterprise or Splunk Cloud environment.
- "Company" (referred to as either "the Company", "We", "Us" or "Our" in this Agreement) refers to TrackMe Limited, U.K.
- "Consequential Loss" includes any consequential loss, indirect loss, real or anticipated loss of profit, loss of benefit, loss of revenue, loss of business, loss of goodwill, loss of opportunity, loss of savings, loss of reputation, loss of use and/or loss or corruption of data, whether under statute, contract, equity, tort (including negligence), indemnity or otherwise.
- "Content" refers to content such as text, images, or other information that can be posted, uploaded, linked to or otherwise made available by You, regardless of the form of that content.
- "Country" refers to: United Kingdom.

- "Third-Party Services" means any services or content (including data, information, applications and other products services) provided by a third-party that may be displayed, included or made available by the Application.

Acknowledgment

By clicking on "Agree to Download" button in SplunkBase Website, or downloading or using the Application, you are agreeing to be bound by the terms and conditions of this Agreement. If you do not agree to the terms of this Agreement, do not click on the "Agree to Download" button in SplunkBase Website, do not download or do not use the Application.

You must be at least 16 years old to use the Application.

This Agreement is a legal document between you and the Company and it governs your use of the Application made available to you by the Company.

This Agreement is between you and the Company only and not with the Application Store. Therefore, the Company is solely responsible for the Application and its content.

The Application is licensed, not sold, to you by the Company for use strictly in accordance with the terms of this Agreement.

We may amend this Agreement at any time, by providing written notice to you, unless otherwise stated in this Agreement. By clicking "I accept" or continuing to use the Application after the notice or 30 days after notification (whichever date is earlier), you agree to the amended Agreement. If you do not agree to the amendment, you may cease accessing the Application.

License

Scope of License

Subject to your compliance with this Agreement, the Company grants you a revocable, non-exclusive, non-transferable, royalty free, limited license to download, install and use the Application strictly in accordance with the terms of this Agreement. All other uses are prohibited without our prior written consent.

You may only use the Application on a device that you own or control and as permitted by the Application Store's terms and conditions.

License Restrictions

When using the Application, you agree not to, and you will not permit others to:

- do or attempt to do anything that is unlawful or inappropriate;
- anything that would constitute a breach of an individual's privacy (including uploading private or personal information without an individual's consent) or any other legal rights;
- use the Application to defame, harass, threaten, menace or offend any person, including using the Application to send unsolicited electronic messages;
- tamper with or modifying the Application (including by transmitting viruses and using trojan horses);
- use data mining, robots, screen scraping or similar data gathering and extraction tools on the Application;
- License, sell, rent, lease, assign, distribute, transmit, host, outsource, disclose or otherwise commercially exploit the Application or make the Application available to any third party; or
- Remove, alter or obscure any proprietary notice (including any notice of copyright or trademark) of the Company or its affiliates, partners, suppliers or the licensors of the Application.

Intellectual Property

The Application, including without limitation all copyrights, patents, trademarks, trade secrets and other intellectual property rights (**Our Intellectual Property**) are, and shall remain, the sole and exclusive property of the Company.

We authorise you to use Our Intellectual Property solely for your limited commercial use. You must not exploit Our Intellectual Property for any other purpose, nor allow, aid or facilitate such use by any third party.

You must not, without our prior written consent:

- *(a)* copy, in whole or in part, any of Our Intellectual Property;

- *(b)* reproduce, retransmit, distribute, disseminate, sell, publish, broadcast or circulate any of Our Intellectual Property to any third party; or
- *(c)* breach any intellectual property rights connected with the Application, including (without limitation) altering or modifying any of Our Intellectual Property, causing any of Our Intellectual Property to be framed or embedded in another website, or creating derivative works from any of Our Intellectual Property.

Modifications to the Application

The Company reserves the right to modify, suspend or discontinue, temporarily or permanently, the Application or any service to which it connects, with notice and without liability to you.

Updates to the Application

The Company may from time to time provide enhancements or improvements to the features/functionality of the Application, which may include patches, bug fixes, updates, upgrades and other modifications.

Updates may modify or delete certain features and/or functionalities of the Application. You agree that the Company has no obligation to (i) continue to provide or enable any particular features and/or functionalities of the Application to you.

You further agree that all updates or any other modifications will be (i) deemed to constitute an integral part of the Application, and (ii) subject to the terms and conditions of this Agreement.

Maintenance and Support

The Company provides maintenance and support for licensed customers, customers using the Foundation Edition trial are not entitled to any maintenance or support. To the extent that any maintenance or support is required by applicable law, the Company shall be obligated to furnish any such maintenance or support.

Third-Party Services

The Application may display, include or make available third-party content (including data, information, applications and other products services) or provide links to third-party websites or services.

You acknowledge and agree that the Company shall not be responsible for any Third-party Services. To the maximum extent permitted by law, we shall have no liability for any Third-Party Services, or any unavailability of the Application due to a failure of the Third-Party Services.

Our solution use a number of third party components, which are documented at the following address: https://docs.trackme-solutions.com/latest/third_party_credits.html

By using our product, you also agree to the terms and conditions of these third party components.

Indemnification

Neither party may benefit from the limitations and exclusions set out in this clause in respect of any liability arising from its deliberate default.

The restrictions on liability in this Indemnification clause apply to every liability arising under or in connection with this Agreement including liability in statute, contract, equity, tort (including negligence), misrepresentation, restitution, indemnity or otherwise.

Nothing in this Agreement limits any liability which cannot legally be limited, including liability for:

- *(a)* death or personal injury caused by negligence;
- *(b)* fraud or fraudulent misrepresentation;
- *(c)* breach of the terms implied by section 2 of the Supply of Goods and Services Act 1982 (title and quiet possession); and
- *(d)* defective products under the Consumer Protection Act 1987.

To the maximum extent permitted by law:

- *(a)* you agree to indemnify us for any liability we incur due to your breach of the Acknowledgement and/or Licence clauses and the Intellectual Property clause of this Agreement;
- *(b)* neither party will be liable for Consequential Loss;

- *(c)* each party's liability for any liability under this Agreement will be reduced proportionately to the extent the relevant liability was caused or contributed to by the acts or omissions of the other party or any of that party's personnel, including any failure by that Party to mitigate its losses; and
- *(d)* our aggregate liability for any liability arising from or in connection with this Agreement will be limited to us resupplying the Application to you.

No Warranties

2.1 You represent, warrant and agree that:

- *(a)* you will not use our Application, including Our Intellectual Property, in any way that competes with our business;
- *(b)* if you are agreeing to this Agreement not as an individual but on behalf of your company, government, or other entity for which you are acting (for example, as an employee or governmental official), then you access and use the Application on behalf of that entity;
- *(c)* there are no legal restrictions preventing you from entering into this Agreement;
- *(d)* all information and documentation that you provide to us in connection with this Agreement is true, correct and complete; and
- *(e)* you have not relied on any representations or warranties made by us in relation to the Application (including as to whether the Application is or will be fit or suitable for your particular purposes), unless expressly stipulated in this Agreement.

Severability

If any provision of this Agreement is held to be unenforceable or invalid, such provision will be changed and interpreted to accomplish the objectives of such provision to the greatest extent possible under applicable law and the remaining provisions will continue in full force and effect.

Waiver

Except as provided herein, the failure to exercise a right or to require performance of an obligation under this Agreement shall not affect a party's ability to exercise such right or require such performance at any time thereafter nor shall the waiver of a breach constitute a waiver of any subsequent breach.

Access, Term and Termination

This Agreement shall remain in effect until terminated by you or the Company. The Company may, in its sole discretion, at any time and for any or no reason, suspend or terminate this Agreement with or without prior notice.

We may revoke access to the Application at any time by giving 30 days' written notice to you.

Should we suspect that you are in breach of this Agreement, we may suspend your access to the Application while we investigate the suspected breach. Should we determine that you are in breach of this Agreement, your access to the Application will be terminated immediately.

You may also terminate this Agreement by deleting the Application and all copies thereof from your device or from your computer.

Upon termination of this Agreement, you shall cease all use of the Application and delete all copies of the Application from your device.

Termination of this Agreement will not limit any of the Company's rights or remedies at law or in equity in case of breach by you (during the term of this Agreement) of any of your obligations under the present Agreement

Termination and Exit Strategy

TrackMe Limited provides customers with clear termination rights and an exit strategy to ensure a seamless transition in case of service discontinuation.

Termination Rights:

- Customers may terminate their agreement with TrackMe by providing a written notice of 30 days, to be sent by email to contact@trackme-solutions.com.

- TrackMe reserves the right to terminate the agreement if the customer breaches its terms, fails to comply with applicable regulations, or engages in unauthorized use of the services.

Exit Strategy and Data Retrieval:

- Upon termination, customers will have 30 days to download or request a copy of their data before deletion.
- TrackMe will provide reasonable assistance in transitioning data to another service provider if requested.
- After the grace period, all customer data will be securely deleted, except where legal or regulatory retention requirements apply.

These provisions ensure that customers maintain control over their data and can transition away from TrackMe services with minimal disruption.

Cooperation with Regulatory Authorities

TrackMe Limited is committed to compliance with applicable regulatory frameworks, including the Digital Operational Resilience Act (DORA). As part of this commitment, TrackMe agrees to:

- **Regulatory Requests**: Cooperate with financial regulators, supervisory authorities, and other relevant bodies by providing necessary information related to operational resilience, security, and risk management.
- **Inspections and Assessments**: Allow authorized regulators to conduct inspections and assessments of TrackMe's systems and processes related to ICT risk management.
- **Incident Reporting Assistance**: Provide timely support to financial entities in fulfilling their regulatory obligations, including the reporting of ICT-related incidents.
- **Compliance Documentation**: Maintain detailed records of security, performance, and business continuity measures, making them available to regulators upon request.

These commitments ensure transparency and regulatory compliance while upholding the security and confidentiality of TrackMe's services.

Incident Reporting and Notification

TrackMe Limited prioritizes transparency and accountability in managing ICT-related incidents. In accordance with regulatory requirements, including the Digital Operational Resilience Act (DORA), TrackMe follows a structured incident reporting framework.

Incident Notification Commitments:

- **Significant Incidents**: TrackMe will notify affected customers within 24 hours of detecting a security breach, data compromise, or major service disruption.
- **Regulatory Assistance**: TrackMe will provide customers with relevant details needed to fulfill their regulatory incident reporting obligations.
- **Communication Channels**: Incident notifications will be sent via TrackMe's support helpdesk.
- **Remediation Updates**: TrackMe will provide ongoing updates about mitigation efforts and expected resolution timelines for critical incidents.

TrackMe ensures that all incidents are logged, investigated, and remediated promptly, with continuous improvement to prevent recurrence.

Information Security and Compliance

TrackMe Limited is committed to maintaining high security standards to protect customer data and ensure operational resilience. TrackMe adheres to industry-recognized security frameworks and best practices, including:

- **ISO 27001 Compliance**: TrackMe follows the principles of ISO 27001 for information security management.
- **SOC 2 Controls**: TrackMe implements security, availability, and confidentiality controls aligned with SOC 2 standards.
- **Regular Security Audits**: TrackMe conducts periodic internal and external security audits to validate compliance with regulatory and security requirements.

- **Secure Development Practices**: TrackMe employs secure coding practices, vulnerability testing, and continuous monitoring to safeguard its applications.
- **Customer Assurance**: Upon request, TrackMe can provide security documentation detailing compliance measures and risk management processes.

By adhering to these standards, TrackMe ensures the security, integrity, and confidentiality of its services, in compliance with DORA and other applicable regulations.

Access and Audit Rights

TrackMe Limited acknowledges the importance of regulatory compliance and operational resilience. To ensure adherence to applicable financial regulations, including the Digital Operational Resilience Act (DORA), TrackMe grants authorized financial entities and regulatory authorities the right to conduct audits and assessments of TrackMe's services related to operational resilience, cybersecurity, and incident response.

Such audits shall be conducted with reasonable notice and during normal business hours. TrackMe shall provide all necessary documentation, access to relevant systems, and support to facilitate these audits, ensuring transparency and compliance with applicable laws.

Financial entities using TrackMe's services may also conduct internal assessments, subject to confidentiality and security agreements.

Service Performance Standards

TrackMe Limited is committed to maintaining a high standard of service performance to support operational resilience and regulatory compliance. As part of this commitment, TrackMe ensures the following service levels:

- **Availability**: TrackMe aims to maintain an uptime of 99.5% measured on a monthly basis, excluding planned maintenance periods.
- **Response Time**: TrackMe's support team will respond to critical service issues within twenty fours (24) business hours.
- **Maintenance and Updates**: Regular maintenance and security updates will be communicated in advance, with minimal disruption to service.
- **Data Processing Performance**: TrackMe ensures that all data processing activities meet industry standards for accuracy and efficiency.

Any deviations from these service levels will be investigated and remediated promptly. TrackMe Limited will also provide customers with performance reports upon request.

Service Locations and Data Processing

TrackMe Limited operates its services in secure data centers located in the United Kingdom and EU. Customer data may be processed and stored in these locations based on applicable regulatory and compliance requirements.

- **Primary Hosting Locations**: TrackMe Limited uses cloud service providers and data centers located in [List countries or regions].
- **Data Transfers**: Any data transfers between regions comply with applicable data protection laws, including the General Data Protection Regulation (GDPR) where applicable.
- **Subcontractors**: TrackMe may engage third-party cloud providers or partners for infrastructure services. A list of such subcontractors is available upon request.
- **Customer Control**: Customers may request information on where their specific instance of TrackMe services is hosted.

TrackMe Limited ensures that all service locations meet high security and operational resilience standards.

Data Protection and Confidentiality

TrackMe Limited is committed to protecting the confidentiality, integrity, and security of customer data. All data collected, processed, and stored within TrackMe services is handled in compliance with applicable data protection laws, including but not limited to the General Data Protection Regulation (GDPR).

Key Data Protection Measures: - **Data Encryption**: Customer data is encrypted at rest and in transit using industry-standard encryption protocols. - **Access Controls**: Strict access controls ensure that only authorized personnel can access sensitive data. - **Data Minimization**: TrackMe collects and processes only the minimum necessary customer data required for service operation. - **Confidentiality Commitments**: TrackMe employees, contractors, and third-party service providers are bound by confidentiality obligations. - **Customer Rights**: Customers have the right to request information on how their data is processed and may request data deletion or correction.

TrackMe Limited continuously evaluates and improves its security measures to maintain compliance with evolving regulatory requirements.

Business Continuity and Disaster Recovery

TrackMe Limited is committed to ensuring the resilience and availability of its services, even in the event of disruptions. To maintain operational stability, TrackMe has implemented comprehensive business continuity and disaster recovery plans.

Key Resilience Measures: - **Redundant Infrastructure**: TrackMe operates on a highly available infrastructure with redundant components to minimize downtime. - **Regular Backups**: Customer data is backed up at regular intervals to prevent data loss and ensure quick recovery in case of incidents. - **Incident Response Procedures**: TrackMe maintains a structured incident response framework to detect, investigate, and mitigate potential threats. - **Disaster Recovery Plan**: A formal disaster recovery plan is in place, ensuring timely restoration of services in the event of system failures. - **Testing and Reviews**: Continuity plans and recovery strategies are regularly tested and updated to adapt to evolving risks.

In case of a major disruption, TrackMe will promptly inform customers and provide updates on recovery efforts.

Governing Law

The laws of the Country, excluding its conflicts of law rules, shall govern this Agreement and your use of the Application. Your use of the Application may also be subject to other local, state, national, or international laws.

Entire Agreement

The Agreement constitutes the entire agreement between you and the Company regarding your use of the Application and supersedes all prior and contemporaneous written or oral agreements between you and the Company.

You may be subject to additional terms and conditions that apply when you use or purchase other Company's services, which the Company will provide to you at the time of such use or purchase.

Assignment

You must not assign or deal with the whole or any part of your rights or obligations under this Agreement without our prior written consent.

Contracts (Rights of Third Parties) Act 1999

Notwithstanding any other provision of this Agreement, nothing in this Agreement confers or is intended to confer any right to enforce any of its terms on any person who is not a party to it.

Contact Us

If you have any questions about this Agreement, you can contact Us:

- By visiting this page on our website: www.trackme-solutions.com
- By sending us an email: contact@trackme-solutions.com

4.2 Terms & Conditions

`Download the Terms & Conditions as a text file`

Our Terms & Conditions were last updated on 25th of January 2026.

4.2.1 TrackMe Limited IT Software Terms and Conditions

In these terms and conditions (Terms), when we say you or your, we mean both you and, if applicable, any entity you are authorised to represent (such as your employer). When we say we, us, or our, we mean TrackMe Limited, a company registered in England and Wales with company number 13817409.

Please read these Terms carefully before using our downloadable platform ("TrackMe") for Splunk Enterprise, Splunk Cloud software or before accessing TrackMe through our direct website.

These Terms form our contract with you, and set out our obligations as a service provider and your obligations as a customer. You cannot use TrackMe unless you agree to these Terms. By using our software, you agree to be bound by these Terms.

1. License Types & Restrictions

You and Each Authorised User must be at least 16 years old to use TrackMe. If you are using TrackMe on behalf of your employer or a business entity, you, in your individual capacity, represent and warrant that you are authorised to act on behalf of your employer or the business entity and to bind the entity and the entity's personnel to these Terms.

You represent, warrant and agree that:

- *(a)* you will not use TrackMe, including Our Intellectual Property, in any way that competes with our business;
- *(b)* there are no legal restrictions preventing you from entering into these Terms;
- *(c)* all information and documentation that you provide to us in connection with these Terms is true, correct and complete; and
- *(d)* you have not relied on any representations or warranties made by us in relation to TrackMe (including as to whether TrackMe is or will be fit or suitable for your particular purposes), unless expressly stipulated in these Terms.

You must not:

- *(a)* access or use TrackMe in any way that is improper or breaches any laws, infringes any person's rights (for example, intellectual property rights and privacy rights), or gives rise to any civil or criminal liability;
- *(b)* interfere with or interrupt the supply of TrackMe, or any other person's access to or use of TrackMe;
- *(c)* introduce any viruses or other malicious software code into TrackMe;
- *(d)* use any unauthorised or modified version of TrackMe, including but not limited to for the purpose of building similar or competitive software or for the purpose of obtaining unauthorised access to TrackMe;
- *(e)* attempt to access any data or log into any server or account that you are not expressly authorised to access;
- *(f)* use TrackMe in any way that involves service bureau use, outsourcing, renting, reselling, sublicensing, concurrent use of a single user login, or time-sharing;
- *(g)* circumvent user authentication or security of any of our networks, accounts or hosts or those of any third party; or
- *(h)* access or use TrackMe to transmit, publish or communicate material that is, defamatory, offensive, abusive, indecent, menacing, harassing or unwanted.

License Types:

While you have an account with Splunk or with us (Account), we grant you a right to use TrackMe (which may be suspended or revoked in accordance with these Terms). This right cannot be passed on or transferred to any other person. The types of licences that we offer will be set out on our website or on the Splunk Enterprise or Splunk Cloud software (as applicable).

2. Support

We offer support for features and behaviors which relate directly to the usage of TrackMe for Splunk Cloud and Splunk Enterprise. Issues related to Splunk products or any other third-party applications are not covered by our support agreement. Prioritized support is included for customers with a valid TrackMe Enterprise or TrackMe Unlimited. Support is available by email. We will use reasonable endeavours to respond to all email enquiries within 24 hours.

Contacting TrackMe support:

- Customers with a valid TrackMe Enterprise or TrackMe Unlimited can contact us at support@trackme-solutions.com
- If the support case requires it, we will propose a virtual support meeting through our Zoom meeting services, or your own meeting tools depending on your preferences

Prioritized developments:

- If you have specific needs or requirements that are not covered by our product, we will prioritize developments if you are a customer under active subscription.
- The company remains the sole owner of the developments and the intellectual property of the developments made for the product.
- We also reserve the right not to implement a feature if it is not in line with our product roadmap or if it is not technically feasible, although we will always do our best to meet your requirements.

Unless we agree otherwise, the support we may agree to provide cannot be used to support any other products or services, and does not include training, installation of software or hardware, software development or the modification, deletion or recovery of data or any on-site services.

Additional Services: If you require additional services, we may, in our sole discretion, provide such additional services (to be scoped and priced in a separate contract provided by us).

Third Party Products or Services: Where you engage third parties to operate alongside our services (for example, any third-party software systems you wish to integrate with TrackMe), those third parties are independent of us and you are responsible for (meaning we will not be liable for) the goods or services they provide, unless we expressly agree otherwise.

3. License Subscription Renewal and Expiration

If you wish not to renew your TrackMe Foundation, TrackMe Enterprise or TrackMe Unlimited license, TrackMe will automatically transition to the Foundation Edition trial mode (read-only after expiry), and components out of the scope of the Foundation Edition will automatically be disabled. If you renew your subscription, your license will be extended accordingly. You are responsible for paying any levies or taxes associated with your use of TrackMe, for example sales taxes, value-added taxes or withholding taxes (unless we are required by law to collect these on your behalf.

4. Changes to TrackMe

While we strive to always make TrackMe available to you, we do not make any guarantees that it will be available 100% of the time. Our services may be disrupted during certain periods, including, for example, as a result of scheduled or emergency maintenance. Our services (including TrackMe) may interact with, or be reliant on, products or services provided by third parties, such as cloud hosting service providers. To the maximum extent permitted by law, we are not liable for disruptions or downtime caused or contributed to by these third parties. We will try to provide you with reasonable notice, where possible, of any disruptions to your access to TrackMe.

Minor changes to TrackMe: We may change TrackMe:

- *(a)* to reflect changes in relevant laws and regulatory requirements; and
- *(b)* to implement minor technical adjustments, improvements, and to keep up-to-date with technological advancements. These changes will not substantially affect your use of TrackMe.

More significant changes to TrackMe: We will try to avoid making any significant changes to TrackMe which are likely to materially disadvantage your use of TrackMe. However, where we intend to make a change to TrackMe which may materially disadvantage your use of TrackMe, we will notify you in advance of making any changes, and you may then contact us to terminate these Terms and receive a full refund for any unused services (if applicable) before the changes take effect.

5. Changes to the Terms

We reserve the right to modify, amend, or update these Terms at any time and for any reason without prior notice. Such modifications, amendments, or updates will be effective immediately upon posting on our website.

To ensure transparency and keep our customers fully informed of any changes that may affect their use of the TrackMe software for Splunk Enterprise and Splunk Cloud, we commit to sending an automated notification of any such

changes to the designated point of contact for each customer. This notification will be sent to the email address on file with us for such communications.

Customers are encouraged to periodically review the most current version of the Terms, which will always be available on our website. Continued use of the TrackMe software after any changes to the Terms signifies acceptance of those changes. It is the responsibility of the customer to update their designated point of contact and corresponding email address as necessary to ensure that notifications of changes are received in a timely manner.

If you disagree with the revised Terms, you have the right to terminate your use of the TrackMe software and we agree to refund you for any prepaid unused Fees on a pro-rata basis.

6. Payments

The license can be activated in your Splunk environment at any time, with or without online verification through Cryptolens Licensing API.

For more details and technical information about the Cryptolens API service and our registration process, please consult the following documentation: https://docs.trackme-solutions.com/latest/license_registration.html

We provide a license key which requires online verification through Cryptolens Licensing API, and a license file which allows offline registration for Splunk environments with no outside communications capabilities.

Once you have chosen the licence that you require, you agree to pay the fees set out on TrackMe (Fees) by the date specified on TrackMe to access certain features of TrackMe. You agree that the Fees will be payable in advance of you receiving access to TrackMe and your chosen licences (if licence Fees are payable). We accept payments by bank transfer once we issue a tax invoice (U.K. national and international IBAN, payments can be processed in USD, GBP AND EUR currencies).

7. Delivery

After you agree to our Terms and accept our quotation, we will issue an invoice through our billing system. Once the invoice is generated and the Fees are paid as set out above, we will provide you with the TrackMe license key and license file via our licensing services.

The TrackMe Enterprise or TrackMe Unlimited license key and license key file which allows offline registration is provided by electronic means, we will also deliver the license through our DocuSign service to electronically sign the delivery.

8. Authorised Users

You may be permitted to invite a number of users to TrackMe, who will be permitted to download and use TrackMe under your license (**Authorised Users**).

You must ensure that each Authorised User complies with these Terms and our End User Licence Agreement. You are responsible and liable for the acts or omissions of your Authorised Users.

Each Authorised User must agree to our End User Licence Agreement (as available at [insert URL]) in order to download and use TrackMe.

9. Legal Compliance and Jurisdiction

We are committed to ensuring that any information we store is secure and required for the purposes of providing our services to you.

As a Software which runs on your environment, whenever you are a Splunk Enterprise or Splunk Cloud customer, we do not store any personal data, and we do not have access to your data.

Information stored by us is restricted to the minimal required information for support and billing purposes notably the end customer name and contact details and the TrackMe Enterprise or TrackMe Unlimited license details.

10. Termination and Refund Policy

This clause defines the conditions under which subscriptions may be terminated and the applicable refund policy for TrackMe licenses purchased through our standard ordering channels.

Refund Policy (30-day window):

Customers may request a full refund within **thirty (30) days** from the date of purchase. Refund requests made within this period will be processed in full. After the 30-day refund window has elapsed, all fees paid are non-refundable.

Refunds are handled through the original payment method and processed by our authorized payment provider.

Subscription Termination by the Customer:

TrackMe subscriptions are non-renewing by default. Customers may choose not to renew their subscription without formal notice. If a customer wishes to discontinue use of TrackMe before the end of the subscription term, access will remain available until the subscription expires. Early termination does not entitle the customer to a refund beyond the defined 30-day refund window.

Termination by TrackMe:

We reserve the right to terminate or suspend a subscription in cases of material breach of these Terms, misuse of the software, or failure to comply with payment obligations. In such cases, no refund will be provided except where required by applicable law.

Subscription Expiration:

Upon subscription expiration, access to paid features will be suspended and the software may revert to a limited or free edition where applicable.

Policy Changes:

We reserve the right to update this policy from time to time. Material changes will be communicated via our website or direct notification where appropriate.

If you have any questions regarding subscription termination or refunds, please contact us at contact@trackme-solutions.com.

11. Intellectual Property

You acknowledge and agree that any Intellectual Property or content (including copyright and trademarks) available on TrackMe, TrackMe itself (including how it looks and functions), any algorithms or machine learning models used on TrackMe, as well as our copyrighted works, trademarks, inventions, designs and other intellectual property (**Our Intellectual Property**) will at all times vest, or remain vested, in us.

We authorise you to use and download Our Intellectual Property solely for your limited commercial use. You must not exploit Our Intellectual Property for any other purpose, nor allow, aid or facilitate such use by any third party. Use must be limited to Authorised Users on devices that are controlled or approved by you.

You must not, without our prior written consent:

- *(a)* copy, in whole or in part, any of Our Intellectual Property;
- *(b)* reproduce, retransmit, distribute, disseminate, sell, publish, broadcast or circulate any of Our Intellectual Property to any third party; or
- *(c)* breach any intellectual property rights connected with TrackMe, including (without limitation) altering or modifying any of Our Intellectual Property, causing any of Our Intellectual Property to be framed or embedded in another website, or creating derivative works from any of Our Intellectual Property.

This Clause 11 will survive the termination or expiry of these Terms.

12. Liability

Neither party may benefit from the limitations and exclusions set out in this clause in respect of any liability arising from its deliberate default.

The restrictions on liability in this 'Liability' clause apply to every liability arising under or in connection with these Terms including liability in statute, contract, equity, tort (including negligence), misrepresentation, restitution, indemnity or otherwise.

Nothing in these Terms limits any Liability which cannot legally be limited, including Liability for:

- *(a)* death or personal injury caused by negligence;
- *(b)* fraud or fraudulent misrepresentation; and
- *(c)* defective products under the Consumer Protection Act 1987.

To the maximum extent permitted by law, we shall have no Liability for any third party products or services, or any unavailability of TrackMe due to a failure of the third party products or services.

To the maximum extent permitted by law:

- *(a)* you agree to indemnify us for any Liability we incur due to your breach of these Terms;
- *(b)* neither party will be liable for any Consequential Loss; and
- *(c)* a party's liability for any Liability under these Terms will be reduced proportionately to the extent the relevant liability was caused or contributed to by the acts or omissions of the other party, including any failure by that other party to mitigate its loss; and
- *(d)* our aggregate liability for any Liability arising from or in connection with these Terms will be limited to us resupplying the services to you or, in our sole discretion, to us repaying you the amount of the fees paid by you to us in respect of the supply of the relevant services to which the Liability relates.

The terms implied by sections 3, 4 and 5 of the Supply of Goods and Services Act 1982 are, to the maximum extent permitted by law, excluded from these Terms.

This 'Liability' clause will survive the termination or expiry of these Terms.

13. General

Assignment: Subject to the below clause, a party must not assign or deal with the whole or any part of its rights or obligations under these Terms without the prior written consent of the other party (such consent is not to be unreasonably withheld).

Assignment of Debt: You agree that we may assign or transfer any debt owed by you to us, arising under or in connection with these Terms, to a debt collector, debt collection agency, or other third party.

Contracts (Rights of Third Parties) Act 1999: Notwithstanding any other provision of these Terms, nothing in these Terms confers or is intended to confer any right to enforce any of its terms on any person who is not a party to it.

Disputes: Neither we or you may commence court proceedings relating to any dispute, controversy or claim arising from, or in connection with, these Terms (including any question regarding its existence, validity or termination) (Dispute) unless we and you first meet (in good faith) to resolve the Dispute. Nothing in this clause will operate to prevent us or you from seeking urgent injunctive or equitable relief from a court of appropriate jurisdiction. If the Dispute is not resolved at that initial meeting:

- *(a)* where you are resident or incorporated in England and Wales, refer the matter to mediation, administered by The Centre for Effective Dispute Resolution; or
- *(b)* where you are not resident or incorporated in England and Wales, refer the matter to arbitration administered by the London Court of International Arbitration (LCIA), with such arbitration to be conducted in London, before one arbitrator, in English and in accordance with the LCIA Arbitration Rules.

Force Majeure: To the maximum extent permitted by law, we shall have no Liability for any event or circumstance outside of our reasonable control.

Marketing: You agree that we may send you electronic communications about our products and services. You may opt-out at any time by using the unsubscribe function in our electronic communications

Governing law: These Terms are governed by the laws of England and Wales. Each party irrevocably and unconditionally submits to the exclusive jurisdiction of the courts operating in England and Wales and any courts entitled to hear appeals from those courts and waives any right to object to proceedings being brought in those courts. TrackMe may be accessed in the UK and overseas. We make no representation that TrackMe complies with the laws (including intellectual property laws) of any country outside of the UK. If you access TrackMe from outside the UK, you do so at your own risk and are responsible for complying with the laws in the place you access TrackMe. The United Nations Convention of Contracts for the International Sale of Goods is expressly excluded from these Terms.

Privacy: All personal data you and your Authorised Users provide to us will be treated in accordance with our privacy policy. You can find our privacy policy at https://trackme-solutions.com/privacy-policy/.

Severance: If a provision of these Terms is held to be void, invalid, illegal or unenforceable, that provision is to be read down as narrowly as necessary to allow it to be valid or enforceable, failing which, that provision (or that part of

that provision) will be severed from these Terms without affecting the validity or enforceability of the remainder of that provision or the other provisions in these Terms.

Third party sites: TrackMe may contain links to websites operated by third parties. Unless we tell you otherwise, we do not control, endorse or approve, and are not responsible for, the content on those websites. We recommend that you make your own investigations with respect to the suitability of those websites. If you purchase goods or services from a third party website linked from TrackMe, such third party provides the goods and services to you, not us. We may receive a benefit (which may include a referral fee or a commission) should you visit certain third-party websites via a link on TrackMe (Affiliate Link) or for featuring certain products or services on TrackMe. We will make it clear by notice to you which (if any) products or services we receive a benefit to feature on TrackMe, or which (if any) third party links are Affiliate Links.

14. Definitions

Consequential Loss includes any consequential loss, indirect loss, real or anticipated loss of profit, loss of benefit, loss of revenue, loss of business, loss of goodwill, loss of opportunity, loss of savings, loss of reputation, loss of use and/or loss or corruption of data, whether under statute, contract, equity, tort (including negligence), indemnity or otherwise.

Intellectual Property means any copyright, registered or unregistered designs, patents or trade marks, business names, get-up, goodwill, domain names, know-how, inventions, processes, trade secrets or confidential information, circuit layouts, software, computer programs, databases or source codes, including any application for registration of, and any improvements, enhancements or modifications of, the foregoing, and any right to apply for and be granted, renewals or extensions of, and rights to claim priority from, such rights and all similar or equivalent rights or forms of protection which subsist or will subsist now or in the future, including in respect of the foregoing.

Liability means any expense, cost, liability, loss, damage, claim, notice, entitlement, investigation, demand, proceeding or judgment (whether under statute, contract, equity, tort (including negligence), misrepresentation, restitution, indemnity or otherwise), howsoever arising, whether direct or indirect and/or whether present, unascertained, future or contingent and whether involving a third party or a party to these Terms or otherwise.

4.3 Support

4.3.1 Contacting Support

All support requests must be directed to our support team through the following channels:

- **Support Portal:** https://support.trackme-solutions.com
- **Email:** support@trackme-solutions.com

For licensing, sales, or general inquiries, please contact:

- **Email:** contact@trackme-solutions.com

> **Note**
>
> Support requests submitted through any channel other than the support portal or the support email address above will not be processed.

4.3.2 Support Portal Access

As a registered TrackMe customer, one or more points of contact within your organisation will be identified, and personal access credentials will be provided for our support portal.

Once connected to the support portal, you can:

- Open a new support request
- Review and manage the status of your existing support requests

If your organisation does not yet have a registered account, please send an email to support@trackme-solutions.com **and we will create one for you.**

Once your request has been received and processed, an activation email will be sent with your personal access credentials.

You can also submit a support case by emailing support@trackme-solutions.com **directly; a support request will be created automatically and associated with your user account.**

4.3.3 Minimum Version Requirement

Important

To ensure efficient support delivery, we require customers to be running **TrackMe version 2.3.x or later**. If you are running an older version, upgrading to the latest release will very likely be requested as a first step before investigating any reported issue.

4.3.4 SLA, Response Time and Support Coverage

- We provide support for features and behaviours that relate directly to the usage of TrackMe for Splunk Cloud and Splunk Enterprise.
- Issues related to Splunk products or any other third-party applications are not covered by our support agreement.
- Prioritised support is included for all customers with a valid subscription.
- Support is available by email with a Service Level Agreement (SLA) of 24 hours for a support request to be acknowledged, Monday to Friday, 8 am to 8 pm UK time.
- If a support case requires it, we will propose a virtual meeting through our Zoom meeting services or your own meeting tools if preferred.
- If you have specific needs or requirements that are not covered by our product, we will prioritise developments for customers under an active subscription.

4.3.5 Support Diagnostic Archive

When investigating a customer-reported issue, our support team will frequently ask for a **Support Diagnostic Archive**. The TrackMe app ships with a self-service page that generates this archive directly from your Splunk environment, so you no longer need to run ad-hoc searches or export KV Store collections by hand.

Where to find it

The page is available in the TrackMe app navigation under both:

- **API & tooling → Support - generate diags**
- **Audit & troubleshoot → Support - generate diags**

It requires the `trackme_power` or `trackme_admin` role.

What it does

The page offers two diagnostic modes:

- **Entity diag** — for when the question is about one (or a small number of) specific entities in a given tenant. Pick the tenant, the component, then up to 20 entities. The archive will include each entity's record, the last 7 days of metrics, and the most recent summary / notable events for those entities.
- **Global diag** — for when the question is about the system as a whole (degraded scheduler, slow trackers, generic skipping). The archive will include the central KV Store collections, knowledge objects for every enabled tenant, the last 24 hours of scheduler skipping and performance reports, the last 24 hours of TrackMe runtime metrics, and the last 10 000 ERROR events across the TrackMe REST API, custom commands, and alert actions over the past 7 days.

In both cases the result is a single timestamped `.tgz` archive that you can attach to the support ticket on the portal or send by email.

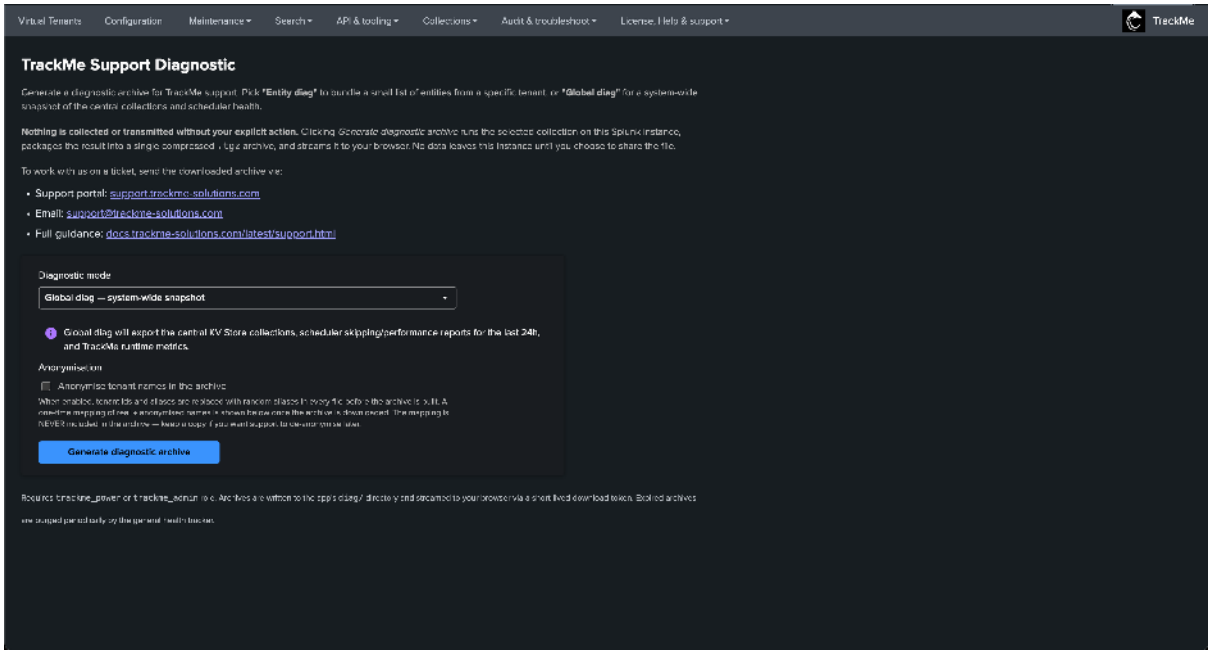
Note

Nothing is collected or transmitted automatically. The page only runs the selected collection on your Splunk instance, packages the result locally, and streams the archive to your browser. No data leaves the instance until you choose to share the file with TrackMe Support.

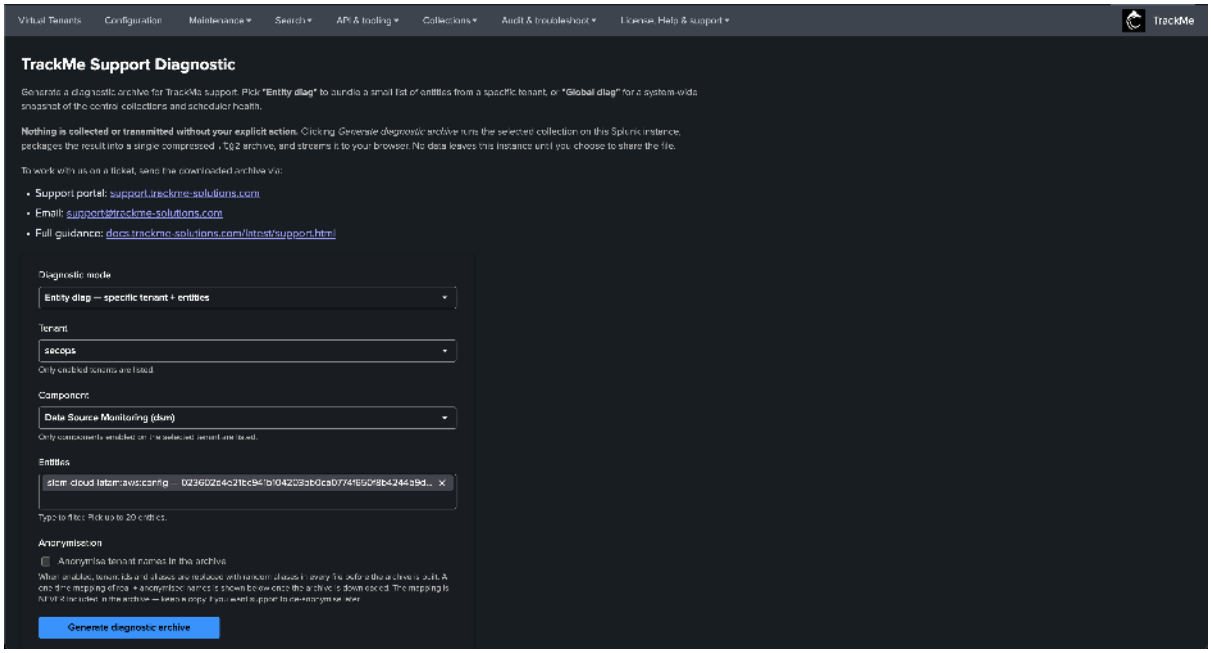
Optional anonymisation

If your environment uses tenant names that are sensitive or non-shareable, tick the **Anonymise tenant names** checkbox before clicking *Generate diagnostic archive*. The worker will rewrite every occurrence of every tenant id and tenant alias to a stable random alias (for example `tenant_anon_0003_ab12cd`) across every file in the archive — including filenames — and present the original-to-anonymised mapping to you on screen once the archive is ready. The mapping is **never written into the archive itself**; you keep a local copy and share it with TrackMe Support separately if and when needed.

Global diag



Entity diag



Tip

When you open a support case, our team may ask you to attach a fresh diagnostic archive — generated as close as possible to the time the issue was last observed. Running the page yourself before contacting support, and attaching the archive to your initial ticket, will significantly accelerate triage.

4.3.6 Reporting Bugs and Enhancement Requests

To report a bug or submit a request for enhancement, please contact us through:

- **Support Portal:** https://support.trackme-solutions.com
- **Email:** support@trackme-solutions.com

Our team will triage your request and keep you informed of progress through the support portal.

4.3.7 Community Resources

Splunk Community Slack:

- https://splunk-usergroups.slack.com

Splunk Community:

- https://community.splunk.com

Note

Community channels are provided for general Splunk discussions and peer-to-peer assistance. For TrackMe-specific support, please use the official support channels listed above.

CHAPTER

FIVE

COMPATIBILITY AND DOWNLOAD:

5.1 Compatibility

Important

We strongly recommend running the latest release of TrackMe at all times.

Keeping TrackMe up to date ensures you benefit from the latest features, bug fixes, security patches, and performance improvements. If a support case is opened and the running version is identified as significantly outdated, **an upgrade to a current release may be required before further investigation can proceed**.

5.1.1 Splunk core compatibility

Splunk core

- TrackMe is compatible with Splunk 9.1 and later.
- TrackMe is developed, tested and qualified against latest generation of Splunk Enterprise and Splunk Cloud Victoria in priority.

5.1.2 Splunk Enterprise and Splunk Cloud compatibility

Splunk Enterprise compatibility

- TrackMe is compatible with Splunk Enterprise from Splunk 9.2.x
- TrackMe fully supports Python 3.9.x/3.13.x (which are both used by currently support main Splunk versions) and later.

Operating system compatibility for Splunk Enterprise customers

OS compatibility for Splunk Enterprise customers

- TrackMe only officially supports **Linux** as the Operating System for Splunk Enterprise customers.
- On Windows and MacOS, TrackMe might partially work, but advanced features such as Machine Learning Outliers detection will not be available.

Splunk Cloud compatibility

- TrackMe is compatible with Splunk Cloud Victoria and Splunk Cloud Classic
- On Splunk Cloud Classic, TrackMe Version 2.0.60 and later is required to address some issues due to Splunk SLIM partitioning

Appinspect and vetting

We carefully comply with Splunk development best practices to ensure that we provide the highest level of application quality.

Therefore, TrackMe releases are reviewed and validated with Splunk Appinspect:

- https://dev.splunk.com/enterprise/reference/appinspect

When a new release of TrackMe is published, our automation also processes the release through Appinspect automation and the Appinspect HTML report is available in the release directory of our download Website:

- https://downloads.trackme-solutions.com/

TrackMe is compatible with Splunk Enterprise and Splunk Cloud products.

5.1.3 Python compatibility

Python 3 compatibility

- TrackMe supports **Python 3** only.
- TrackMe is fully compatible with **Python 3.9.x/3.13.x** (which are both used by currently support main Splunk versions) and later.

5.1.4 Artificial Intelligence features compatibility

TrackMe AI features — Splunk & Python requirements

- **TrackMe remains fully compatible with all supported Splunk releases.** The AI features are additive and opt-in; the Python/Splunk requirements below do not affect TrackMe's core data-monitoring capabilities.
- The **AI Assistant** (conversational chat) and the **AI Concierge** are compatible with **Python 3.9.x and later** — i.e. they run on the same Splunk releases as the rest of TrackMe.
- The **AI Advisors** (ML, Feed Lifecycle, FLX Threshold, FQM, and Component Health) are "agentic" features built on the Splunk Agent SDK and require **Python 3.13.x**, which ships only with **Splunk 10.2.x and later** (Splunk Enterprise or Splunk Cloud). These advanced AI features are therefore only available on Splunk 10.2.x and later.
- **AI Routines** and the **AI Agents for findings** (the UAM AI Agent, the Cribl Stream AI Agent and the Cribl Edge AI Agent) are built on the same SDK and have the same requirement: Splunk 10.2.x and later.
- **Automatic safeguards:** TrackMe automatically prevents an Advisor from being invoked when the Python version requirement is not met, returning a clear message about the incompatibility with the running Splunk release. In addition, the AI Assistant will not propose an AI Advisor when it detects that the system is not running a compatible release.

In summary: TrackMe remains fully compatible with previous Splunk releases (Python 3.9.x), including the AI Assistant and the AI Concierge. The advanced AI Advisors require Splunk 10.2.x and later (Python 3.13.x). See *Artificial Intelligence in TrackMe* for the full AI feature set.

5.1.5 Dedicated tenant types compatibility

User Activity Monitoring, Cribl Stream and Cribl Edge

- These tenant types require the **Enterprise** or **Unlimited** edition (trial and Developer licences included); they are not available on the Foundation edition.

- **User Activity Monitoring** reads `_audit`, `_introspection` and the search completion records of the indexers. Splunk Enterprise 9.4, 10.4 and 10.6 and Splunk Cloud 10.5 are qualified; other releases run as well and only add a soft diagnostic in Collection health. See *User Activity Monitoring*.
- **Cribl Stream** and **Cribl Edge** monitor a Cribl.Cloud workspace or a self-managed Leader, through a read-only API account, and read Cribl's internal metrics from a Splunk metric index. See *Cribl Stream*, *Cribl Edge* and *Cribl connections*.

5.1.6 FIPS Mode compatibility

TrackMe and FIPS mode

- **Since TrackMe version 2.0.99, TrackMe is officially compatible with Splunk FIPS mode, and continuously validated on FIPS.**
- About FIPS: https://docs.splunk.com/Documentation/Splunk/latest/Security/SecuringSplunkEnterprisewithFIPs
- In Splunk 9.3.0, several changes were made and some aspects of FIPS are correctly applied, this requires TrackMe 2.0.99 and evolutions we have made to rely on sha256 instead of md5 crypto in various search and Python logics.

5.1.7 Web Browser compatibility

TrackMe is supported on Splunk supported Web Browsers:

See: https://docs.splunk.com/Documentation/Splunk/latest/Installation/Systemrequirements

Supported Web Browsers:

- Firefox (latest)
- Safari (latest)
- Chrome (latest)
- Microsoft Edge (latest)

5.2 Download

5.2.1 Product brochure

A nine-page overview of TrackMe for Splunk: what it watches, the two ways of watching (entities and findings), Topology Studio, the AI layer, operating at scale and the editions.

- `TrackMe for Splunk, product brochure (PDF)`

5.2.2 TrackMe for Splunk Enterprise & Splunk Cloud

TrackMe for Splunk Enterprise & Splunk Cloud can be downloaded from Splunk Base, as well as from our release Website:

- https://splunkbase.splunk.com/app/4621
- https://downloads.trackme-solutions.com

5.2.3 TrackMe App on SOAR

We provide a TrackMe application for Splunk SOAR (Phantom), this application for SOAR allows powerful actions to automate and interact with TrackMe straight from Splunk SOAR:

- https://downloads.trackme-solutions.com/trackme-app-on-soar

You can also access the source code and the releases from our GitHub repository:

- https://github.com/trackme-limited/trackme-app-on-soar

5.2.4 TrackMe Configuration Manager (TCM)

The TrackMe Configuration Manager (TCM) is a Splunk Application which can be used for CI/CD and configuration management purposes of TrackMe, it acts as a utility which can receive and replay configuration transactions, to promote changes between environments and also to restore configuration steps by replaying these, it can be downloaded from our release Website.

For more information about the TCM, see: *Configuration Manager (CI/CD)*

- https://downloads.trackme-solutions.com/TA-trackme-conf-manager

You can also access the source code and the releases from our GitHub repository:

- https://github.com/trackme-limited/TA-trackme-conf-manager

5.2.5 TA-trackme-cribl

This Splunk application provides API integration between Splunk and Cribl API, it acts as an SPL interface to the Cribl API so you can even more interactions between the platforms, leverage real time requests from Splunk dashboard and also leverage it in TrackMe such as custom Flex Object trackers, it can be downloaded from:

- https://downloads.trackme-solutions.com/TA-trackme-cribl

You can also access the source code and the releases from our GitHub repository:

- https://github.com/trackme-limited/TA-trackme-cribl

CHAPTER

SIX

REQUIREMENTS:

6.1 Requirements for TrackMe

6.1.1 Target for deployments

For Splunk Enterprise customers

For Splunk on-premise customers, we recommend to deploy TrackMe on:

- A dedicated Search Head or Search Head Cluster, especially if you intend to monitor a large number of environments or if you are a large scale Splunk customer
- Alternatively, you can deploy TrackMe on the instance used for the purposes of the Splunk Monitoring Console

Splunk premium applications

- We do not support colocating TrackMe with any of the Splunk premium applications (Splunk Enterprise Security, Splunk ITSI)
- The reason is that both TrackMe and premium applications can have heavy requirements in term of workload, and TrackMe could therefore slightly impact these products

For Splunk Cloud customers

From Splunk Cloud Victoria, applications are deployed through self-services equally on all Search Heads, including Premium applications Search Head:

- When deploying TrackMe on Splunk Cloud, the application will be deployed automatically on all Search Heads, including your Premium application Search Heads, if any
- However, a virgin deployment of TrackMe has no workload as long as there are no Virtual Tenants created
- TrackMe should be configured and used from the first Search Head tier of your Splunk Cloud stack, commonly called the Ad-hoc Search Head tier

Splunk premium applications

- Similarly to on-premise deployments and while TrackMe is deployed on the premium applications Search Heads, we do not support running TrackMe on these Search Heads
- The reason is that both TrackMe and premium applications can have heavy requirements in term of workload, and TrackMe could therefore slightly impact these products

6.1.2 System requirements for the use of TrackMe

Supported Operating Systems

Warning

Linux is the only fully supported Operating System for TrackMe.

All other environments (Windows, MacOS) are provided on a **best effort** basis only. We develop, test, and qualify TrackMe exclusively on Linux and Splunk Cloud Victoria. If you encounter issues on a non-Linux platform, we will do our best to assist, but resolution cannot be guaranteed.

- **Linux** – fully supported (strongly recommended, and used by the vast majority of customers)
- **MacOS** – best effort support only (suitable for development and testing purposes)
- **Windows** – best effort support only (not recommended; we do not expect good performance from Splunk on Windows in general)

Containerized computing platforms

Similarly to Splunk Enterprise, running TrackMe on containerized environment is supported:

- https://docs.splunk.com/Documentation/Splunk/latest/Installation/Systemrequirements

Resources requirement

The requirements for TrackMe in terms of CPU slightly relies on its usage and configuration, the main factors are:

- If the Splunk instance hosting TrackMe is itself more than a Search Head (if the instance is as well an indexer for instance in the case of all in one Splunk instance, which is not recommended)
- The number of enabled TrackMe Virtual Tenants
- The number of enabled Hybrid, Flex and Elastic Trackers
- The number of entities monitored, which influence factors like the number of Machine Learning models to be created and maintained for instance
- The repartitions between local tracking and Splunk Remote Searches tracking, which influence how much the load is shared between the local instance and the remote Splunk deployments, if any
- The number of active users, the more users are actively using TrackMe, the less search slots are available for the back-end purposes

Splunk typical requirements:

- TrackMe relies on Splunk and shares its typical requirements
- We recommend to honour the minimal specifications for Splunk: https://docs.splunk.com/Documentation/Splunk/latest/Installation/Systemrequirements

Minimal CPU requirements:

- We recommend a minimal setup of **16 vCPUs** for running TrackMe in a Production context.

- This highly depends on the number of trackers and use cases that are implemented, the nature of the use cases, as well as the number and activity of users in TrackMe.

Recommended requirements:

- **32 vCPUs** (or more) for running TrackMe in a Production context with a large scale deployment, and a large number of use cases.
- **32 GB** of memory is recommended for running TrackMe in a Production context.

Applications dependencies

Hint

TrackMe 2.2.0 and later:

- Since **TrackMe 2.2.0**, the Splunk_SA_CIM application is no longer a required dependency, it is now optional and only required for CIM tracking purposes.

Important

TrackMe 2.4.1 and later — no Machine Learning add-on dependency:

Starting with **TrackMe 2.4.1**, TrackMe **no longer requires** the Splunk AI Toolkit (formerly Splunk Machine Learning Toolkit) or the Python for Scientific Computing packages.

Every Machine Learning driven feature now runs on TrackMe's **built-in native density function engine** (`TrackMeNativeDensityFunction`), which uses scipy directly and stores its models in per-tenant KVstore collections:

- **ML Outliers detection** — native by default since TrackMe 2.3.15.
- **Adaptive delay thresholding** — migrated to the native engine in TrackMe 2.4.1. This was the last feature relying on the Splunk AI Toolkit's `fit DensityFunction` command; it now performs the same statistical (density) calculation inline through the native engine, with no model retained.

You can therefore deploy and run TrackMe without installing either add-on.

Optional applications:

The following applications are **optional** and are not required for any default TrackMe feature:

- Splunk AI Toolkit (formerly Splunk Machine Learning Toolkit): https://splunkbase.splunk.com/app/2890
- Python for Scientific Computing: https://splunkbase.splunk.com/app/2882

Note

These packages are only needed if you explicitly select the Splunk AI Toolkit `DensityFunction` algorithm for an ML Outliers model (see *Outlier detection*). The default native engine (`TrackMeNativeDensityFunction`) requires neither add-on.

CHAPTER

SEVEN

INSTALLATION:

7.1 Installation of TrackMe

7.1.1 Installation Target

TrackMe is a Search Head component only; therefore, it must be deployed only on a target Search Head layer:

Splunk roles	Required
Search head	yes (*)
Monitoring console	yes (*)
Indexer tiers	no
Heavy Forwarders	no

- You can deploy TrackMe on a dedicated Search Head or Search Head Cluster, or alternatively on the machine hosting the Splunk Monitoring Console.
- If you choose to install TrackMe on your Search Head layer in a Search Head Cluster (SHC), TrackMe must be deployed through the SHC deployer node.

7.1.2 Indexes Definition

Default Indexes

TrackMe requires at least 4 indexes to be defined. In a distributed context, this usually means defining indexes in your manager node:

Default index name	Purpose	Minimal recommended retention
trackme_summary	TrackMe entities activity such as the state, flipping events, and Smart Status	3 months
trackme_audit	TrackMe modifications and application audit activity	1 year or more
trackme_notable	Notable events are generated by the TrackMe notable alert action	3 months
trackme_metrics	Various metrics are generated depending on the components	1 year or more (notably to allow long term outliers detection and metrics analytics)

Indexes are defined by default in the application package:

```
trackme/default/indexes.conf
```

Typically:

- If TrackMe is running on an "all-in-one" instance, you do not need to define the indexes as the application defines these already (mostly for testing and development purposes).
- It is good practice to use Splunk volumes rather than the default SPLUNK_DB variable to define the location of the buckets (which is required when using SmartStore).

Therefore, a typical definition would be:

```
[trackme_notable]
coldPath = volume:primary/trackme_notable/colddb
homePath = volume:primary/trackme_notable/db
thawedPath = $SPLUNK_DB/trackme_notable/thaweddb

[trackme_summary]
coldPath = volume:primary/trackme_summary/colddb
homePath = volume:primary/trackme_summary/db
thawedPath = $SPLUNK_DB/trackme_summary/thaweddb

[trackme_audit]
coldPath = volume:primary/trackme_audit/colddb
homePath = volume:primary/trackme_audit/db
thawedPath = $SPLUNK_DB/trackme_audit/thaweddb

[trackme_metrics]
coldPath = volume:primary/trackme_metrics/colddb
homePath = volume:primary/trackme_metrics/db
thawedPath = $SPLUNK_DB/trackme_metrics/thaweddb
datatype = metric
```

Adapt with the volume definitions in your context.

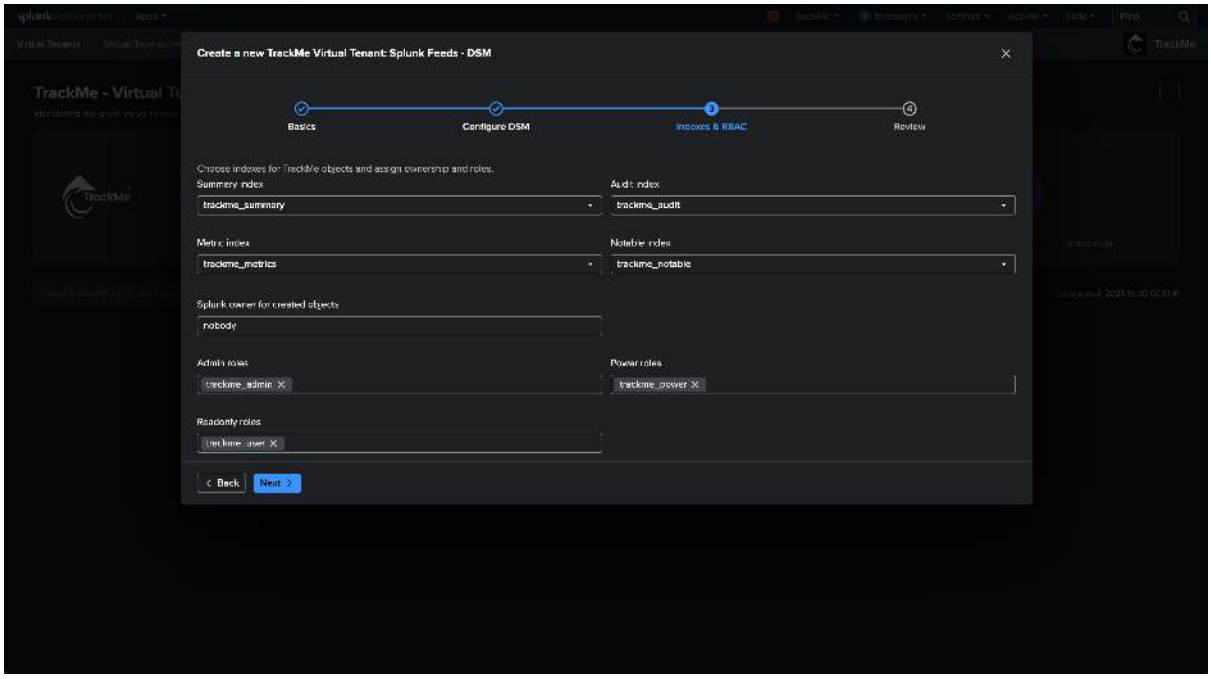
Virtual Tenants Specific Indexes

A core concept of TrackMe is called Virtual Tenants, which provides many powerful features. Part of this concept provides the capability to define a per-tenant specific set of indexes.

Therefore, you can choose to define specific indexes for one or more tenants, and a different set of indexes for other tenants.

This allows TrackMe to comply with any Role-Based Access Control (RBAC) requirements, for instance, to allow a population of users to access specific tenants while another population can access others.

Example: Virtual Tenant indexes definition configuration screen:



7.1.3 Installing TrackMe

Splunk Enterprise

Installing TrackMe on Splunk Enterprise on-premises deployments depends on the type of deployment.

- For standalone instances, refer to: https://docs.splunk.com/Documentation/AddOns/released/Overview/Singleserverinstall
- For distributed deployments, refer to: https://docs.splunk.com/Documentation/AddOns/released/Overview/Distributedinstall

Notes for Older Generations of Splunk (prior to Splunk 9.x)

TrackMe is developed for the latest generation of Splunk software; therefore, some built-in parameters are primarily targeting Splunk 9.x compatible configurations.

If you are running TrackMe on a version prior to Splunk 9.x, you should apply the following customizations:

Create a local/distsearch.conf:

```
# distsearch.conf

# Avoid the replication to the indexers of the KVstore backup tarball compressed␣
↪files
[replicationBlacklist]
trackme_backup_tgz = apps/trackme/backup/*.tgz
trackme_backup_dirs = apps/trackme/backup/...

# These lookups do not need to be replicated
trackme_cim_regex = apps/trackme/lookups/trackme_cim_regex.csv

# Machine Learning models: Anomaly detection will generate various ML models␣
↪files, these are not needed on the indexer layers
trackme_mlmodels = apps/trackme/lookups/__mlspl_*.mlmodel
```

Notes:

- In Splunk 9.x, biased language has been addressed; this stanza became replicationDenylist.

- In TrackMe, this stanza prevents ML models files from being unnecessarily replicated to the indexers and being part of the knowledge bundle.

Splunk Cloud

Installing TrackMe on Splunk Cloud relies on Cloud self-services. Refer to:

- https://docs.splunk.com/Documentation/SplunkCloud/latest/Admin/SelfServiceAppInstall

7.1.4 Upgrading TrackMe

In summary, upgrading TrackMe follows the same process as installation:

- In Splunk Enterprise, you will download the updated release, extract the new version, restart the instance if in a standalone Search Head, or apply the SHC bundle if running in an SHC.
- In Splunk Cloud, when a new release has been published and vetted, the new version release number appears as upgradable through the application management interface; you will therefore follow the self-services process.

TrackMe implements an automated concept to perform required application-level upgrade procedures, called `schema version`. The complete upgrade guide, including a step-by-step procedure with checkpoints, the post-upgrade validation and the rollback rules, is in *Upgrading TrackMe*.

7.2 Upgrading TrackMe

Upgrading TrackMe is a standard Splunk application upgrade followed by an automated, per-tenant **schema migration** that TrackMe runs on its own. The package replaces the shipped code; TrackMe then reshapes each Virtual Tenant's knowledge objects and KVstore collections to the new release, tenant by tenant, and reports its progress in the user interface.

This section is the upgrade guide. It is written to be executed, not only read: the procedure page is a step-by-step runbook with the screen to look at, the search to run and the expected result at every step, and the other pages hold the reference material behind it.

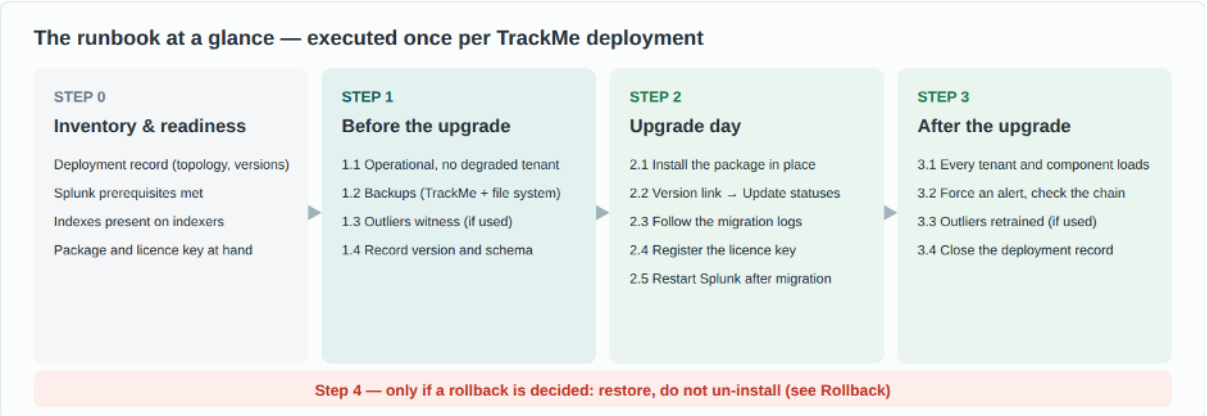
Upgrade procedure The step-by-step runbook: before the upgrade, upgrade day, after the upgrade, with checkpoints.

Upgrade procedure Schema migrations How the automated per-tenant migration works, how to follow it, what runs between releases.

Schema migrations Validating after an upgrade The built-in validation screens, the extended checklist, the behaviour changes to brief operators on, the evidence searches.

Validating after an upgrade Rollback Why a rollback is a restore and never a re-install of the older package, and how to do it.

Rollback



The upgrade procedure at a glance. Step 0 is done once per estate; steps 1 to 3 run on every TrackMe deployment.

7.2.1 Upgrade procedure

This page is the runbook. It is organised in four steps: **step 0** is done once per estate (or once, for a single deployment), **steps 1 to 3** run on every TrackMe deployment, and **step 4** applies only if a rollback is decided. Each step ends with a checkpoint.

In every search of this page, replace `<component>` with the component acronym (`dsm`, `dhm`, `mhm`, `flx`, `fqm`, `wlk`) and `<tenant_id>` with the Virtual Tenant identifier. Screenshots come from a two-tenant lab; replace tenant and entity names with your own.

Step 0 — Inventory and readiness

Deployment inventory

One record per TrackMe deployment. It is the input of the planning and the header of the validation record (see *Validating after an upgrade*).

Field	Where it comes from / notes
Deployment name	Your internal reference
Splunk topology	Standalone search head, distributed (search head + indexers), search head cluster (with deployer), or Splunk Cloud
Splunk version	From the search head; see *Compatibility* for the supported range
TrackMe version and schema	Virtual Tenants header, and the **Tenants Update statuses** screen behind the version number (step 1.4)
Tenants and components	Number of Virtual Tenants; components enabled per tenant
ML Outliers in use?	Yes / no per tenant (the search of step 1.3 returns rows). Decides whether steps 1.3 and 3.3 apply
Alert actions and integrations	Stateful alerts, notables, email delivery accounts, free-style REST actions, SOAR: what your downstream tooling consumes (the target of the step 3.2 test)
Custom knowledge objects	Your own saved searches, dashboards or lookups built on TrackMe data
Change window and contact	Agreed window; the person who confirms the downstream side of the step 3.2 test

Platform readiness

- Splunk version within the supported range for the target release; a splunkd restart is possible in the change window (Splunk Enterprise).
- KVstore healthy on the search head, or on every search head cluster member: `| rest /services/kvstore/status` reports *ready*.
- The four TrackMe indexes exist on the indexers: `trackme_summary`, `trackme_metrics` (metric index), `trackme_audit`, `trackme_notable` (see *Installation of TrackMe*).
- Free disk on the search head for the application (2.4.x packages bundle Python libraries and are larger than 2.1.x) and for the KVstore backups.
- The target package downloaded from https://downloads.trackme-solutions.com/ and checksummed; the same file is used for every deployment of a programme.
- The licence key at hand for step 2.4, if the deployment is not registered yet.

Hint

Search head clusters

In a search head cluster the application is upgraded through the deployer (step 2.1). The members' own `local/` configuration is preserved by the bundle push; do not remove the application from the deployer's `shcluster/`

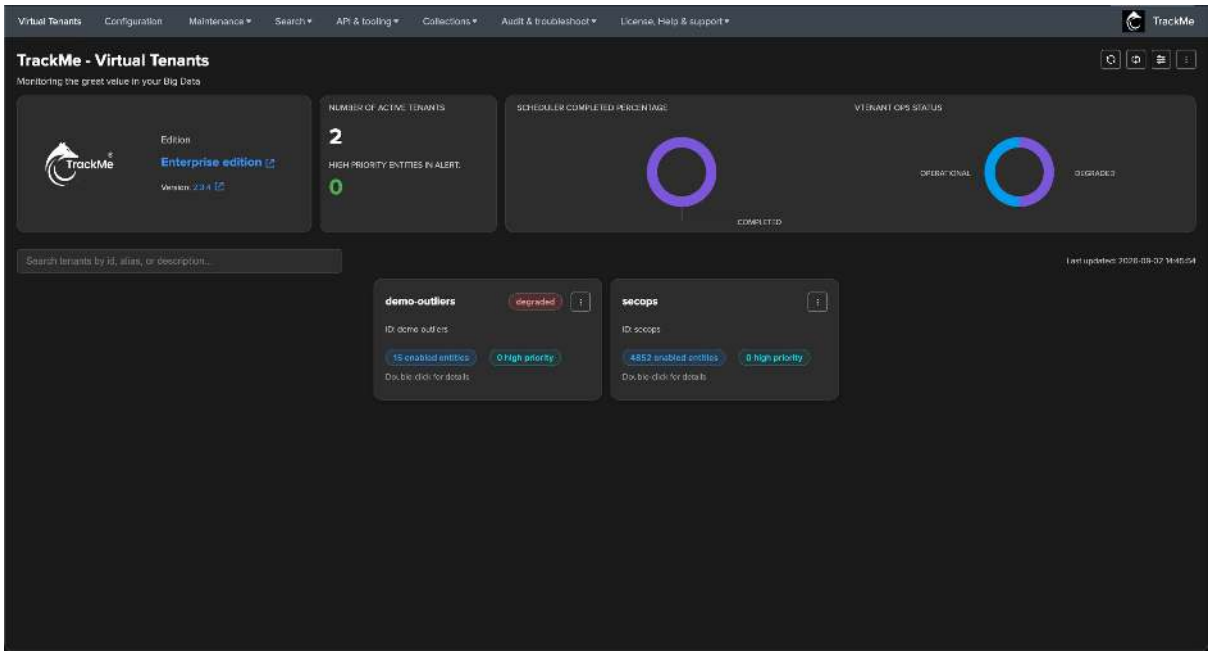
`apps` and re-add it, that would reset it. Migrations run once per tenant, on whichever member runs the tenant's health tracker; the KVstore is replicated, so every member sees the result.

Step 1 — Before the upgrade

Per deployment. Prerequisites, backups, baseline. About 30 minutes.

1.1 Confirm TrackMe is operational and no tenant is degraded

Open **Virtual Tenants**. Every tenant card must be free of the **degraded** badge and the tenant operations status must be fully OPERATIONAL. A degraded tenant means at least one of its scheduled reports failed on its last run.



The same check from a search, for the record:

```
| savedsearch trackme_ops_status
```

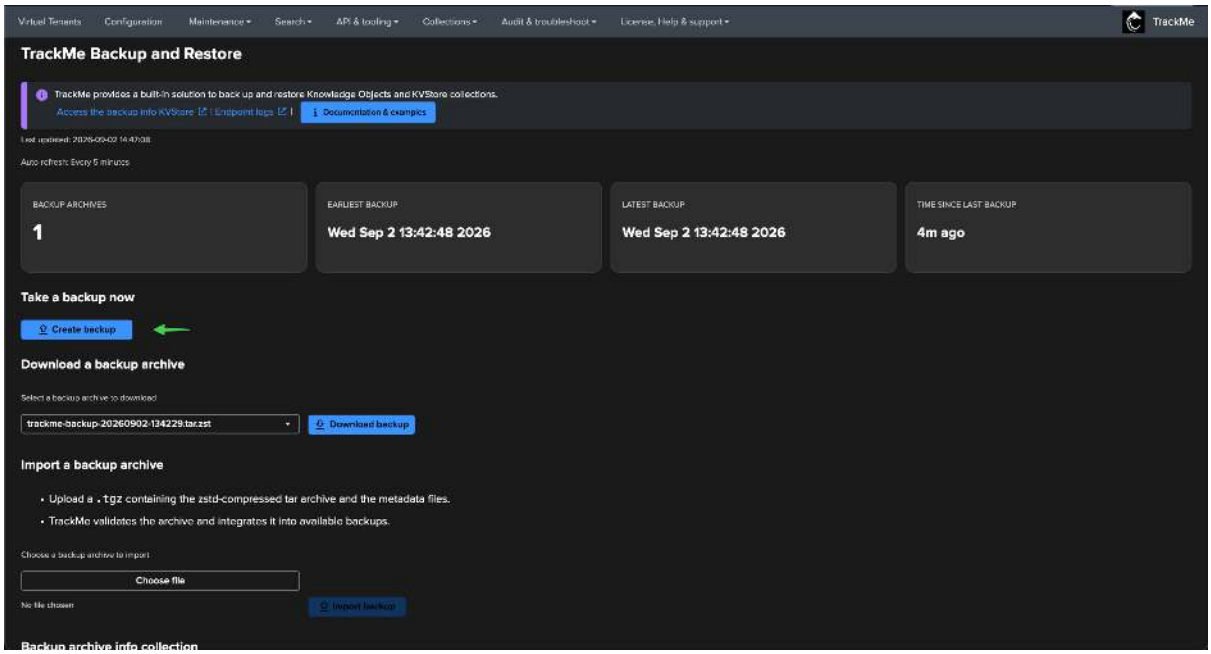
Warning

If a tenant is degraded

Identify the failing report (header → **Ops Status**, filter on failure) and address the root cause before the upgrade. Migrating a tenant whose trackers already fail makes the post-upgrade picture impossible to read: you will not know whether a failure is old or new.

1.2 Take the backups

TrackMe backup. Open **API & tooling → Backup & Restore** and click **Create backup**. The archive (knowledge objects and KVstore collections) is listed on the same page and can be restored from there. See *Backup & restore*.



File-system and KVstore backup (Splunk Enterprise). On-premises, also take a copy of the application directory and a KVstore backup; together they are the fastest restore path if anything goes wrong:

```
tar -czf /tmp/trackme-app-$(date +%Y%m%d).tgz -C $SPLUNK_HOME/etc/apps trackme
$SPLUNK_HOME/bin/splunk backup kvstore -archiveName trackme-pre-upgrade-$(date␣
↪+%Y%m%d)
```

Run both on the search head (on every search head cluster member for the application directory; the KVstore backup once, on the captain). The KVstore archive lands in `$SPLUNK_HOME/var/lib/splunk/kvstorebackup/`. Keep both copies outside the search head.

Note

On Splunk Cloud the file system is not accessible; the TrackMe backup is the restore path, and Splunk Cloud's own platform backups are a last resort to be requested from Splunk.

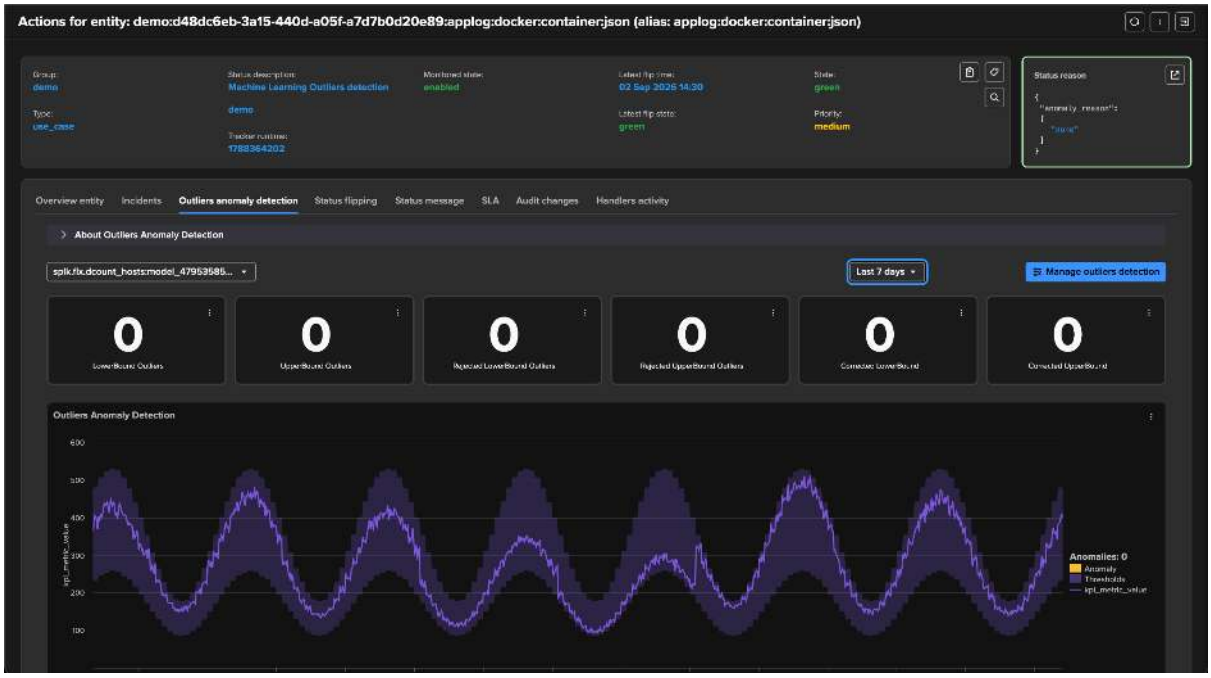
1.3 ML Outliers baseline — only where ML Outliers are in use

When upgrading from a release earlier than 2.3.15, every Outliers model refers to the Splunk AI Toolkit algorithm `DensityFunction`. The upgrade migrates the models to TrackMe's native engine (`TrackMeNativeDensityFunction`) and they are retrained automatically afterwards (step 3.3). Record the pre-migration state per tenant and component:

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| where match(entities_outliers, "\"algorithm\": \"DensityFunction\"")
| stats count
```

Then pick one well-behaved entity per component as the witness (trained model, normal confidence, no current outlier, green state), open it in **Tenant Home** and screenshot its **Outliers anomaly detection** tab:

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id> where␣
↪confidence="normal"
| lookup trackme_<component>_outliers_entity_data_tenant_<tenant_id> object OUTPUT␣
↪models_summary, isOutlier
| where isOutlier=0
| lookup trackme_<component>_tenant_<tenant_id> object OUTPUT object_state
| where object_state="green"
```



1.4 Record the running version and schema state

On **Virtual Tenants**, note the version in the header card, then click the version number. The **Tenants Update statuses** screen must show every tenant with *Schema version* equal to *Schema version required*, status **updated**. Screenshot it; you will compare it with the same screen in step 2.

TrackMe License Informations & Tenants Update statuses
After an upgrade of TrackMe, the schema upgrade is triggered by the Health Tracker of the Virtual Tenant. Once terminated, trackers are allowed to be executed and the schema version is upgraded to reflect the readiness of the tenant.
License info: TrackMe is currently registered and operating in Enterprise edition.

Step 1 checkpoint — go / no-go

- All tenants OPERATIONAL, none degraded (1.1)
- TrackMe backup taken minutes before the change window, status success (1.2)
- On Splunk Enterprise: application directory and KVstore backups taken and stored off the search head (1.2)
- Where Outliers are used: model count exported and witness entity screenshot captured (1.3)
- Update-status screen captured: every tenant updated (1.4)
- Target release confirmed (never 2.3.22 to 2.4.1; one release for the whole estate)

Step 2 — Upgrade day

Install in place, follow the migration, register the licence, restart.

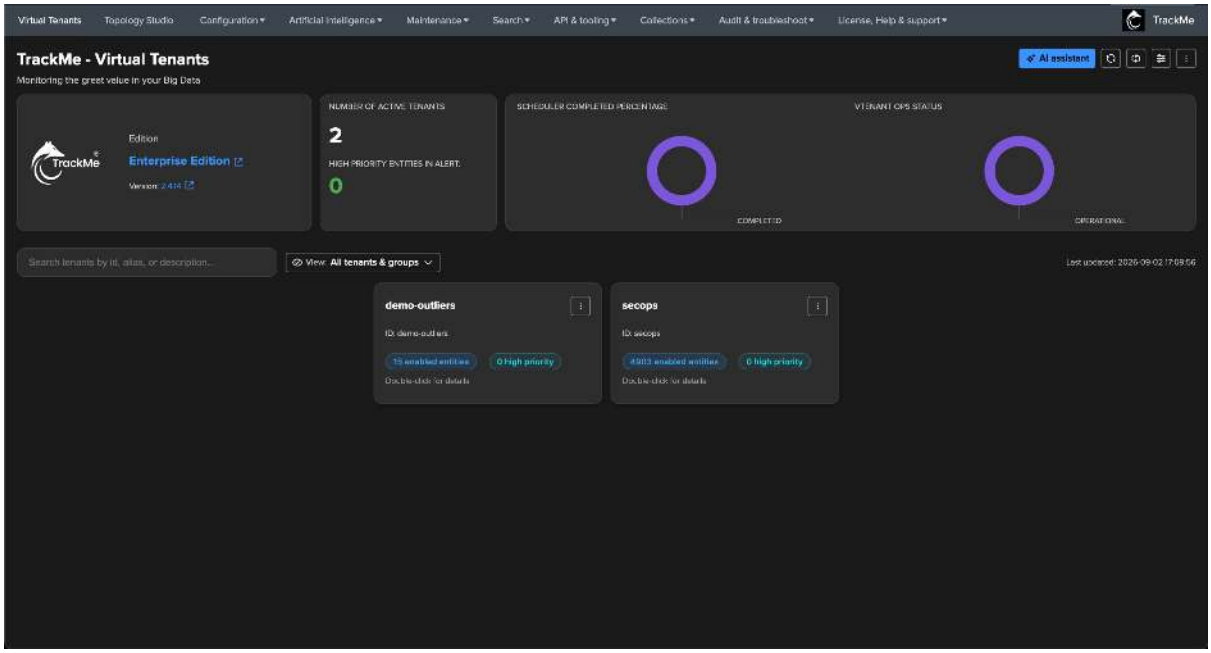
2.1 Install the package in place

The upgrade is a standard Splunk application upgrade: the new package replaces `default/`, `bin/` and `lib/`, and leaves `local/`, the KVstore and the indexes untouched. **Never remove the application directory first.**

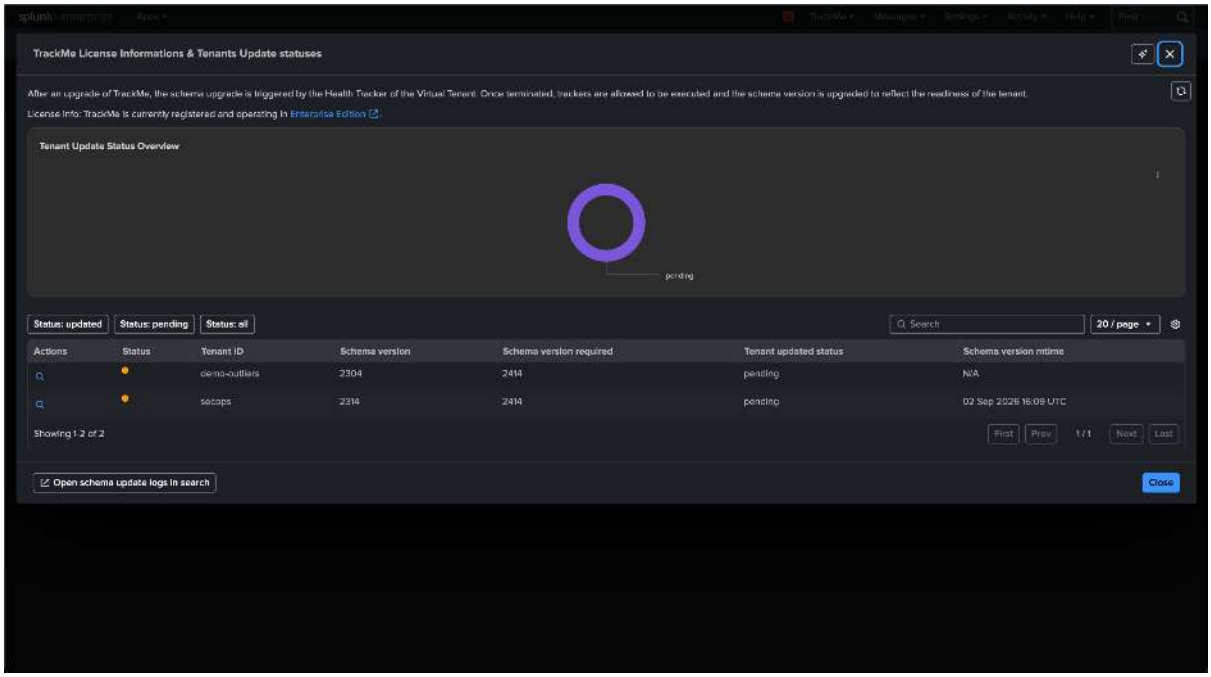
Topology	Procedure
Standalone or distributed search head	Splunk Web → **Apps → Manage Apps → Install app from file**, choose the package, tick **Upgrade app**, install. Or from the CLI: `splunk install app trackme_<version>_<build>.tgz -update 1`. Restart splunkd when prompted (new custom commands and Python libraries require it).
Search head cluster	On the deployer, replace the application under `$SPLUNK_HOME/etc/shcluster/apps/trackme` with the extracted package (overwrite in place; keep any deployer-side `local/`), then `splunk apply shcluster-bundle -target https://<captain>:8089`. Members restart in a rolling fashion. Do not install the package directly on members.
Splunk Cloud	When the release has been vetted, it appears as upgradable in the application management interface; follow the self-service process. There is usually a delay between the request and the installation, so by the time you connect to TrackMe the upgrade has often already happened.
Indexers	Nothing to do beyond the index definitions already in place (step 0).

2.2 Read the new version and open the update-status screen

Once splunkd is back, reload **Virtual Tenants**. The header shows the new version. Click it.



The screen explains what happens next: *the schema upgrade is triggered by the Health Tracker of the Virtual Tenant; once terminated, trackers are allowed to run and the schema version is updated to reflect the readiness of the tenant.* Immediately after the installation, every tenant is **pending** with the new required schema.

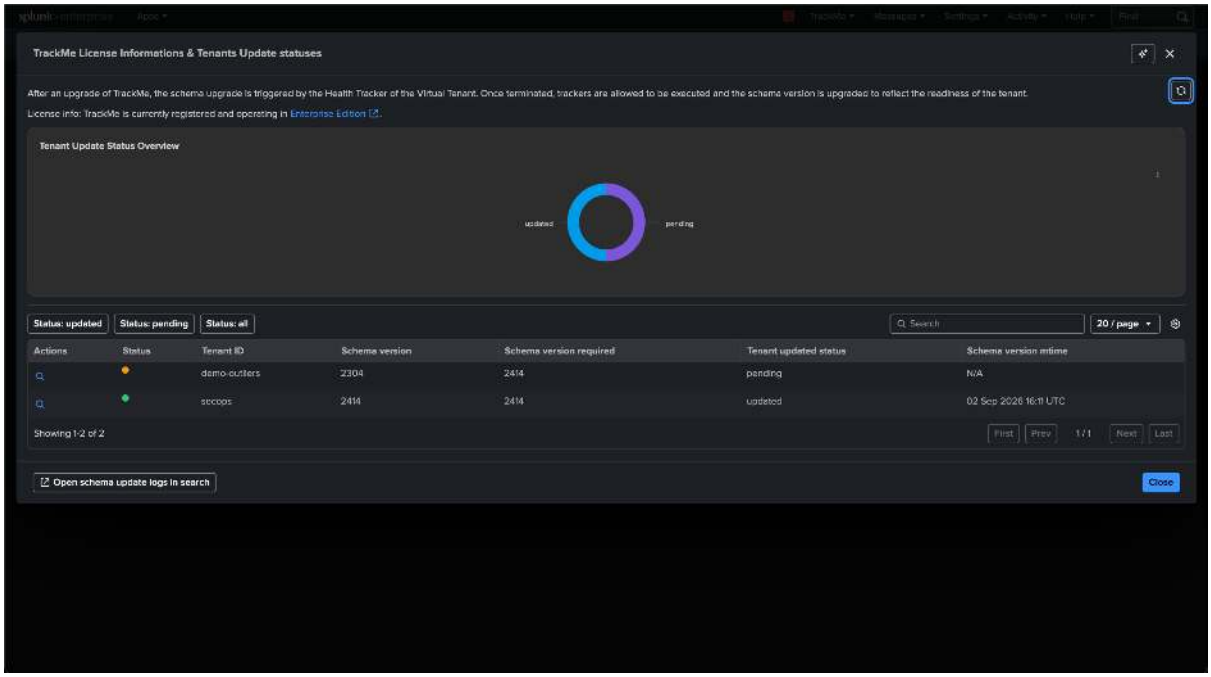


2.3 Follow the migration

Each tenant's health tracker runs the migration chain on its next cycle (every 5 minutes): every migration from the tenant's stored schema up to the required one, in order, after an automatic safety backup. Refresh the screen with the icon at the top right; enabled tenants move from *pending* to *updated* one by one. A large version jump means a long chain; allow two to three cycles per tenant, and more on large tenants, since some migrations touch every entity record.

Note

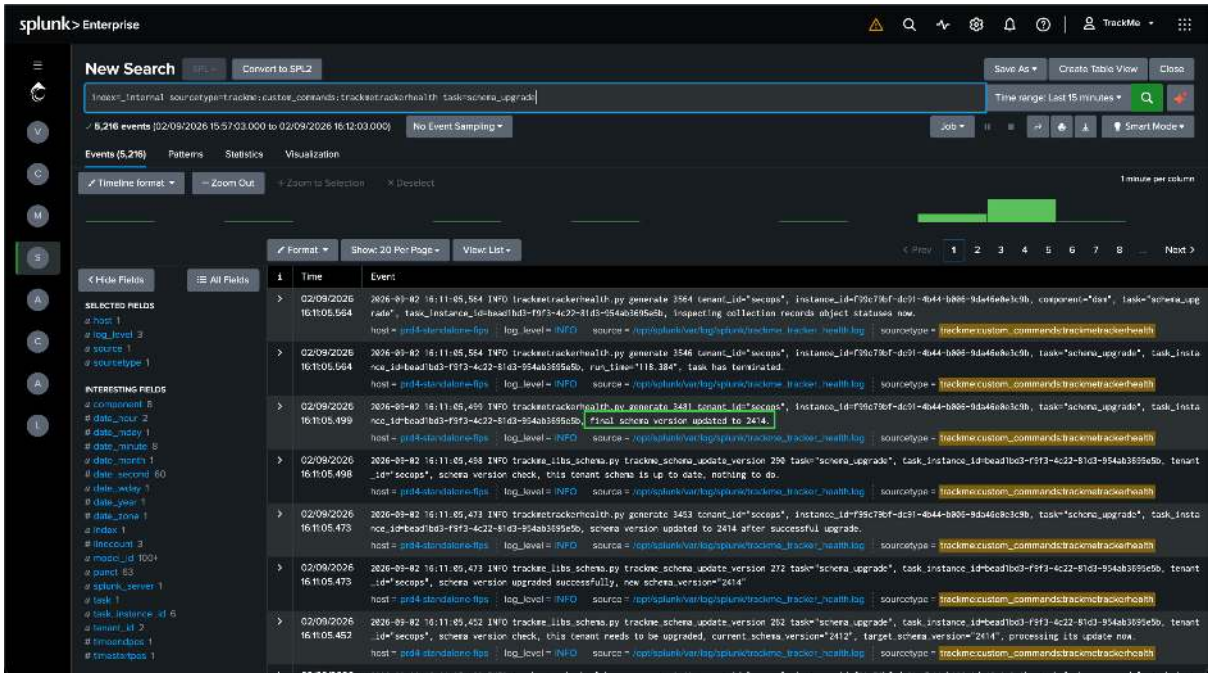
Disabled Virtual Tenants stay pending. A disabled tenant's health tracker does not run, so the tenant is not migrated and keeps showing *pending* until it is re-enabled (its migration then runs within the next 5 minutes). Either re-enable such tenants during the change window so that they migrate with the others, or record them explicitly as excluded from the completion criteria; the checkpoint below counts enabled tenants only.



The migration log is one click away, **Open schema update logs in search**, or per tenant through the magnifier in the Actions column. Manually:

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪task=schema_upgrade
```

Each migration logs its start and its outcome; the tenant's chain ends with **final schema version updated to <required>**. See *Schema migrations* for the meaning of every line.



Then filter on errors:

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪task=schema_upgrade log_level=error
```

Migrations are fail-soft: a failing item is logged and skipped, the chain continues, and the schema version still advances. TrackMe also runs reconciliation logic on regular cycles (the longest every 24 hours) that repairs the vast majority of such conditions on its own. An error here is therefore rarely a concern for the upgrade itself. Do share the errors with TrackMe Support (see *Support*) so that each one can be confirmed. Do not judge anything before the update-status donut is fully *updated*: that screen is the authoritative progress view.

2.4 Register the licence key

If the deployment is not registered yet (for example a former Community Edition install), open **License, Help & support → License**, register the licence key and confirm the page shows the edition registered with its expiry date. See *License registration*. Licensed deployments keep their licence through the upgrade; verify the page anyway and record the edition and expiry in the deployment record.

2.5 Restart Splunk once every tenant is migrated

On a **standalone or distributed search head**, for a large version jump we recommend one more restart of splunkd **after** the update-status screen shows every tenant *updated* and the licence is registered. The migration chain refreshes many per-tenant knowledge objects (transforms, lookup definitions, saved searches) in `local/`; a restart guarantees that every search process and scheduled report starts from the final, fully reloaded configuration. Run `splunk restart` in the change window.

This step is **exempt** on the other topologies:

- Search head cluster: no restart after the migration. The members already restarted during the bundle push (2.1), and the knowledge objects the migration refreshes are written through the REST API, replicated and reloaded on every member without a restart.
- Splunk Cloud: not applicable.

Where the restart applies, wait until the health trackers have run once more (about 5 minutes) before starting step 3.

Step 2 checkpoint

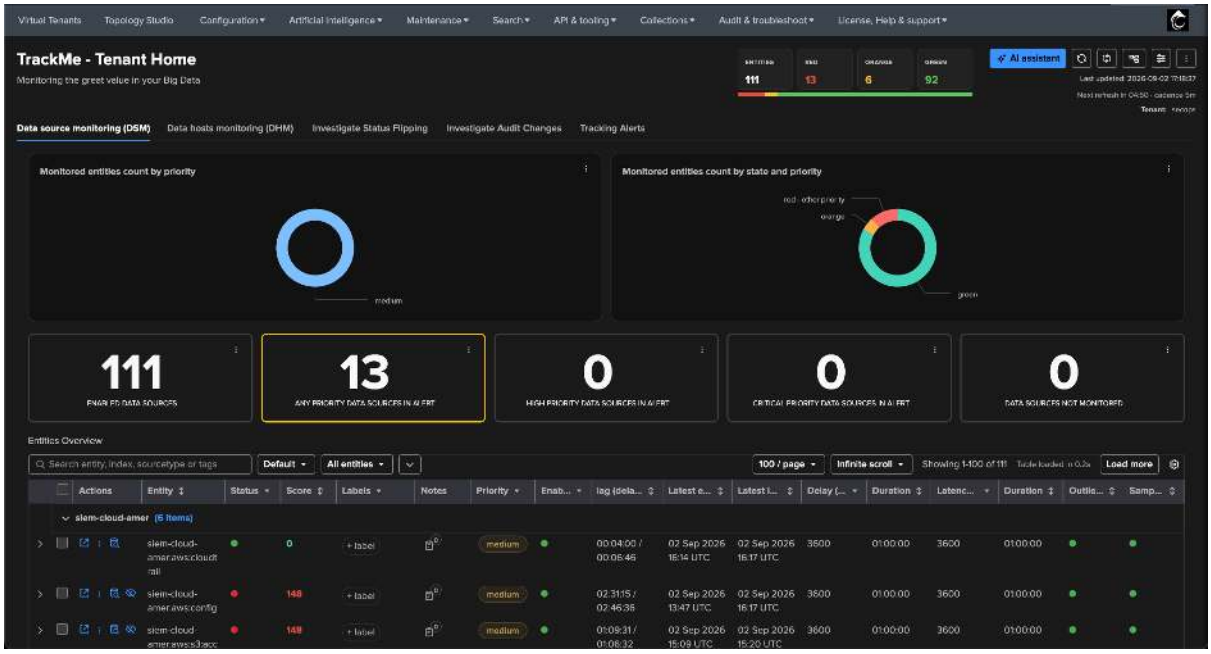
- Header shows the target version (2.2)
- Update-status screen: every enabled tenant at the required schema, status *updated* (2.3)
- Migration log shows *final schema version updated* for every tenant; errors captured and sent to Support (2.3)
- Licence page shows the edition registered, with its expiry date (2.4)
- Standalone or distributed search head only: splunkd restarted after the migration; health trackers have run once since (2.5). Search head cluster and Splunk Cloud: recorded as exempt

Step 3 — After the upgrade

Platform, alerting chain, ML Outliers, hand-over.

3.1 Every tenant and every component loads without error

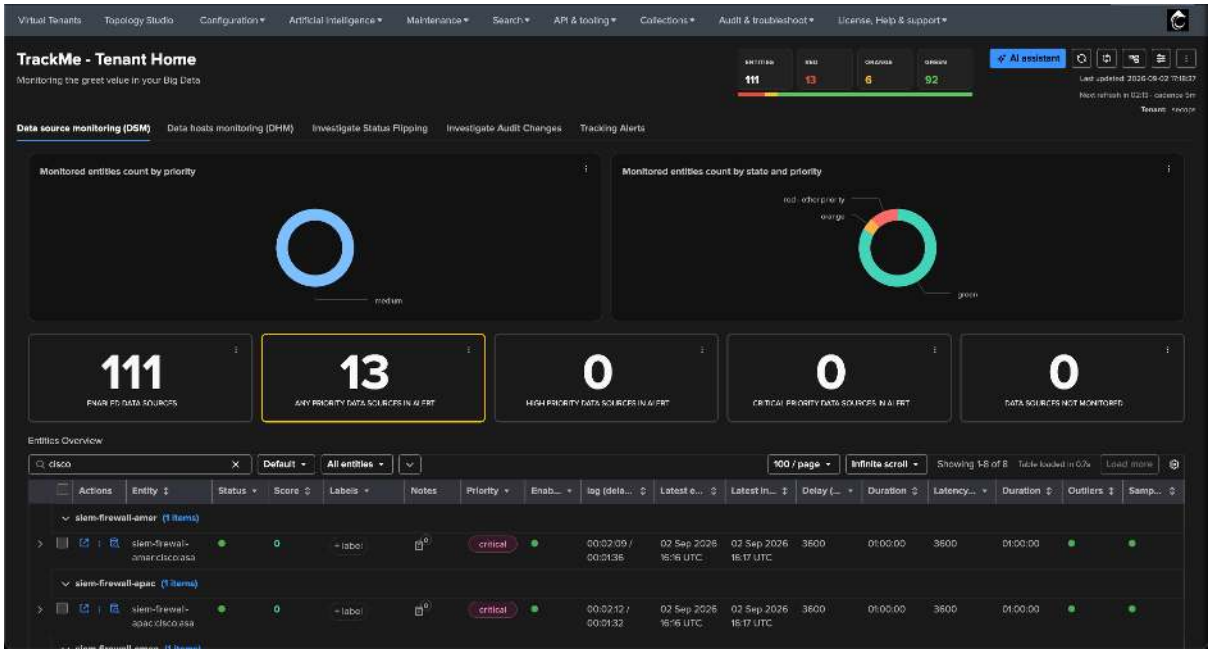
Wait about 15 minutes after the post-migration restart (or, where step 2.5 is exempt, after the last tenant reached *updated*): the health tracker also reschedules trackers and reconciles feature gates during the first cycles. Then open **Virtual Tenants**: the page loads, no error toast, every tenant OPERATIONAL. Open each tenant (**Tenant Home**) and click through its enabled component tabs: entity tables load, counters are populated, no error toast. Finally open **Configuration → Configuration Guardian**: it lists misconfigurations with remediation steps; anything raised must have a documented cause (see *Configuration Guardian*).



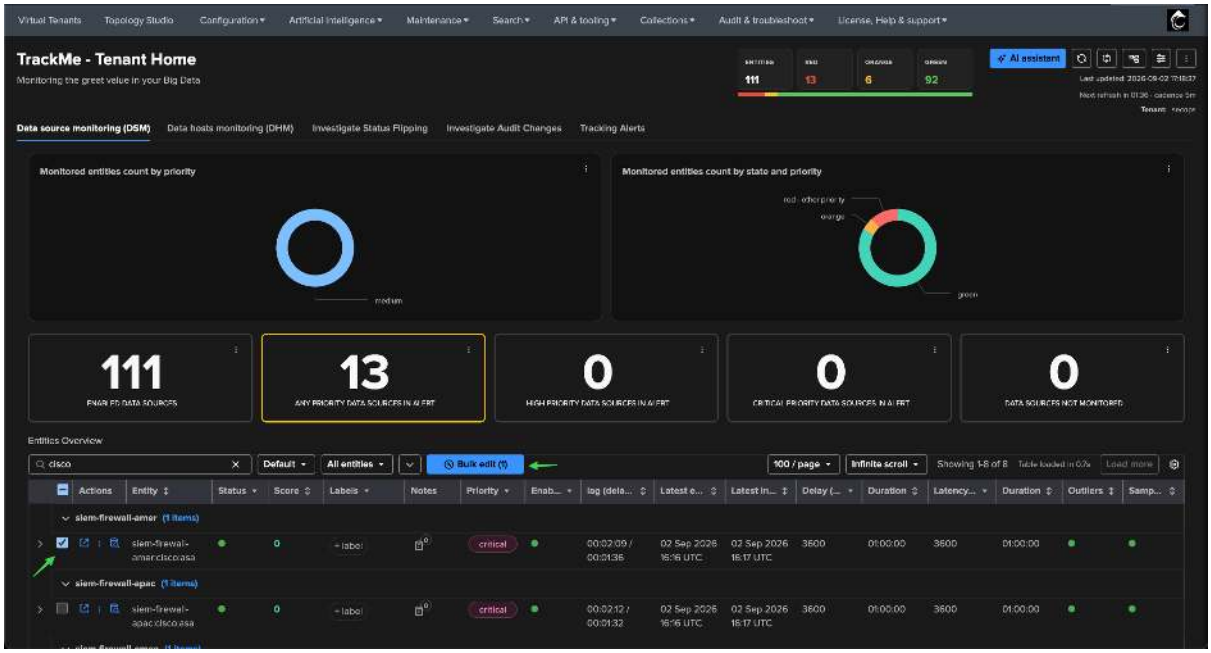
3.2 Validate the full alerting chain with a manual score influence

An entity's colour is driven by an impact score (0 = green, below 100 = orange, 100 and above = red; see *Impact scoring & thresholds*). The score can be influenced manually, which gives a clean, reversible way to force a healthy entity into alert and exercise everything downstream: notable creation, stateful alerts and emails, and your own tooling (ticketing, paging).

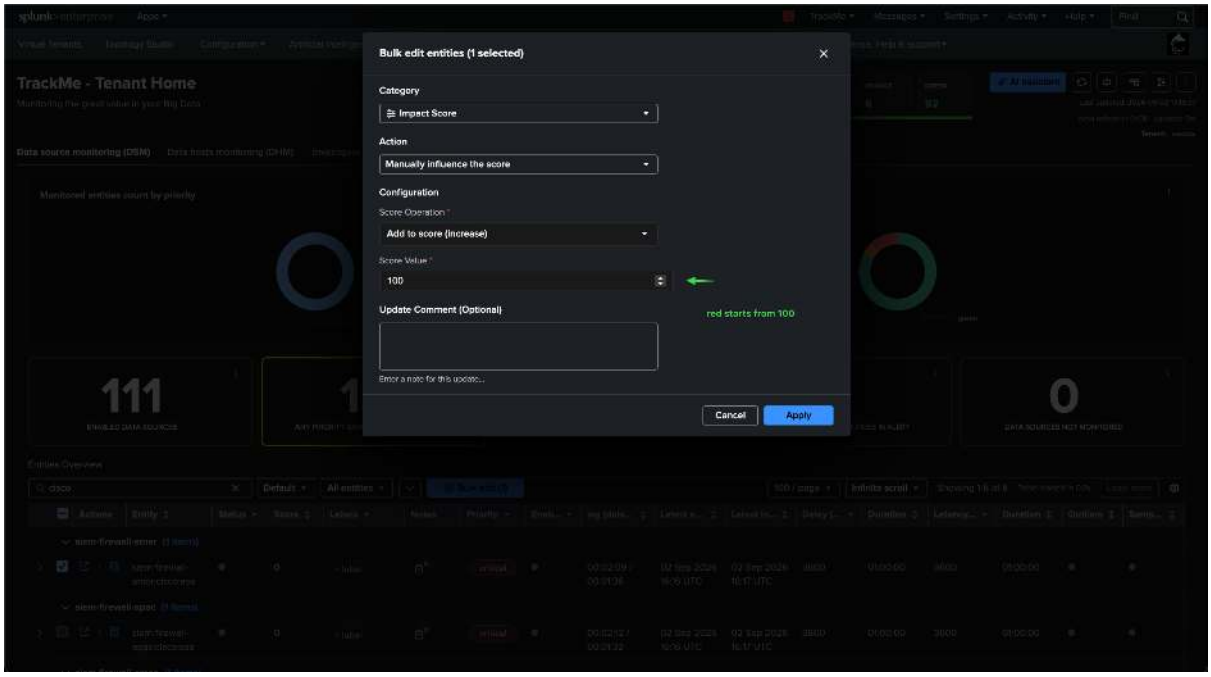
a. Pick a healthy, high-priority entity. In Tenant Home, search for a critical or high-priority entity that is green with a score of 0.



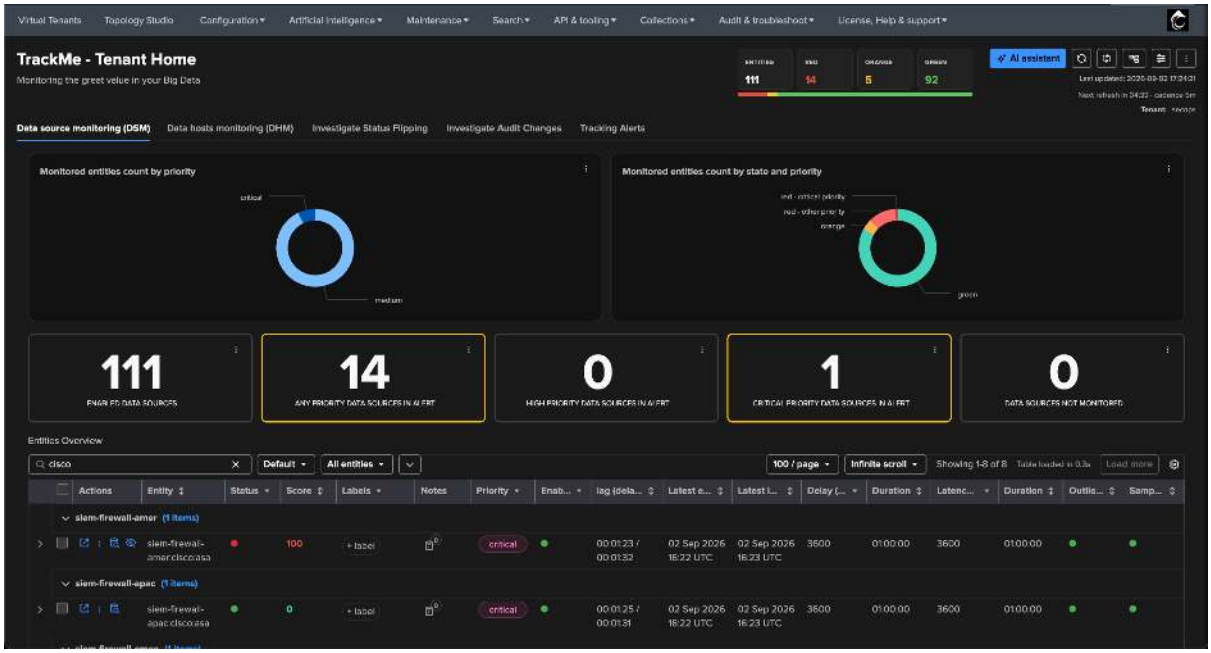
b. Select it and open Bulk edit. Tick the entity's checkbox; the **Bulk edit (1)** button appears above the table.



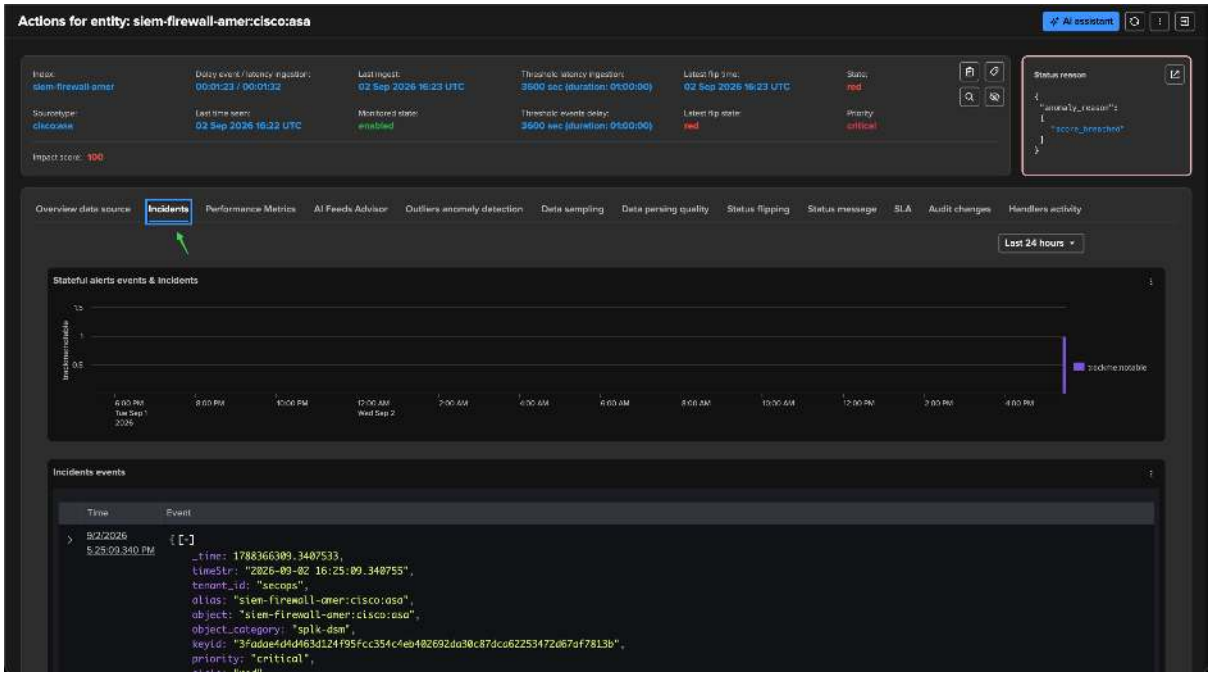
c. Add 100 to the score. Category **Impact Score**, action **Manually influence the score**, operation **Add to score (increase)**, value **100** (red starts from 100). Enter a comment such as "post-upgrade alerting chain test" and apply. The same action exists on a single entity from its **Actions** menu.



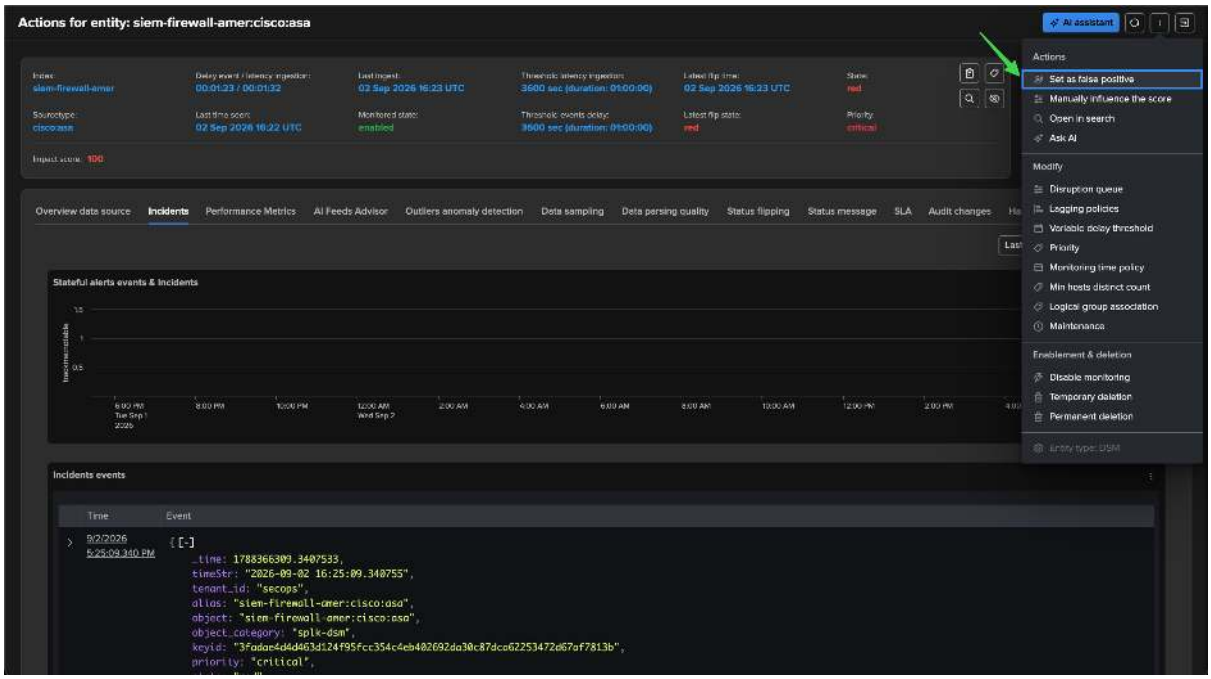
d. Watch the entity turn red. On the next evaluation the entity shows a score of 100 and a red state, with the anomaly reason `score_breached`. This can take a few minutes.



e. Confirm the incident. Alerts run on their own schedule, so the incident typically appears 5 to 10 minutes later. Open the entity's **Incidents** tab: the `trackme:notable` event is listed with the entity's fields. This is the payload your downstream tooling consumes; verify that the ticket, page or email arrived.



f. Clear the test. From the entity's **Actions** menu choose **Set as false positive** and enter a comment. This records a negative score that cancels the manual influence; the entity returns to green on the next evaluation and the stateful alert, if any, closes on its own.



Hint

What this proves

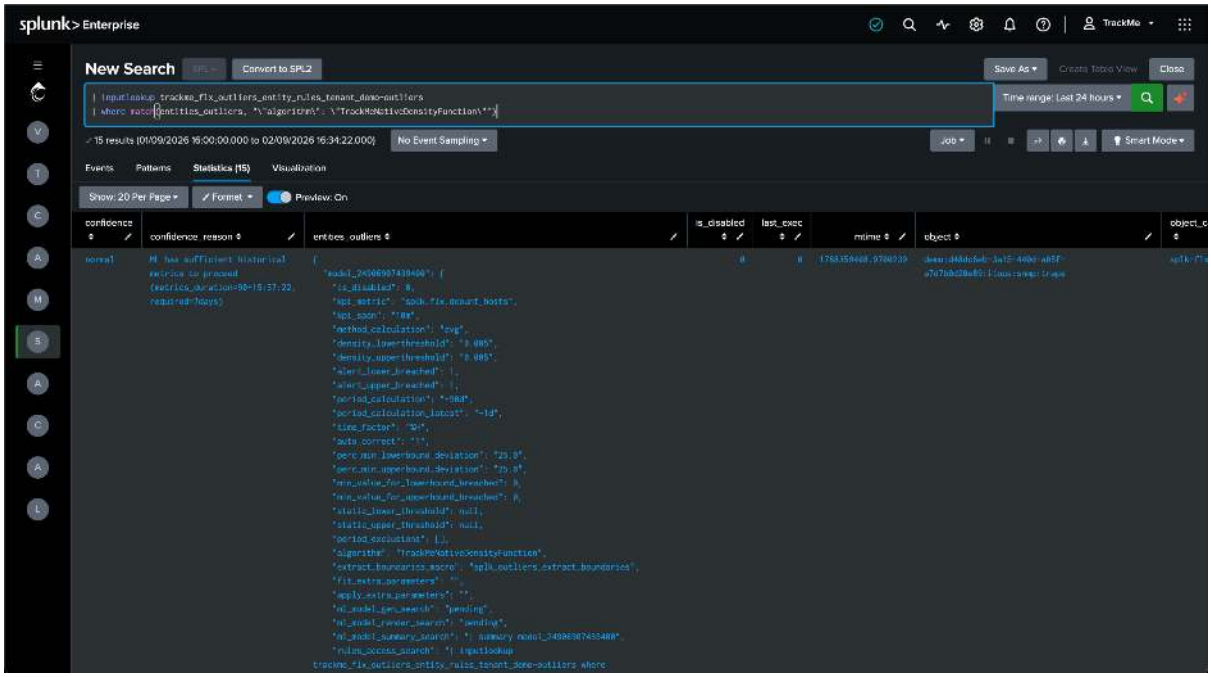
Score evaluation, state flip, notable emission and your downstream chain all work on the new release, with one reversible action and no synthetic data. Repeat it once per class of tenants if they feed different downstream pipelines.

3.3 ML Outliers — only where they are in use

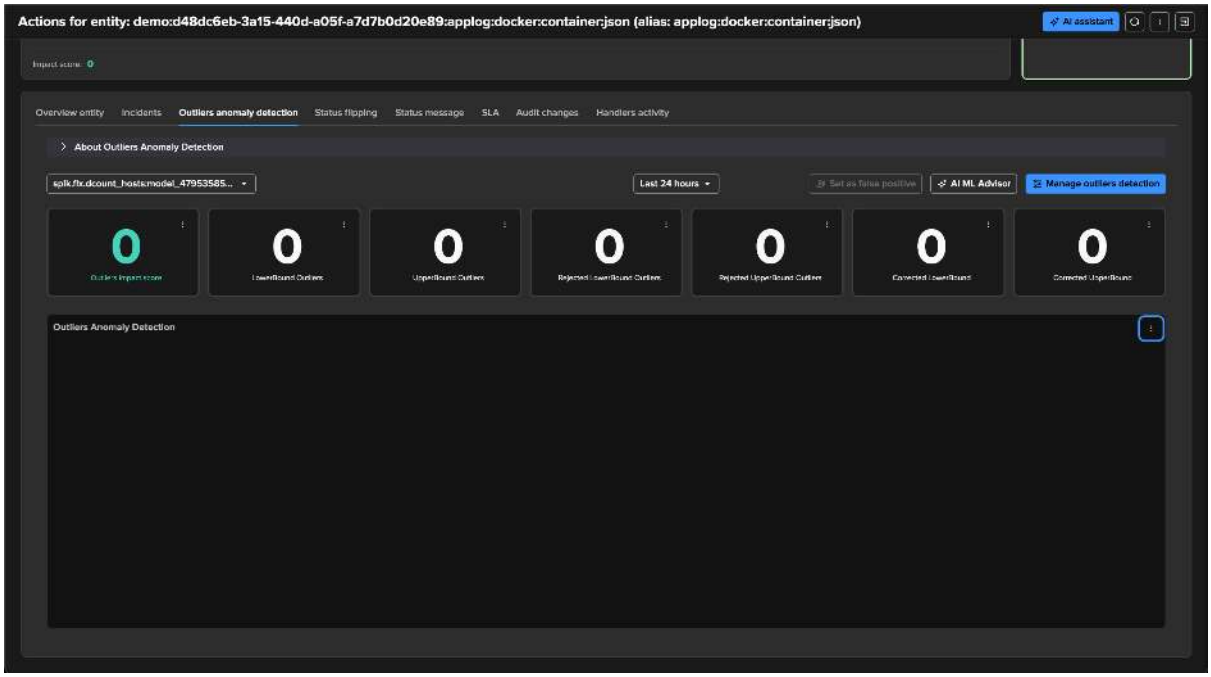
When the upgrade crosses the native ML engine migration (release 2.3.15), every model definition is rewritten to `TrackMeNativeDensityFunction` and reset for retraining (`last_exec=0`). The migration does **not** train the new models: until a model is trained its Outliers chart is empty and it produces no detection. Training runs automatically through the per-tenant, per-component report `trackme_<component>_outliers_mltrain_tracker_tenant_<tenant_id>`, which processes the backlog in batches over its scheduled runs. Three checks:

a. Definitions migrated. The step 1.3 count search now returns 0; the positive form shows the migrated records: `algorithm` is `TrackMeNativeDensityFunction`, the stored searches read `pending` and the record's `last_exec` is 0. That reset is the instruction to the training job.

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| where match(entities_outliers, "\"algorithm\": \"TrackMeNativeDensityFunction\"")
```



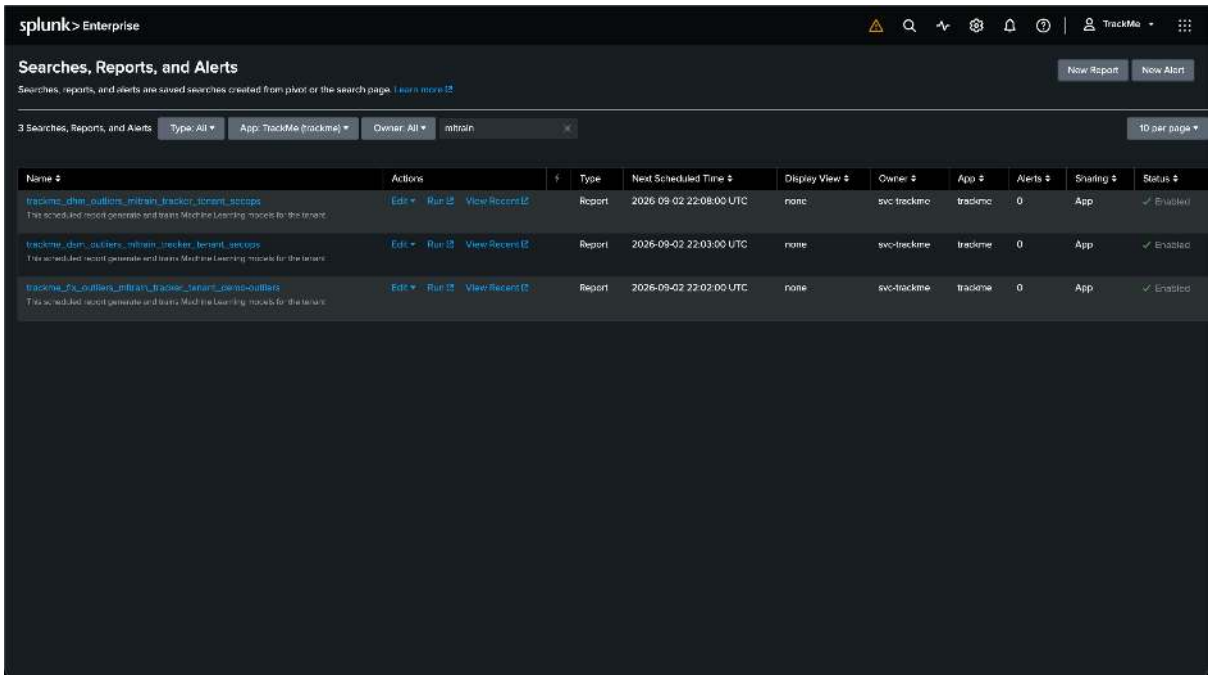
Until retraining, the witness entity's Outliers tab shows the model in the selector, the counters at zero and an empty chart. This is expected at this point, not a fault.

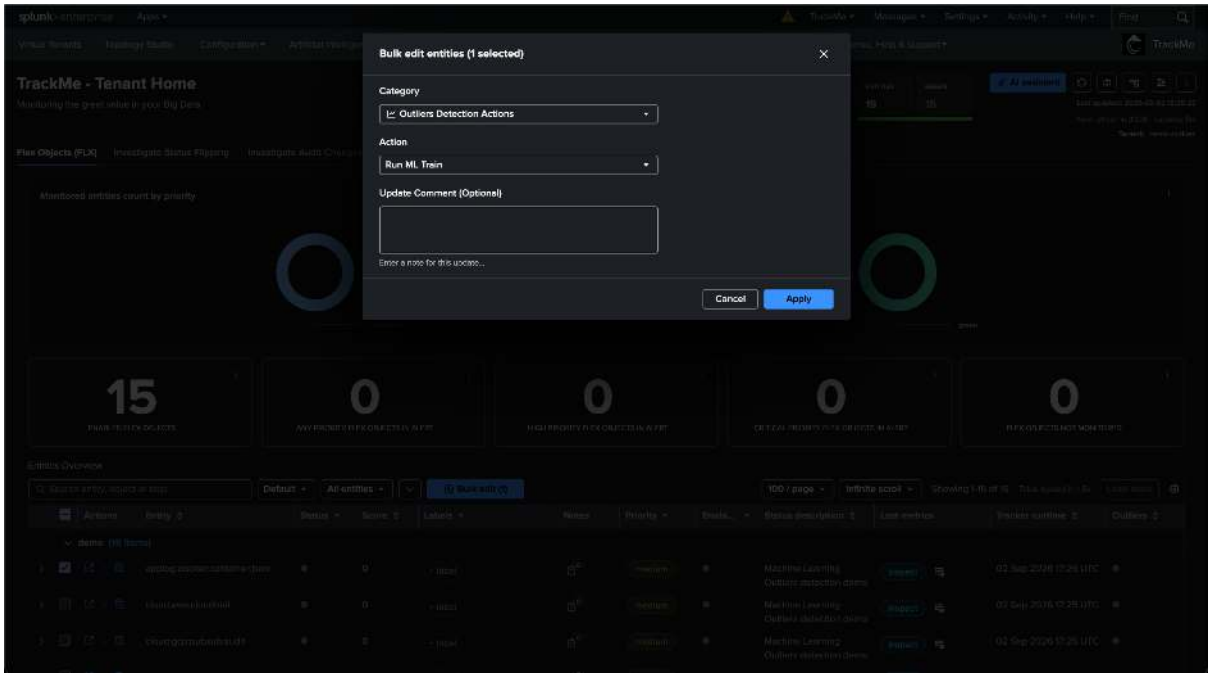


b. Backlog draining. The following search drains to 0 rows as training progresses:

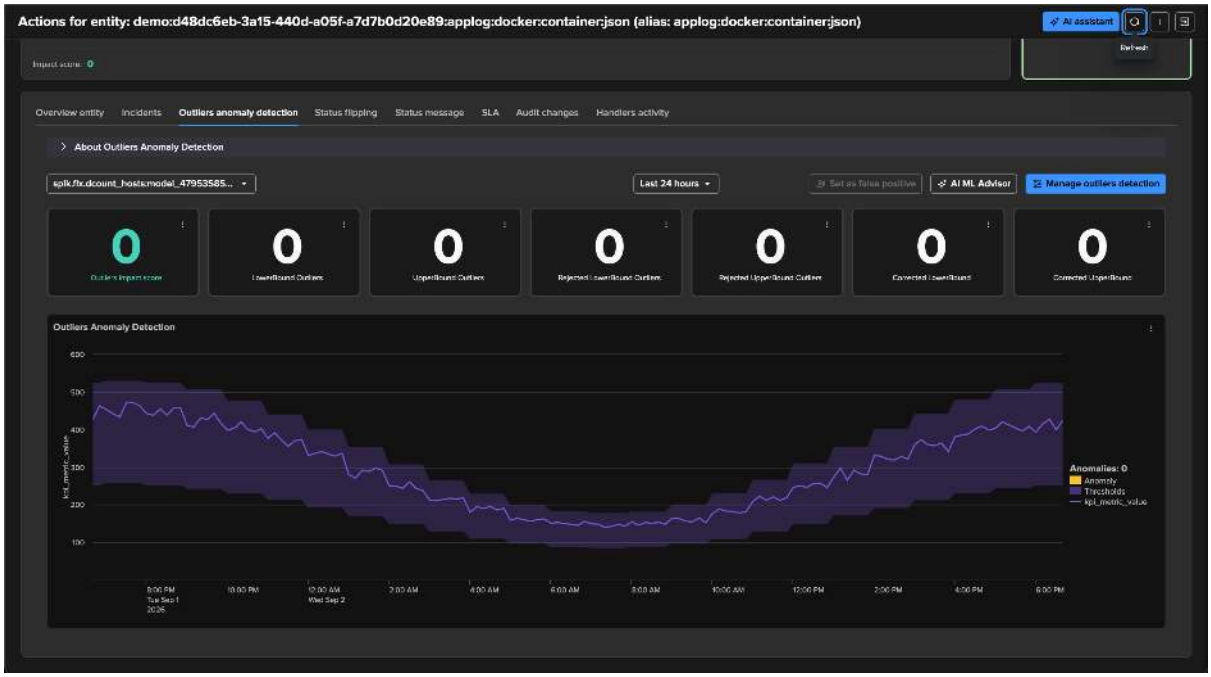
```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| where is_disabled=0 AND last_exec=0
```

To accelerate, run the mltrain report from Splunk's **Searches, Reports, and Alerts** page (application TrackMe, filter `mltrain`) with the **Run** action, once per tenant and component, repeated until the backlog is empty; or select entities in Tenant Home and use **Bulk edit → Outliers Detection Actions → Run ML Train**. Opening an entity whose native model is missing also triggers an automatic first training (expect a slow first render rather than an error).





c. Witness entity renders again. Reopen the step 1.3 witness: once trained, its Outliers tab shows the chart again on the native engine. The band may differ slightly from the step 1.3 screenshot, the model having been refitted on the current rolling window. See *Outlier detection* for the model tuning reference.



3.4 Close the deployment record and hand over

Complete the validation record for the deployment (template in *Validating after an upgrade*), archive the step 1 screenshots and exports next to it, and inform the operators that the upgrade is complete and that the alerting test has been cleared. Brief them on the behaviour changes of the new release (see *Validating after an upgrade*).

Step 3 checkpoint

- Virtual Tenants, every tenant / component and the Configuration Guardian page load with no unexplained item (3.1)

- Forced alert turned the test entity red; notable created; downstream incident confirmed; test cleared as false positive (3.2)
- Where Outliers are used: no legacy-engine model left; backlog drained; witness entity renders again (3.3)
- Validation record completed and archived; operators informed (3.4)

Step 4 — Only if a rollback is decided

Danger

A rollback is a restore, not an un-install.

Schema migrations are forward-only: reinstalling the previous package reverts the code and none of the migrated data, and the update-status screen would even report *updated*. The reliable rollback is to restore the step 1.2 backups on the reinstalled package. When the driver is alerting behaviour (impact-score weights, outlier score, policy cadence, threshold locks), tune first: those are configurable on the current release. Changes that are not configurable (the native ML engine, the schema shape, the rebuilt interface) are the only ones a rollback reverts; if the decision stands, follow *Rollback*.

The runbook in four lines

- **Upgrade path:** in place, one release for the whole estate.
- **Progress view:** click the version number.
- **Proof of health:** force one alert and clear it.
- **Rollback model:** restore the backups.

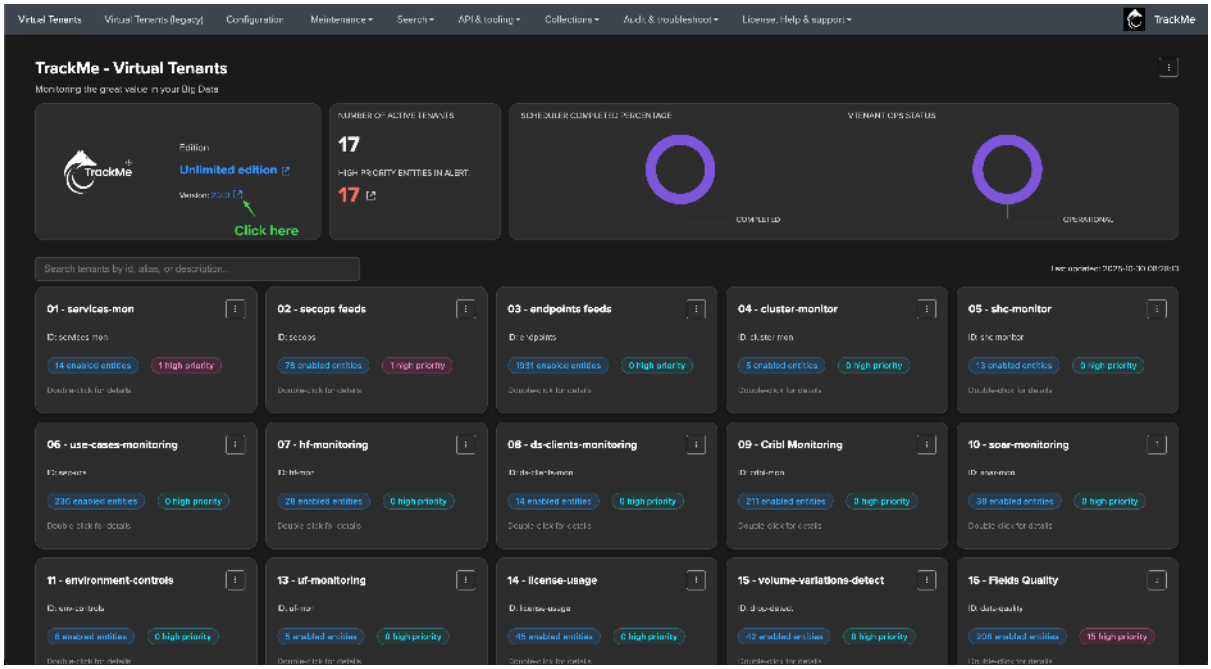
7.2.2 Schema migrations

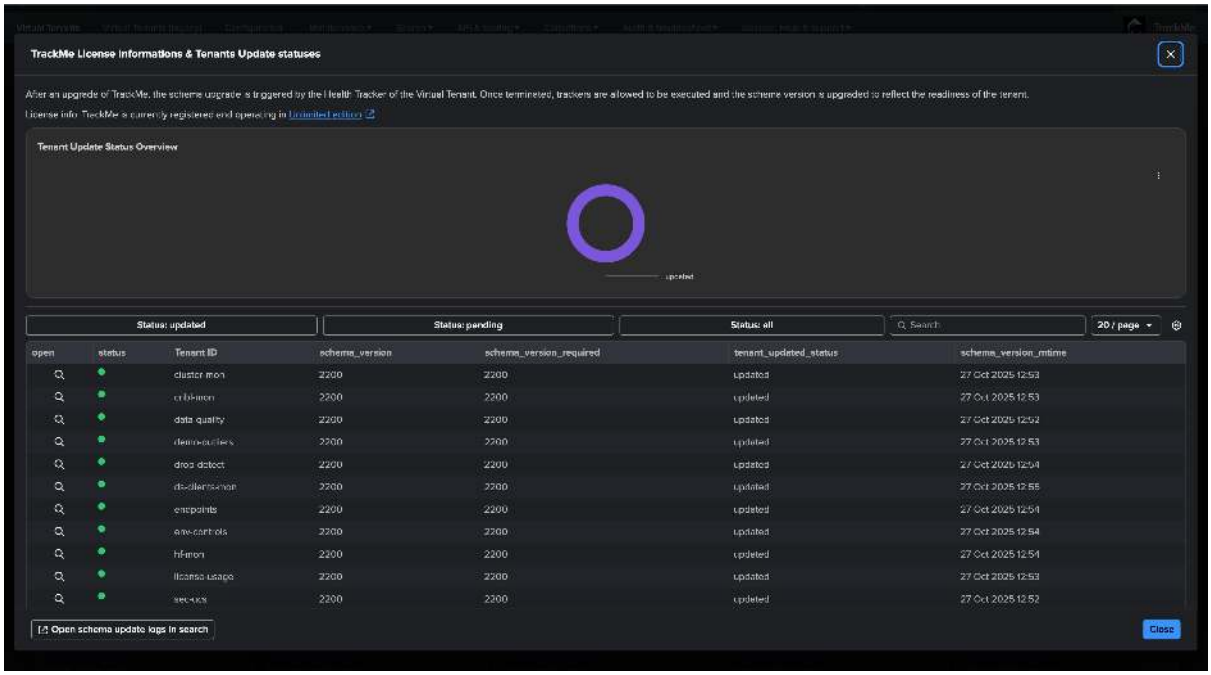
Once TrackMe has been upgraded through the standard Splunk process (Splunk Enterprise or Splunk Cloud, search head cluster or standalone), TrackMe automatically verifies and performs the additional upgrade procedures each Virtual Tenant needs. This mechanism is the **schema version**: an automated, per-tenant, forward-only migration chain that creates, updates or deletes TrackMe knowledge objects and KVstore collections depending on the origin version and the state of the tenant. This page describes how it works, how to follow it, and what runs between releases.

The schema marker

The schema version is versioning information stored in the KVstore record of each Virtual Tenant. It corresponds to the TrackMe version without the dots, with a two-digit patch number: version 2.1.0 is schema `2100`, version 2.3.4 is `2304`, version 2.4.14 is `2414`.

```
| inputlookup trackme_virtual_tenants | eval keyid=_key
| fields keyid, tenant_id, schema_version, schema_version_mtime
```





The required schema version derives from the running application version. The `trackmetenantstatus` command returns both, together with the derived *updated* / *pending* status, for every tenant the user can access:

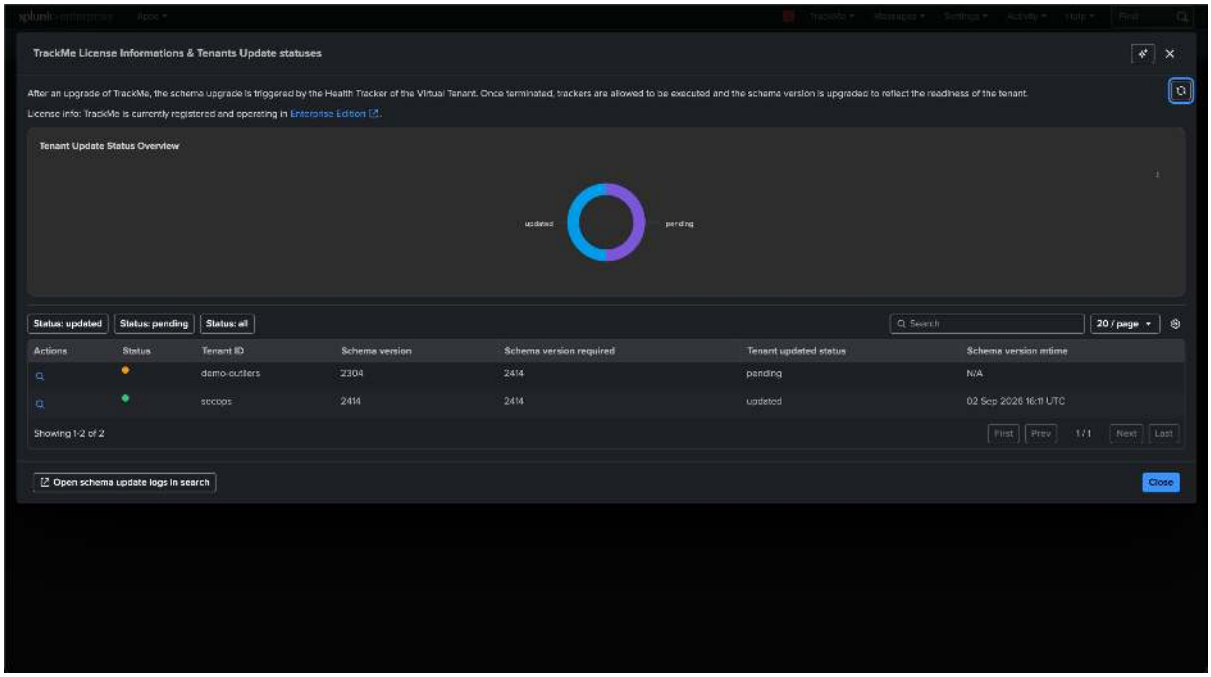
```
| trackmetenantstatus output="tenants"
| table tenant_id, tenant_status, schema_version, schema_version_required,␣
↪tenant_updated_status, schema_version_mtime
```

The Tenants Update statuses screen

On the **Virtual Tenants** page, the version number in the header is a link. It opens the **Tenants Update statuses** screen, the authoritative progress view of a migration:

- a donut of tenants *updated* vs *pending*;
- one row per tenant with **Schema version**, **Schema version required**, **Tenant updated status** and **Schema version mtime**;

- a per-row action and a global **Open schema update logs in search** button, both landing on the migration log of the tenant.



Who runs the migration

The schema verification is handled by the **Health tracker** of the Virtual Tenant. When a tenant is created, TrackMe creates a dedicated health tracker for it, responsible for administration tasks such as detecting issues in the tenant's trackers, and for running the schema verification:

- `trackme_health_tracker_tenant_<tenant_id>`

The health tracker runs every 5 minutes. When it detects that the stored schema version is behind the required one, it runs every migration between the two, in order, and advances the marker after each one. Migrations therefore run on the health-tracker cycle, **not at package installation time**: allow one to two cycles per tenant before judging anything, and more on large tenants, since some migrations touch every entity record.

Disabled Virtual Tenants

- Disabled Virtual Tenants are not migrated as long as they are disabled (their health tracker does not run).
- If a tenant is re-enabled, its migration is processed automatically within the next 5 minutes.

Search head clusters

The migration of a tenant runs on whichever member runs the tenant's health tracker. The KVstore is replicated, so the result is visible on every member.

The automatic safety backup

Before the first migration of a chain runs, TrackMe executes a backup job automatically. The run appears in **API & tooling → Backup & Restore** with the comment *Backup initiated for schema migration from version X to Y* (on releases with the multi-archive backup format, one archive per enabled tenant plus one global archive). The backup is deduplicated per required version and day, so several tenants migrating in the same window share one safety backup. See *Backup & restore*.

```
| inputlookup trackme_backup_archives_info
| table backup_run_id, archive_scope, tenant_id, status, mtime, comment
| sort - mtime
```

Reading the migration log

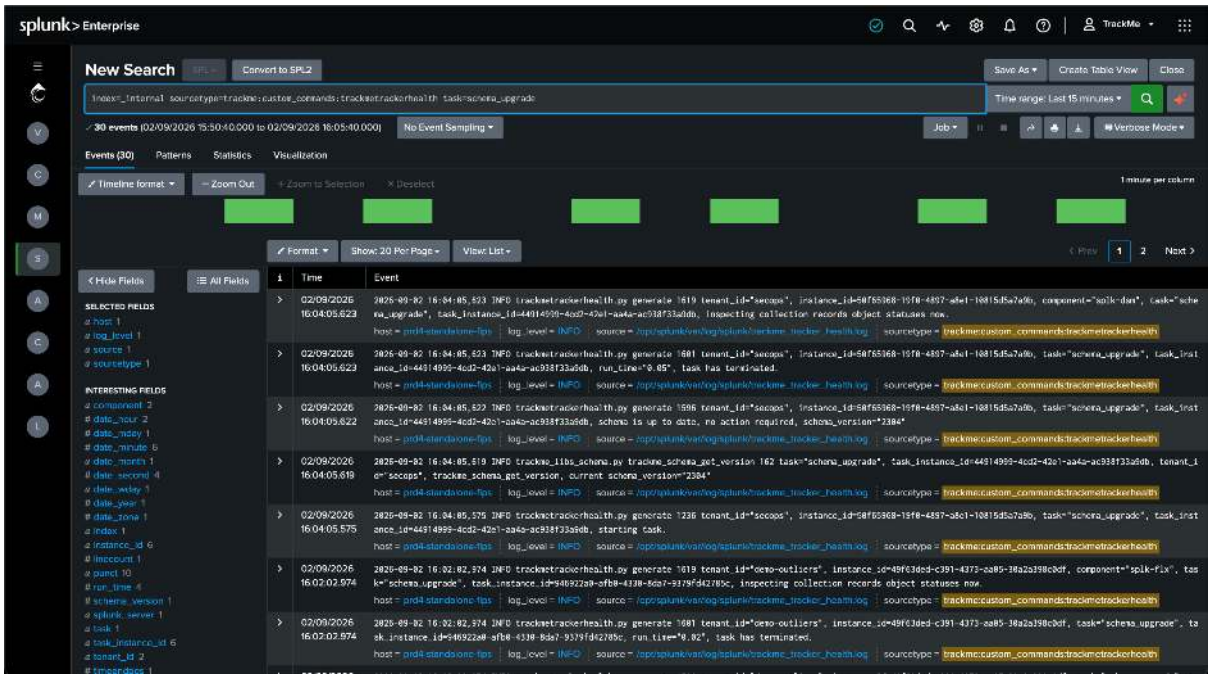
The logs of the health tracker and of every migration are available through the navigation bar shortcut **Audit & troubleshoot → Logs - TrackMe custom commands** and match:

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth task=
↪"schema_upgrade"
```

Every task carries a `task_instance_id` so that one run can be followed end to end. The run time of every health-tracker task can be tracked with:

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪instance_id=* task_instance_id=* task=* run_time=* tenant_id=*
| table _time tenant_id instance_id task task_instance_id run_time _raw
| sort 0 - _time
```

Before an upgrade, the health tracker only logs routine verifications:



When the tracker runs, it verifies the schema version:

```
INFO trackmetrackerhealth.py generate tenant_id="feeds-tracking",␣
↪instance_id=879a5021-..., task="schema_upgrade", task_instance_id=80a9366d-...,␣
↪starting task.
INFO trackme_libs_schema.py trackme_schema_get_version task="schema_upgrade",␣
↪task_instance_id=80a9366d-..., tenant_id="feeds-tracking",␣
↪trackme_schema_get_version, current schema_version="2097"
```

If an upgrade is required, the following message is logged:

```
INFO trackmetrackerhealth.py generate tenant_id="feeds-tracking", ..., task=
↪"schema_upgrade", ..., detected migration required for schema version 2098,␣
↪schema_version="2097", schema_version_required="2100", processing now.
```

The safety backup is executed:

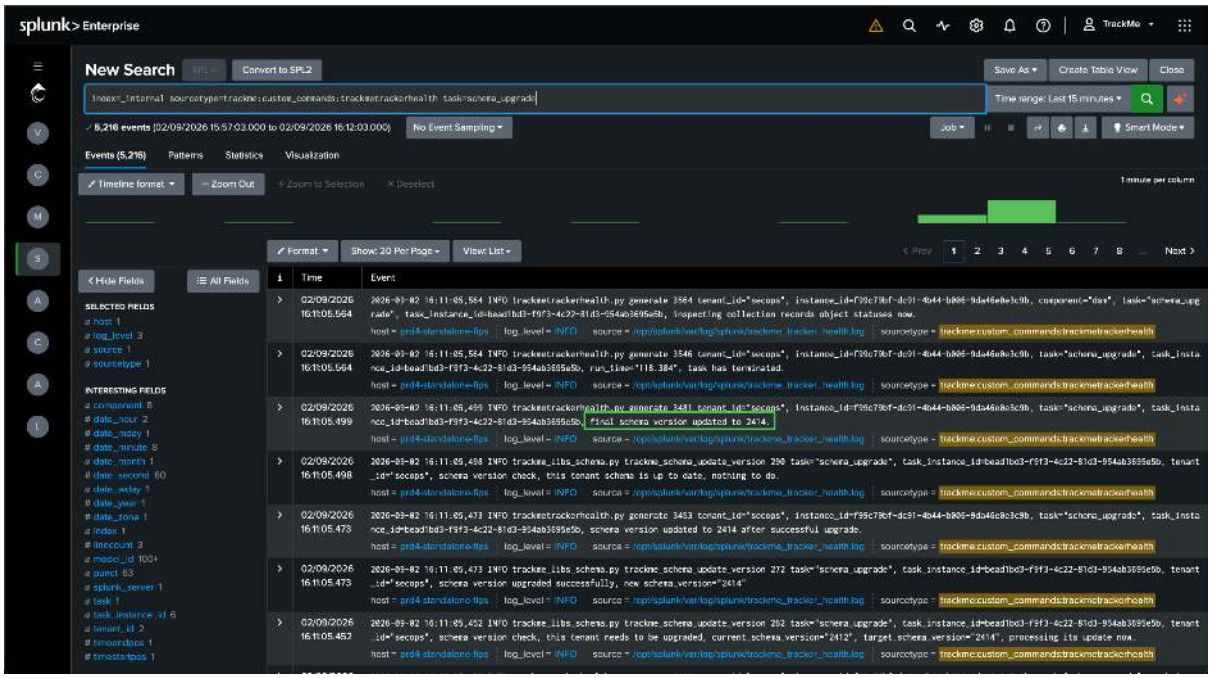
```
INFO trackmetrackerhealth.py generate tenant_id="feeds-tracking", ..., task=
↪"schema_upgrade", ..., backup post call executed successfully
```

Each migration then runs in order and logs its actions:

```
INFO trackme_libs_schema.py trackme_schema_upgrade_2098 task="schema_upgrade", ...,
↪ Starting function trackme_schema_upgrade_2098, tenant_id="feeds-tracking"
INFO trackme_libs_schema.py trackme_schema_upgrade_2098 task="schema_upgrade", ...,
↪ schema migration 2098, tenant_id="feeds-tracking", successfully deleted␣
↪transform definition, transform="trackme_dsm_tenant_feeds-tracking"
```

Once every migration has completed, the marker is updated and the task terminates:

```
INFO trackme_libs_schema.py trackme_schema_update_version task="schema_upgrade", ..
↪., tenant_id="feeds-tracking", schema version upgraded successfully, new␣
↪schema_version="2100"
INFO trackmetrackerhealth.py generate tenant_id="feeds-tracking", ..., task=
↪"schema_upgrade", ..., final schema version updated to 2100.
INFO trackmetrackerhealth.py generate tenant_id="feeds-tracking", ..., task=
↪"schema_upgrade", ..., run_time="26.2", task has terminated.
```



Errors and the fail-soft rule

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪task=schema_upgrade log_level=error
```

Migrations are written to be **fail-soft**: per-item work (a record backfill, a transform refresh, a saved search update) is caught, logged and skipped, the chain continues, and the schema version still advances. A single bad record or knowledge object cannot wedge the chain. The bootstrap of a migration (the connection to splunkd and the initial KVstore read) is deliberately *not* guarded, so that a transient outage propagates and the tracker simply retries on its next cycle without advancing the marker.

Important

updated means the chain ran, not that every item succeeded.

Because of the fail-soft rule, a tenant can report *updated* while one record or knowledge object was skipped with an error. The update-status screen is therefore the progress view, and the error search above is part of the completion criteria: review every error logged during the migration window before signing off the upgrade checkpoint.

TrackMe also runs reconciliation logic on regular cycles (the longest every 24 hours) that repairs the vast majority of skipped items on its own, and the Configuration Guardian surfaces persistent inconsistencies with remediation steps (see *Configuration Guardian*). Handle each logged error as follows:

- **Self-healed**: the same item is processed successfully by a later cycle, or the Guardian raises no alert for it after 24 hours. Record the error and its resolution; nothing else to do.
- **Persistent**: the error repeats, a Guardian alert names the item, or a tenant stays DEGRADED because of it. Apply the Guardian's remediation steps or, for a record that cannot be reconciled, re-run the migration's effect through the corresponding management action (for example a model retrain, a policy re-apply, a tracker re-creation from the tenant's management screen).
- **Unclear**: share the error lines with TrackMe Support (see *Support*) and keep the checkpoint open until they are confirmed as benign or resolved.

What runs between releases

Every release may ship at most one migration, numbered with its schema version. A migration is never modified after it ships; robustness fixes and new fields go into a later one. A chain from an old release therefore runs every migration between the two versions, in order. The condensed catalogue below covers the 2.1 line onward; the full detail of each release is in the *Release notes*.

Schema	Effect (condensed)
2121 to 2132	2.1 line: tenant configuration reconciliation (new tenant-level preferences with defaults), remote-account preferences, transform refreshes; the FQM component initialised disabled on existing tenants; FLX drilldown-search collections; WLK workload trackers moved to the new index. Mechanical, no behaviour change.
2300 to 2314	2.3 line: main-collection transform refreshes; stateful alerts rewritten to use the `trackmestateful` command (2304); lookup refreshes; variable delay collections (2312); per-component lagging classes (2313); policy transforms (2314).
2315	**Native ML engine migration.** Creates the per-tenant native-models KVstore collection and transform; rewrites every Outliers model's `algorithm` from `DensityFunction` to `TrackMeNativeDensityFunction`; sets `model_storage=kvstore`; resets the stored model searches to `pending` and `last_exec` to 0 so that the next training cycles regenerate them. Models retrain automatically on the following mltrain runs (step 3.3 of the *Upgrade procedure*). This is the one migration a rollback must compensate for (see *Rollback*).
2316 to 2322	Shadow read cache and score cache collections; health-tracker state; labels; policy tracker cadence reduced from every 15 minutes to twice daily; outlier result transforms; tenant-level ML settings backfill.
2400 to 2406	Tenant schema reconciliation; AI advisor saved searches created (seeded unscheduled, inert unless AI features are enabled); Smart Status decommission; threshold intent-lock collections; labels backfill; WLK execution-errors collection.
2408 to 2414	DSM `min_records` transform refresh; native-models transform refresh (incremental-training diagnostics); SLA manual-override contract repair (clears the flag that SLA *policies* had stamped on entities, so those entities return to policy evaluation; genuinely manual overrides are preserved).

Two timing consequences for validation

- Migrations run on the health-tracker cycle, not at installation time. The update-status donut moves from *pending* to *updated* as tenants complete; do not judge anything before it is fully updated.
- Migration 2315 resets model searches to `pending` and `last_exec` to 0: that is the migration working, not a failure. Models refit on the following mltrain cycles, and a missing native model is also trained automatically the first time the entity is opened.

What the marker does on a downgrade

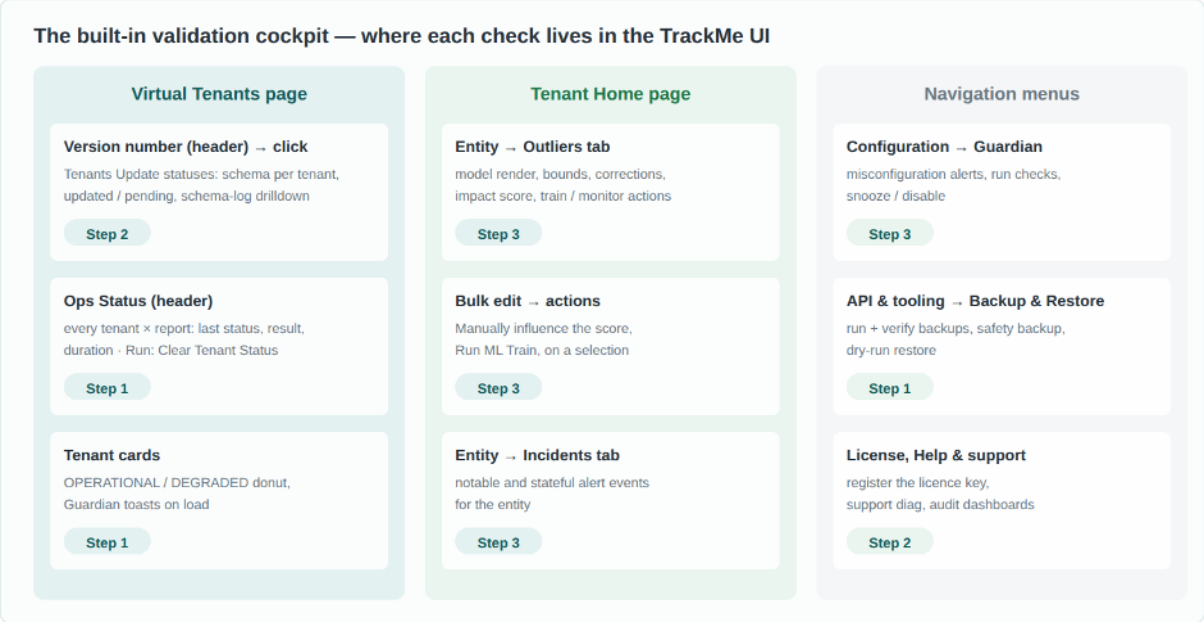
Migrations are forward-only. If an older package is reinstalled over migrated data, no migration runs, nothing is reverted, and the health tracker silently **realigns the marker down** to the running version. The Tenants Update statuses screen then shows every tenant as *updated* while the data keeps its migrated shape. This is why a rollback is a restore of the pre-upgrade backups and never a re-install of the older package, and why post-downgrade validation must inspect the data itself: see *Rollback*. On a later re-upgrade the migrations run again; they are idempotent, so that is safe.

7.2.3 Validating after an upgrade

The *Upgrade procedure* covers what matters on the day. This page is the reference behind it: the built-in screens that answer most checks, the behaviour changes to brief operators on, the exhaustive checklist for formal validation records, the evidence searches, and a record template.

The built-in validation cockpit

Most of the validation is executed from TrackMe's own screens. Use them first; capture screenshots as evidence; fall back to the searches at the end of this page when you need an export or a before/after diff.



Surface	What it tells you	Use it for
Tenants Update statuses (Virtual Tenants → click the version number)	Donut of tenants *updated* vs *pending*; one row per tenant with schema version, required version, status and mtime; per-row and global links to the migration log.	Steps 1.4, 2.2, 2.3
Ops Status (Virtual Tenants → header)	Every tenant × report (tracker) with status, last result, last execution and duration; success / failure filters. **Run: Clear Tenant Status** resets the execution summary so a failure recorded *before* the upgrade does not keep a tenant DEGRADED afterwards.	Steps 1.1, 3.1
Tenant cards (Virtual Tenants grid)	OPERATIONAL / DEGRADED per tenant; Configuration Guardian alerts raised as toasts on page load.	Steps 1.1, 3.1
Configuration Guardian (Configuration menu)	Persistent misconfiguration alerts with remediation steps; per-check enable / snooze; on-demand run. Upgrade-relevant checks include `health_tracker_not_executing`, `tenant_operations_degraded`, `backup_run_incomplete` and `insufficient_tenant_owner_capabilities`. See *Configuration Guardian*.	Step 3.1
Backup & Restore (API & tooling menu)	Run and verify backups; the automatic pre-migration safety backup appears with a *schema migration* comment; restore with a mandatory dry-run preview. See *Backup & restore*.	Step 1.2, rollback
License (License, Help & support menu)	Edition in force, registration, expiry.	Step 2.4
Entity → Outliers tab (Tenant Home)	Per model: rendered bounds over the KPI, corrected-bounds counters, outliers counters, impact score; false-positive and management actions.	Steps 1.3, 3.3
Bulk edit (Tenant Home entity table)	Category **Impact Score → Manually influence the score**; category **Outliers Detection Actions → Run ML Train**, on any selection of entities.	Steps 3.2, 3.3
Audit & troubleshoot (navigation menu)	**Audit - Operational Statuses**, **Audit - Trackers Performance DeepDive**, **Audit - KVstore Collections**, **Audit - Logs Inspector interface** (ERROR / WARN across TrackMe components), **Support - generate diags** (see *Support diagnostics*).	Whenever a check fails

Behaviour changes to brief operators on

None of the changes below modifies stored entities or models destructively, but several change **what alerts fire and when**, which is exactly what operators should be told before an upgrade rather than discover after it. The 2.1 and 2.2 lines, and the 2.3 line up to 2.3.4, bring mechanical changes and user-interface modernisation; the alerting behaviour changes cluster from 2.3.5 onward. The *Release notes* carry the full detail per release.

Since	Change	What operators observe
2.2.0	Splunk 9.1.1 or later required	No compatibility with Splunk 9.0.x and earlier from the 2.1 line onward; see *Compatibility*.
2.3.0	User interfaces rebuilt on Splunk UI native React	Every main interface changes layout; the information is the same, its place on screen is not. Brief users before the upgrade.
2.3.5	**Impact scoring introduced**	The single biggest change. Entity colour is no longer a direct rule outcome but a weighted score: 0 = green, below 100 = orange, 100 and above = red. Alert volumes and severity distribution shift; tuning weights replaces tuning booleans. See *Impact scoring & thresholds*.
2.3.5	Score-based outliers	An outlier no longer turns an entity red on its own; it contributes its model's score (seeded at 36 by default). Isolated blips stop alerting; sustained anomalies still escalate. Low-confidence models emit no score at all.
2.3.15	Native ML engine (migration 2315)	Models move from MLTK `.mlmodel` files to the KVstore; the MLTK dependency is no longer needed for outliers; models retrain once after the migration. Minimum 10 samples per seasonality slot enforced.
2.3.16	Shadow cache and score cache	Faster UI at scale; false-positive and manual score edits take effect on the next evaluation.
2.3.19	Policy tracker cadence	SLA, tags and priority policy re-evaluation drops from every 15 minutes to twice daily; policy changes apply with hours, not minutes, of latency.
2.3.22 to 2.4.1	**ML training regression (fixed 2.4.2)**	In these builds model training silently stops for every component. Never land on them.
2.4.0	Per-entity maintenance mode	Entities can be forced BLUE for a window, taking precedence over acknowledgements and other protections; alerting suppressed until expiry.
2.4.0	AI advisor scheduled searches	New per-tenant saved searches appear, **created unscheduled**; they only activate if AI features are enabled. Their presence is expected, not a fault.
2.4.1	Threshold intent lock	The per-entity adaptive-delay and lagging-class override controls are replaced by a single **Threshold lock**; locked entities show a lock marker and adaptive mechanisms respect it.
2.4.1	Adaptive delay on the native engine	No MLTK dependency; a historic bug silently flooring bounds to zero is fixed, so adaptive thresholds may legitimately differ from earlier values.
2.4.7	Configuration Guardian management UI	Guardian alerts gain a dedicated page, snooze and disable controls and email notifications; the DEGRADED signal has a persistent, tunable surface.
2.4.9	Search-driven diagnostics and backups	Long-running diagnostics and backups run in search processes; backup archives can be downloaded and imported from the UI.
2.4.10	Alert enrichment	Optional per-tenant SPL enrichment merges custom fields into stateful alerts and notables, a supported carrier for downstream ticket references.
2.4.14	Policy apply at scale; SLA contract repair	Priority, tags and SLA policies are applied inside the tracker process (no cut-off on very large tenants). Migration 2414 returns entities that SLA *policies* had frozen to policy evaluation; their SLA class may legitimately change on the next policy cycle.

Warning

Expect the alert-volume profile to change, by design.

Comparing raw incident counts before and after an upgrade that crosses 2.3.5 compares two different alerting models (boolean rules against impact scoring). Use the baselines below to *understand* the delta, not to demand

that it be zero: fewer one-off blips and unchanged-or-better detection of sustained anomalies is the expected signature.

Extended validation checklist

Organised in phases for formal validation records. Each table gives the built-in screen first and the evidence search (E-numbered, at the end of this page) second.

P0 — Platform

Check	Where to look / method	Expected
Running version is the target	Virtual Tenants header; E1.1	The target release
Schema migration completed	Tenants Update statuses; E1.2	Donut 100% *updated*; every enabled tenant at schema version = required version
Migration log clean	*Open schema update logs in search*; E1.3	*final schema version updated* per tenant; errors reviewed and sent to Support
Safety backup was taken	Backup & Restore archives list; E1.4	A backup run with a *schema migration* comment, status success
Licence in force	License page	Edition registered, expiry recorded

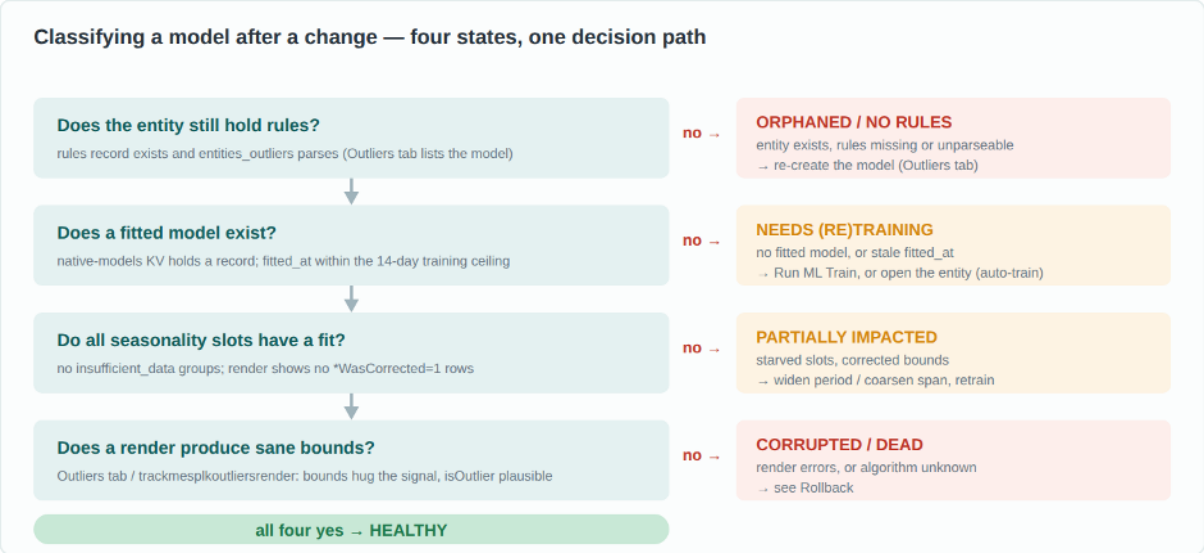
P1 — Tenant operations

Check	Where to look / method	Expected
Every tenant OPERATIONAL	Tenant cards; Ops Status with the failure filter; E4.1	All reports `success`. A failure dated *before* the upgrade window: **Run: Clear Tenant Status** and recheck on the next cycle. A failure dated after: open the report's last result and the Logs Inspector
Health tracker executing per tenant	E4.2	Successful cycle within the last 30 minutes for every enabled tenant
Guardian is clean	Configuration Guardian page (run checks on demand)	No `health_tracker_not_executing`, no `tenant_operations_degraded`; anything raised has a documented cause
No new errors in TrackMe components	Audit - Logs Inspector interface, level ERROR, last 4 hours	No recurring error tied to a tracker or REST handler; one-off warnings during the migration window are acceptable

P2 — Scheduled searches and data

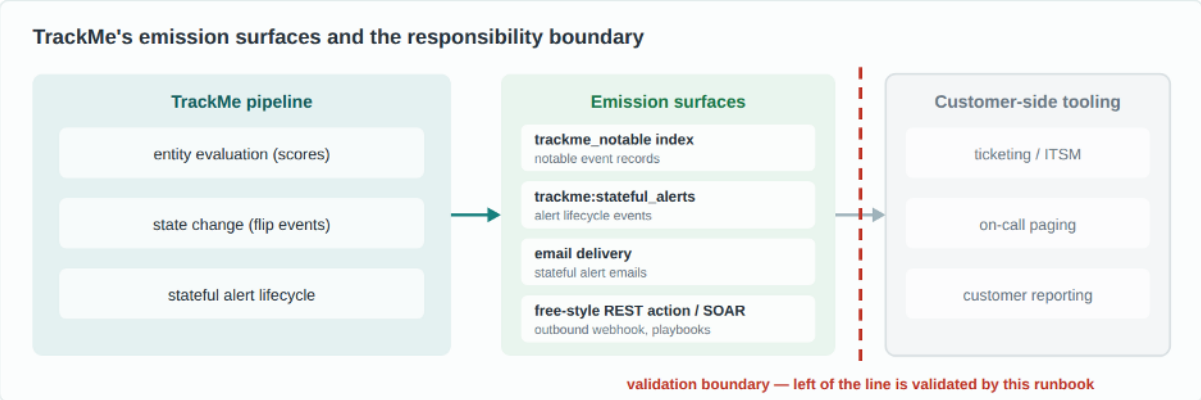
Check	Where to look / method	Expected
Tracker inventory matches the pre-change export	E3.1 re-run, diff	Same set per tenant, plus the expected additions of the new release (for example AI advisor searches, unscheduled); no tracker lost its schedule
Trackers actually firing	Audit - Trackers Performance DeepDive; E3.2 over the first 24 hours	Each enabled tracker shows recent scheduled runs; no persistent skips attributable to TrackMe
KVstore collections intact	Audit - KVstore Collections; E6	Record counts per main entity collection unchanged (plus or minus normal discovery churn); new collections present and small
Custom knowledge objects still work	Open your own TrackMe-based dashboards and reports	They render; a field renamed by a migration is the usual cause of a broken panel

P3 — ML Outliers (where in use)



Check	Where to look / method	Expected
Definitions migrated	E2.1 (algorithm column)	Every model `TrackMeNative-DensityFunction`; no `Density-Function` left
Retraining backlog drained	E2.3	No enabled rules record with `last_exec=0` after the mltrain report has run enough batches
Fitted models present	E2.2	One record per model with a recent `fitted_at`; `confidence=normal` in E2.1 for established entities
Charts render	Outliers tab on the witness and on priority entities	Bounds hug the signal; the *Corrected* counters are zero or rare (a cluster of corrected bounds means models starved of history: lengthen the calculation period and retrain; see *Outlier detection*)
Training history preserved	E2.4	Per-entity training events before and after the window; `fitted_at` *advancing* after the upgrade is correct behaviour (models retrain on a rolling window), not history loss

P4 — Alerting pipeline and the downstream hand-off



Check	Where to look / method	Expected
Notables emitted	Entity **Incidents** tab (step 3.2); E5.2 over the test window	Notable records carry tenant, object, state, score, anomaly reasons, priority and drilldown fields. See *Notable events*
Stateful alert lifecycle	Step 3.2 open → close on the test entity; E5.3	Lifecycle events indexed (`trackme:stateful_alerts`); emails and commands fire per the alert's delivery configuration; close follows the false-positive clean-up. See *Alerting*
Alert actions ran without error	Navigation → *Logs - TrackMe alert actions*	No ERROR from `trackme_stateful_alert`, `trackme_notable`, `trackme_free_style_rest_call`
Email delivery accounts still valid	Configuration → email accounts → test; credentials in `local/` are preserved by the upgrade	Test email received
Downstream hand-off	The step 3.2 forced alert	Your ticket, page or email is produced from the notable or stateful alert, confirmed by its owner

TrackMe's responsibility ends at its emission surfaces: the notable index, the stateful-alert events, email delivery, the free-style REST action and the SOAR integration. Downstream ticketing and paging consume those surfaces; the validation contract at the boundary is the emitted payload, which the forced-alert test of step 3.2 produces on demand. From 2.4.10, alert enrichment can merge custom fields into notables and stateful alerts; a stable correlation key (tenant, entity, alert identifier) as an enriched field gives the downstream pipeline a deterministic join key.

Evidence searches

Each block is one standalone search: run it on its own and export the result to CSV. Running the same searches before and after the change produces the comparison. Index names are the defaults; replace them if the tenant uses custom indexes.

E1 — version, schema, migration log, safety backup

E1.1 Running application version

```
| rest /services/apps/local/trackme | table label version
```

E1.2 Schema state, all tenants in one search (the data behind the Tenants Update statuses screen)

```
| trackmetenantstatus output="tenants"
| table tenant_id, tenant_status, schema_version, schema_version_required,␣
↪tenant_updated_status, schema_version_mtime
```

E1.3 Schema migration log

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪task=schema_upgrade tenant_id="<tenant_id>"
| table _time, log_level, _raw
```

E1.4 Backup archives, including the automatic pre-migration safety backup

```
| inputlookup trackme_backup_archives_info
| table backup_run_id, archive_scope, tenant_id, status, mtime, comment
| sort - mtime
```

E2 — ML Outliers inventory (where in use)

E2.1 Model definitions per entity (per component)

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| rex max_match=0 field=entities_outliers "\"(?<model_id>model_\d+)\":"
| rex max_match=0 field=entities_outliers "\"algorithm\": \"(?<algorithm>[^\"]+)\""
| table object, model_id, algorithm, confidence, confidence_reason, last_exec,␣
↪is_disabled
```

E2.2 Fitted native models (per tenant, 2.3.15 and later)

```
| inputlookup trackme_native_ml_models_tenant_<tenant_id>
| table _key, feature_name, fitted_at, group_count, training_mode, mtime
```

E2.3 Retraining backlog

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| where is_disabled=0 AND last_exec=0
```

E2.4 Training history, one event per entity per training run (audit index)

```
index=trackme_audit sourcetype=trackme:handler tenant_id="<tenant_id>"
    handler="trackme_<component>_outliers_mltrain_tracker_tenant_<tenant_id>"␣
↪earliest=-30d
| stats count as training_runs, min(_time) as first_trained, max(_time) as␣
↪last_trained by object
| convert ctime(first_trained), ctime(last_trained)
```

E3 — scheduled searches

E3.1 Tracker inventory

```
| rest /servicesNS/-/trackme/saved/searches search="trackme_*_tenant_<tenant_id>"
| table title, is_scheduled, disabled, cron_schedule, dispatch.earliest_time,␣
↪dispatch.latest_time
```

E3.2 Scheduler activity, last 24 hours

```
index=_internal sourcetype=scheduler app="trackme" savedsearch_name=
↪"trackme_*_tenant_<tenant_id>" earliest=-24h
| stats count by savedsearch_name, status
```

E4 — tenant operations

E4.1 Per-report execution status (the data behind Ops Status)

```
| trackmetenantstatus tenant_id="<tenant_id>"
```

E4.2 Health-tracker task state

```
| inputlookup trackme_health_tracker_state where tenant_id="<tenant_id>"
| table task_name, execution_count, last_execution_status, last_execution_time,␣
↪last_execution_duration
```

E5 — alert-flow baselines (7 days)

E5.1 State-change (flip) volume, summary index

```
index=trackme_summary sourcetype=trackme:flip tenant_id="<tenant_id>" earliest=-7d
| timechart span=1d count by object_category
```

E5.2 Notable volume

```
index=trackme_notable sourcetype=trackme:notable tenant_id="<tenant_id>" earliest=-
↪7d | timechart span=1d count
```

E5.3 Stateful alert lifecycle events

```
index=trackme_summary sourcetype=trackme:stateful_alerts tenant_id="<tenant_id>"␣
↪earliest=-7d
| timechart span=1d count by object_state
```

E6 — KVstore record counts (repeat per collection of interest)

```
| inputlookup trackme_<component>_tenant_<tenant_id> | stats count as entities
```

Validation record template

One record per deployment: the header from the step 0 inventory, then one row per check with the evidence reference. This is the artefact to retain as validation evidence.

Step	Check	Result	Evidence ref	Notes
0	Platform readiness (Splunk version, KVstore, indexes, package, key)		checklist	
1.1	All tenants operational, none degraded		screenshot / trackme_ops_status	
1.2	TrackMe backup (and on Splunk Enterprise: application directory and KVstore backups) taken		archive names	
1.3	Outliers: model count exported; witness screenshot (if used)		CSV + screenshot	
1.4	Update statuses: all updated at the source schema		screenshot	
2.1	Package installed in place; splunkd restarted		package name	
2.2	Version = target		screenshot	
2.3	All tenants updated at the required schema; final log line present; errors sent to Support		screenshot / E1.3	
2.4	Licence registered or verified, expiry recorded		screenshot	
2.5	splunkd restarted after the migration completed		time of restart	
3.1	Every tenant / component loads; Guardian reviewed		screenshots	
3.2	Forced alert → notable → downstream incident → cleared		Incidents tab + ticket reference	
3.3	Outliers: no legacy model left; backlog drained; witness renders (if used)		E2.3 + screenshot	
3.4	Record archived; operators informed			
P1	Health tracker current; no new errors (Logs Inspector)		E4.2, screenshot	
P2	Tracker inventory matches; trackers firing; KVstore counts stable; custom knowledge objects work		E3.1 diff, E3.2, E6	
P4	Alert actions clean; email delivery test		logs, test email	

7.2.4 Rollback

Danger

A rollback is a restore, not an un-install.

Schema migrations are forward-only. Reinstalling an older package reverts the code and none of the migrated data, over collections and knowledge objects that the migrations already reshaped, and the schema marker is silently realigned so that the Tenants Update statuses screen reports *updated*. The reliable rollback is to restore the pre-upgrade backups on the reinstalled package.

Before deciding, separate the two kinds of change listed in the behaviour changes table of *Validating after an upgrade*. Alerting behaviour (impact-score weights, the score contributed by an outlier, policy cadence, threshold locks, per-entity maintenance) is configurable: if the driver is alert-volume surprises or a scoring or policy outcome, tune on the current release first, a rollback is not needed. Changes that are not configurable (the native ML engine, the schema shape, the rebuilt user interface) are the only ones a rollback actually reverts; weigh them against its cost. A rollback across the native ML engine migration (2.3.15) additionally requires a full retraining of every Outliers model, so the models are inactive until it completes.

Procedure

1. **Decide against fresh evidence.** Capture the post-upgrade evidence first (update-status screenshot, model inventory, Ops Status) so that the comparison stays possible, and confirm the driver is not addressable by configuration on the current release.
2. **Freeze changes and take a final backup.** A TrackMe backup at the current release, plus, on Splunk Enterprise, copies of the application directory and of the KVstore, before any package operation.
3. **Reinstall the previous release in place.** Same procedure as step 2.1 of the *Upgrade procedure* with the previous package. Never remove the application directory: `local/` holds every tenant, tracker and credential.
4. **Restore the pre-upgrade state.** Restore the pre-upgrade KVstore backup (`splunk restore kvstore`) and the pre-upgrade `local/` from the application-directory copy taken in step 1.2 of the procedure. This returns every collection, transform and tracker to their pre-upgrade shape. On Splunk Cloud, or when those copies are not available, restore the pre-upgrade TrackMe backup from **Backup & Restore** (see *Backup & restore*) as a **whole run**, so that every tenant archive and the global archive are restored together (restoring a single archive leaves tenant and global state inconsistent; releases before the multi-archive format produce one archive per run, which is restored as such). Run the restore **dry run** first and review its preview before the real restore. Then apply the manual compensation below.
5. **Fallback only: compensate the native ML engine migration by hand.** If the rollback crosses release 2.3.15 and the KVstore was not restored, rewrite every model's algorithm back to the MLTK engine (see below) and retrain all models. Until retraining completes, Outliers are inactive.
6. **Re-validate.** Steps 1.1, 3.1 and 3.2 of the procedure, with the old behaviour expected (boolean alerting and no score events when rolling back below 2.3.5). The update-status screen will read *updated*; it cannot see a downgrade. Validate the data.
7. **Report to TrackMe Support.** A rollback must be understood before the next attempt; send the validation record and the migration logs (see *Support*).

The native ML engine compensation (fallback only)

Migration 2315 rewrote every Outliers model to `algorithm=TrackMeNativeDensityFunction` and set `model_storage=kvstore`. Code earlier than 2.3.15 has no such engine and does not validate the value: the training search fails at search time and **models stay silently inactive until reverted**. Detect, per tenant and component:

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>
| rex max_match=0 field=entities_outliers "\"algorithm\": \"(?<algorithm>[^\"]+)\""
| stats count by algorithm
```

Rewrite both fields the migration changed, `algorithm` back to `DensityFunction` and `model_storage` back to `file` (back up the collection first; the key-preserving update keeps the records in place):

```
| inputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id> | eval␣
↪keyid=_key
| rex field=entities_outliers mode=sed "s/\"algorithm\": \
↪"TrackMeNativeDensityFunction\"/\"algorithm\": \"DensityFunction\"/g"
| rex field=entities_outliers mode=sed "s/\"model_storage\": \"kvstore\"/\
↪"model_storage\": \"file\"/g"
| outputlookup trackme_<component>_outliers_entity_rules_tenant_<tenant_id>␣
↪append=t key_field=keyid
```

The stored model searches that the migration reset to `pending` are regenerated by the training run that follows; the fitted native models in `kv_trackme_native_ml_models_tenant_<tenant_id>` are simply ignored by the older release.

Then run **ML Train** across the affected models (Tenant Home → Bulk edit → Outliers Detection Actions, or the mltrain reports) and confirm the Outliers charts render again.

What a rollback does not undo without the KVstore restore

Migrated state	Behaviour on the older release
New KVstore collections (native models, score cache, shadow cache, intent locks, labels, maintenance and others)	Ignored: the older code never reads them. Dormant, not harmful. They re-activate on a later re-upgrade.
New fields on existing records; refreshed transforms	Carried along untouched; the older code reads the fields it knows.
Rewritten TrackMe-managed alert SPL and tracker definitions touched by migrations	Remain in their migrated form in `local/`. This is the reason the pre-upgrade `local/` copy matters.
Model `algorithm` and `model_storage` values (migration 2315)	**Actively incompatible below 2.3.15: the one compensation that must be performed by hand if the KVstore is not restored.**
Schema marker	Silently realigned to the running version; the update-status screen reports *updated* (see *Schema migrations*).

Hint

Why retraining is part of every rollback across 2.3.15

The two releases fit models with different engines in different stores, so a retrain on the rolling window is unavoidable, and freshly retrained bounds legitimately differ because the window has moved. The pre-upgrade evidence (step 1.3 of the procedure) makes this explainable instead of surprising.

7.2.5 What a version change actually touches

Every question about *what survives an upgrade* reduces to which of four layers the state lives in.

- **Application code and defaults** (`etc/apps/trackme`: `default/`, `bin/`, `lib/`) are replaced by the package. This is the only layer an upgrade replaces.
- **Local configuration** (`local/`) holds every Virtual Tenant definition, every per-tenant tracker and saved search, every per-tenant KVstore transform, the settings overrides and the account credentials. The package replacement leaves it entirely untouched. The schema migration that follows may then refresh the TrackMe-managed objects it contains (per-tenant transforms, lookup definitions, saved searches) to the new release's shape; user-owned configuration (tenants, settings overrides, credentials, your own knowledge objects) is retained.
- **KVstore data** (`kv_trackme_*` collections: entities, rules, fitted ML models, policies, state) is untouched by the package. Only the forward-only schema migration reshapes it: it creates collections and fields, rewrites values (for example the Outliers model engine) and resets state. This is what the pre-upgrade backups exist to undo.
- **Indexes** (`trackme_summary`, `trackme_metrics`, `trackme_audit`, `trackme_notable`) are never touched.

Danger

Remove and reinstall is not an upgrade path.

Deleting the application directory destroys `local/`: every tenant, every tracker, every per-tenant KVstore transform and every credential. The KVstore *data* survives, but becomes unreachable from SPL until the transforms are rebuilt. Always upgrade **in place**. If a reinstall is ever unavoidable, restore a TrackMe backup immediately afterwards (see *Backup & restore*).

7.2.6 Principles

Upgrade in place, from a backup. Take a TrackMe backup immediately before the change window (and, on Splunk Enterprise, a copy of the application directory plus a KVstore backup). TrackMe also takes an automatic safety backup before the first migration runs, but the explicit one is the one you will want to restore from.

Follow the migration from the screen behind the version number. On the Virtual Tenants page the version number in the header is a link: it opens the **Tenants Update statuses** screen, which shows every tenant's schema version against the required one, its *updated* / *pending* status, and a one-click drilldown to the migration logs. It is the authoritative progress view; do not judge anything before it reads fully updated.

One release for an estate. When several TrackMe deployments are upgraded in a programme (managed service providers, multi-instance customers), validate one release on a representative test deployment and deploy that same release everywhere. Move the whole estate to a newer release later, in one deliberate wave.

Land on a current release. We recommend running the latest release at all times (see *Compatibility*). Never land on the 2.3.22 to 2.4.1 builds: they carry a regression where ML outliers model training silently stops for every component (fixed in 2.4.2).

A rollback is a restore, not an un-install. Schema migrations are forward-only. Reinstalling an older package reverts the code and none of the migrated data; the reliable rollback is to restore the pre-upgrade backups. See *Rollback*.

Validate the data, not the version marker. After a downgrade, the schema marker is silently realigned to the running version, so the update-status screen reports *updated* even though the data kept its migrated shape. Post-downgrade validation must inspect actual behaviour and actual records.

Licensing after an upgrade

Deployments that ran the discontinued Free Community Edition start a 90-day Foundation trial automatically after upgrading to 2.4.x; nothing stops, but the trial must be converted by registering a licence key. Licensed deployments keep their licence. Registering a key is step 2.4 of the *Upgrade procedure*; see also *License registration*.

7.2.7 Where to go next

- Read the *Upgrade procedure* end to end once, then execute it with its checkpoints.
- Keep *Schema migrations* open on upgrade day: it explains every line of the migration log.
- Use *Validating after an upgrade* for formal validation records and to brief operators on the behaviour changes between releases.
- Read *Rollback before* the change window, not after.

7.3 Migrating and Cloning TrackMe

Since TrackMe version 2.1.5, you can easily migrate TrackMe from a deployment to another, or cloning a deployment, using its powerful built-in backup and restore capabilities:

- Consult the white paper: *Backing up and Restoring TrackMe*.

7.4 License registration

7.4.1 TrackMe licensing modes

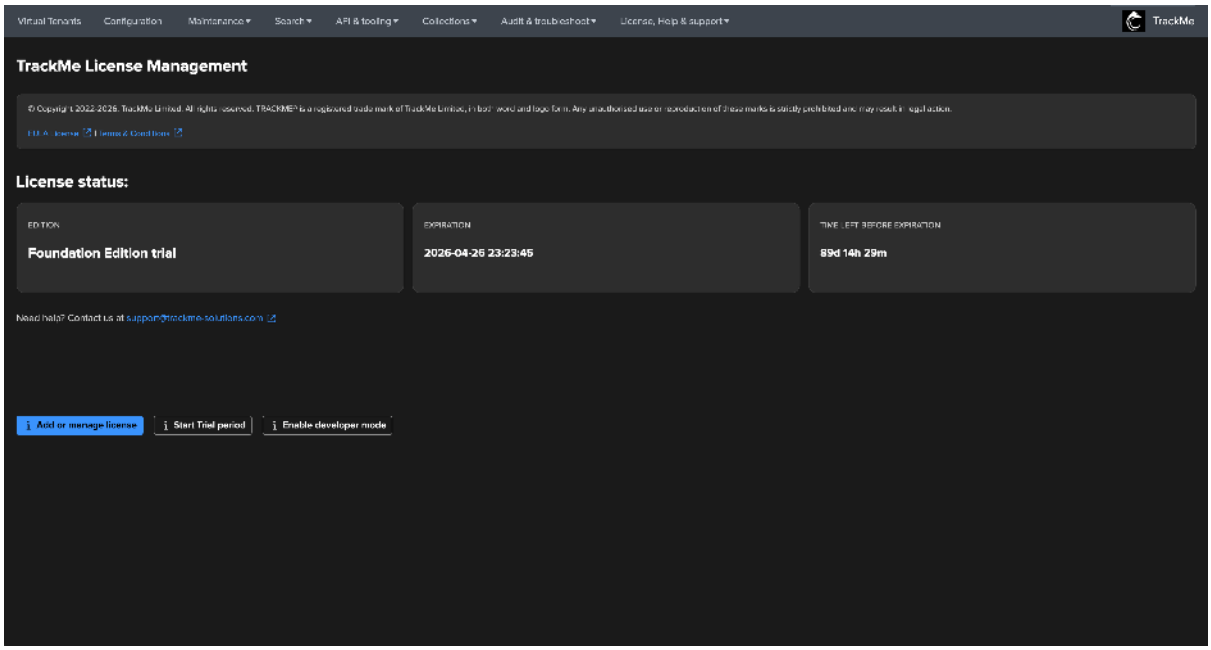
TrackMe has different licensing modes available:

- Foundation Edition trial mode (default)
- Unlimited edition / Enterprise Edition / Trial registered edition
- Developer mode
- Named Developer license

Once TrackMe has been installed, the **Foundation Edition trial mode** is enabled.

To register and manage the license, go to:

- Navigation bar / License, Help & support / License Management



TrackMe Licensing API services

TrackMe for the management of licensing relies on the services of Cryptolens:

- https://help.cryptolens.io

Under the following circumstances, an external call to the Cryptolens API service is made:

- Registering for a Trial license within TrackMe
- Registering the license key for Enterprise and Unlimited customers (online activation)

An external call to the Cryptolens API service is made to verify the validity of the license or generate a new Trial license key if requesting a Trial:

- https://help.cryptolens.io/security/api-ip

The traffic is outgoing:

- https://app.cryptolens.io:443

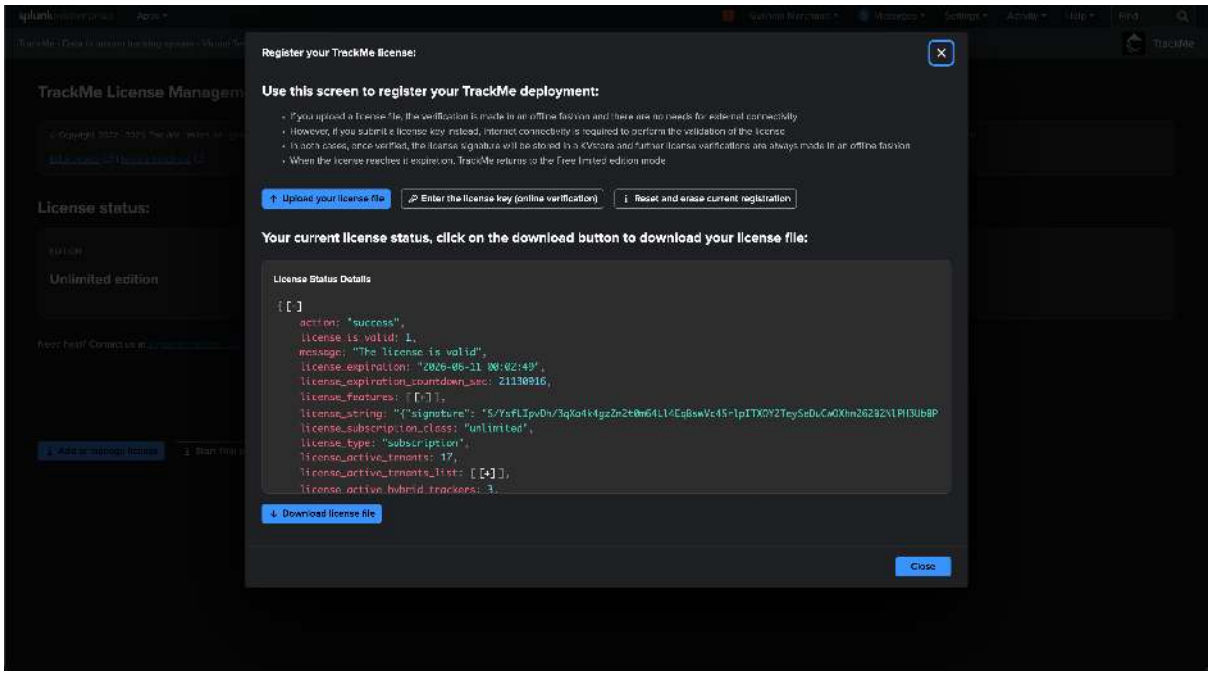
If you do not want this external connection, or if your Search Head cannot access this service, you can use the offline registration process using the license file which we will have provided.

Register your TrackMe license

If you are a licensed customer, you will have received your licensing information:

- A unique license key
- A license file containing the unique signature corresponding to your license

To register your license, click on the button “Add or manage license”:

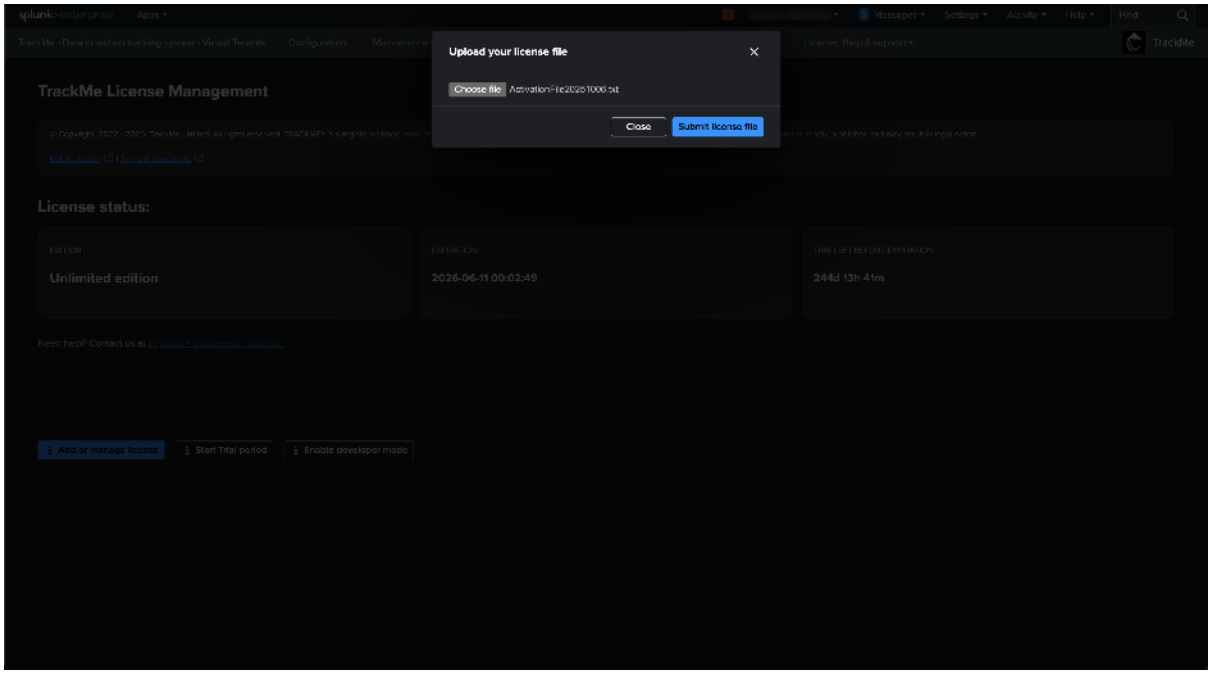


You can choose to:

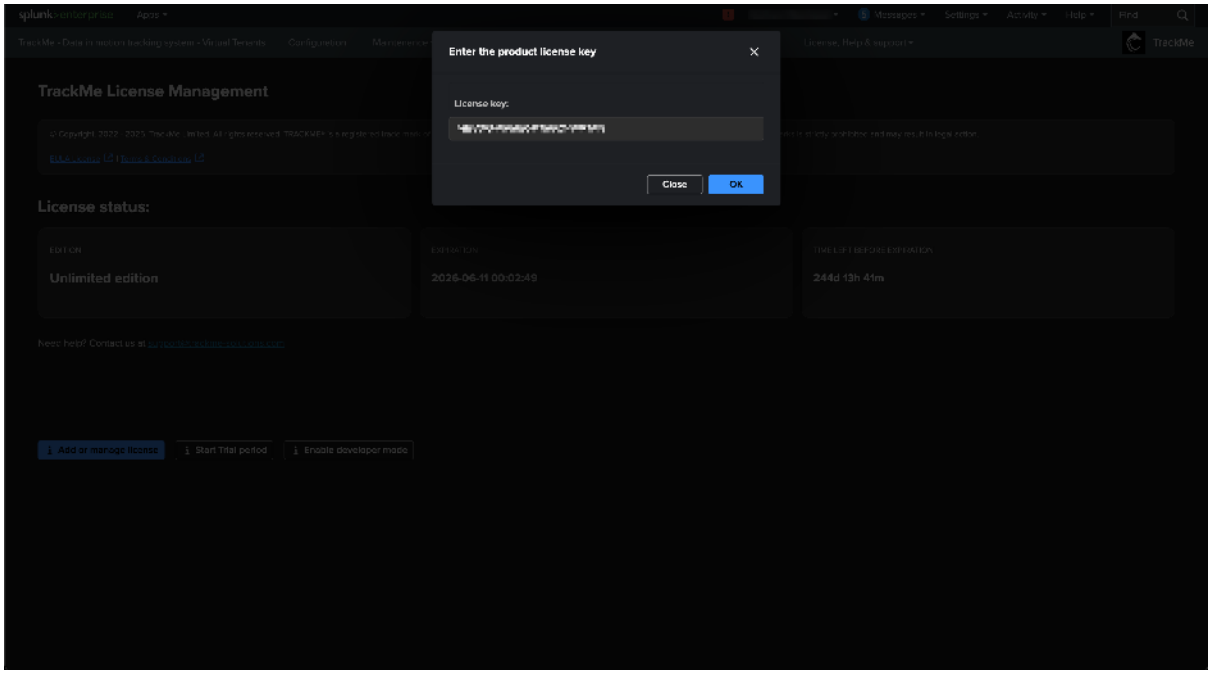
- Upload your license file containing the license signature, which does not require connectivity to our licensing API services
- Submit your license key, TrackMe will contact our licensing API services, verify and validate the license, and if successful will cache the license signature

Once successfully submitted, the license signature is cached in a KVstore, and all further license verifications are systematically made in an offline fashion without the need to contact our licensing API services.

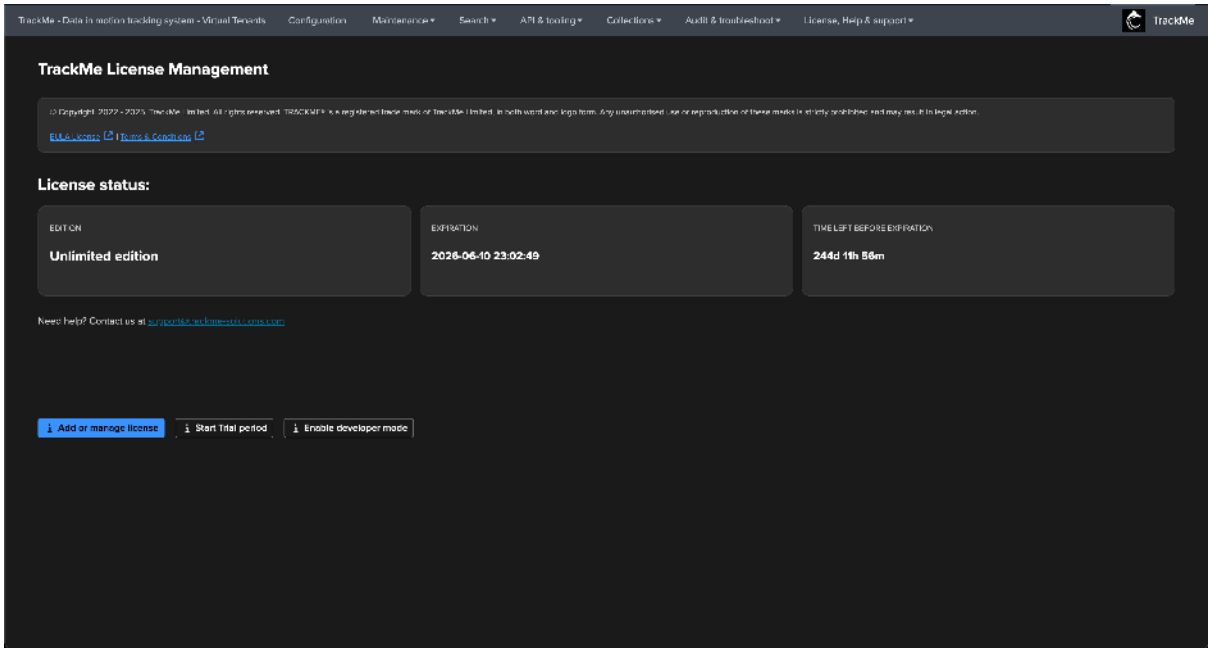
Uploading your license file activation:

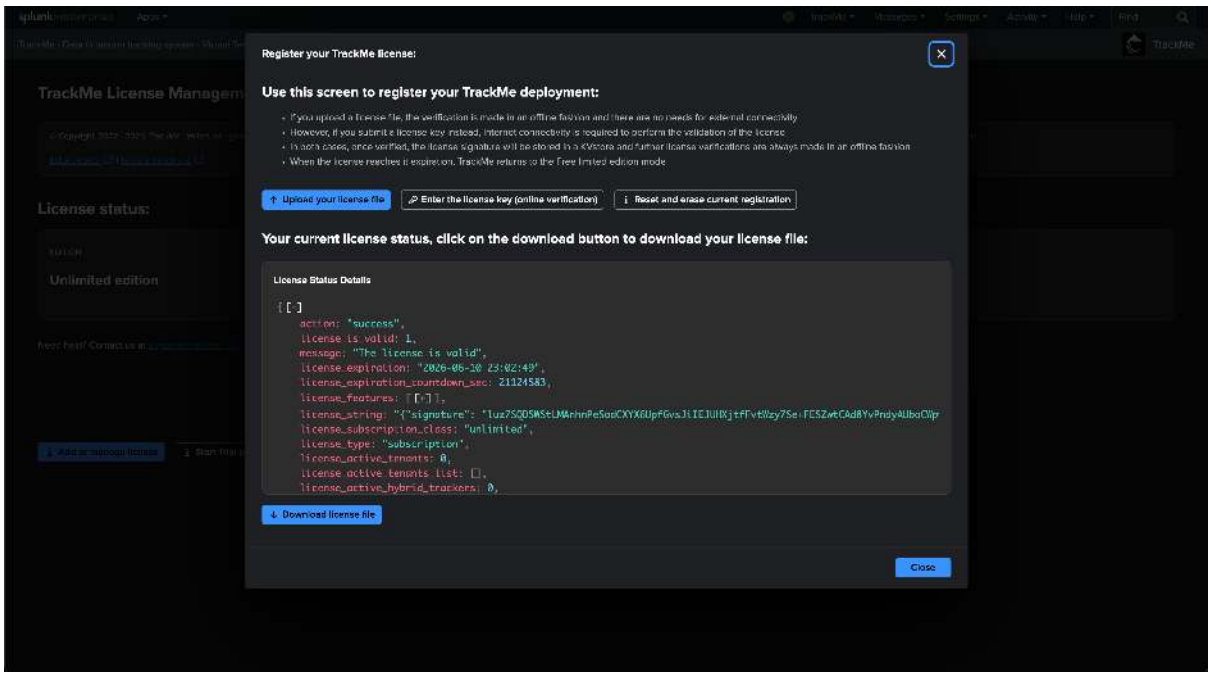


Submitting the license key for verification:



Once registered, the user interface shows the status and the expiration date, you can click on the "Add or manage license" button to review and download the license signature:



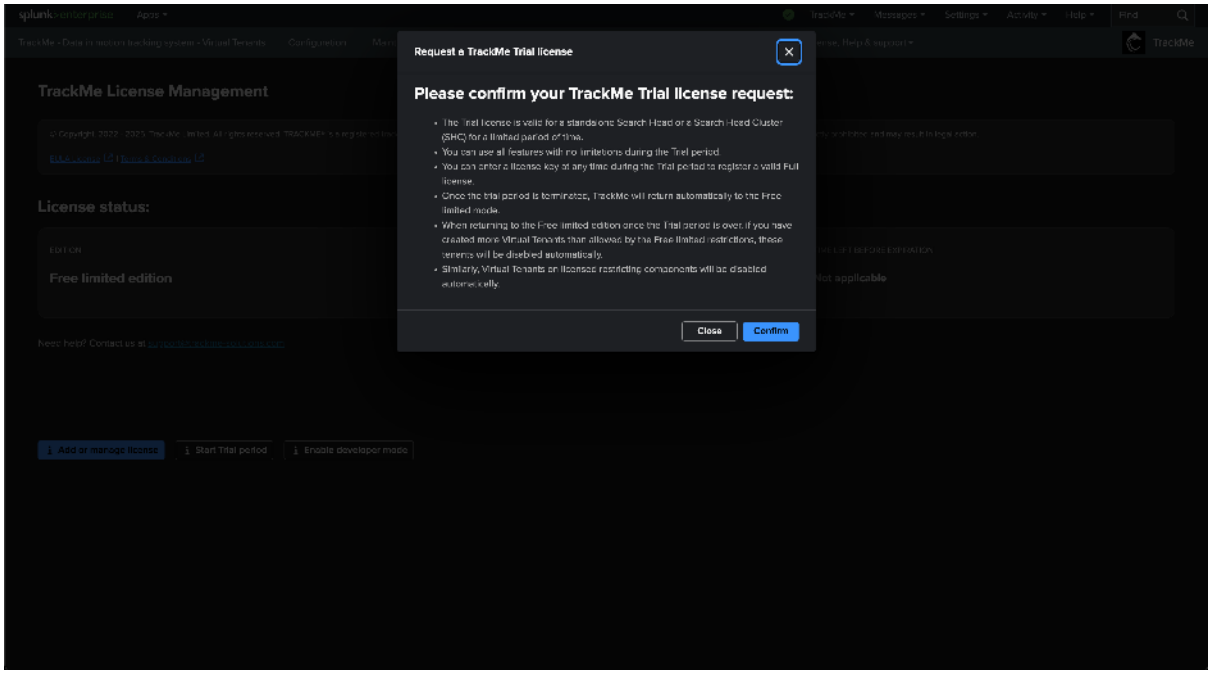


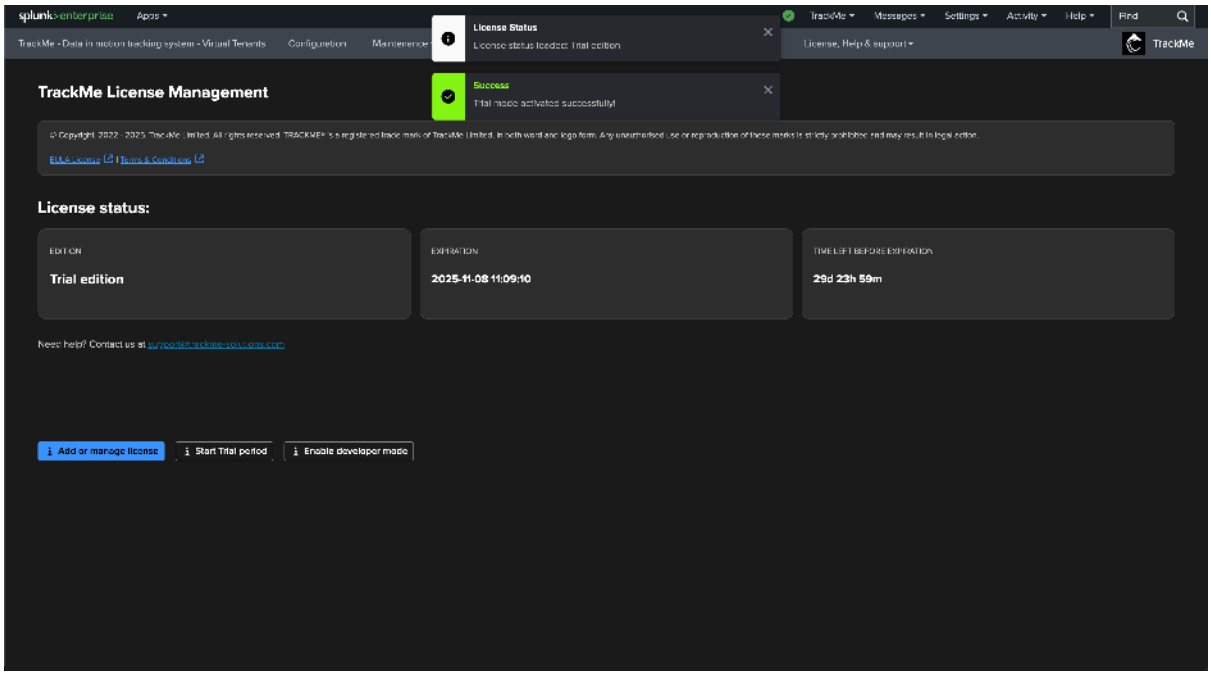
Start a Trial

You can request and start a Trial period immediately in TrackMe. A Trial period allows you to test all features with no restrictions for a limited period of time (90 days).

The Trial license can be generated directly from the application, although it requires that the Search Head has Internet connectivity to our licensing API.

If you need a Trial activation file for an environment with no connectivity, or wish to have a longer Trial period, please contact us at: support@trackme-solutions.com





Trial additional information:

- The Trial license is valid for a standalone Search Head or a Search Head Cluster (SHC) for a limited period of time.
- You can use all features with no limitations during the Trial period.
- You can enter a license key at any time during the Trial period to register a valid Full license.
- Once the trial period is terminated, TrackMe will automatically return to the Foundation Edition trial mode (read-only after expiry).
- When returning to the Foundation Edition trial once the Trial period is over, if you have created more Virtual Tenants than allowed by the Foundation Edition restrictions, these tenants will be automatically disabled.
- Similarly, Virtual Tenants using licensed restricting components (splk-flx, splk-fqm / splk-cim, splk-wlk) will be automatically disabled. The dedicated tenant types (User Activity Monitoring, splk-uam, Cribl Stream and Cribl Edge) are not available on the Foundation Edition either: their collection and their workspace are refused

until a license beyond the Foundation Edition is registered. The Volume Outliers component (splk-vol) is part of the Foundation Edition and is not affected.

Enable the developer mode

You can enable the developer mode in non-Production contexts, which allows you to use all features with no restrictions during a period of 30 days, up to a maximum of 3 activations per instance:

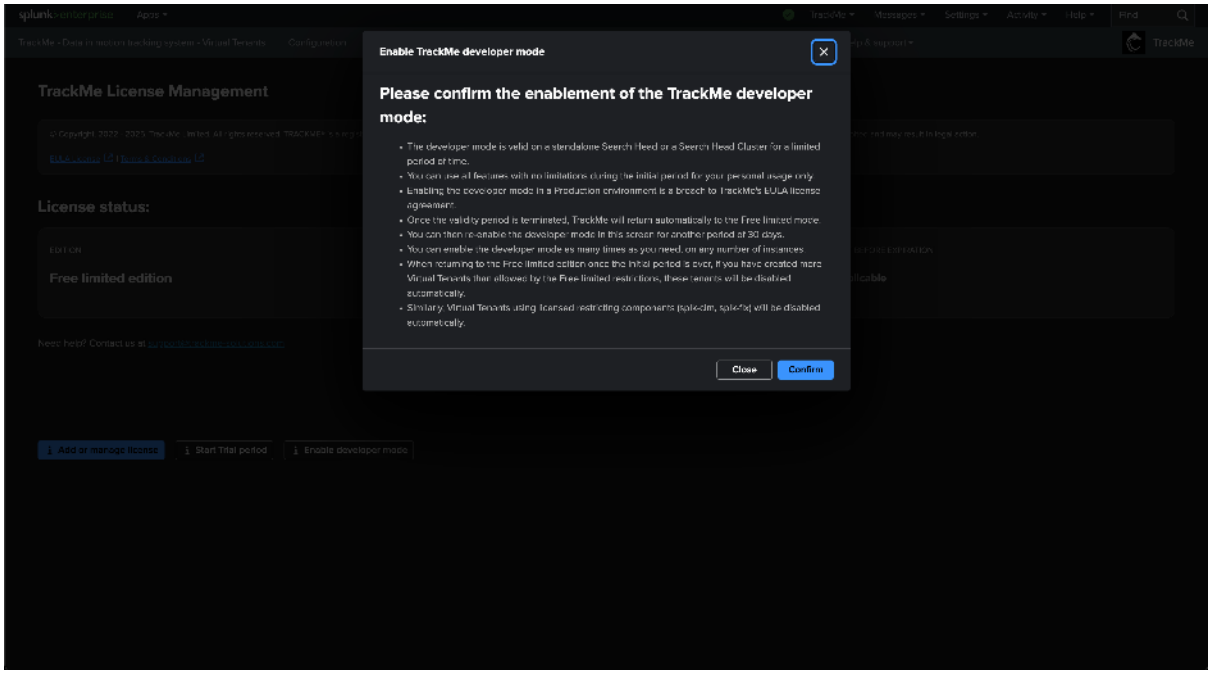
- The developer mode is valid on a standalone Search Head or a Search Head Cluster for a period of 30 days.
- You can use all features with no limitations during this period for your development, testing, and qualification usage only.
- Enabling the developer mode in a Production environment is a breach of TrackMe's EULA license agreement.
- Once the validity period is terminated, TrackMe will automatically return to the Foundation Edition trial mode (read-only after expiry).
- You can enable the developer mode up to 3 times per instance. Each enablement counts toward this limit, even if the current period is still active.
- When returning to the Foundation Edition trial once the initial period is over, if you have created more Virtual Tenants than allowed by the Foundation Edition restrictions, these tenants will be automatically disabled.
- Similarly, Virtual Tenants using licensed restricting components (splk-flx, splk-fqm / splk-cim, splk-wlk) will be automatically disabled. The dedicated tenant types (User Activity Monitoring, splk-uam, Cribl Stream and Cribl Edge) are not available on the Foundation Edition either: their collection and their workspace are refused until a license beyond the Foundation Edition is registered. The Volume Outliers component (splk-vol) is part of the Foundation Edition and is not affected.
- After the 3rd activation expires, contact TrackMe at support@trackme-solutions.com to obtain a **named developer license** for continued developer access with no restrictions.

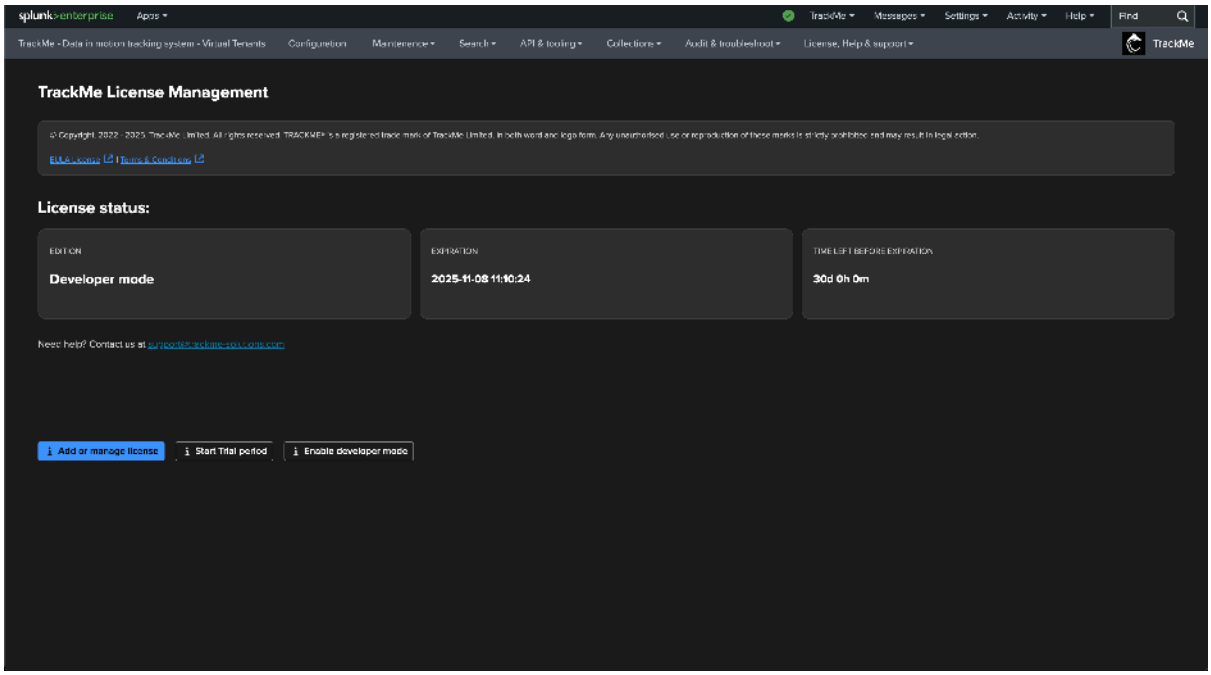
Named Developer license

If you need ongoing developer access beyond the 3 self-service activations, TrackMe can issue a **named developer license**. This is a time-limited subscription license that provides full access to all TrackMe features with no restrictions for its validity period.

To request a named developer license, contact TrackMe at: support@trackme-solutions.com

Once issued, you register the named developer license using the same process as any subscription license (license key or file upload).





Foundation Edition trial mode

TrackMe defaults to the Foundation Edition trial mode for new or unlicensed deployments. The trial is time limited and becomes read-only after expiry. The Foundation Edition covers the DSM, DHM, MHM and VOL (Volume Outliers) components; FLX, FQM and WLK require the Enterprise or Unlimited Edition, and so do the dedicated tenant types (User Activity Monitoring, splk-uam, Cribl Stream and Cribl Edge), which are also available on the Unlimited trial and on the developer license but not on the Foundation Edition or its trial. There are also restrictions in terms of features and the number of hybrid trackers:

Consult our pricing page on TrackMe's Website for more details about the restrictions and plans:

- https://trackme-solutions.com/pricing

If you need more information or if you have any questions, contact us at:

- contact@trackme-solutions.com

To return to the Foundation Edition trial mode from a paid subscription license, use the reset registration option available in the "Add or manage license" screen.

Note

The reset registration option is only available for subscription-based licenses. It is not available for Foundation Edition trial or developer mode license types.

CHAPTER

EIGHT

PRODUCT GUIDE:

8.1 Introduction

This part of the Product Guide gives you the mental model you need before configuring anything. Read it once, top to bottom — it is short — and the rest of the guide will make sense the first time.

- **Overview** — what TrackMe is, who it is for, and what it does for your Splunk platform.
- **Core concepts** — the vocabulary used everywhere else in this guide: entities, components, virtual tenants, state and score, policies, trackers.
- **How TrackMe works** — the monitoring cycle that turns raw `index=…` activity into per-entity states, scores, and alerts.
- **Navigating the UI** — an in-depth visual tour of the TrackMe interface.

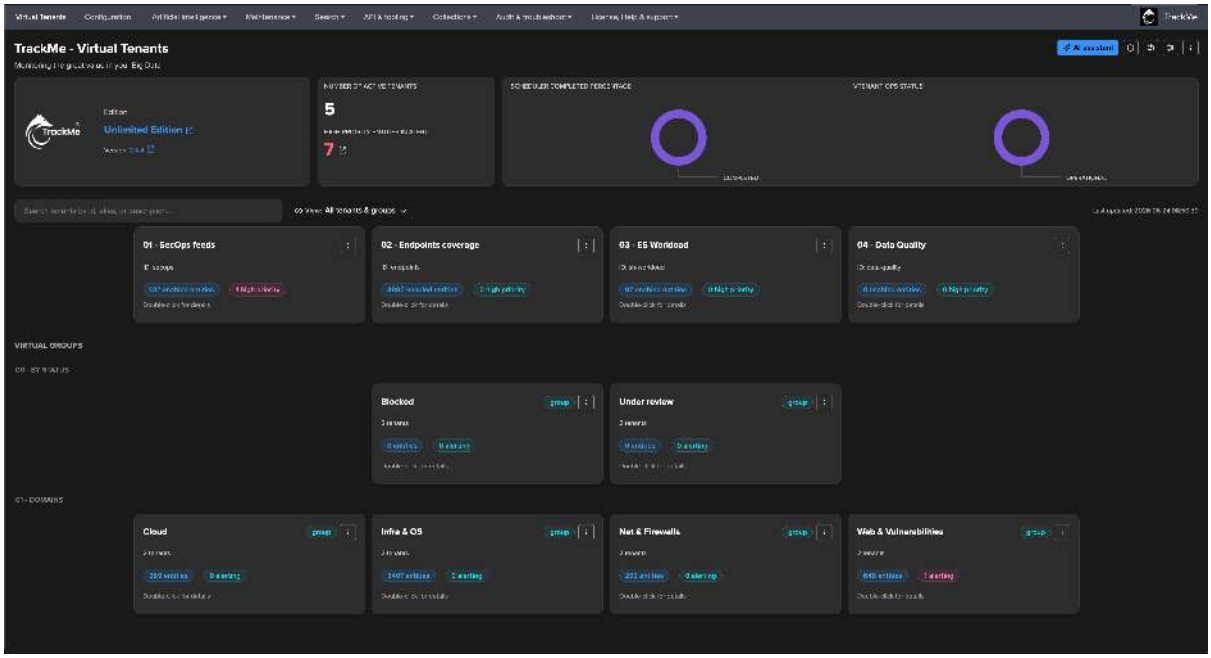
Tip

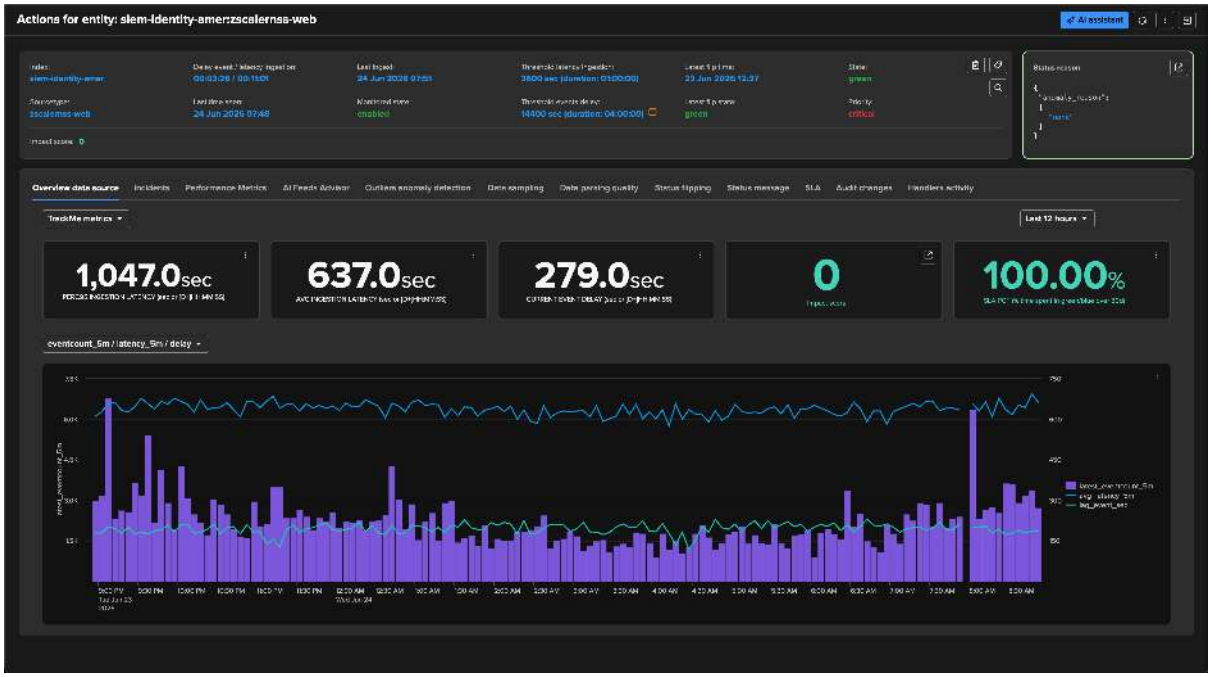
New to TrackMe and want to get something running first? Start with the *Quickstart*, then come back here when you want to understand *why* it works the way it does.

8.1.1 What is TrackMe?

TrackMe is a Splunk app that **discovers, maintains, and monitors the availability and quality of your data** — across one Splunk deployment or many, at any scale.

Think of it as a control plane that sits *on top of* Splunk. It continuously watches raw `index=…` activity and turns it into something you can actually operate on: per-entity health states, service-level objectives, stateful alerts, and — optionally — LLM-generated investigations.





What problem does it solve?

In a large Splunk environment, data silently breaks. A forwarder stops, a sourcetype starts arriving late, a field stops parsing, a scheduled search begins skipping. Splunk itself will not tell you — the searches simply return less, or nothing, and nobody notices until a detection misses or a dashboard goes blank.

TrackMe answers the questions that classic Splunk monitoring leaves open:

- **Is my data still flowing?** Every data source, host, and metric feed is tracked for delay, latency, and volume.
- **Is my data still good?** Field parsing quality and CIM compliance are monitored, not assumed.
- **Are my searches still healthy?** Scheduled-search execution, skipping, and errors are tracked as first-class entities.
- **Is my license volume normal?** Every index's licensed volume is tracked for drops, spikes, inactivity and trend.

- **Who do I tell, and how urgently?** Priority, SLA, and impact scoring decide what is worth an alert and what is just noise.

Who is it for?

- **Splunk administrators** who need to prove the platform is healthy and catch silent failures before users do.
- **SOC and detection engineers** who depend on complete, timely, well-parsed data for their correlation searches.
- **Service owners** who report availability and SLA attainment upward.
- **Managed service providers** who operate many isolated customer environments from one place.

What can you monitor?

Everything tracked in TrackMe is an **entity**, and every entity belongs to one of seven **monitoring components**. The component decides what is measured. Four **dedicated tenant types** — User Activity Monitoring, Cribl Stream, Cribl Edge and Splunk HEC — raise **findings** instead of tracking entities (see *Findings, Finding groups and findings actions*).

Code	Component	What it tracks
DSM	Data Source Monitoring	`(index, sourcetype)` data feeds — delay, latency, volume, format quality.
DHM	Data Host Monitoring	Host × sourcetype activity — delay, latency, host count.
MHM	Metric Host Monitoring	Hosts sending `metric` data — metric lag per category.
VOL	Volume Outliers	The licensed volume of every index, read from the license usage logs — ML outliers (drops / spikes), inactivity, daily volume, trend and month projection.
FLX	Flex Objects	*Any* SPL you write, turned into a tracked entity with custom KPIs and dynamic thresholds.
FQM	Field Quality Monitoring	Field parsing quality and CIM compliance — coverage and success per field.
WLK	Workload Knowledge	Scheduled-search execution health — skip ratio, errors, execution delay.
UAM	User Activity Monitoring	Who is doing what on the platform — the accounts, their scheduled searches, their search activity and resource usage, read from the audit trail and the introspection and raised as **findings**. A dedicated tenant type rather than an entity component: see *User Activity Monitoring*.
Cribl Stream	Cribl Stream	The health and traffic of a Cribl Stream deployment — Sources, Destinations, Pipelines, Routes and Workers — read from the Cribl metrics in Splunk and the Cribl Leader API and raised as **findings**. A dedicated tenant type: see *Cribl Stream and Cribl Edge*.
Cribl Edge	Cribl Edge	The Fleets of a Cribl Edge Leader, their Edge Nodes and the Sources and Destinations they run — connectivity, rollouts and version drift, health, disk — read from the Leader API at any fleet size and raised as **findings**. A dedicated tenant type: see *Cribl Edge*.
Splunk HEC	Splunk HEC	The HTTP Event Collector endpoints of a Splunk deployment, their pools and tokens — availability, refused requests, back pressure, load balancing, rejected data, silent tokens — read from the HEC telemetry Splunk already writes and raised as **findings**. A dedicated tenant type: see *Splunk HEC*.

The short version: **DSM, DHM, and MHM** answer "is the data arriving?", **FQM** answers "is it well-formed?", **WLK** answers "are my searches healthy?", **VOL** answers "is my license volume normal?", **FLX** lets you monitor anything else by writing the SPL yourself. Four dedicated findings tenants complete the picture: **UAM** answers "who is doing what?", a **Cribl Stream** tenant answers "is my Cribl pipeline healthy?", a **Cribl Edge** tenant answers "is

every Edge Node where it should be?" and a **Splunk HEC** tenant answers "are my HEC endpoints receiving, and who is refused?".

Each component is covered in *Part 3 — Monitoring Components*.

How TrackMe is built

TrackMe is organised around three layers. You do not need to know the internals to use it, but the shape explains why the product behaves the way it does.

Layer	What it does
Data plane	Scheduled searches ("trackers") run on a cycle and a shared *decision maker* computes each entity's state and score. This is where "is it healthy?" is decided.
Control plane	A REST API and a per-tenant KV Store hold all configuration and current state — the single source of truth.
Presentation	A modern React interface (Virtual Tenants, Tenant Home, dashboards) and an optional AI Assistant.

The mechanics of the cycle are explained in *How TrackMe works*.

Editions and licensing

TrackMe ships in several editions (Foundation, Enterprise, Unlimited, and trial / developer variants). A new install automatically starts a **90-day Foundation Trial** with full functionality. When a license expires, TrackMe enters **read-only mode**: monitoring keeps running and all data, dashboards, alerts, and history stay visible, but creating or editing configuration is disabled until a license is applied.

See the *License* page for the full edition matrix and the *License registration* page to apply one.

- *Quickstart* — get a tenant running in minutes.

8.1.2 Core concepts and vocabulary

TrackMe has a small, consistent vocabulary. These dozen terms appear on every page of this guide and in the interface itself. Learn them once here.

The mental model in one sentence

> TrackMe tracks **entities** (grouped into **components**, isolated inside **virtual tenants**); on every cycle a **decision maker** gives each entity a **state** and a **score**, **policies** classify it, and **alerting** turns critical states into notifications.

Everything below expands one word of that sentence.

Entity

An **entity** is the fundamental unit TrackMe monitors — one data source, one host, one metric feed, one scheduled search, or one custom object you defined. Each entity has an `object_id` (its identity, e.g. an `index|sourcetype` pair), a current state, a score, and the metadata attached to it (priority, tags, labels, SLA, and so on).

There is no global list of entities — every entity lives inside exactly one virtual tenant.

Component

Every entity belongs to one of seven **components**, which decide *what* is measured: **DSM**, **DHM**, **MHM**, **VOL**, **FLX**, **FQM**, **WLK**. The component determines the metric axes (delay, latency, volume, licensed volume, quality, execution health…) and the tracking logic applied. See *What is TrackMe?* for the one-line description of each, and Part 3 for the deep dives.

User Activity Monitoring (UAM) is not an eighth component but a dedicated *tenant type*: a UAM tenant has no entities. It turns the audit trail and the introspection of a deployment into accounts, scheduled searches, activity, resource usage and **findings**. See *User Activity Monitoring*.

Cribl Stream is another dedicated tenant type: a Cribl Stream tenant has no entities. It turns the Cribl metrics already in Splunk and the Cribl Leader API into the inventory, the traffic, the Workers and the **findings** of one Cribl Stream deployment. See *Cribl Stream and Cribl Edge*.

Cribl Edge, the third dedicated tenant type, follows the Fleets of a Cribl Edge Leader and their Edge Nodes, read in bulk from the Leader's node directory, and raises **findings** too. See *Cribl Edge*.

Splunk HEC, the fourth dedicated tenant type, monitors the HTTP Event Collector endpoints, pools and tokens of one Splunk deployment from the telemetry Splunk already writes, and raises **findings** too. See *Splunk HEC*.

The four dedicated tenant types share one findings model: policies, findings, Finding groups, notifications and findings actions. See *Findings, Finding groups and findings actions*.

Virtual Tenant

A **virtual tenant** is an isolated monitoring domain — typically one customer, one environment, or one team. Each tenant has its own entities, its own configuration and policies, its own set of Splunk roles, and optionally its own remote Splunk deployment to monitor.

Tenants are the unit of isolation and the unit of scale: you create, scope, experiment with, and destroy them independently. Everything else in TrackMe is scoped *to* a tenant.

Virtual Group

A **virtual group** is a read-only card that aggregates entities from several tenants into a single cross-tenant view — useful for a NOC screen that spans many customers. A virtual group is *not* a tenant: it does not run monitoring of its own, it only summarises what the underlying tenants already computed.

Entity state

At every cycle each entity is assigned an **object state** — one of four colours:

State	Meaning
green	Healthy — no active anomaly.
orange	Warning — a non-critical anomaly is active (score above zero, below critical).
red	Critical — the entity has crossed the critical threshold.
blue	Suppressed — the entity is *protected* from alerting (logical-group protection, a disruption grace period, or maintenance), even though an anomaly may be present.

The state machine and the blue "protected" state are covered in Part 4.

Impact score

The state is derived from a numeric **impact score**. TrackMe adds up the contributions of everything that is currently wrong with an entity — delay breach, latency breach, ML outliers, breached dynamic thresholds — into a single `total_score`:

- `total_score == 0` → green
- `0 < total_score < 100` → orange
- `total_score ≥ 100` → red

The weight of each contribution is configurable per tenant and can be overridden per entity, so you decide whether (say) a latency breach matters more than a volume drop. Impact scoring is covered in Part 4.

Tracker

A **tracker** is a scheduled search that runs on a cycle and feeds the decision maker. Trackers are what make TrackMe *active* rather than a static dashboard — they periodically re-evaluate every entity. Most are managed for you; advanced users can add **hybrid trackers** (Part 7) to inject extra signals.

Decision maker

The **decision maker** is the shared engine that, each cycle, reads an entity's metrics and metadata and computes its state and score. It is the single place where "is this entity healthy?" is answered, so the answer is consistent across the UI, alerts, and the API.

Policy

Manually setting priority or SLA on thousands of entities does not scale. A **policy** assigns metadata automatically using a rule — a regex, a Splunk lookup, or an SPL search. Three policy families exist: **priority**, **tags**, and **SLA**. Policies *suggest*; a manual override always wins, and removing a policy auto-cleans the assignments it made. Policies are covered in Part 5.

Priority, tags, labels, SLA

These are the four kinds of classification metadata you attach to entities:

- **Priority** — `critical / high / medium / low / pending`. How much an entity matters.
- **Tags** — free-form string metadata for filtering and grouping.
- **Labels** — a curated, colour-coded catalogue of chips (distinct from tags: different storage, different UI, and assignable by rules).
- **SLA class** — `platinum / gold / silver` with associated thresholds.

Note

Tags and labels are not the same feature. Both are chip-style metadata, but tags are free-form strings while labels come from a managed, coloured catalogue and can be assigned automatically by rules. Part 5 shows them side by side.

Logical group

A **logical group** clusters N entities and judges them *collectively*. If the percentage of green members stays above a threshold, struggling members are demoted from red to blue ("group protection") — so one flaky member of a healthy cluster does not page you.

Disruption queue

The **disruption queue** is a grace period. When an anomaly first appears, the entity is held in blue until the anomaly has persisted for a configured minimum time — absorbing transient blips so only sustained problems escalate to red.

Acknowledgment (ACK)

An **acknowledgment** suppresses further notifications for an entity you already know about. *Sticky* ack stays until you clear it; *unsticky* ack expires automatically after a set period. Ack can be revoked automatically if the underlying anomaly reason changes.

Notable event

A **notable event** is the traditional Splunk alerting output — an event written for Enterprise Security or a custom correlation workflow. It is one of several delivery channels TrackMe's stateful alerting can drive; see Part 6.

See also

- *How TrackMe works* — how these pieces interact on every cycle.
- *What is TrackMe?* — what TrackMe is and the seven components.

8.1.3 How TrackMe works

This page traces the path from raw Splunk activity to an alert in your inbox. It is the "why does it behave like that?" companion to the vocabulary in *Core concepts and vocabulary*.

The monitoring cycle

TrackMe is not a live dashboard that queries Splunk when you open it. It is a set of **trackers** (scheduled searches) that run on a cycle and persist their results. Opening the UI just reads the last computed state. This is what lets TrackMe scale to thousands of entities and alert without anyone watching a screen.

Each cycle, for every tenant, the following happens:

```
1. DISCOVER     trackers scan the tenant's indexes and find entities
                (new (index,sourcetype) pairs, hosts, searches, …)
                     |
2. MEASURE      each entity's metrics are refreshed
                (delay, latency, volume, parsing quality, execution health)
                     |
3. DECIDE       the decision maker computes, per entity:
                  • impact score  = Σ (delay, latency, outliers, thresholds…)
                  • object state  = green / orange / red   (from the score)
                     |
4. CLASSIFY     policies assign priority, tags, SLA; labels are evaluated
                     |
5. PROTECT      logical groups, disruption grace, maintenance, ack
                may demote an entity to blue (suppress alerting)
                     |
6. ALERT        stateful alerting opens / updates / closes alert records
                and delivers email, notable events, ingest, commands
```

Steps 3–6 are the heart of the product. The rest of this guide is, essentially, a detailed tour of each step.

Step 3 — how state is decided

The decision maker computes a single `total_score` by summing every active problem:

```
total_score =  base_score              (from the metrics index)
            +  impact_score_delay       (if the delay threshold is breached)
            +  impact_score_latency     (if the latency threshold is breached)
            +  impact_score_outliers    (from ML outlier detection)
            +  threshold_scores         (sum of breached dynamic thresholds)
            +  …
```

The score is then mapped to a colour: `0` is green, `< 100` is orange, `≥ 100` is red. Because every contribution is just a number with a configurable weight, you control exactly what makes an entity "critical" — see Part 4 for tuning impact scores and thresholds.

Step 5 — why an entity might *not* alert

A red score does not always mean a page. Four mechanisms can hold an entity in **blue** (suppressed) instead:

- **Logical group protection** — the entity's group is mostly green, so this member is carried.
- **Disruption grace** — the anomaly is too new; TrackMe waits to see if it persists.
- **Maintenance mode** — the entity, tenant, or whole instance is in a maintenance window.
- **Acknowledgment** — someone already accepted this problem.

This separation — *what state* (decision maker) versus *whether to tell you* (protection and alerting) — is deliberate, and it is why TrackMe is quiet in practice despite tracking so much.

Step 6 — how you get told

The **stateful alerting** system tracks each anomaly as it opens, persists, and closes:

- It opens a stateful record when an entity first turns red (or orange, if you opt in), updates it each cycle the problem persists, and closes it when the entity goes green.
- On those transitions it can deliver an **email** (with embedded 24-hour charts and, optionally, an AI-written incident summary), write a **notable event**, ingest an **event**, and/or run a **saved-search command**.

Alerting is covered in Part 6.

Multi-tenancy and remote deployments

Everything above happens **per tenant**. A tenant can monitor the local Splunk search head, or point at a **remote Splunk deployment** (Enterprise or Cloud) over an authenticated, token-rotated connection with automatic failover. From the user's point of view the experience is identical — only the data source differs. Remote deployments are covered in Part 8.

Where the AI fits

TrackMe's AI features sit *alongside* this cycle, never in the critical path:

- The **AI Assistant** is a context-aware chat drawer on every page, off by default until you configure a provider.
- **AI Advisors** are on-demand agents that can inspect TrackMe's state and propose (or, with consent, apply) tuning.
- **AI Routines** are scheduled agents you configure to evaluate TrackMe on a cadence and then notify (email or Splunk event) or, with granted scope, act on what they find.
- **AI status reports** are the LLM summaries optionally embedded in alert emails.

All of this is opt-in and documented in the dedicated *Artificial Intelligence* section.

See also

- *Core concepts and vocabulary* — definitions for every term used above.
- *Artificial Intelligence* — the AI Assistant, Advisors and Routines.

8.1.4 Navigating the TrackMe UI — in depth

Tip

This is an **in-depth visual tour** of the TrackMe user interface. For the conceptual introduction, start with *Overview* and *How it works*. This page walks the Virtual Tenant interface, the Tenant Home, the three-dot menus, bulk editing, theme preferences, and hiding tenants.

Note

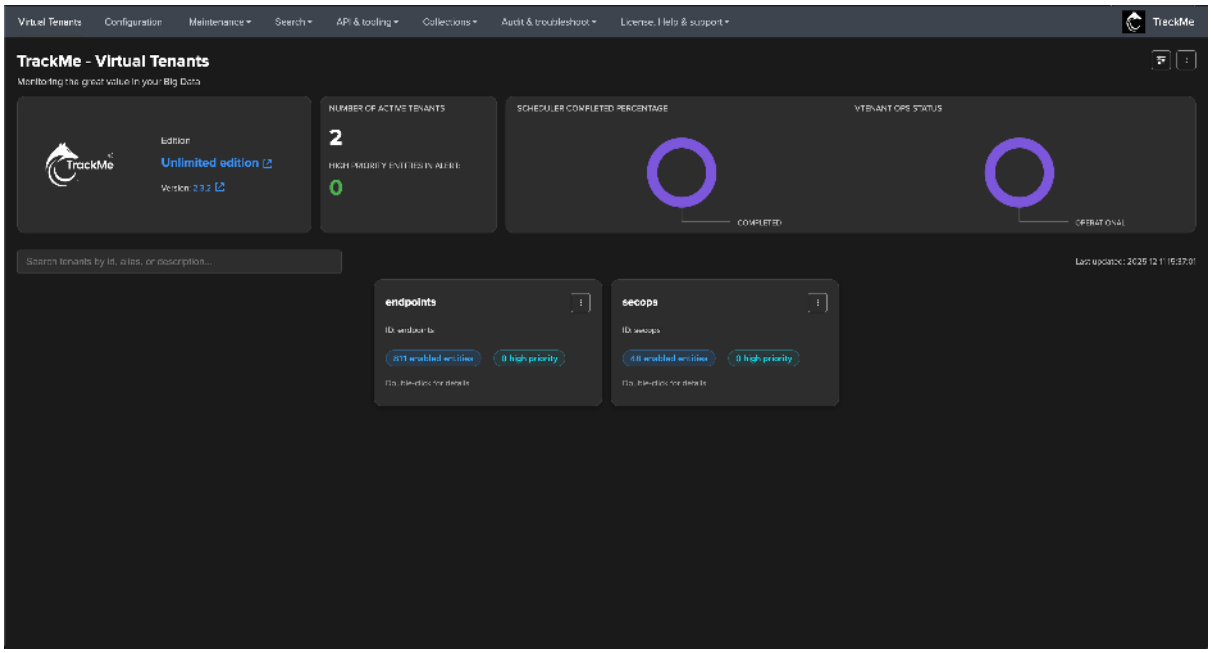
TrackMe Design

- This page describes the essential concepts and design principles behind TrackMe's user interfaces.
- TrackMe 2.3.0 introduced a complete rewrite of the user interfaces, built on Splunk's native React UI.
- It covers the key things to know to navigate the interface and use its features.

TrackMe has **two primary interfaces**: the **Virtual Tenant interface** — the landing page where you see and manage all your tenants — and the **Tenant Home** — the rich per-tenant screen where you work with entities. A consistent **three-dot menu** exposes actions everywhere, and a per-user **theme** (dark or light) applies across both. This page tours each in turn.

The Virtual Tenant interface

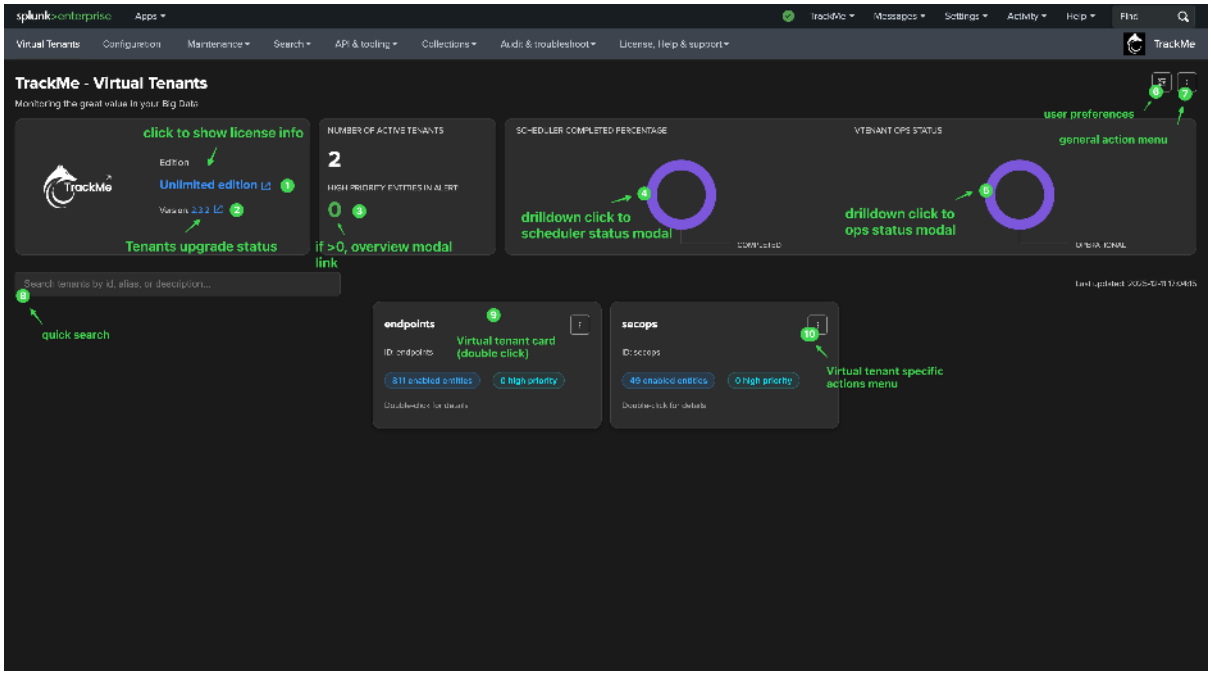
When you open TrackMe, the default page is the **Virtual Tenant interface**. It gives an overview of your Virtual Tenants and the actions you can perform on them — such as creating, managing, or entering a specific tenant.



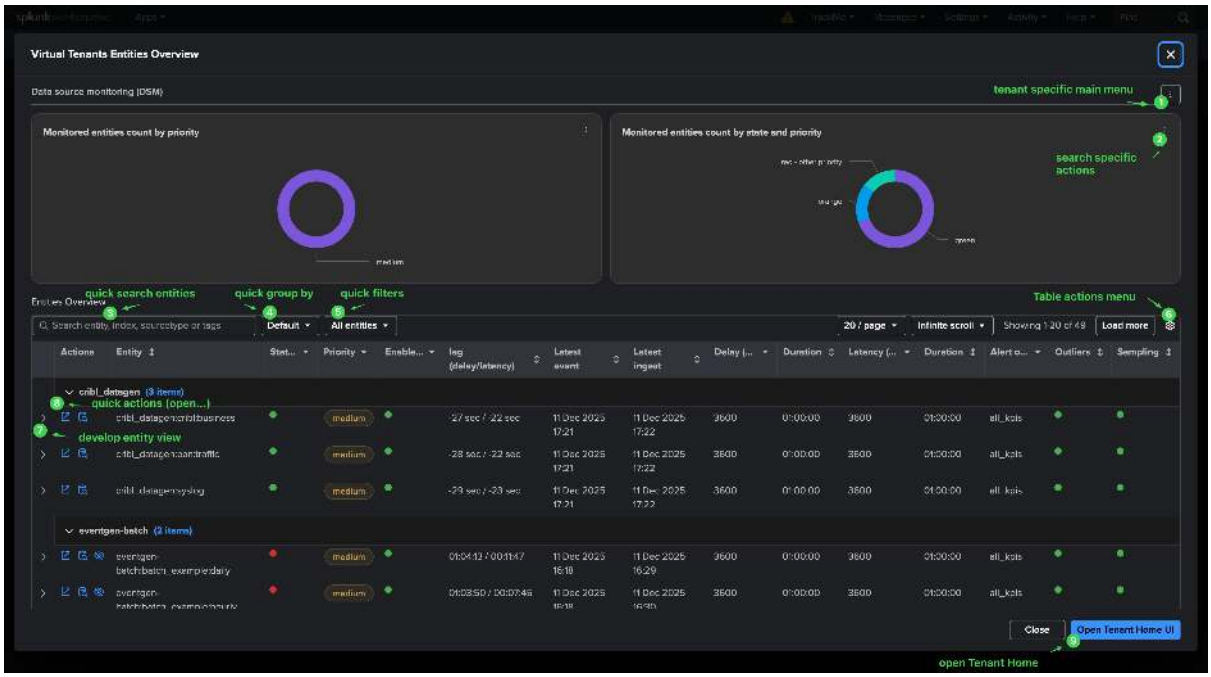
The home page at a glance

The key interactions of the Virtual Tenant interface:

main screen:

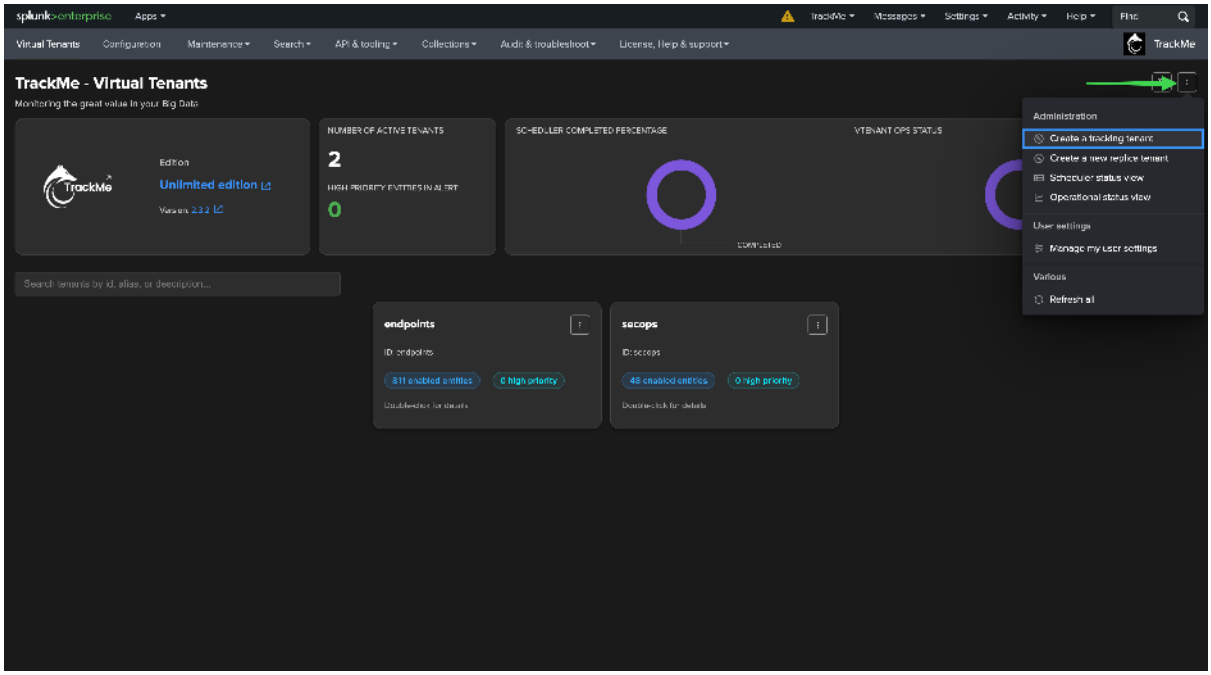


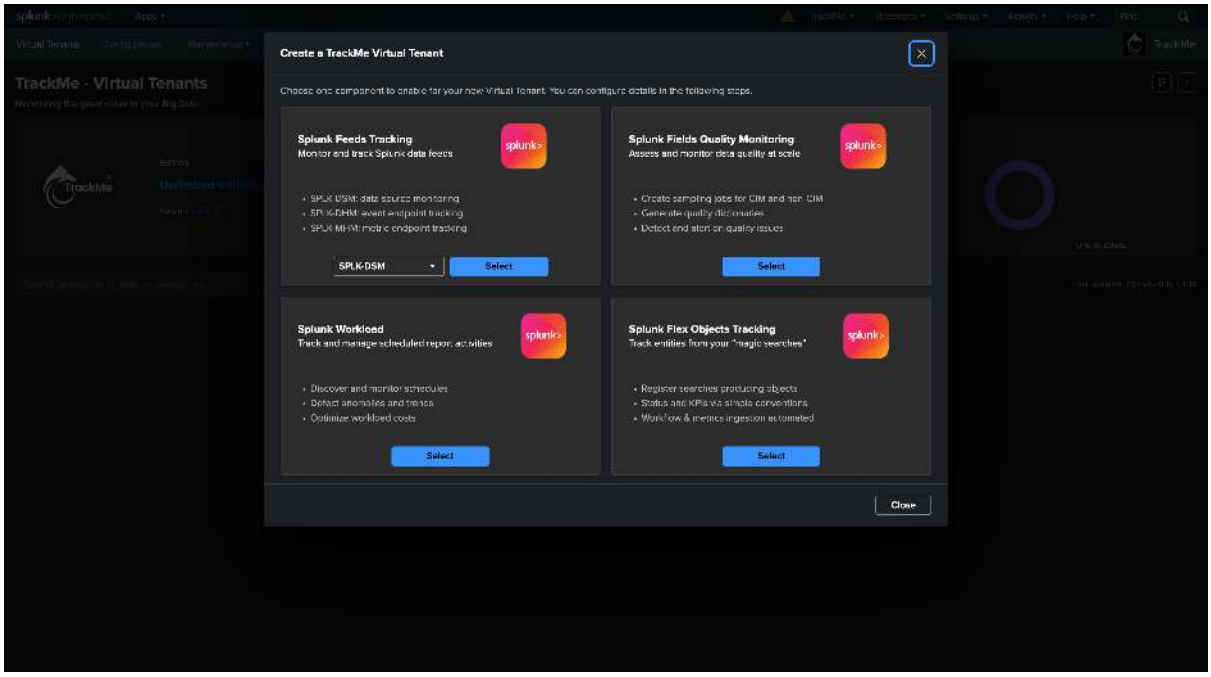
tenant overview:



The three-dot menu

The three vertical dots in the top right of the screen are the **main selector menu**. They give quick access to the main actions, such as creating a new Virtual Tenant:

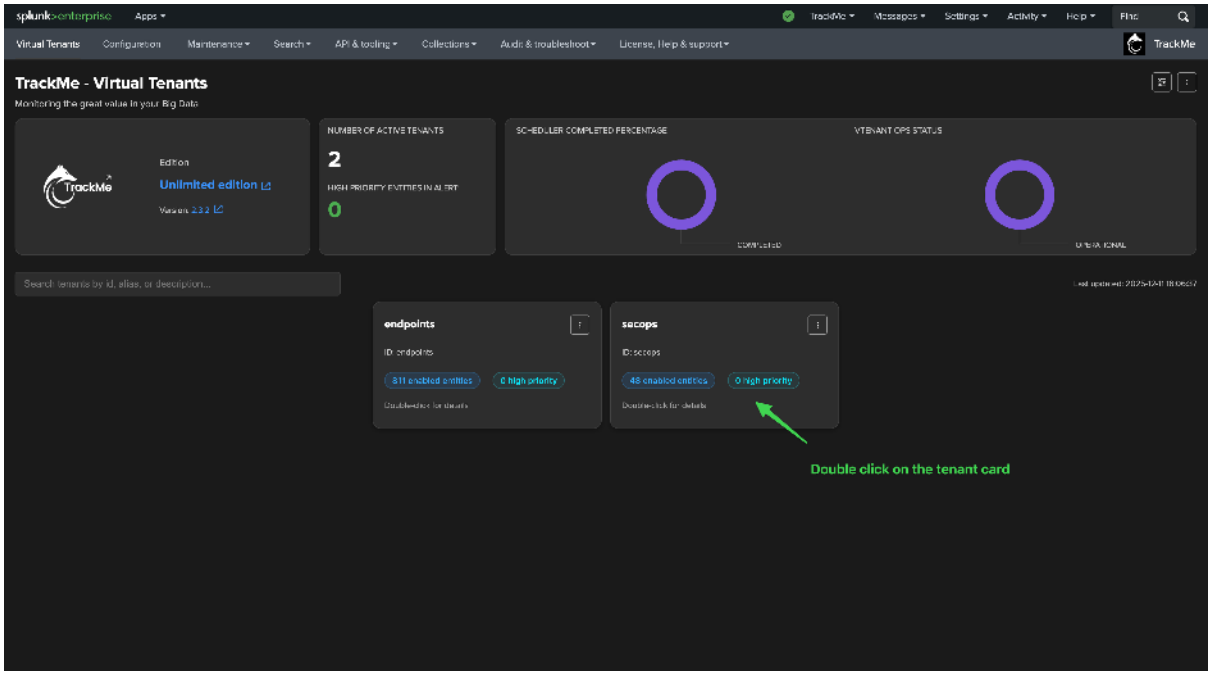


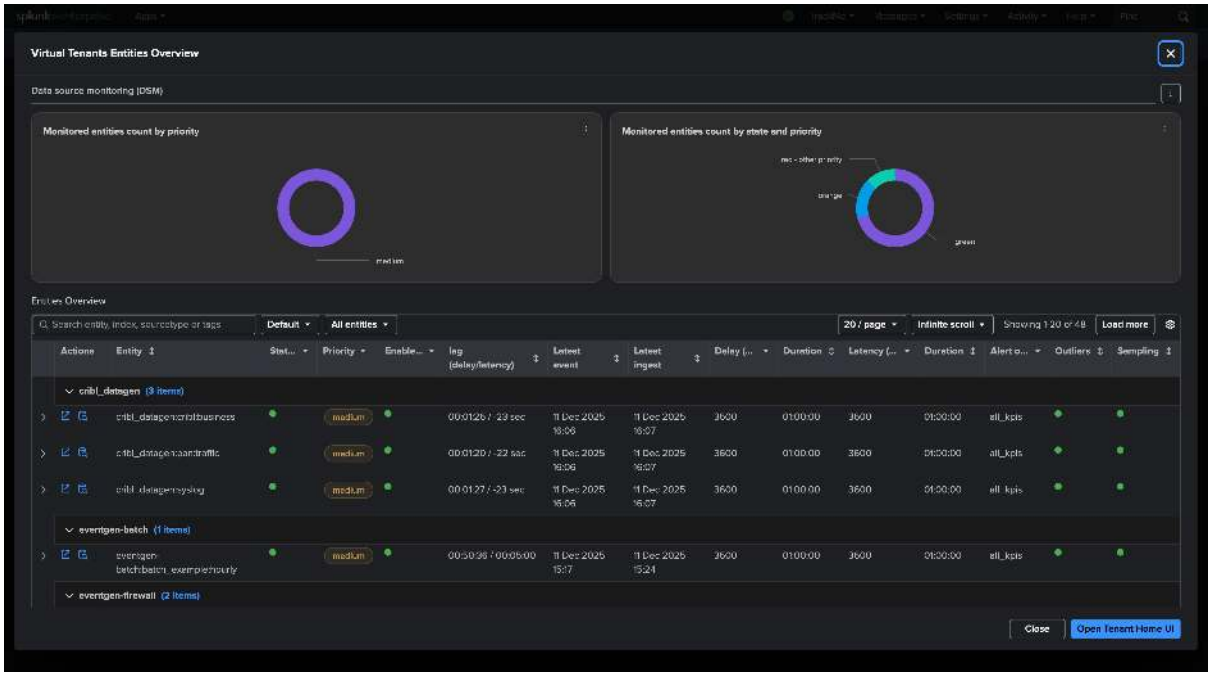


As a core design principle, **every action in TrackMe** — whether on a Virtual Tenant, an entity, a chart, and so on — is available through this same three-dot menu, placed on the relevant element.

Opening a Virtual Tenant overview

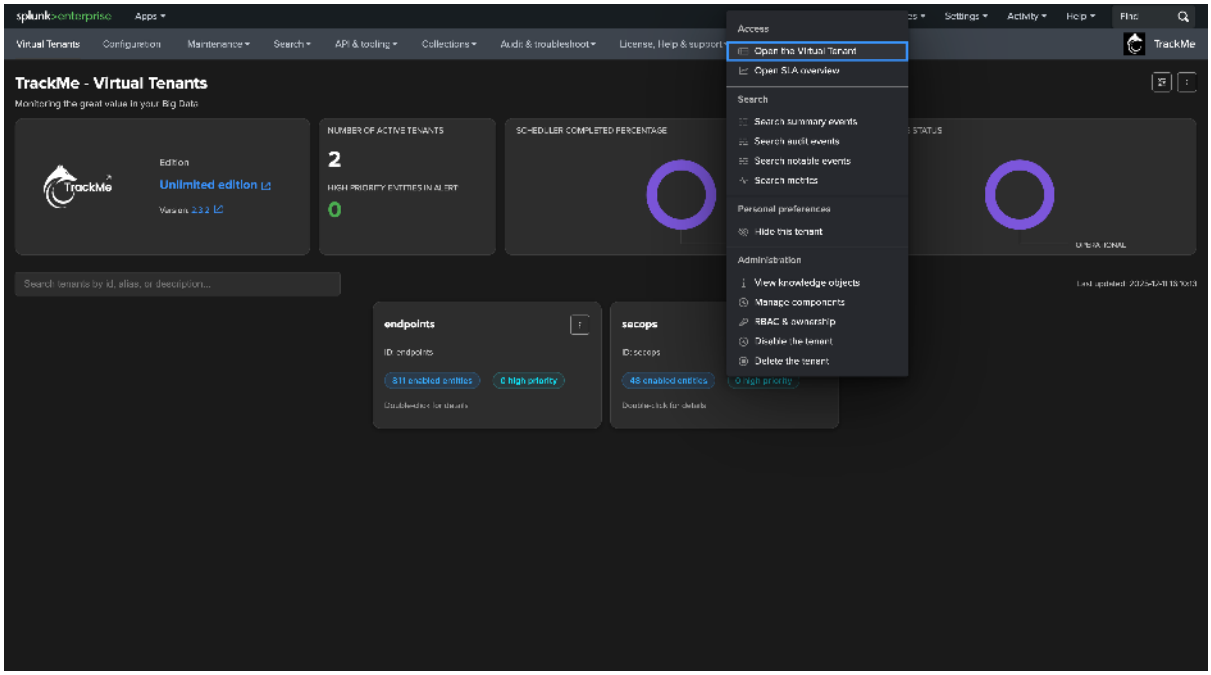
Double-click a Virtual Tenant card to open its **overview** — a modal that summarises the tenant and offers actions such as managing or entering it.





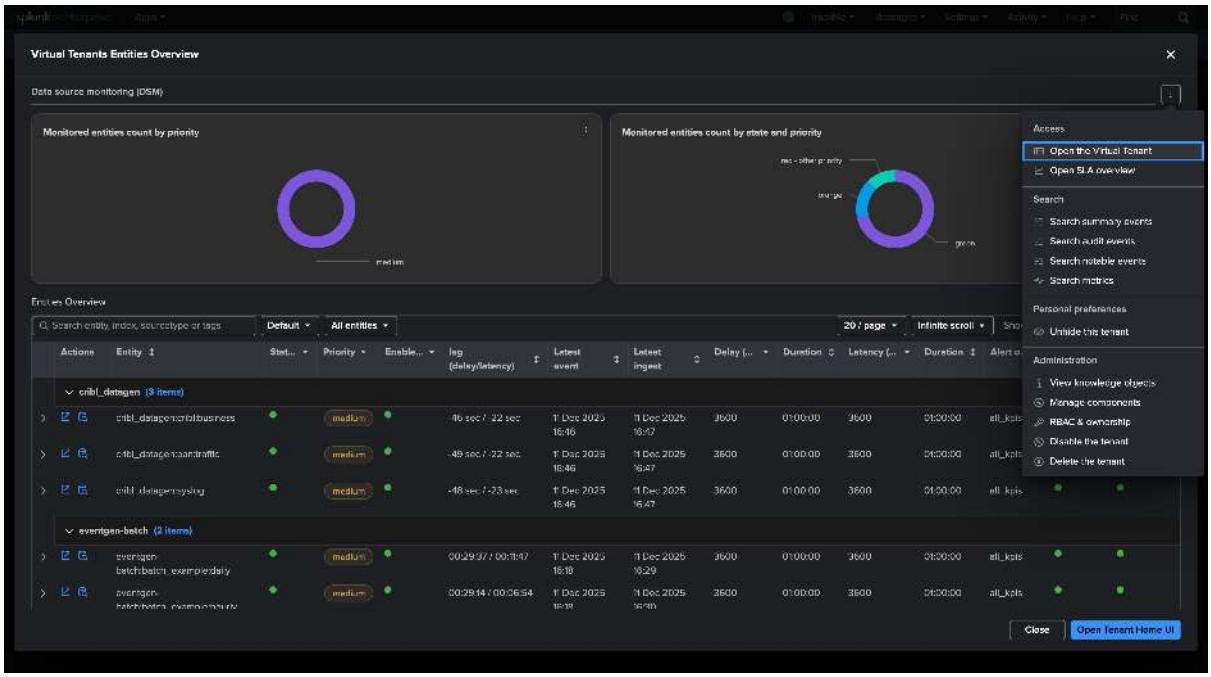
The tenant actions menu

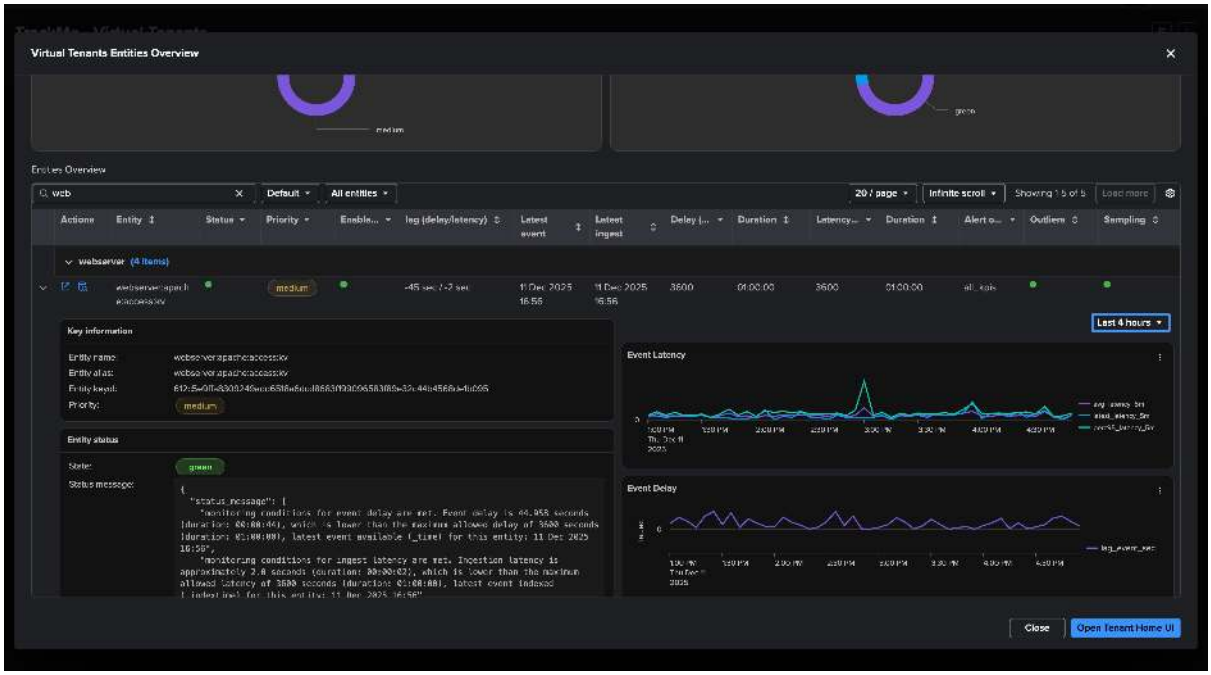
Click the tenant's three-dot icon to open the menu specific to that tenant. The available actions depend on your privileges and the tenant's status.



Reviewing entities (read-only)

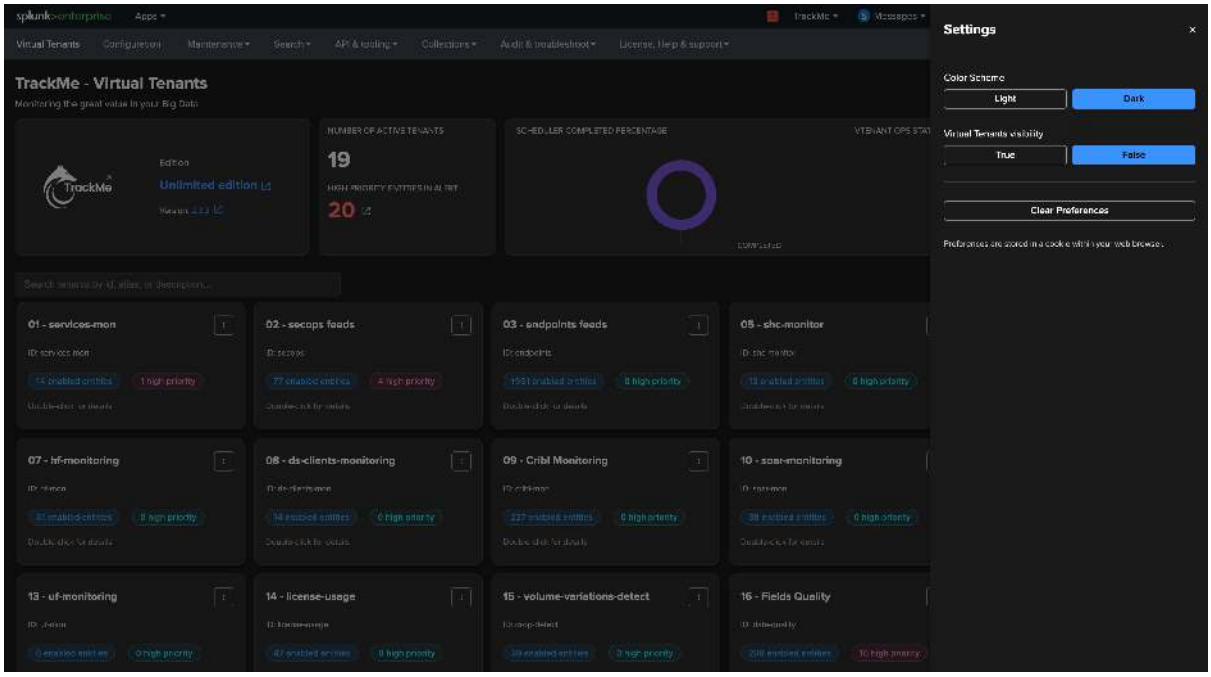
From the Virtual Tenant overview you can browse the tenant's entities in **read-only** mode. Many actions are available — for instance, expand an entity to review detailed information and mini-charts.

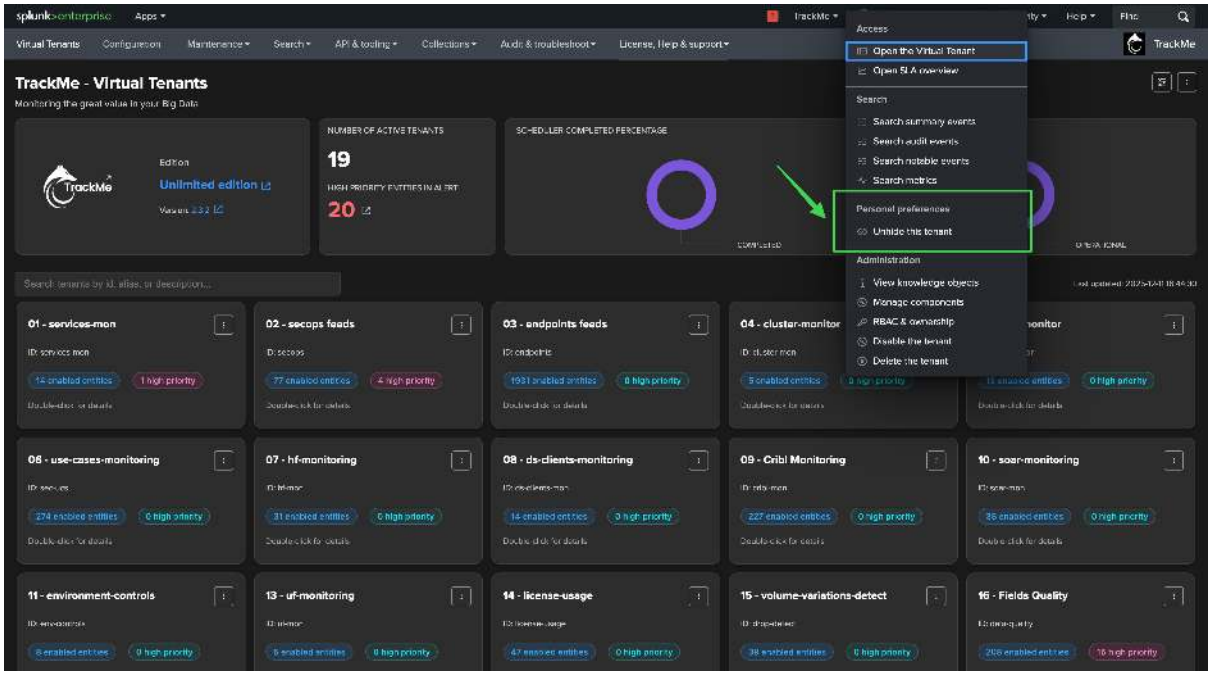




Hiding a Virtual Tenant

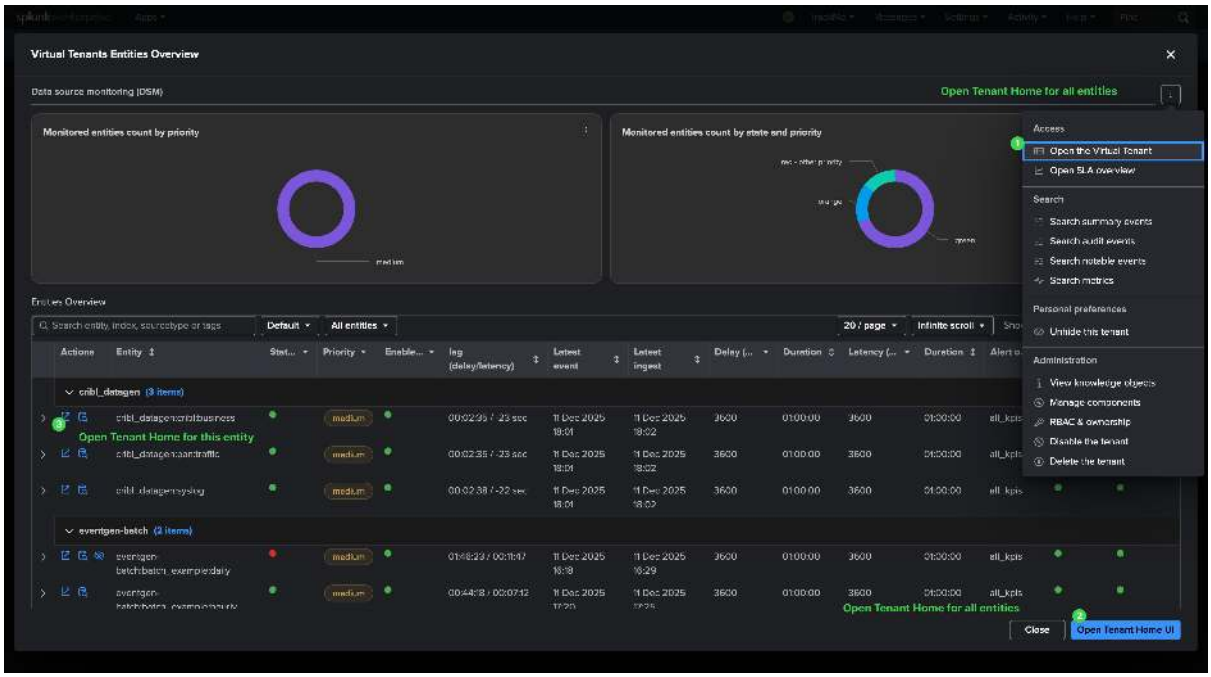
You can **hide** a specific Virtual Tenant from the interface (tenant menu → *Personal preferences* → **Hide this tenant**); the choice is kept in your browser with your other personal preferences and affects no one else. In a large environment this is useful when a user has access to a tenant (through *RBAC*) but does not need to see it in the UI. A hidden tenant's menu offers **Unhide this tenant**, and once at least one tenant is hidden the Settings panel shows a **Virtual Tenants visibility** switch to display them all again.

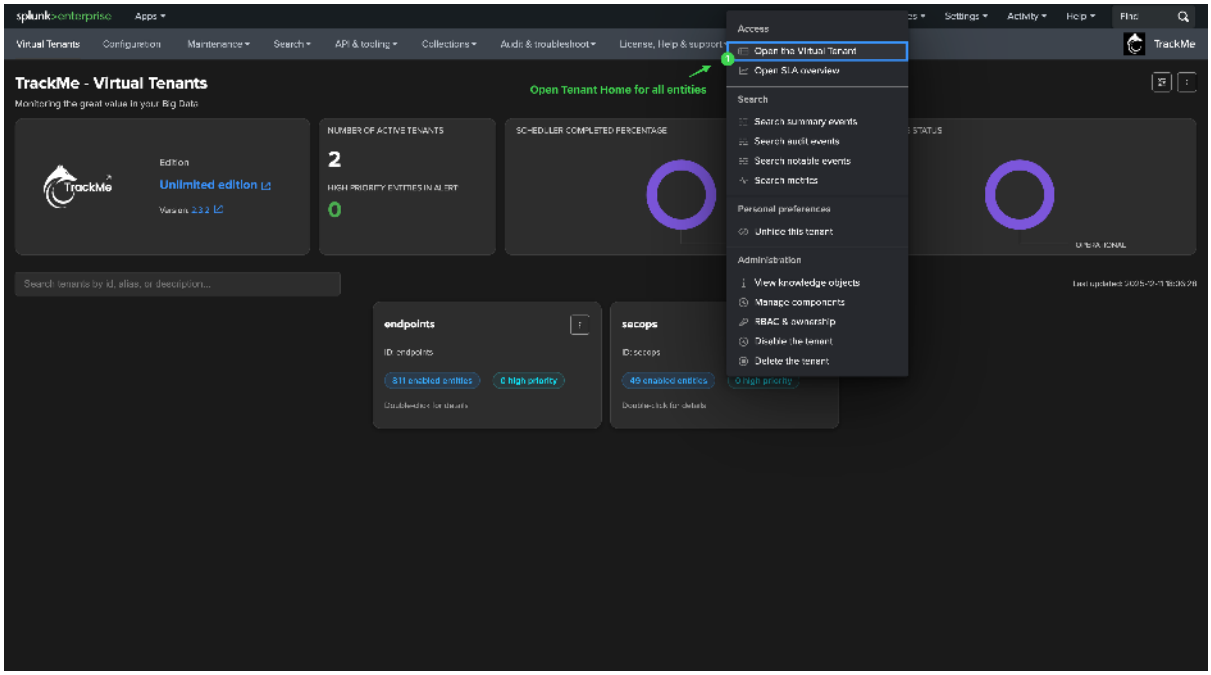




The Tenant Home interface

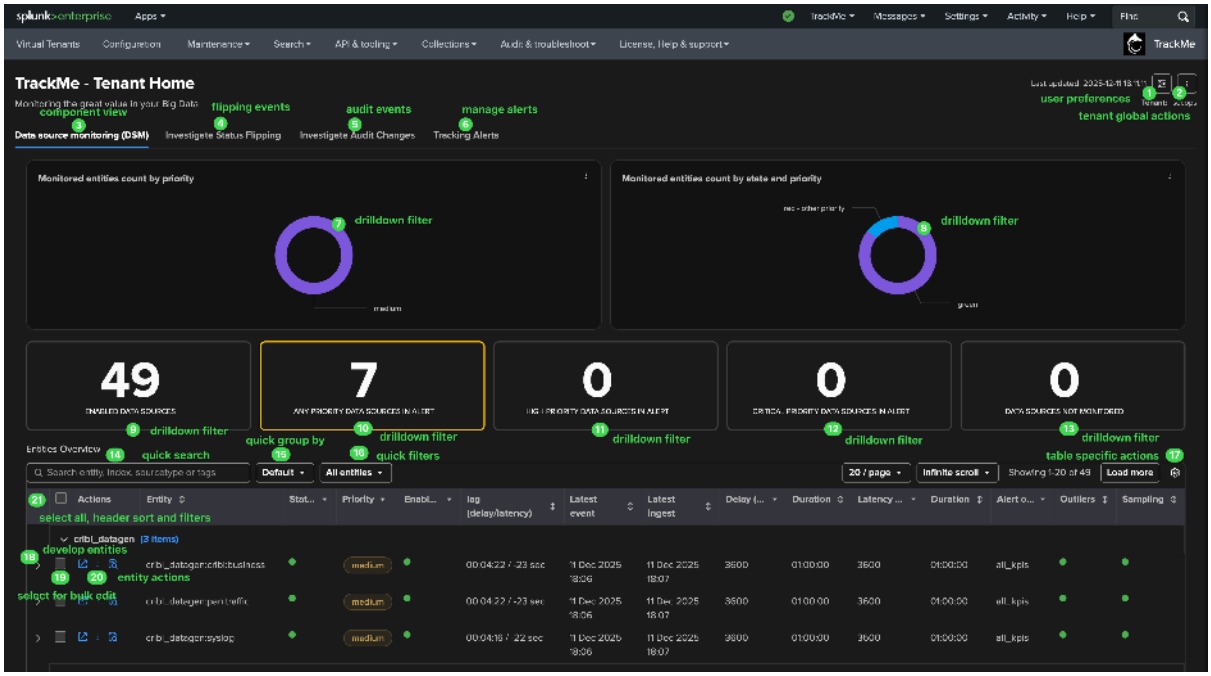
The **Tenant Home** is the main interface for managing a tenant's entities — a rich screen whose interactions vary by component type. You can reach it several ways from the Virtual Tenant interface:



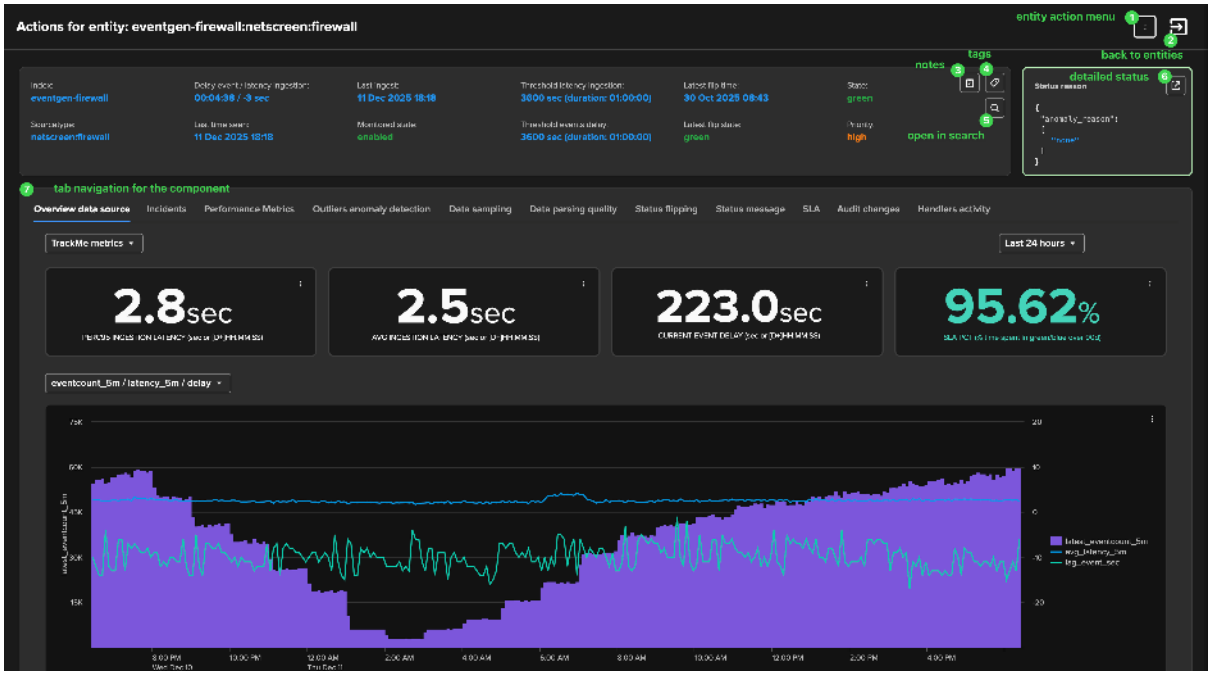


Key interactions

The key interactions in the Tenant Home (the exact view varies by component type):



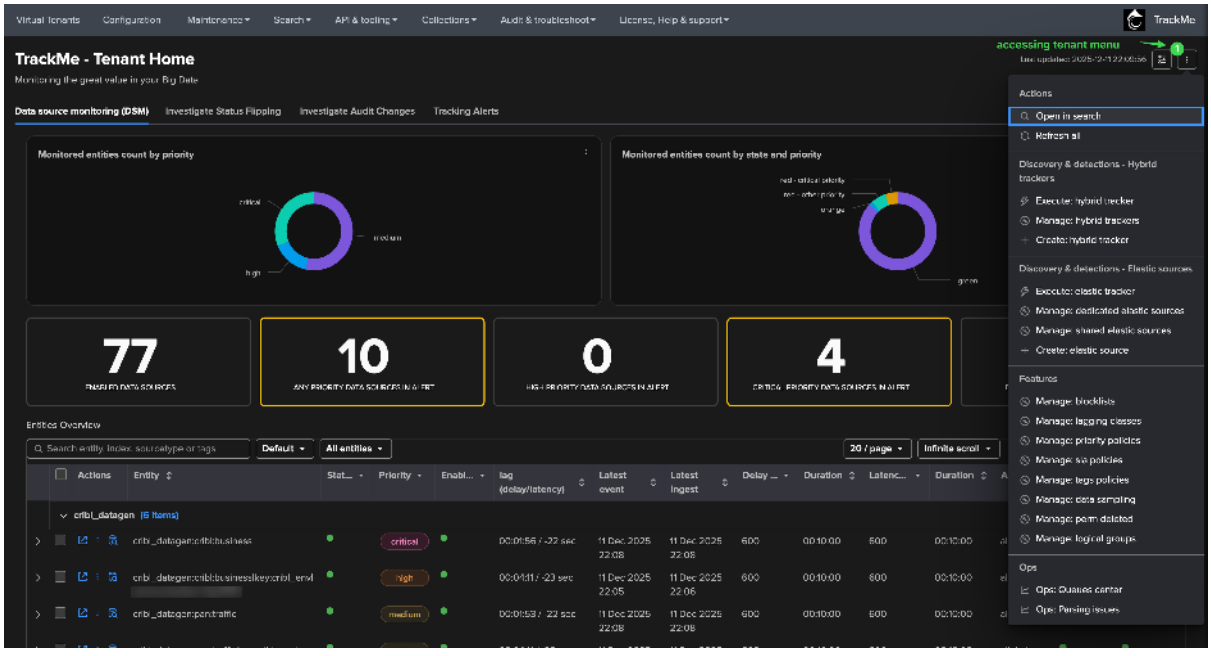
key interactions from the entity view:



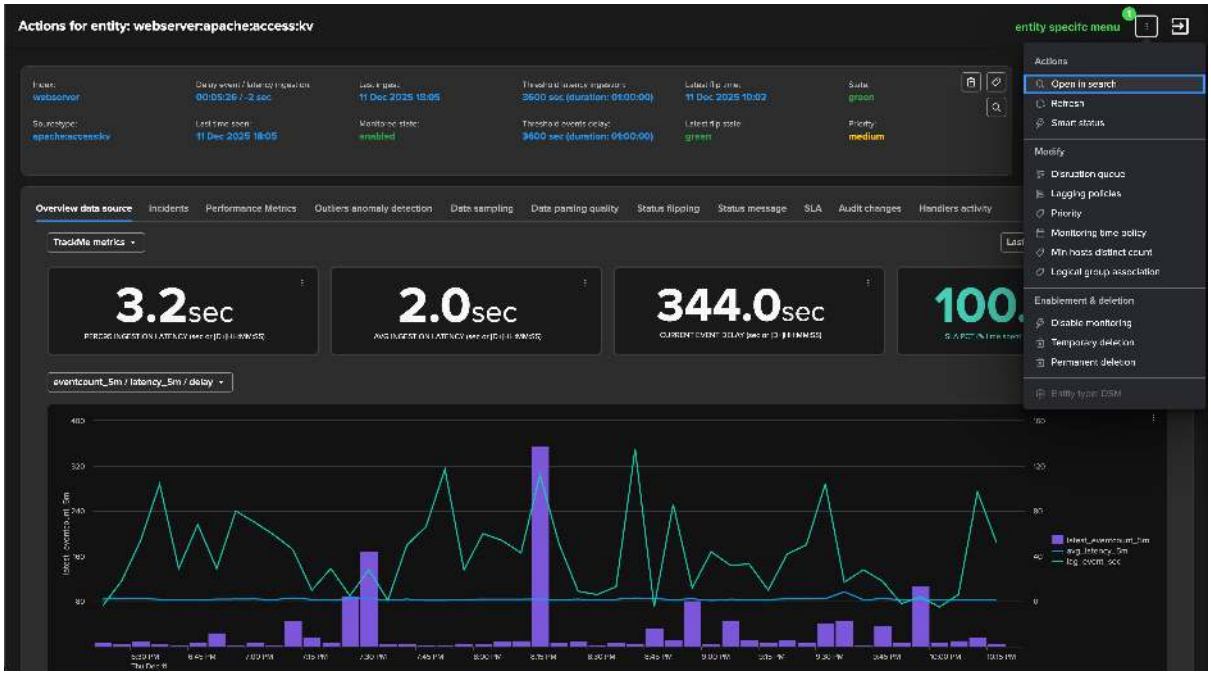
Entity and tenant menus

As everywhere in TrackMe, actions are reached through three-dot menus (the exact items depend on the component type):

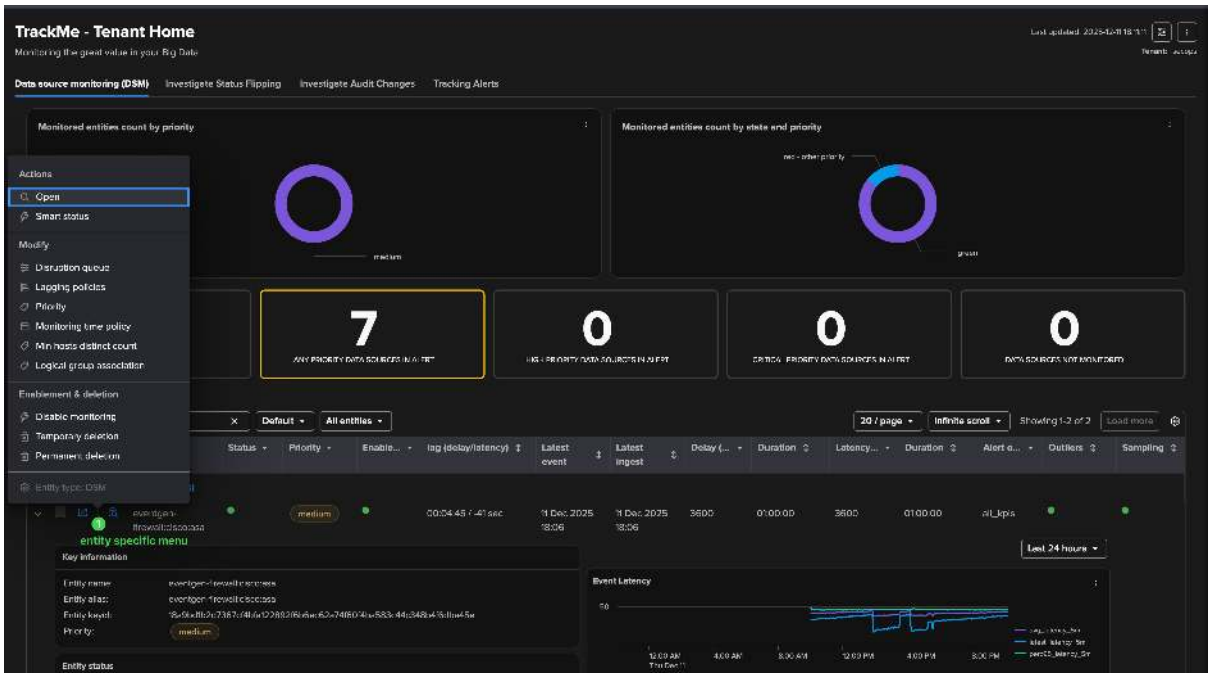
the tenant menu:



the entity menu from the top selector:



the entity menu from the entity table:



Bulk editing

The Tenant Home supports **dynamic bulk editing**: select one or more entities and the bulk action button appears automatically.

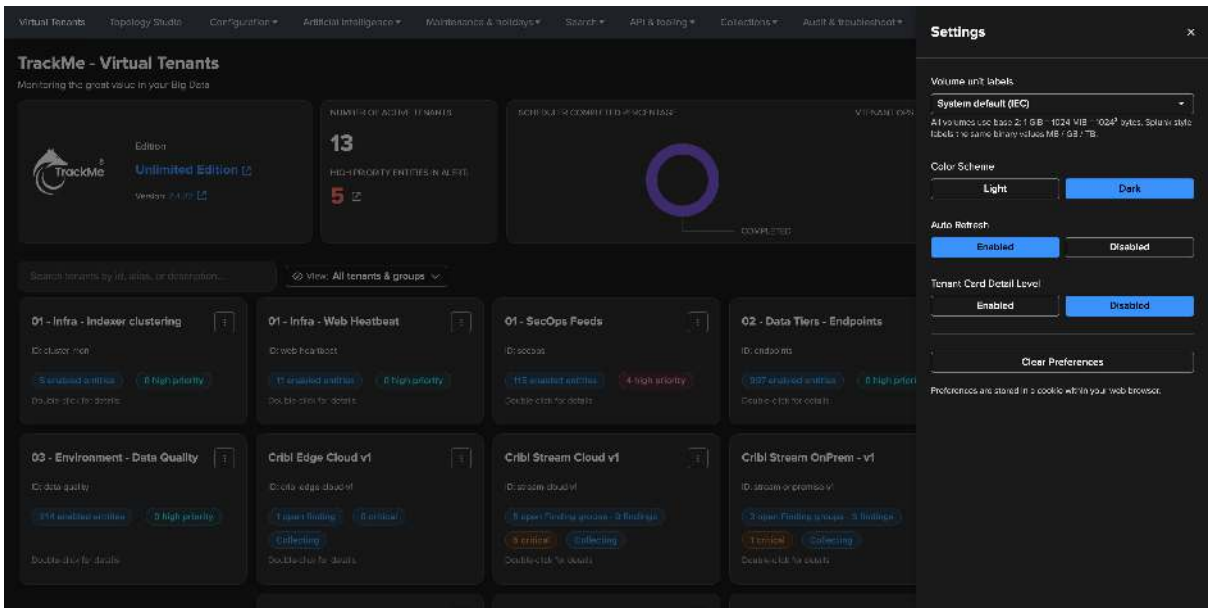
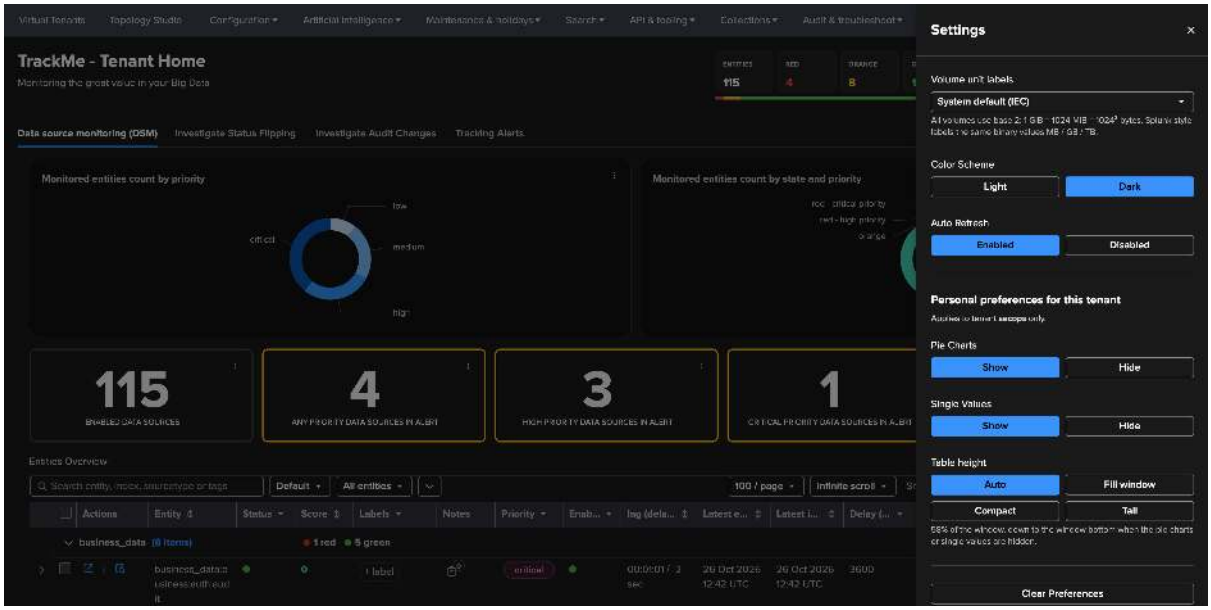
Themes & personal preferences

TrackMe has two colour schemes — **Dark** and **Light** — applied globally across all interfaces. Each user's choice is kept in a browser cookie with their other personal preferences; until they choose, the administrators' default applies (dark after installation).

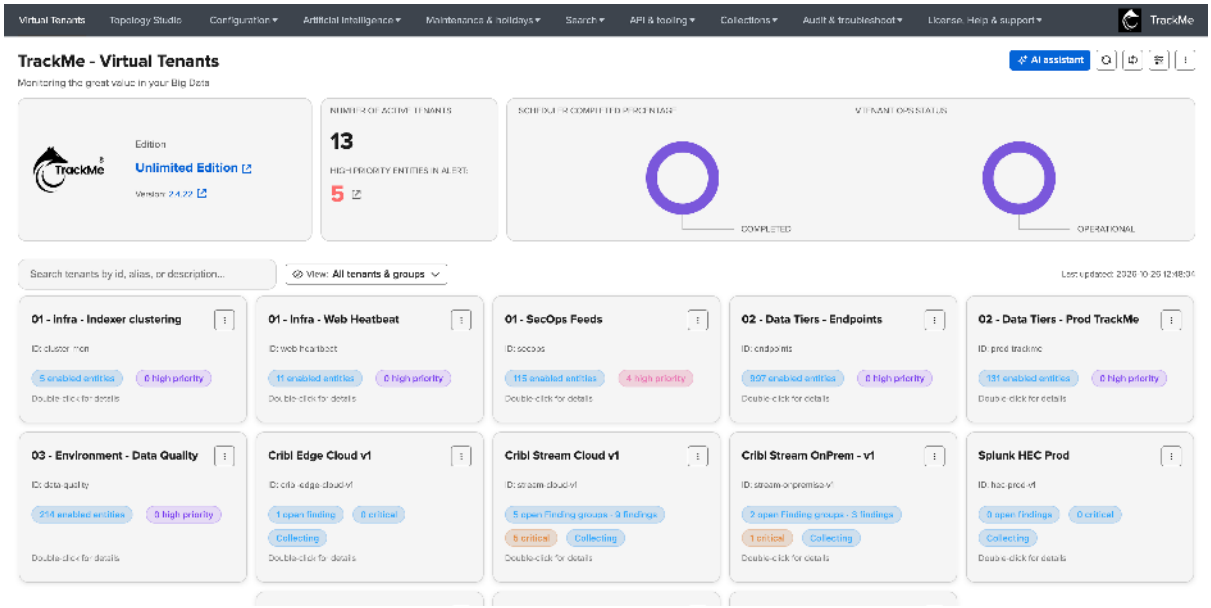
Setting your theme

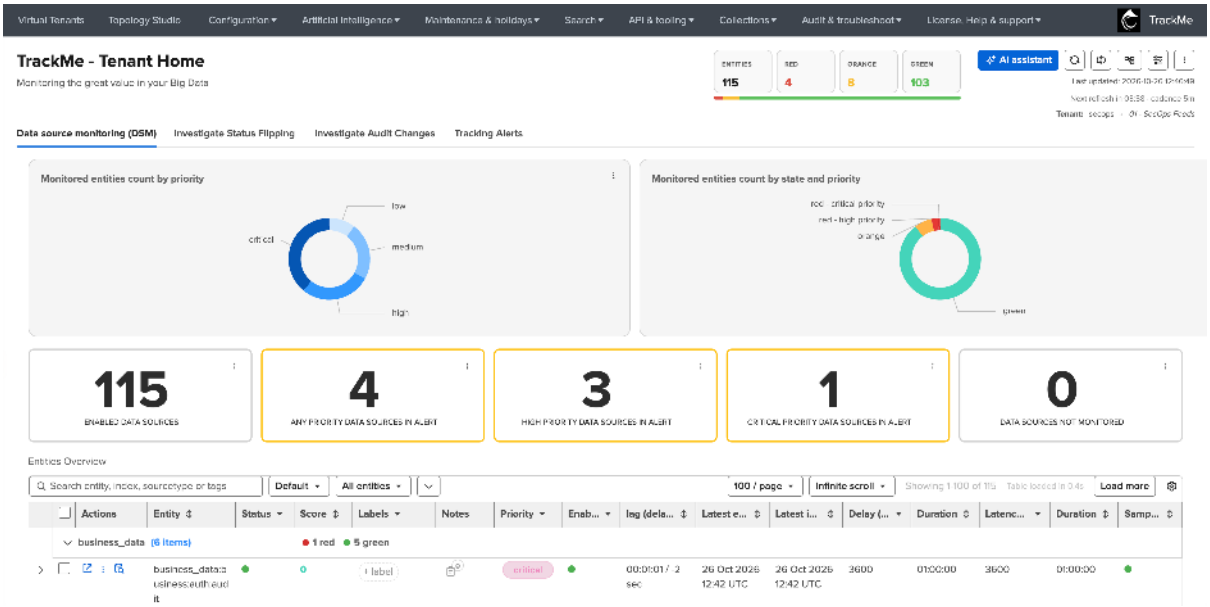
From the Virtual Tenant interface, a Tenant Home or Topology Studio, click the **settings** icon (the sliders button) at the top right to open the **Settings** panel, then pick **Light** or **Dark** under **Color Scheme**. The same panel holds the other personal preferences — auto-refresh, volume unit labels, the tenant card detail level, and on a Tenant Home the layout of that tenant's page:





TrackMe in Light mode:





Every preference, the administrators' defaults and how to reset them are described in *Personal preferences*.

See also

- *What is TrackMe?* and *How TrackMe works* — the conceptual introduction.
- *Virtual Tenants & Access* — creating, managing, and securing Virtual Tenants.
- *Monitoring Components* — the per-component views the Tenant Home adapts to.

8.2 Virtual Tenants & Access

Everything in TrackMe lives inside a **virtual tenant** — an isolated monitoring domain with its own data, configuration, trackers, and access control. This part covers the full tenant lifecycle and the role model that governs who can see and change what.

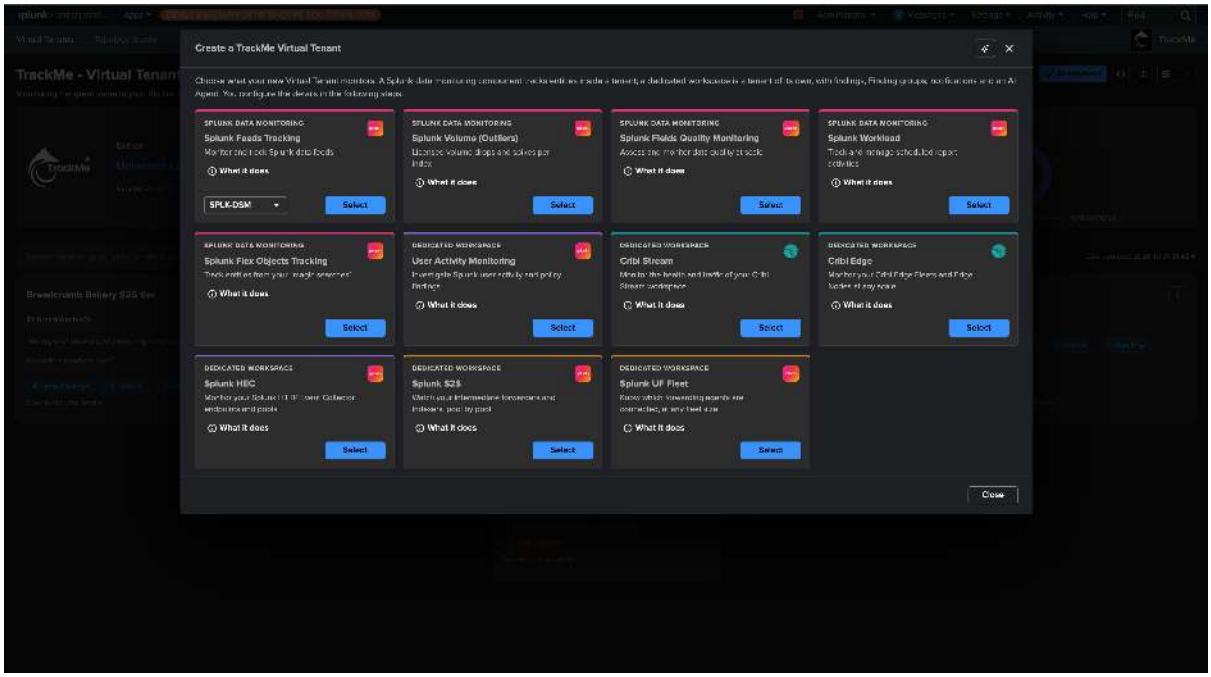
- **Overview** — what a tenant is, why you create them, and a tenant's anatomy.
- **Creating a tenant** — the creation wizard and the choices it asks you to make.
- **Managing tenants** — editing, enabling/disabling, deleting, operational status, and scheduling health.
- **Virtual groups** — read-only cards that aggregate entities across several tenants.
- **Roles & access control** — the three-role model and how to scope access cleanly.
- **Personal preferences** — per-user theme, refresh and layout settings, and the defaults administrators set for them.

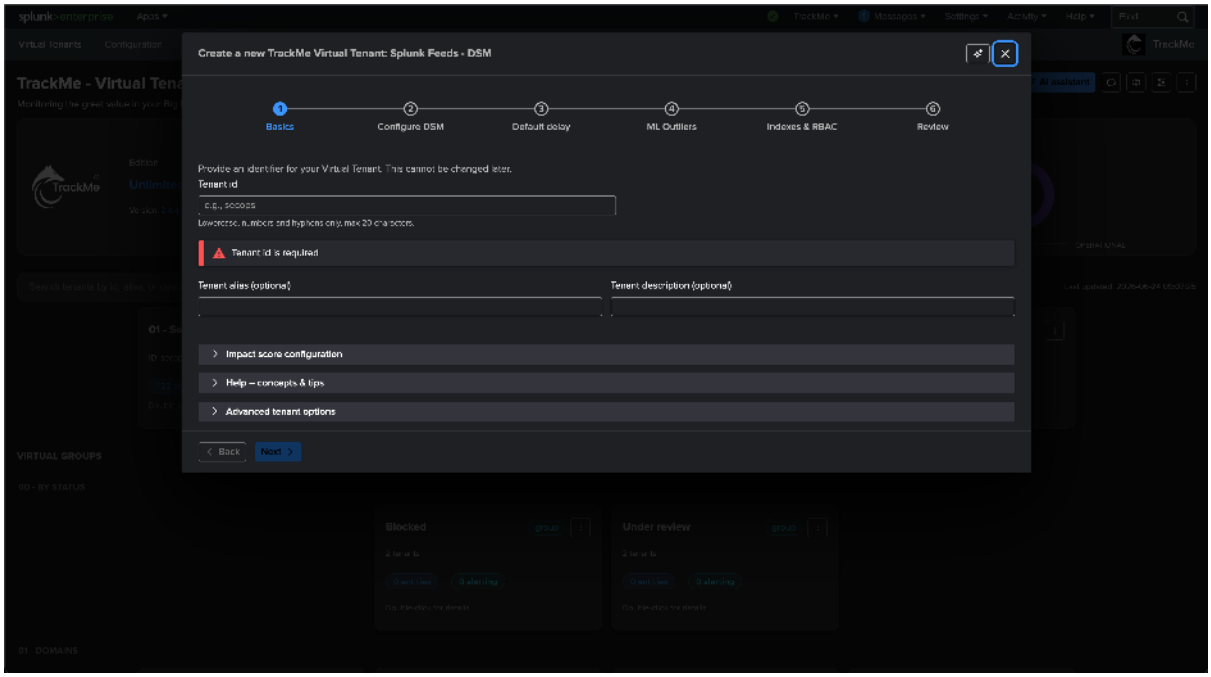
Note

A fresh TrackMe install has **no tenants yet** — creating your first tenant is the first thing you do. If you haven't, start with the *Quickstart*.

8.2.1 Virtual Tenants explained

A **virtual tenant** is TrackMe's unit of multi-tenancy: a self-contained, isolated instance of TrackMe living inside your Splunk app. It owns its data, its configuration, its trackers, its access control, and — optionally — its own remote Splunk deployment to monitor. You create, scope, operate, and destroy tenants independently of one another.





Why tenants exist

Manually, a single flat monitoring space does not survive contact with a real Splunk estate. Tenants let you carve that estate into domains that match how your organisation actually works. Common reasons to create separate tenants:

- **Segmentation** — by company, country, business unit, or team.
- **By technology** — keep firewall data, performance data, and application logs in their own spaces with their own thresholds.
- **By scope** — one tenant per Splunk cluster, per index family, or per search head tier.
- **Access control** — give different teams ownership of different data spaces without exposing each other's entities (see *Roles & access control*).

Everything else in TrackMe — entities, policies, thresholds, alerts — is scoped *to* a tenant. There is no global entity list.

Anatomy of a tenant

From a user's point of view, a tenant is made of the following:

Element	What it is
Tenant identifier (`tenant_id`)	The immutable internal name (lowercase letters, digits, underscores; up to 40 characters). It is stamped as an indexed field on every event and metric TrackMe generates for the tenant. **Choose it carefully — it cannot be changed later.**
Tenant alias	A human-readable display name shown in the UI and used to order tenants. Editable at any time.
Description	Free text describing the tenant's purpose.
Status	`enabled` or `disabled` — the source of truth for whether the tenant's trackers run and its entities are maintained.
Owner	The Splunk user that owns the tenant's knowledge objects and on whose behalf its trackers execute.
Enabled components	Which monitoring components the tenant runs (see below).
Indexes	The Splunk indexes the tenant uses (summary, audit, metric, notable).
Default settings	Per-tenant defaults — time range, monitoring policy, default priority, ML outliers configuration — that cascade down to entities and can be overridden per entity.

Components and tenant types

A tenant is tied to one or more **monitoring components**. When you create a tenant you choose which to enable; each can be turned on or off later.

Tenant type	Components it brings
splk-feeds	The data-flow family: **DSM** (Data Source Monitoring), **DHM** (Data Host Monitoring), and **MHM** (Metric Host Monitoring). Each is enabled independently.
splk-vol	**VOL** — Volume Outliers: the licensed volume of every index, read from the license usage logs. One tenant covers a whole Splunk deployment, local or remote.
splk-wlk	**WLK** — Workload Knowledge: scheduled-search execution health and SVC consumption.
splk-flx	**FLX** — Flex Objects: custom trackers you define with your own SPL.
splk-fqm	**FQM** — Fields Quality Monitoring.
splk-cim	Common Information Model compliance tracking.
splk-uam	**UAM** — User Activity Monitoring: a *dedicated* tenant type with no entity component — the accounts, their scheduled searches, activity and resource usage on one indexing layer, through one or more search head tiers, turned into findings. A tenant is either an entity tenant or a UAM tenant.
cribl-stream	**Cribl Stream**: a *dedicated* tenant type with no entity component — one Cribl Stream connection, its Sources, Destinations, Pipelines, Routes, Packs and Workers, read from the Cribl metrics in a Splunk metric index and from the Cribl Leader API, with findings from policies and traffic ML models. Requires the Enterprise or Unlimited edition.
cribl-edge	**Cribl Edge**: a *dedicated* tenant type with no entity component — the Fleets of one Cribl Edge Leader and their Edge Nodes, Sources and Destinations, read in bulk from the Leader's node directory at any fleet size, with findings from policies. Requires the Enterprise or Unlimited edition. A tenant is either Cribl Stream or Cribl Edge.

Each component is covered in *Part 3*.

Saved Views

On a large estate the Virtual Tenants grid can hold dozens of tenant and Virtual Group cards. A **Saved View** is a named, curated subset of that grid — a hand-picked set of tenant cards (optionally narrowed to specific components) plus Virtual Group cards — so a team lands on just the tenants relevant to them instead of the whole estate. It is a pure **display** convenience: Saved Views never touch monitoring, scoring, or alerting.

A power or admin user creates one from the Virtual Tenants page (**Create a saved view**) via a short wizard — identity, the tenants and components to include, the Virtual Groups to include, and the **roles** allowed to use it. Each user then picks a view from the selector in the search-bar row (the default is *All tenants & groups*); the choice is remembered per browser and silently falls back to *All* if the view is later removed or access is revoked.

Note

Saved Views are **RBAC-scoped** — a view lists the Splunk roles allowed to see it (administrators always can). Creating and managing views requires the power capability (`trackmepoweroperations`); simply using one needs only read access.

License limits

Some license editions **cap the number of tenants** you can create. If you reach the limit, creation is refused until you remove a tenant or apply a higher edition. See the *License* page for the edition matrix.

- *Roles & access control* — control who can see and manage a tenant.
- *Virtual Groups* — aggregate entities across several tenants.

8.2.2 Creating a tenant

Tenants are created from a guided wizard in the Virtual Tenants UI (and, for automation, through the REST API). The wizard adapts to the component type you choose, but every path ends with the same access-control step.

Important

The Splunk **indexes** a tenant uses (summary, audit, metric, notable) must already exist before you create the tenant. The wizard references them; it does not create them.

Identity (all tenant types)

Every tenant begins with its identity:

- **Tenant identifier** (`tenant_id`) — unique and **immutable**. Lowercase letters, digits, and underscores, up to 40 characters.
- **Tenant alias** — optional human-readable display name (editable later).
- **Description** — optional free text.

Creating a splk-feeds tenant

The feeds wizard is the richest, because it configures live discovery of your data. You choose which feeds components to enable — **DSM**, **DHM**, **MHM** — and, per component, set:

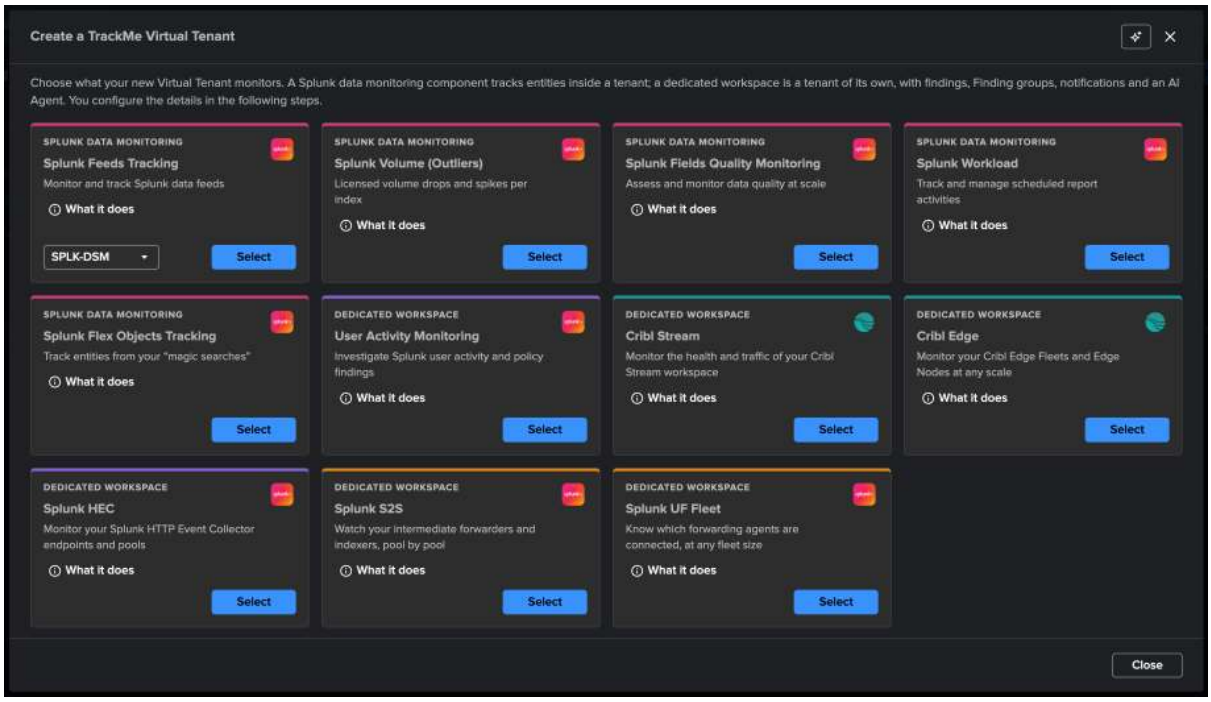
- **Create tracker now** — optionally create a tracker during creation (this produces a *Hybrid Tracker*; you can also add trackers later from inside the tenant).
- **Splunk deployment** — whether the data is **local** to this Splunk, or on a **remote** Splunk deployment (see *Integrations & Remote Deployments*).
- **Splunk root search constraint** — the base constraint that governs which entities are discovered and maintained.
- **Restrict indexes discovery** — narrow the scope further with explicit and wildcard index patterns.
- **Advanced options** — Hybrid-tracker settings plus component-specific options.
- **Test now** — run a preview search against your settings and confirm entities are found before committing.

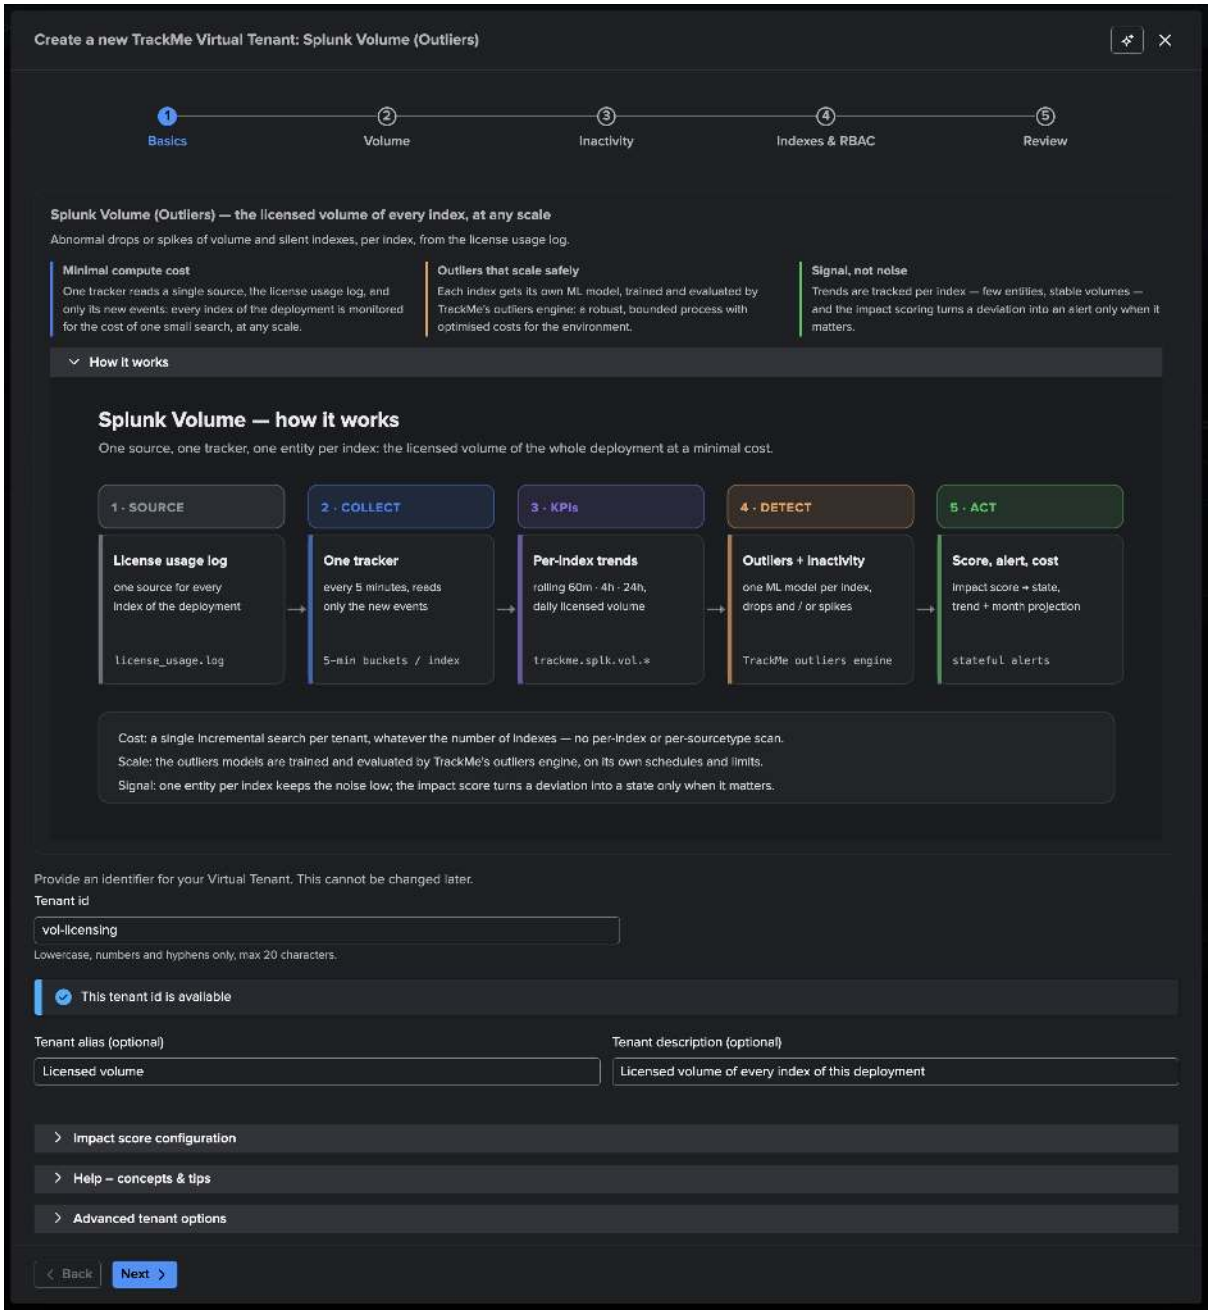
Component nuances:

Component	What you configure
DSM	Tracks data feeds by `(index, sourcetype)`, with an optional custom *break-by* field. Produces KPIs, ML outliers, and data-quality signals.
DHM	Tracks sourcetype activity per **endpoint**. The endpoint defaults to the `host` metadata but can be any custom field.
MHM	Tracks metric-category availability per endpoint. The endpoint defaults to `host` but can be any metric dimension.

Creating a splk-vol tenant

The **Splunk Volume (Outliers)** card creates a *Volume Outliers* tenant: one entity per Splunk **index**, fed by the license usage log, with ML outliers on the licensed volume (drops and / or spikes), inactivity detection, the daily licensed volume, a trend and a month projection. One tenant covers a whole Splunk deployment; there are no use cases to pick. VOL is available on the **Foundation** edition as well as Enterprise and Unlimited.





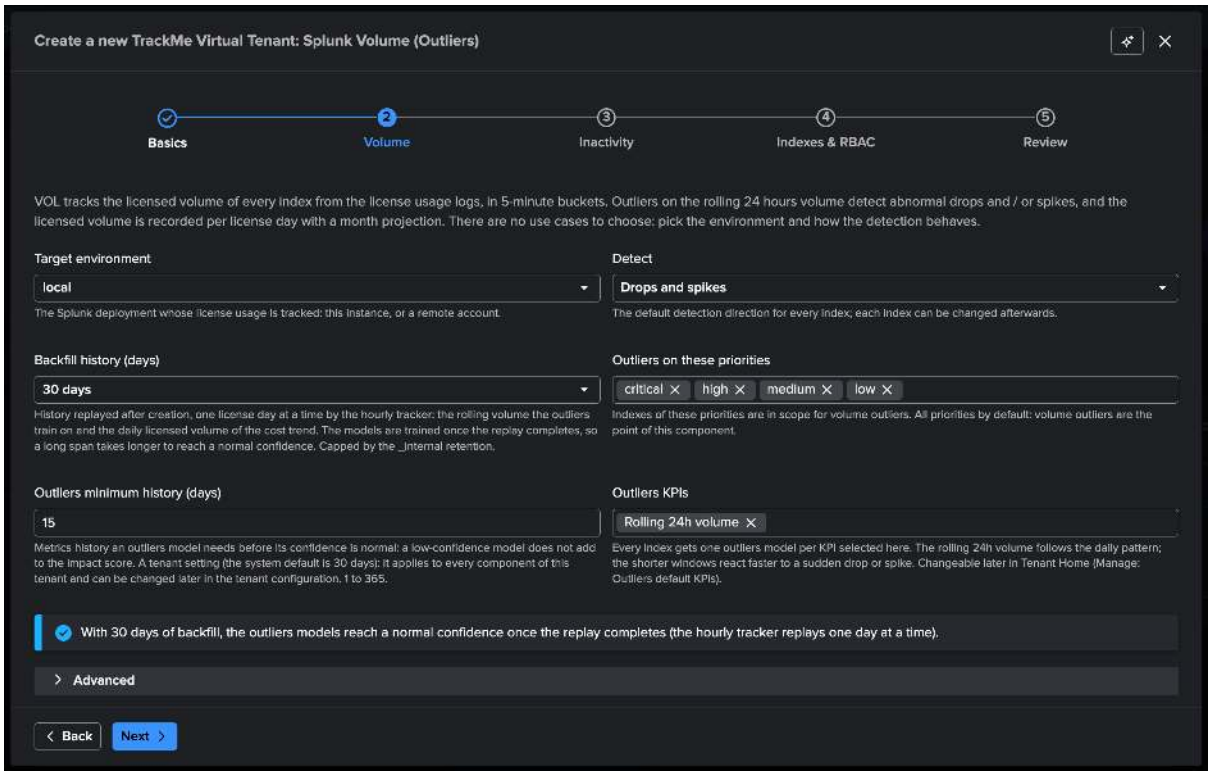
The wizard has five steps:

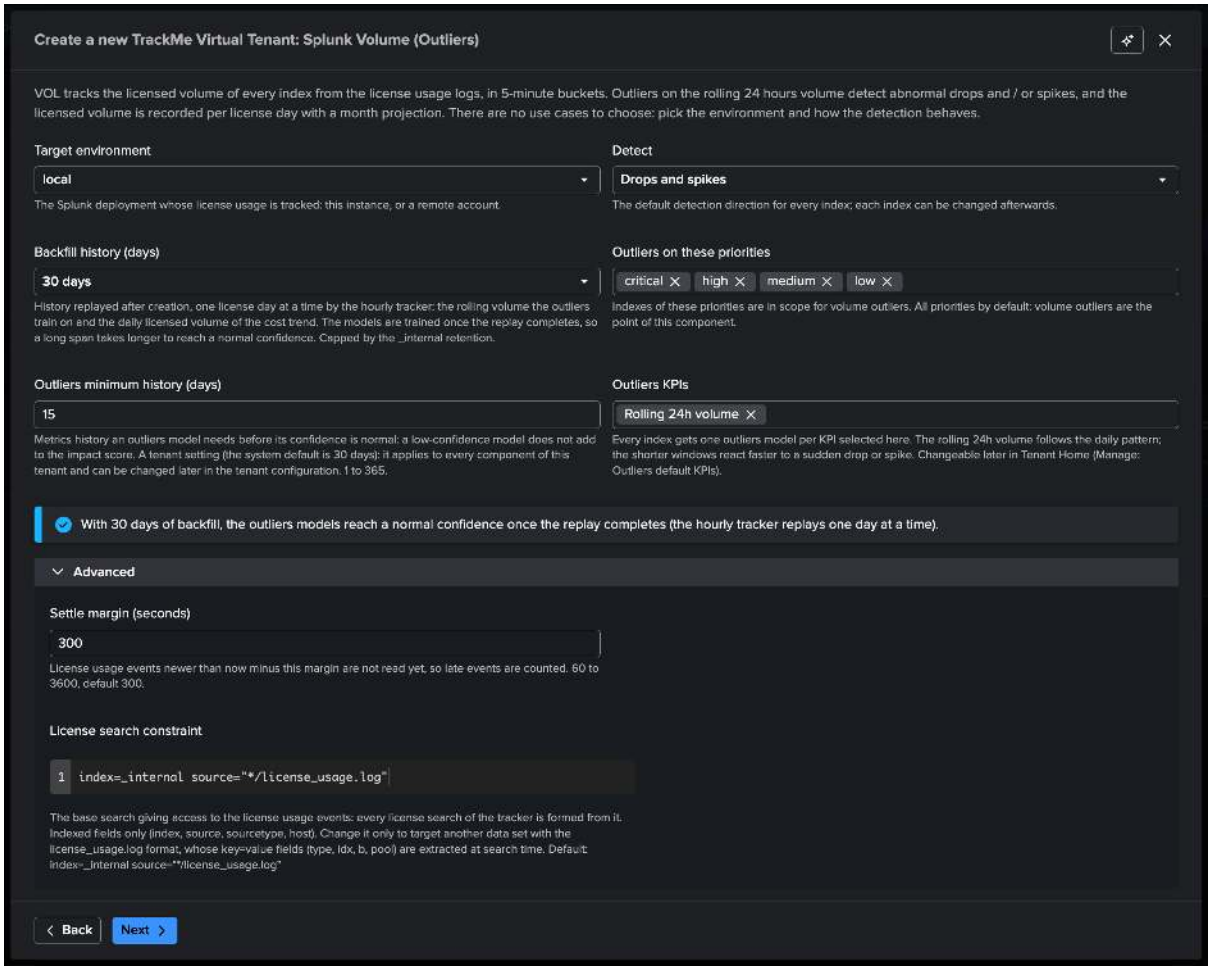
1. **Basics** — the tenant identifier, alias and description, with an optional impact score configuration. Expand **How it works** for the pipeline in one picture.
2. **Volume** — how the volume is collected and how the detection behaves:
   - **Target environment** — this Splunk deployment (`local`), or a **remote account** whose license usage is collected; a remote target runs the connectivity check.
   - **Detect** — the default detection direction of every new index: **drops and spikes**, drops only, or spikes only. Each index can be changed afterwards with one click.
   - **Backfill history (days)** — no backfill, 7, 14, 30 (default), 60 or 90 days, or **Custom…** for any number of days up to 400, capped by the retention of the license usage log. The history is replayed after creation, one license day at a time by the hourly tracker, and the models are trained once the replay completes: a long span takes longer to reach a normal confidence.
   - **Outliers on these priorities** — the priorities in scope for volume outliers, every priority by default

(volume outliers are the point of this component).

- **Outliers minimum history (days)** — the history a model needs before its confidence is *normal* (15 by default on a VOL tenant); the step tells you whether the backfill covers it.
- **Outliers KPIs** — the rolling KPIs every new index gets a model on (the rolling 24 hours by default).
- **Advanced** — the **license search constraint** (leave the default, `index=_internal source="*/license_usage.log"`, unless the license usage events live elsewhere — see *The license search constraint (advanced)*) and the **settle margin** before a 5-minute bucket is read.

3. **Inactivity** — the tenant's inactivity policy: after how long without licensed volume an index turns red. The default is **variable**: 1 day during working hours (Monday to Friday, 08:00–19:59 server time), 7 days for nights and week-ends. Quick templates, a static threshold, or your own day / hour slots.
4. **Indexes & RBAC** — the access-control and indexes step common to every tenant.
5. **Review** and create. The first collection runs immediately; the backfill job plans itself at its first hourly run, and the tenant card reads **Backfill pending** until then, then **Backfilling N %**.





Create a new TrackMe Virtual Tenant: Splunk Volume (Outliers)
VOL tracks the licensed volume of every index from the license usage logs, in 5-minute buckets. Outliers on the rolling 24 hours volume detect abnormal drops and / or spikes, and the licensed volume is recorded per license day with a month projection. There are no use cases to choose: pick the environment and how the detection behaves.
Target environment
local
The Splunk deployment whose license usage is tracked: this instance, or a remote account.
Detect
Drops and spikes
The default detection direction for every index; each index can be changed afterwards.
Backfill history (days)
30 days
History replayed after creation, one license day at a time by the hourly tracker: the rolling volume the outliers train on and the daily licensed volume of the cost trend. The models are trained once the replay completes, so a long span takes longer to reach a normal confidence. Capped by the _internal retention.
Outliers on these priorities
critical
high
medium
low
Indexes of these priorities are in scope for volume outliers. All priorities by default: volume outliers are the point of this component.
Outliers minimum history (days)
15
Metrics history an outliers model needs before its confidence is normal: a low-confidence model does not add to the impact score. A tenant setting (the system default is 30 days): it applies to every component of this tenant and can be changed later in the tenant configuration. 1 to 365.
Outliers KPIs
Rolling 24h volume
Every index gets one outliers model per KPI selected here. The rolling 24h volume follows the daily pattern; the shorter windows react faster to a sudden drop or spike. Changeable later in Tenant Home (Manage: Outliers default KPIs).
With 30 days of backfill, the outliers models reach a normal confidence once the replay completes (the hourly tracker replays one day at a time).
Advanced
Settle margin (seconds)
300
License usage events newer than now minus this margin are not read yet, so late events are counted. 60 to 3600, default 300.
License search constraint
1 index=_internal source="*/license_usage.log"
The base search giving access to the license usage events: every license search of the tracker is formed from it. Indexed fields only (index, source, sourcetype, host). Change it only to target another data set with the license_usage.log format, whose key=value fields (type, idx, b, pool) are extracted at search time. Default: index=_internal source="*/license_usage.log"

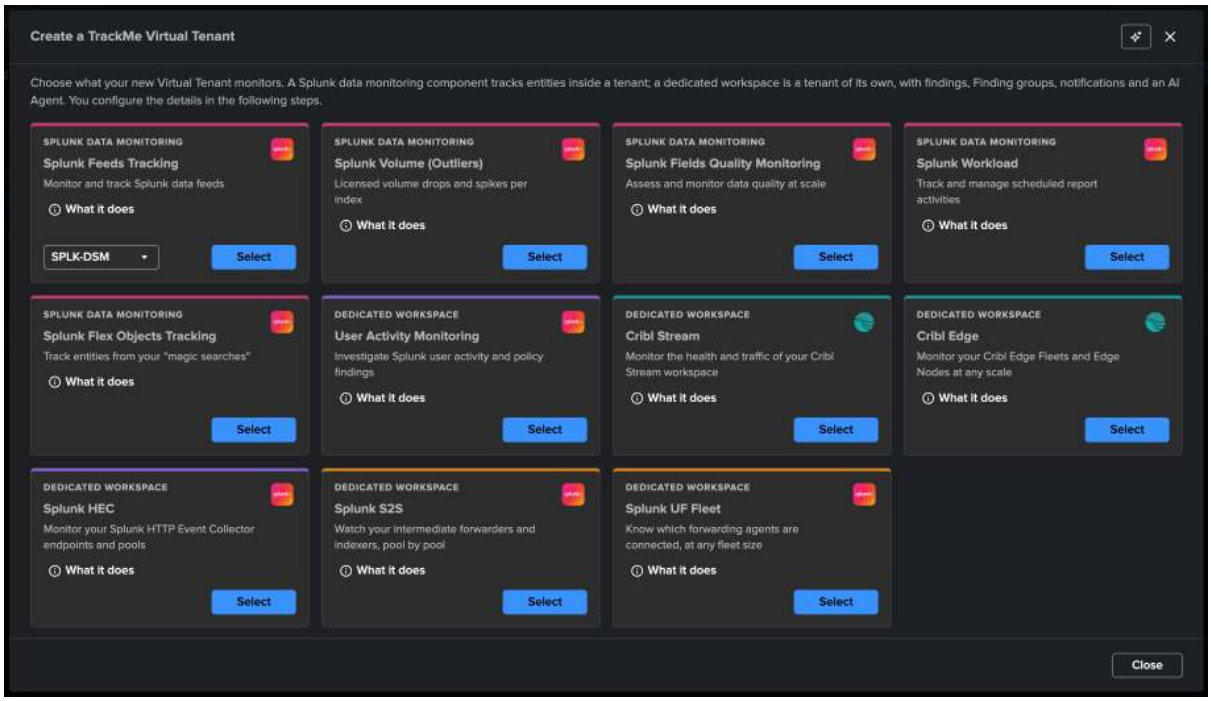
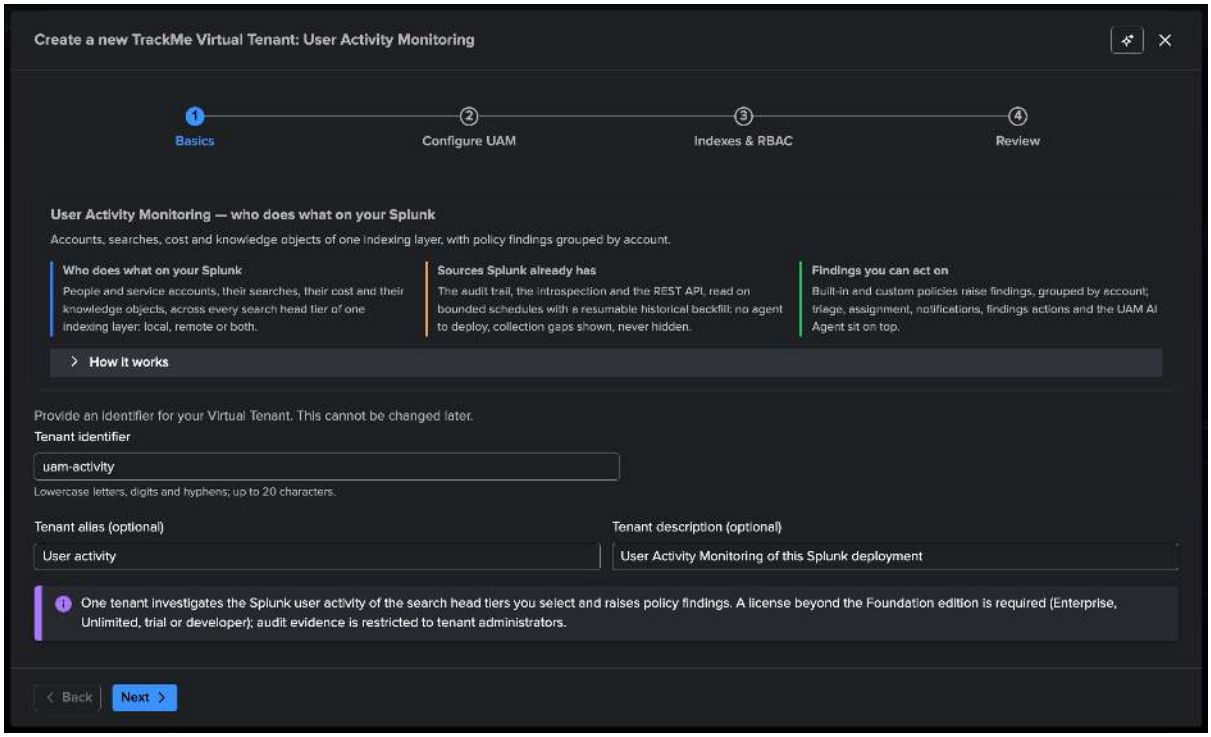
Tip

A single VOL tenant per Splunk deployment is the natural shape: the license usage log already covers every index. Monitor several deployments from one TrackMe with one VOL tenant per remote account.

Creating a splk-uam tenant

The **User Activity Monitoring** card (the first of the chooser's dedicated workspaces) creates a *UAM* tenant: a **dedicated tenant type** — no entity component can be added to it — that inventories the scheduled searches, users and roles of one or more **search head tiers**, reads the search activity and the resource usage of the shared indexing layer, classifies the accounts and raises **findings** from a catalogue of policies. UAM is available on the **Enterprise** and **Unlimited** editions, the Unlimited trial and the **Developer** license; the card is refused on the Foundation edition and the Foundation trial.

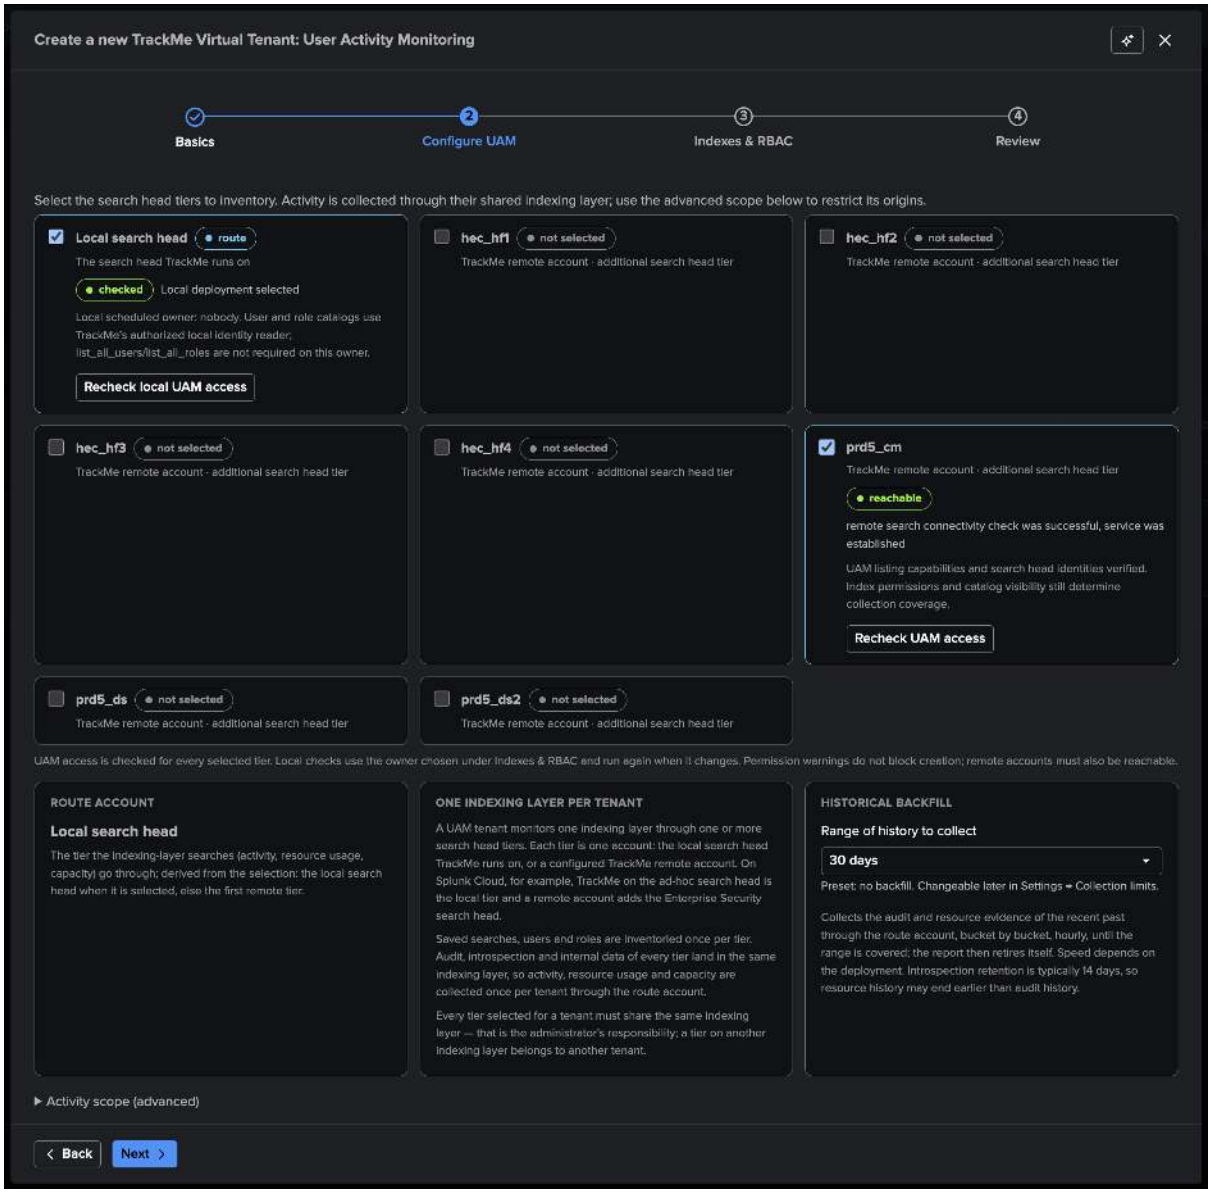




The wizard has four steps:

1. **Basics** — the tenant identifier (lowercase letters, digits and hyphens, up to 20 characters for a UAM tenant), alias and description.
2. **Configure UAM** — the shape of the tenant:
   - **Search head tiers** — the local search head and / or remote accounts, every selected account feeding the **same indexing layer** (one remote account per tier of that layer). Every remote tier runs its connectivity test and must pass it before the creation is allowed. Every selected tier also runs a **UAM access check** (the local one with the owner chosen under *Indexes & RBAC*, again whenever it changes); its permission warnings do not block the creation. The **route** account of the indexing-layer searches (audit activity, resource usage, capacity, account signals) is derived: the local search head when selected, else the first tier.
   - **Historical backfill** — the range of audit and resource history collected before the live start, hourly in 5-minute buckets, until covered: **none** (the default), 7, 14, 30, 60 or 90 days, bounded by the retention of the sources (the introspection retention is typically shorter than the audit one). Changeable later in *Settings → Collection limits*.
   - **Activity scope (advanced)** — optional search head hostname patterns to include or exclude, written into the base searches so that the indexers return only the activity of the search heads in scope.
3. **Indexes & RBAC** — the access-control and indexes step common to every tenant. Prefer a **dedicated service account with administrative rights** as the owner (`svc-trackme`, for instance): the trackers and the scheduled AI review run as the owner, who must administer the tenant. Classify that account and the administrators as **system** in the workspace afterwards, so they never appear in the findings.
4. **Review** and create. The trackers are scheduled immediately — one inventory report per tier every 15 minutes with its full listing as a report of its own (the first within the hour, then daily off-peak), the audit activity and the resource usage every 5 minutes from their durable checkpoints, the account signals and the policies every 15 minutes — and, when a range was chosen, the backfill plans itself at its first hourly slot.

Several search head tiers. When the deployment has more than one search head over the same indexing layer — on Splunk Cloud the ad-hoc search head cluster and an Enterprise Security cluster, on Splunk Enterprise any search head with a TrackMe remote account — tick every tier in the *Configure UAM* step. Each remote account is tested as soon as it is selected and the creation waits until every selected account is reachable; the inventory then runs once per tier while the audit activity, the resource usage, the capacity and the account signals are collected once through the route account.



Create a new TrackMe Virtual Tenant: User Activity Monitoring

TrackMe remote account · additional search head tier
UAM access is checked for every selected tier. Local checks use the owner chosen under Indexes & RBAC and run again when it changes. Permission warnings do not block creation; remote accounts must also be reachable.
ROUTE ACCOUNT
Local search head
The tier the indexing-layer searches (activity, resource usage, capacity) go through; derived from the selection: the local search head when it is selected, else the first remote tier.
ONE INDEXING LAYER PER TENANT
A UAM tenant monitors one indexing layer through one or more search head tiers. Each tier is one account: the local search head TrackMe runs on, or a configured TrackMe remote account. On Splunk Cloud, for example, TrackMe on the ad-hoc search head is the local tier and a remote account adds the Enterprise Security search head.
Saved searches, users and roles are inventoried once per tier. Audit, introspection and internal data of every tier land in the same indexing layer, so activity, resource usage and capacity are collected once per tenant through the route account.
Every tier selected for a tenant must share the same indexing layer — that is the administrator's responsibility; a tier on another indexing layer belongs to another tenant.
HISTORICAL BACKFILL
Range of history to collect
30 days
Preset: no backfill. Changeable later in Settings » Collection limits.
Collects the audit and resource evidence of the recent past through the route account, bucket by bucket, hourly, until the range is covered; the report then retires itself. Speed depends on the deployment. Introspection retention is typically 14 days, so resource history may end earlier than audit history.

Through the REST API, the same creation is `POST /trackme/v2/vtenants/admin/add_tenant` with `tenant_uam_enabled=true` and no other component flag, plus an optional `uam_config` object holding any subset of the *tenant options* — the wizard sends `tiers`, `scheduled` and `backfill_days`:

```
| trackme url="/services/trackme/v2/vtenants/admin/add_tenant" mode="post"
    body="{'tenant_name': 'user-activity', 'tenant_desc': 'User Activity Monitoring
↪',
          'tenant_roles_admin': 'trackme_admin', 'tenant_roles_user':
↪'trackme_user',
          'tenant_owner': 'svc-trackme', 'tenant_idx_settings': 'global',
          'tenant_uam_enabled': 'true',
          'uam_config': {'tiers': ['local'], 'scheduled': true, 'backfill_days':␣
↪30}}"
```

Tip

One UAM tenant per **indexing layer**: add every search head tier of that layer to the same tenant, so a user present on several tiers is one account and the activity is collected once. Monitor another deployment with another UAM tenant.

See also

- *User Activity Monitoring* — what UAM tracks, the workspace and the policies.
- *User Activity Monitoring — reference* — the tiers, the trackers, the evidence and every `uam_config` option.
- *Who is doing what on your Splunk? User Activity Monitoring (UAM)* — a UAM tenant from its creation to its first decisions, on a live Splunk Cloud deployment.

Creating a Cribl Stream or Cribl Edge tenant

The **Cribl Stream** and **Cribl Edge** cards create a dedicated Cribl tenant: no entity component can be added to it, and its objects are Cribl objects monitored through findings. Both need a *Cribl connection* declared beforehand, and an Enterprise, Unlimited, trial or Developer license.

Each wizard has four steps — the identity of the tenant, the connection with its Worker Groups (Cribl Stream) or Fleets (Cribl Edge), the indexes and roles, and a review — and is described step by step in its guide:

- *Cribl Stream* — create a Cribl Stream tenant, then explore its workspace.
- *Cribl Edge* — create a Cribl Edge tenant, then explore its workspace.
- *Cribl Stream & Cribl Edge* — which Cribl tenant to use, and the Cribl connections.

Creating a Splunk HEC tenant

The **Splunk HEC** card creates a dedicated tenant that monitors the HTTP Event Collector endpoints of one Splunk deployment: no entity component can be added to it, and its endpoints, pools and tokens are monitored through findings. It needs no connection: its source is this search tier or a TrackMe remote account to the search tier that sees the endpoints' internal indexes, and an Enterprise, Unlimited, trial or Developer license. The wizard has four steps — the identity of the tenant, the source with the discovered endpoints and their pools, the indexes and roles, and a review — described step by step in *Splunk HEC*.

Creating a splk-wlk tenant

The Workload wizard walks through:

- **Deployment type** — for example Splunk Cloud, which creates a tracker for SVC consumption summary metrics.
- **Deployment target** — local or a remote account (searches switch transparently to the remote deployment).
- **Root search constraint** — optional filters for the introspection, scheduler, and SVC searches (by app, or by `host` / `splunk_server`).
- **ML Outliers** — auto-create and train ML models when entities are discovered (trains against the `elapsed` metric by default).
- **Inactive entities** — auto-purge scheduled entities that have been inactive beyond a configured period; this is handled by the Workload tracker named `inactive_entities`.

Tip

Multiple search head tiers: restrict the root constraint so it targets only the intended members (for example `host=sh1 OR host=sh2`). The simplest, most robust pattern is **one tenant per search head tier**.

Creating splk-flx, splk-fqm, splk-cim tenants

These wizards are minimal — you provide the identity, description, and the access-control step. The actual entity configuration happens later, inside the tenant UI, once it exists.

Access control, ownership & indexes (all tenant types)

Every creation path finishes with the same step:

- **Roles (RBAC)** — choose which Splunk roles administer the tenant (admin / power) and which have read-only access (user). See *Roles & access control* for the full model.
- **Owner** — the Splunk user that owns the tenant's knowledge objects and runs its trackers. Future objects are auto-assigned to this owner.
- **Indexes** — select the (already-existing) Splunk indexes the tenant will use.

Tip

You can preset the default owner and roles that the creation UI proposes, under **Configuration → System settings → General → Knowledge objects & RBAC defaults**, so every new tenant starts from sensible defaults.

What happens when you target a remote deployment

Choosing a remote target triggers an automatic **connectivity and authentication test**, and the result is shown before you can continue. Creation also checks that your license edition allows another tenant and that you are permitted to use the chosen remote account.

Automating with the REST API

Everything the wizard does is also available through the REST API — useful for scripting tenant creation or managing it as code. Browse the full endpoint list and options under **API & Tooling → TrackMe REST API Reference** in the UI. Tenants are created by posting to `/services/trackme/v2/vtenants/admin/add_tenant`; for example, a splk-dsm tenant:

```
| trackme url="/services/trackme/v2/vtenants/admin/add_tenant" mode="post"
    body="{'tenant_name': 'mytenant', 'tenant_desc': 'Demo tenant',
           'tenant_roles_admin': 'trackme_admin', 'tenant_roles_user':
↪'trackme_user',
           'tenant_owner': 'admin', 'tenant_idx_settings': 'global',
           'tenant_dsm_enabled': 'true'}"
```

The body carries the same choices as the wizard — identity, RBAC roles, owner, indexes — and a per-component **enable flag**: `tenant_dsm_enabled` / `tenant_dhm_enabled` / `tenant_mhm_enabled` for feeds, `tenant_vol_enabled` for Volume Outliers (its options — `vol_account`, `vol_backfill_days`, `vol_default_direction`, the inactivity policy… — can be set in the same body, see *Volume Outliers — in depth*), and `tenant_flx_enabled` / `tenant_fqm_enabled` / `tenant_wlk_enabled` for the other tenant types. Set the flag(s) for the component(s) you want; the minimal tenant types (flx, fqm, cim) need only the identity, RBAC, and that flag. A **UAM** tenant is created with `tenant_uam_enabled` alone — it is a dedicated tenant type and cannot be mixed with a component flag — and an optional `uam_config` object (see *Creating a splk-uam tenant*). A **Cribl Stream** or **Cribl Edge** tenant is created the same way with `tenant_cribl_stream_enabled` or `tenant_cribl_edge_enabled` alone and a `cribl_config` object, by a TrackMe administrator (the `trackmeadminoperations` capability, see *Creating a Cribl Stream or Cribl Edge tenant*). A **Splunk HEC** tenant is created with `tenant_splunk_hec_enabled` alone and a `hec_config` object, by a TrackMe administrator too (see *Creating a Splunk HEC tenant*).

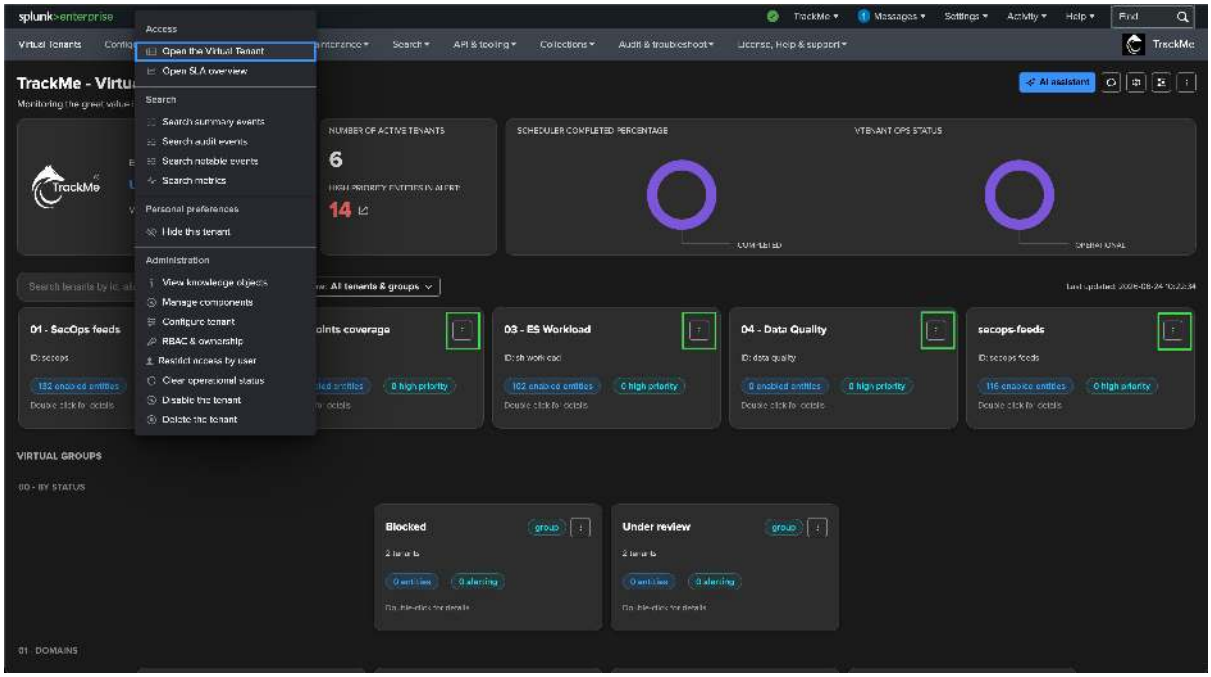
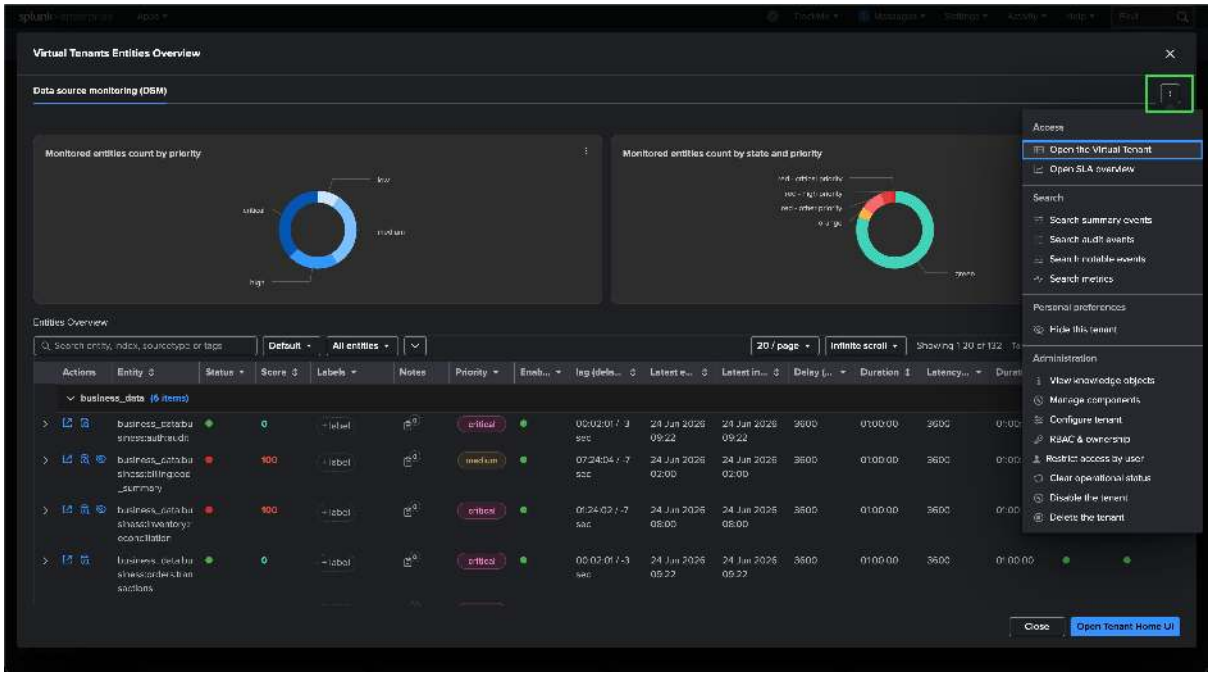
8.2.3 Managing tenants

Once a tenant exists, everything you do to it is on its **three-dot menu** in the Virtual Tenants grid. This page covers that menu — configuration, access, enabling and disabling, deletion — and the two things you watch to keep a tenant healthy: its **operational status** and its **scheduling**.





The tenant menu

Everything you can do to a tenant is on its **three-dot menu** on the tenant card. The menu is grouped into *Access*, *Search*, and *Administration* actions, plus a *Personal preferences* entry to hide the tenant from your own grid; the administration actions are available to tenant admins.

Menu action	What it does
Open the Virtual Tenant	Opens the tenant's home page (you can also double-click the card).
Open SLA overview	Opens the SLA dashboard — the percentage of time each entity spent green.
Search summary / audit / notable events, Search metrics	Deep links into Splunk search, pre-scoped to the tenant's indexes.
View knowledge objects	Lists every knowledge object the tenant owns, with its type — useful for auditing.
Manage components	Add or remove monitoring components on the tenant.
Configure tenant	The per-tenant settings editor (see *Configuring a tenant*).
RBAC & ownership	Change the admin / power / user roles and the owner; existing knowledge objects are re-permissioned and, if the owner changes, re-assigned. See *Roles & access control*.
Restrict access by user	Limit the tenant to a named list of users, on top of role-based access; the card then shows a *Restricted* badge.
Clear operational status	Reset a stuck operational status once you have fixed the cause (see *Operational status*).
Disable / Enable the tenant	Pause or resume the tenant without deleting anything (see below).
Delete the tenant	Permanently destroy the tenant (see below).
Hide / Unhide this tenant	A personal preference that removes the tenant from *your* grid only; other users are not affected and the tenant is neither disabled nor restricted. Bring hidden tenants back with **Unhide this tenant** or with **Virtual Tenants visibility** in the Settings panel (see *Personal preferences*).

Warning

Removing a component (via *Manage components*) permanently deletes that component's knowledge objects and purges its data. The only way back is a restore from backup. Prefer disabling the tenant if you are unsure.

Configuring a tenant

Configure tenant opens a tabbed editor for everything about a tenant that is not its identity or its components. From here you set, per tenant: documentation and access control, entity discovery and labels, the **Tables & views** defaults of the Tenant Home (pagination, default time range, tab order, table group-by — see *Personal preferences*), feed delays, the delayed-entities inspector and auto-disablement, ML outliers, the *disruption queue* and *impact scoring*, *CMDB integration*, *AI settings* and bank holidays. Most of these features are explained in their own parts of this guide — this modal is where you tune them for one tenant.

Enabling and disabling

Disabling a tenant is the safe, reversible alternative to deleting it:

- **Disable the tenant** sets the status to `disabled`: all the tenant's knowledge objects are disabled in Splunk, no trackers run, no entities are maintained — but **no data is destroyed**. A disabled tenant stays on the Virtual Tenants grid with a **disabled** badge, and its entities no longer count in the page's alert totals.
- **Enable the tenant** brings it straight back.

Deleting a tenant

Warning

Deletion is permanent and irreversible. It drops the tenant's data collections, removes its configuration and its role triplet, deletes its scheduled trackers, and purges its Configuration Guardian alerts. Previously generated events and metrics are left untouched in your indexes. Hybrid trackers must be re-created if you ever rebuild the tenant. The only recovery path is a restore from backup — when in doubt, **disable instead of delete**.

Operational status

TrackMe continuously monitors itself. Every tracker and custom command reports failures to a central register, and a per-tenant **health tracker** (running every five minutes) turns that into health events you can see directly on the tenant card.

Common causes of a failing operational status:

- An overloaded environment with no available search slots.
- A search head in detention.
- Network or credential issues (especially toward a remote deployment — see *Integrations & Remote Deployments*).
- Corrupted configuration: missing knowledge objects or incorrect permissions.

To investigate:

- Click the operational-status chart on a tenant to see the affected tenants, related accounts, and the root cause; **Open in search** drills into the per-tracker results.
- Health events land in the tenant's audit index, for example `index=trackme_audit sourcetype="trackme:health" last_status="failure"`.
- Once you have fixed the cause, use **Clear operational status** from the tenant menu to reset the recorded status. It defaults to the current tenant but you can widen the scope to others — or all tenants — and optionally **re-run the health-check tracker** as it clears, with a note for the audit trail.
- The **Audit → Operational Statuses** dashboard gives the cross-tenant view.
- The per-tenant execution summary is stored centrally; inspect it with:

```
| inputlookup trackme_virtual_tenants | fields tenant_id,␣
↪tenant_objects_exec_summary
```

Scheduling and tracker health

TrackMe depends on its trackers being scheduled and running on time. You monitor that from the Virtual Tenants UI:

- **Aim for zero skipped searches.** Skipped trackers mean the deployment is short on search slots or CPU — review search performance or add capacity.
- Trackers log their own run-time KPIs; the **TrackMe Performance Deepdive** dashboard surfaces them.
- **Automatic re-attempts:** when maximum search concurrency is hit, TrackMe retries (logged as a temporary failure). If the retry limit is reached it logs a permanent failure and cancels that run.

Tip

`DEBUG` logging is very verbose — enable it only while troubleshooting, from **Configuration → System settings → Logging**, and turn it back down afterwards.

Under the hood and via the API

The tenant lifecycle is fully scriptable through the `vtenants/admin` endpoints (all `mode=post` unless noted): `update_tenant_rbac`, `enable_tenant`, `disable_tenant` and `del_tenant` (`mode=delete`). Operational status is produced by a per-tenant health tracker, `trackme_health_tracker_tenant_<tenant_id>` (every ~5 min, running `| trackmetrackerhealth tenant_id="<tenant_id>"`); read it with the `configuration/get_tenant_ops_status` endpoint and clear it with `vtenants/admin/clear_exec_summary`. The trackers themselves are orchestrated by the `trackmetrackerexecutor` command — inspect scheduling at `index=_internal sourcetype=trackme:custom_commands:trackmetrackerexecutor`.

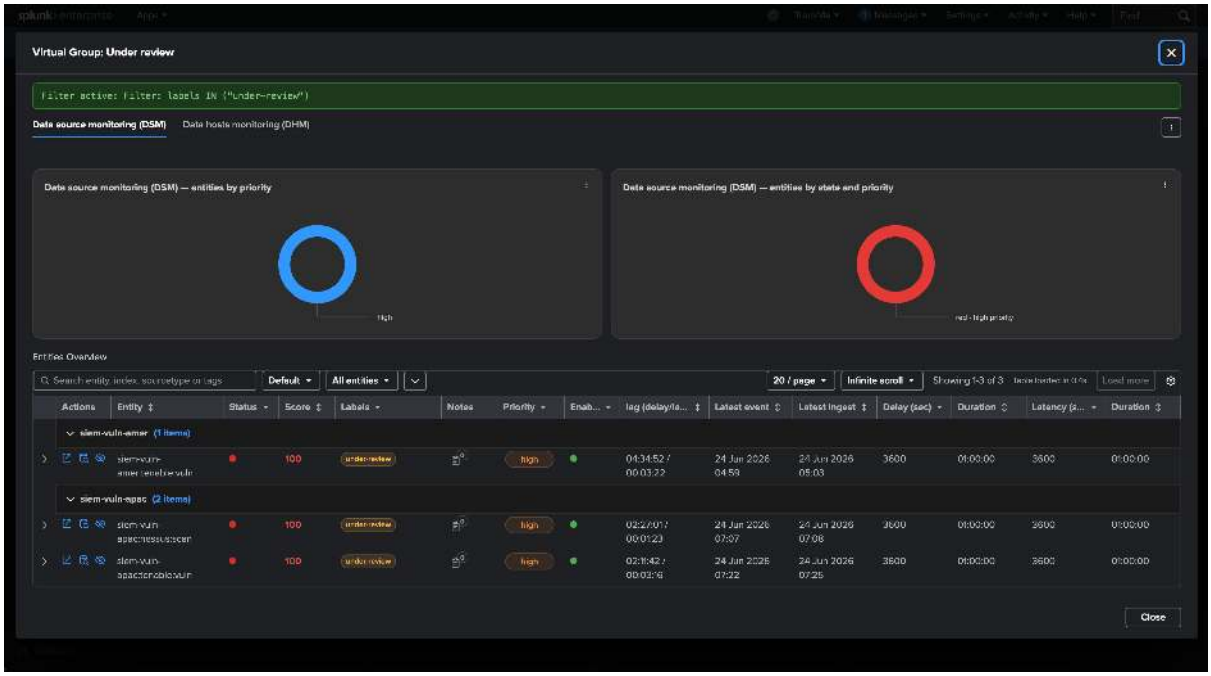
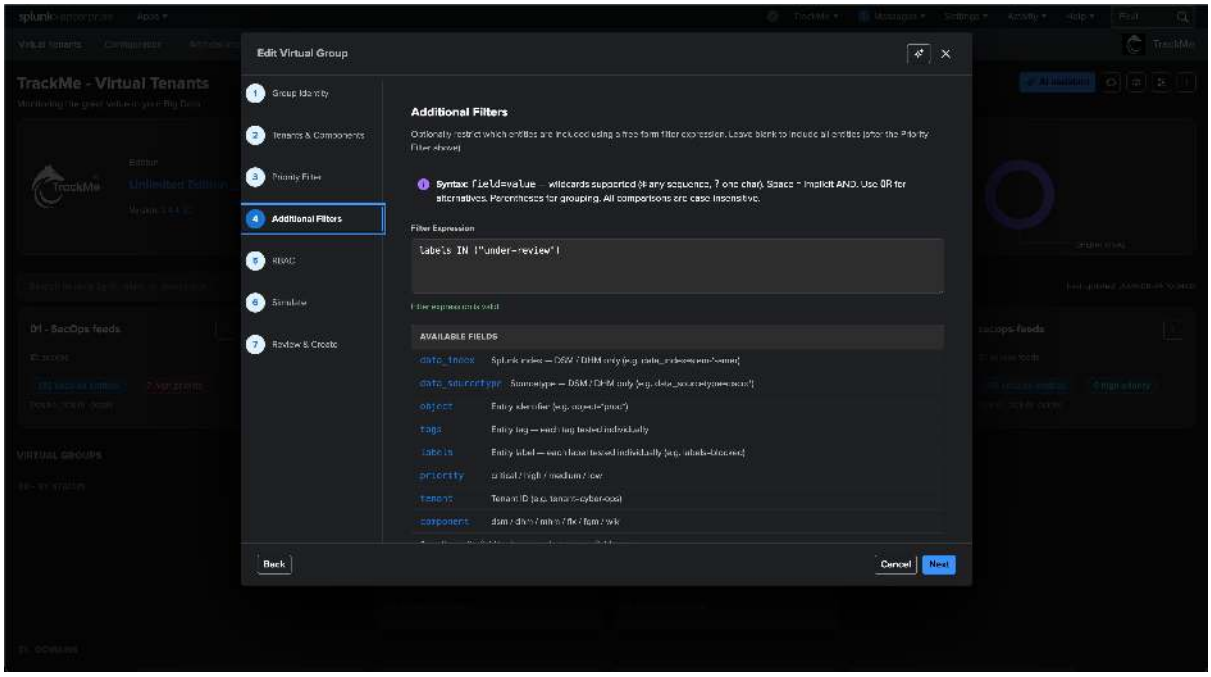
8.2.4 Virtual Groups

A **virtual group** is a read-only card, shown alongside your real tenants in the Virtual Tenants grid, that aggregates entities from **several tenants** into one view. Use it when you want a single pane that spans tenant boundaries — "all of finance across three regions", or "every high-priority entity regardless of tenant".





Important

A virtual group is **not a tenant**. It has no configuration stanza, no roles of its own, no trackers, and no entity ownership. It is **not seen by the decision maker** and **cannot open alerts**. It is a visibility layer only. If you need monitoring, ownership, or alerting, create a real tenant instead.

What a group shows

The card displays an aggregated entity count and a priority breakdown across all the tenants in scope. A **details** button opens a group overview. Summaries are **always computed live** from the underlying tenants' current state — nothing is cached — so a group is always as fresh as the tenants it aggregates.

Creating a virtual group

The creation wizard asks for:

1. **Tenants and components in scope** — which tenants, and which of their components, to aggregate.
2. **Optional priority filter** — restrict the group to (say) high and critical entities; leave empty for all.
3. **Allowed roles** — which Splunk roles may see the group.
4. **Alias and description** — the display name and purpose.
5. **Review and create.**

You also set a `group_id` (lowercase, up to 40 characters) and a display `group_alias`.

Behaviour and limitations

- **Graceful degradation.** Deleted tenants, disabled tenants, and disabled components in scope are silently skipped — the group simply reports fewer entities, never an error.
- **Empty groups are not auto-hidden.** A group whose scope yields nothing shows zero counts; delete it manually if you no longer want it.
- **Visibility follows roles.** A user who belongs to none of the group's allowed roles simply does not see it.
- **No SLA rollup and no group-level acknowledgment** today — entities are still acknowledged in their own tenant.

8.2.5 Roles & access control

Start with the identity doing the work. The person using TrackMe, the owner of a scheduled report, and the account reading a remote system can be three different users. Giving one of them access does not grant it to the others.

This guide explains those boundaries for all tenants, with a setup map for the next-generation components: **UAM, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge**. Use *Roles & access control — in depth* for the capability lists, index permissions, examples and checks.

Four identities: the TrackMe user (capability and tenant role), the scheduled owner (owner permissions), the source reader (search and index access), and the additional API account (destination permissions). A remote Splunk account needs both local permission to use it and destination permission to read.

Four questions before granting access

Table 1: Put each permission on the account that uses it

Question	Identity	Where to grant access
Who may use this tenant?	The person signed in to TrackMe	TrackMe capabilities, the tenant's role lists and access to its TrackMe indexes
Who runs its schedules?	The **tenant owner**: `nobody` or a named Splunk service account	On the search tier hosting TrackMe; see *The scheduled owner and service account*
Who searches the source data?	Locally: the scheduled execution identity. Remotely: the Splunk user behind the selected remote account's token	On the search tier where the search runs: search capability, source indexes and any component-specific reads
Who reads the additional API?	A separate Splunk remote-account user, or a **Cribl connection** credential	On the endpoint being read: HEC endpoint, cluster manager, Deployment Server or Cribl Leader

A remote account has **two access checks**. On TrackMe, its role list decides who may use it. On the destination, the token user's capabilities and index permissions decide what it can read. Both must work for scheduled collection; testing the account as a Splunk administrator does not prove that the tenant owner may use it.

The three TrackMe user levels

TrackMe ships three roles. You can assign them directly or inherit them into your own roles; `trackme_admin` inherits `trackme_power`, which inherits `trackme_user`.

Table 2: Day-to-day access to a tenant

Built-in role	Capability	What it is for
`trackme_user`	`trackmeuseroperations`	Read the tenant and its monitoring results.
`trackme_power`	`trackmepoweroperations`	Operate existing monitoring. In findings workspaces: triage findings, assign them, add notes and perform the actions the component exposes.
`trackme_admin`	`trackmeadminoperations`	Create and administer TrackMe content. For a tenant the user administers: source settings, policies, collection and automation settings.

The capability grants an **operation level**; the tenant's **user, power and admin role lists** grant the **scope**. A TrackMe administrator of one tenant does not thereby administer every tenant. Splunk administrators retain administrative access.

These are the permissions of **TrackMe users**. They do not automatically provide a remote Splunk account with cluster-read capabilities, allow a search of internal indexes, or satisfy the requirements of a named scheduled owner.

Important

UAM has a narrower workspace

UAM contains audit and account activity. Its workspace is for **tenant administrators** (`trackmeadminoperations` plus a tenant admin role), or a Splunk administrator with `admin_all_objects`. Tenant power users have selected REST read and action access; read-only tenant users have no UAM access. See *UAM: audit access and per-tier inventories*.

Choosing the scheduled owner

A dedicated service account makes scheduled activity attributable to a named identity. It is optional for ordinary collection: `nobody` is also a supported knowledge-object owner, with execution supplied by Splunk. **Scheduled AI Agents require a named account**; `nobody` and `splunk-system-user` cannot run them.

For **HEC, S2S, UF Fleet, Cribl Stream and Cribl Edge**, the current creation and collection checks require a named owner to hold the three TrackMe capabilities, `schedule_search`, `list_settings`, `list_storage_passwords` and `admin_all_objects` (or be a member of `admin` / `sc_admin`). Search and index access must also be configured. These broader permissions belong to the scheduled owner, not to every person using its workspace.

UAM's collection requirements are checked separately. Its identity and audit reads have different local and remote requirements. The general Configuration Guardian owner check is broader than the UAM collection check; see *The scheduled owner and service account* and *UAM: audit access and per-tier inventories* before treating them as the same requirement.

What each next-generation component reads

Table 3: Choose the source and the additional account independently

Component	Data searched in Splunk	Additional API access
UAM	`_audit`, `_introspection` and `_internal` through the chosen route account; inventories collected separately from each search head tier	User, role, knowledge-object and, for a cluster, SHC member reads on each tier
Splunk HEC	`_internal` and `_introspection` on the local or remote source search tier	Optional accounts on the HEC endpoints' **splunkd management API** for configuration comparisons
Splunk S2S	`_internal`; `_metrics` when used; `_introspection` for resources. Local or remote	`list_indexer_cluster` on the source reader for cluster discovery; optional **cluster manager account** for the manager's view
Splunk UF Fleet	Forwarding telemetry on its source tier; **separate Deployment Server source** for `_dsphonehome`, `_dsclient` and `_dsappevent`	Optional **Deployment Server API accounts** for current server-class membership; these accounts also need the three `_ds*` indexes on the Deployment Server
Cribl Stream	Cribl internal metrics in a metric index searchable from the **local TrackMe tier**; a remote metric-source account is not supported	Required **Cribl connection** with read access to Stream inventory, configuration and Leader-proxied Worker status
Cribl Edge	No Splunk source index required for core API monitoring; optional local System Metrics index for node CPU and memory	Required **Cribl connection** with read access to Edge Fleets, Nodes, configuration and Leader-proxied status

`local` describes **where a search is dispatched**, not where events are stored. A local TrackMe search head can search distributed indexers. Conversely, a remote Deployment Server account can search indexes held on that server itself.

Tip

Internal indexes need an explicit grant

Access to all ordinary indexes (`*`) does not include internal indexes. Grant the source reader the actual indexes it needs, especially UF Fleet's three `_ds*` indexes. The detailed reference includes *index-access examples*.

Grant tenant access without exposing every tenant

1. Define your user, power and admin roles in Splunk, with the appropriate TrackMe capabilities and application access. SSO group mappings can assign these roles.
2. Put those roles in the matching **RBAC lists of each tenant**.
3. Give users access to that tenant's TrackMe result indexes. Grant source indexes and remote-account use separately when their investigations need them.
4. Configure the owner and each source/API account using the component requirements above.
5. Check a scheduled collection, not only a manual run. The two may execute under different identities. Follow *Validate each identity and diagnose the missing layer* for a repeatable check.

Warning

Role inheritance can widen tenant scope

A new tenant's default lists include the built-in TrackMe roles. If your custom role inherits one of them and it remains listed on other tenants, the inherited role can grant access there too. Replace the default tenant lists with your scoped roles, or grant capabilities directly to your custom roles. Include the lower-level capabilities needed by each higher-level role when using direct grants.

System configuration and tenant administration

Configuration → System settings and the dedicated account-management pages are Splunk administrator tasks. They are separate from managing a tenant you administer. Cribl credentials are managed under **Configuration → Manage Cribl connections**; Splunk remote-account credentials under **Configuration → Manage Remote deployment accounts**.

Set defaults for **new tenants** under **System settings → General → Knowledge objects & RBAC defaults**. To change an **existing tenant's** roles or owner, use its Virtual Tenant UI; TrackMe updates the tenant and its knowledge-object permissions. Changing defaults alone does not re-permission existing tenants.

8.2.6 Roles & access control — in depth

Use this reference to provision the **right identity on the right system**. It covers the TrackMe user, the scheduled owner, the Splunk source reader and any additional API account, with separate requirements for UAM, Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge. For the shorter setup guide, start with *Roles & access control*.

- *UAM*
- *Splunk HEC*
- *Splunk S2S*
- *Splunk UF Fleet*
- *Cribl Stream*
- *Cribl Edge*

How TrackMe RBAC works

TrackMe combines **capabilities**, **tenant scope** and **Splunk object/index permissions**:

- A capability authorizes an operation. The user's effective capabilities include grants inherited through Splunk roles.
- The tenant's admin, power and user role lists determine which tenants the user can administer, operate or read. Higher-level access includes the lower-level operations.
- Splunk ACLs protect the tenant's knowledge objects. Index permissions govern searches of its results and of source data. A capability does not replace index access.
- TrackMe authorizes a caller before performing privileged work on their behalf. A successful UI operation does not mean the caller's own search session, a scheduled owner, or a remote token can perform every underlying read directly.

The built-in roles

Table 4: User permissions on the TrackMe search tier

Role	Capability	Tenant operations
`trackme_user`	`trackmeuseroperations`	Read the tenant's monitoring results, subject to the component's access rules.
`trackme_power`	`trackmepoweroperations`	Operate existing monitoring. In HEC, S2S, UF Fleet, Stream and Edge: triage findings and Finding groups, assign, annotate and use permitted actions.
`trackme_admin`	`trackmeadminoperations`	Create tenants and trackers; administer source settings, policies, collection and automation for tenants in the user's admin scope.

`trackme_power` inherits `trackme_user`; `trackme_admin` inherits `trackme_power`. Membership and inheritance both work. If you grant capabilities directly instead, include all the levels the role needs. On the five findings workspaces above, read access accepts any tenant role, triage requires a power or admin role, and configuration requires an admin role, in addition to the matching capability. `admin` / `sc_admin` and Splunk's internal execution context have administrative access.

UAM is different: its workspace requires tenant-administrator access. Its limited power access is through selected REST operations; a tenant user has no UAM access. See *UAM: audit access and per-tier inventories* for the complete distinction.

The scheduled owner and service account

A tenant's **owner** owns its reports and scheduled monitoring. It is set at creation and can be changed through the tenant's RBAC/ownership controls. A service account is simply a named Splunk user chosen for that role; it is not the person currently viewing the tenant, nor automatically the user behind any remote token.

`nobody` and a named owner

- ``**nobody**`` is supported for ordinary collection. It is a knowledge-object ownership value: Splunk supplies the scheduled execution identity. It is not a remote username or a credential to create on another system. Source/API authorization still applies.
- **A named owner** must be able to run the scheduled work and access its inputs. Configure its permissions on the TrackMe search tier, then separately configure every remote user and Cribl credential it uses.
- **Scheduled AI Agents require a named owner.** `nobody` and `splunk-system-user` are rejected for scheduled agent execution. The named owner also needs the agent's tenant access and access to the records the agent uses; changing the owner is not itself proof that an agent run will succeed. `splunk-system-user` is not a selectable replacement for a named owner in the HEC/S2S/UF/Cribl creation flows.

Current owner capability checks

For **Splunk HEC, Splunk S2S, Splunk UF Fleet, Cribl Stream and Cribl Edge**, the current creation and collection checks accept `nobody`, a member of `admin` / `sc_admin`, or an account holding **all seven** of these capabilities:

Table 5: Named-owner requirement on the TrackMe tier

Capability	Scope
`trackmeuseroperations`	TrackMe user operations
`trackmepoweroperations`	TrackMe power operations
`trackmeadminoperations`	TrackMe administration operations
`schedule_search`	Scheduled searches
`list_settings`	Splunk settings reads
`list_storage_passwords`	Splunk credential-store reads
`admin_all_objects`	Splunk knowledge-object administration

This is an **enforced owner requirement**, not a claim that every individual collection read needs all seven. They may be inherited or granted directly. Add `search` and the source/result index permissions needed by the work; the owner check alone does not verify search coverage. A custom owner role can inherit `trackme_admin` and `power` and add the remaining required capabilities, but it is still a privileged role.

The general Configuration Guardian check ``**insufficient_tenant_owner_capabilities**`` uses this same seven-capability list for named owners of enabled tenants, including UAM. **UAM's own collection preflight is narrower**: it checks the identities and capabilities in *UAM: audit access and per-tier inventories* and does not require `list_settings` or `list_storage_passwords` for those reads. A successful UAM collection check therefore does not necessarily clear the general owner warning. Diagnose the named check rather than combining the two lists into a requirement for every remote UAM account.

Important

Keep owner permissions separate from user and remote-account permissions

Do not copy this seven-capability set onto every TrackMe user, or onto a cluster manager or Deployment Server reader. The first needs the relevant tenant role; the latter need their destination-specific reads. Their requirements are listed below.

Local searches, remote searches and API accounts

A **search tier** is the search head or search head cluster that dispatches searches. It may search distributed indexers; choosing `local` does not mean the data must be stored on the TrackMe search head.

- Local search: tenant report → local execution identity → searchable source indexes.
- Remote search: tenant owner may use the remote account → destination token user → source indexes and REST reads on the remote tier.

- Additional API: component collection → selected API credential → endpoint or Leader.

Interactive fetches may use the caller. Validate the schedule separately.

Table 6: Which identity must have the permission?

Read	Acting identity	Access to check
Scheduled local search	Named tenant owner, or Splunk's execution context for `nobody`	Search and index permissions on the TrackMe search tier
Scheduled remote search	The owner starts the work; the destination search runs as the **remote token user**	The owner's effective roles may use the TrackMe remote account; the token user may search the destination's indexes and perform the required REST reads
Additional Splunk API read	Token user of the selected HEC, cluster manager or Deployment Server account	That system's endpoint permissions; these can differ from the telemetry source
Cribl API read	Cribl.Cloud API client or self-managed Cribl user in the **Cribl connection**	Cribl product, group/Fleet and API read permissions
Interactive search or live fetch	The caller, or the remote token selected for that action	The caller's source/result index access and permission to use the remote account when applicable; do not infer these from a successful schedule

Remote-account RBAC is configured on TrackMe. Its `rbac_roles` allows local roles to use the stored account. Inherited roles count. For HEC, S2S and UF Fleet, creation/settings check that the selected owner may use the source and enrichment accounts; an explicit refusal is reported as `remote_account_refused`. UAM also checks account use for its collection and live reads. Internal scheduler handling does not grant additional capabilities to the destination token.

Destination permissions are configured on the destination. A token authenticates a Splunk user on that system. Grant that user the required capabilities and index access there. Giving the local owner `list_indexer_cluster` cannot repair a remote source token that lacks it. TrackMe need not be installed on a remote telemetry tier merely to run Splunk searches; UAM's remote administrative check has a specific consequence when the TrackMe capability is absent (see below).

The account's endpoint matters. The telemetry source usually points to a search head. A cluster manager account must point to the manager; a Deployment Server API account to the Deployment Server; HEC enrichment to the endpoint's splunkd management API. They are independent account selections, even when some use the same user or system.

Source indexes and TrackMe result indexes

Grant index access to the identity that **actually searches on that tier**. The source index names below are defaults; use the configured names when they differ.

Table 7: Source data required by each component

Component	Indexes	Reader / condition
UAM	`_audit`, `_introspection`, `_internal`	The route account that searches audit, resource and indexer activity. Inventory accounts on other tiers have separate REST/object requirements.
Splunk HEC	`_internal`, `_introspection`	Owner for a local source; token user for a remote source
Splunk S2S	`_internal`; `_metrics` when the metrics form is used; `_introspection` for resource observations	Source reader. Keep `_internal` available for logs and qualification even when connection telemetry uses `_metrics`.
Splunk UF Fleet	Telemetry: `_internal`, plus `_metrics` / `_introspection` when used. Deployment Server data: `_dsphonehome`, `_dsclient`, `_dsappevent`	Telemetry reader and Deployment Server source reader can be different accounts on different systems. The optional DS API user also needs the three DS indexes.
Cribl Stream	The configured Cribl internal-metrics index, for example `cribl_metrics`	Local TrackMe execution identity; no remote metric-source account
Cribl Edge	Optional configured System Metrics index	Local TrackMe execution identity, for node CPU and memory. Core API monitoring does not depend on a Splunk source index.

TrackMe result indexes are a second set. The tenant's summary, audit, metric and notable indexes store TrackMe's own results. Give the people investigating the tenant access to the results they need, and ensure the scheduled owner can use the configured stores and searches. These indexes are not the same as Splunk's `_audit` or source `_metrics`. When results are on another deployment, follow the tenant's configured storage/search arrangement as well as its source arrangement.

``*`` does not include internal indexes. In a Splunk role, `srchIndexesAllowed = *` covers ordinary indexes, not names beginning with _. Grant the required internal indexes explicitly; `_*` grants all internal indexes and is broader. Search filters and explicit disallowed indexes can still restrict visibility. See the Splunk authorize.conf reference.

For example, a **remote HEC telemetry reader** can inherit basic search capabilities and be restricted to its two source indexes:

```
[role_trackme_hec_telemetry]
importRoles = user
srchIndexesAllowed = _internal;_introspection
```

This is a **source-reader example**, not the complete role for a named TrackMe tenant owner. Check the user's other inherited roles too: this stanza does not revoke broader access already granted elsewhere. Index permission also cannot make data visible if it was never forwarded to the indexers searched by that tier.

UAM: audit access and per-tier inventories

UAM separates the **route account**, which searches the audit/resource data, from the **inventory accounts**, which read users, roles and knowledge objects on each search head tier. One tier can serve both purposes. Do not assume that a search head holding all the audit data can also enumerate another tier's local users and private objects.

Who may use UAM

Caller	Access
Splunk administrator with `admin_all_objects`	Administrative access across UAM tenants
`trackmeadminoperations` + a tenant admin role	UAM workspace, configuration, collection, policies and decisions
`trackmepoweroperations` + a tenant power role	Selected REST read operations, user communications and findings actions; no UAM workspace
Tenant user	No UAM access

Workspace searches and live **Fetch SPL / Fetch definition** operations can use the caller's own access. The user needs the relevant TrackMe/source indexes and, for a remote fetch, permission to use that remote account. An owner collecting successfully does not grant these rights to the person investigating.

Collection-account requirements

Table 8: Requirements on the tier being read

Capability / access	Local tier: named owner	Remote tier: token user
`search`	Required	Required
`trackmeadminoperations` or `admin_all_objects`	Required; with TrackMe admin access, the owner also needs a tenant admin role	Required. Without TrackMe installed there, `trackmeadminoperations` is not defined: `admin_all_objects` is the available alternative.
`list_all_users` and `list_all_roles`	Not needed for the local identity catalogs: TrackMe's authorized identity reader performs those reads	Required to enumerate all users and roles. `edit_user` / `edit_roles` also satisfy the corresponding checks, but are broader than the read capabilities.
`list_search_head_cluste`	Required for a search head cluster	Required for a search head cluster
Source index access	`_audit`, `_introspection`, `_internal` when this is the route account	The same indexes when this is the route account
Knowledge-object / lookup access	Determines which objects and definitions are visible	Determines which objects and definitions are visible; REST access alone does not guarantee all private objects are visible

Before Splunk 10.4, UAM also reads `admin/file-explorer` for CSV lookup sizes; that read must be allowed on each inventory tier for lookup-footprint coverage, and a least-privilege account is refused it by default. A refused read is shown as **Lookup sizes refused**. From Splunk 10.4 the lookup listing reports the size, with no extra access. Granting `list_all_users` does not solve an unrelated lookup-size or object-ACL refusal.

The UAM collection check does not require `list_settings` or `list_storage_passwords`. It runs at tenant creation and through Configuration Guardian, which reports **UAM collection permissions need attention** with the affected tier. It checks capabilities, not complete data coverage: ``**identity_visibility_limited**`` means the user/role catalog still reflects only the reading account. See *UAM collection accounts* for collection details and *The scheduled owner and service account* for the separate general owner check.

Splunk HEC: telemetry and optional configuration reads

The telemetry reader needs `search` and access to `_internal` and `_introspection` on the selected source tier. For `local`, this is the scheduled execution identity; for a remote source, the remote token user. The owner must be allowed to use the remote account. These searches support monitoring without management access to individual HEC endpoints.

Optional splunkd API accounts add HEC token consistency and the HEC-settings portion of configuration drift. Each account points to the endpoint's **management port**, not the HEC ingestion port, and uses a Splunk authentication token, not an HEC ingestion token. The owner must be allowed to use each of these accounts independently of the source account.

The destination user must be allowed to GET:

- `/services/server/info`;
- `/services/data/inputs/http/http` (global HEC settings);
- `/services/data/inputs/http` (HEC input configuration).

Splunk defines ``**list_token_http**`` for viewing HTTP token-input settings; use that read capability where supported by the target version and check that the account can read all three endpoints. `edit_token_http` is broader: it also allows changes. TrackMe performs GETs only, but that does not turn a broadly privileged token into a read-only credential. The capability definitions are in the Splunk authorize.conf reference. The exact minimum for this three-endpoint combination is not established by TrackMe's capability preflight; verify the reads on the target Splunk version instead of applying the owner capability bundle to the endpoint user.

HEC token **values** are discarded while parsing the response. If an enrichment read is refused, Collection health reports the affected account; telemetry monitoring continues. On **Splunk Cloud**, customer access to the indexers' management API is not used by this enrichment. Monitor Cloud HEC through the source search tier's internal indexes. See *Splunk HEC* for the complete workflow.

Splunk S2S: two levels of indexer-cluster access

Telemetry uses the source-reader permissions in *Source indexes and TrackMe result indexes*, plus the named owner requirements on TrackMe. Cluster discovery adds a requirement on that **source reader**, even when no cluster manager account has been configured.

Table 9: Keep the two cluster identities separate

Read	Account and capabilities	What it adds
Search head's cluster view	Local owner or remote **source token user**: `search`, `rest_properties_get` and `list_indexer_cluster`	`cluster/searchhead/generation` and peer `cluster/peer/info` reads: cluster membership and the view available through the search tier
Optional manager view	**Cluster manager account's token user**, on the manager: `search`, `rest_properties_get`, `list_indexer_cluster`	Manager configuration, maintenance/rolling-restart state and peers from `cluster/config/config`, `cluster/manager/info` and `cluster/manager/peers`

A missing source-reader `list_indexer_cluster` can appear as no rows from `| rest`. TrackMe reports ``**cluster_read_refused**`` rather than treating that as an empty cluster. For a deployment without an indexer cluster, **Indexer clusters as pools → Off** disables that discovery; it is not a fix for a clustered deployment with missing access.

The optional manager account is configured per cluster pool, and its local account RBAC must allow the owner. TrackMe recommends this **read-oriented role on the manager**:

```
[role_trackme_cluster_reader]
importRoles =
search = enabled
rest_properties_get = enabled
list_indexer_cluster = enabled
```

This is the capability set recommended by the product's account check, not a certified minimum for every Splunk release. Check all three manager reads in the wizard or Settings; the result identifies refused reads. `edit_indexer_cluster` is not part of the recommendation: TrackMe observes the cluster and does not change its configuration.

Without a manager account, the search head's cluster view remains available. A failing manager account is reported as ``**cluster_manager_unreadable**``; manager-specific facts are unavailable and maintenance handling relies on the search head's view. It does not remove the source reader's own cluster-read requirement.

Splunk UF Fleet: three independent access paths

UF Fleet can read its forwarding telemetry, Deployment Server event data and Deployment Server API from different systems. Configure all the paths you use, even when they happen to share a credential.

UF Fleet has three paths:

1. Telemetry source: search on the local or remote tier; internal/metrics/introspection indexes used by the configured collection.
2. Deployment Server source: search where the phonehome, client and app-event indexes live.
3. Optional Deployment Server API: search, rest_properties_get, list_deployment_server, and all three DS indexes on the Deployment Server itself.

Access to DS event copies on the indexers does not grant the API user access on the DS.

Table 10: UF Fleet account map

Selection	Required access	Purpose
Source	Local execution identity or remote source token: `search` and forwarding telemetry indexes (`_internal`; `_metrics` / `_introspection` when used)	Receivers' connection records, agent logs and resource observations
Deployment Server source	Local execution identity or its own remote token: `search` and `_dsphonehome`, `_dsclient`, `_dsappevent` (or configured replacements)	Phonehomes, client properties and app-deployment events
Deployment Server API accounts — optional	On each Deployment Server: `search`, `rest_properties_get`, `list_deployment_server` **and access to the three DS indexes**	Read `/services/deployment/server/clients` for current server-class membership

The **Deployment Server source** is a search location, separate from the main telemetry source. When the DS indexes are searchable on the TrackMe tier, it can be local. Otherwise choose a remote account on the tier that holds them. In particular, when the main source is Splunk Cloud and the DS data remains on an on-premises Deployment Server, select a remote account on that Deployment Server for the DS source.

The optional **DS API account** is a separate selection. Adding it does not change where telemetry or DS events are searched. Without it, server-class groups use clients observed in app events over the last 60 days, labelled **App events (60 days)**; this is not a complete current client listing, and its coverage is not judged as such.

Important

An HTTP 200 with no clients can be an index-permission problem

The Deployment Server builds its client listing from searches of `_dsphonehome`, `_dsclient` and `_dsappevent` as the API caller. `list_deployment_server` alone can therefore return an empty listing. Grant the API user access to these indexes **on the Deployment Server**, even if another account already searches copies on your indexers. Splunk documents this behaviour in Deployment clients are not visible for non-admin users.

A dedicated **DS API reader** role can be:

```
[role_trackme_ds_reader]
importRoles =
```

(continues on next page)

(continued from previous page)

```
search = enabled
rest_properties_get = enabled
list_deployment_server = enabled
srchIndexesAllowed = _dsphonehome;_dsclient;_dsappevent
```

This does not need a Splunk administrator role or Deployment Server edit capabilities. If the same account also serves the DS telemetry source, add whatever other indexes that source reads. If it also serves the general telemetry source, add those indexes too.

The wizard and Settings check the selected DS API account's identity, capabilities and client listing. If the listing is empty they also check visible phonehomes. No phonehomes can mean missing index access **or no recent data**; if phonehomes are visible, a clustered Deployment Server may have another member that serves the listing. Check the member and the actual data rather than treating an empty response as proof of a healthy empty fleet.

Expected-agent and group lookup tables introduce another read: the scheduled owner needs the lookup's ACLs locally, or permission to use the chosen remote lookup account, whose user must be able to read the lookup there.

Cribl Stream: local metrics plus a Cribl connection

A Stream tenant has **two required inputs with different credentials**:

1. **Cribl internal metrics** in a Splunk metric index searchable from the local TrackMe tier. The scheduled execution identity needs `search` and access to that index. The index may be on distributed indexers, but the current Stream metric source is `local`; a TrackMe remote metric-source account is not supported.
2. **A Cribl connection** to Cribl.Cloud or the self-managed Leader. This uses a Cribl API client/user, not a Splunk user or a Splunk remote-deployment account.

The Cribl credential needs read access to the selected **Worker Groups and Workers**, Sources, Destinations, Pipelines, Routes and Packs, Leader system information, and Leader-proxied Worker system information and input/output status. Scope it to the groups being monitored while allowing those reads. TrackMe does not prescribe a universal Cribl role name; permissions depend on the Cribl deployment and its role model.

Both inputs matter: successful Cribl authentication does not grant access to the Splunk metrics index, and a metrics search succeeding does not prove inventory/status API coverage. Configure the named owner's capabilities separately using *The scheduled owner and service account*. See *Cribl Stream* and *What the Cribl account needs* for setup and connection details.

Cribl Edge: API monitoring and optional System Metrics

Edge's core monitoring reads the **Cribl Leader API** through a Cribl connection. The credential needs read access to the selected **Fleets and Edge Nodes**, their Source and Destination configuration, Leader system information, and Leader-proxied node status, system information and system metrics. This is a Cribl permission grant; adding Splunk capabilities to a remote Splunk user does not provide it.

A Splunk source index is **not required for core API monitoring**. For node CPU and memory policies/charts, configure the optional **System Metrics index** and grant the local TrackMe execution identity search access to it. A remote metric-source account is not supported. Without this index, the relevant features report that System Metrics are needed; that does not mean the Cribl connection has failed.

The tenant still has its own TrackMe result stores and scheduled-owner requirements. For both Stream and Edge, a Splunk administrator manages the stored Cribl connection; tenant users operate the workspace through their TrackMe role without being given the Cribl credential. All monitoring reads leave Cribl configuration unchanged. See *Cribl Edge* and *What the Cribl account needs*.

Validate each identity and diagnose the missing layer

1. **Record the account map.** Note the tenant owner, local/remote source, optional API accounts, and the actual user behind each remote token. For UF Fleet, record the Deployment Server source separately. For UAM, record the route and every inventory tier.

2. **Check local entitlement.** Verify the operator's TrackMe capability and tenant role, and the scheduled owner's required capabilities. Verify permission to use each selected remote account for the owner and for users making live remote reads.
3. **Check the destination identity.** Test connectivity in the native account-management UI, then run the component's account/collection checks. A valid token is not proof of cluster access, a complete user catalog, or access to the source indexes.
4. **Check data visibility as the reader.** Confirm that known recent events or metric series are visible in the configured indexes and time range, with the required host scope. Check lookup/object ACLs too. A test performed as your administrator account does not test the token user's or the owner's visibility.
5. **Check a scheduled run.** Use Collection health and Configuration Guardian to confirm successful, recent collection after the changes. Manual collection can be dispatched after privileged authorization and can succeed where the scheduled owner fails.
6. **Check the intended user experience.** Sign in as a scoped user/power/admin account and verify the tenants, results and operations each should see. For UAM, verify its stricter workspace boundary. If scheduled AI is enabled, verify an actual agent run under its named owner as well.

Table 11: Symptoms identify different permission layers

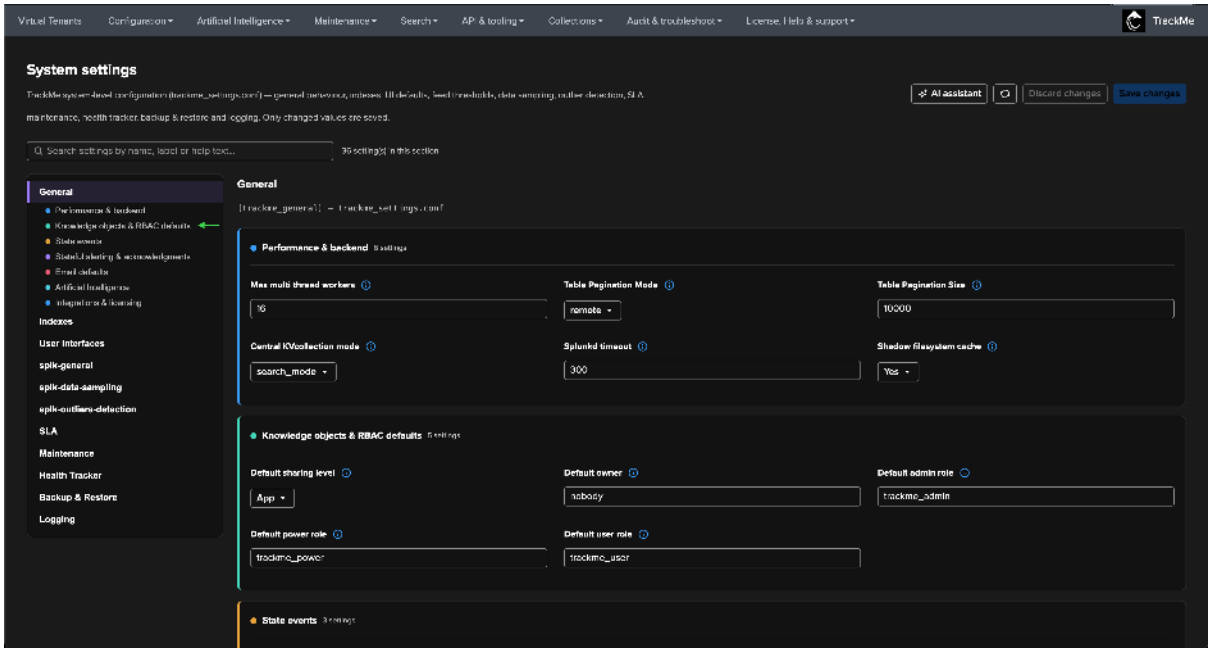
Symptom	Check first
Tenant missing or an action forbidden	TrackMe capability, tenant role lists, inherited roles and the username allowlist
`insuffi-cient_tenant_owner_capabilit`	The **named owner's** general seven-capability requirement on TrackMe; do not add these capabilities to every remote account
Manual collection works; scheduled collection fails	The owner, its remote-account use, source/result index access and collection receipt
`remote_account_refused` / `account_access_denied`	Local permission to **use** the account, distinct from destination token permissions
UAM catalog contains only the reader	Remote `list_all_users` / `list_all_roles` and effective identity visibility
`cluster_read_refused`	`list_indexer_cluster` on the **source reader**, not only on the manager account
`cluster_manager_unreadable`	The separate manager account, its destination, connectivity and three manager reads
DS API returns no clients	The API user's `_ds*` index access, recent phonehomes and the DS cluster member
Source search succeeds but returns no expected data	Allowed/disallowed indexes, search filters, forwarding, retention, host scope and correct search tier; transport success alone does not establish coverage
Cribl API works but traffic or CPU charts are empty	Stream metrics-index access or Edge's optional System Metrics configuration and data
Scheduled AI Agent reports a system owner	Reassign to a named owner with the required tenant and automation access

Configuration-UI requirements

TrackMe provides native interfaces under **Configuration**, replacing the Splunk UCC configuration page. System settings and account management require a Splunk administrator-class user with TrackMe admin capabilities, typically `trackme_admin` together with `admin` / `sc_admin`. A denied request produces an **Insufficient permissions** message.

- **System settings → General → Knowledge objects & RBAC defaults** sets the proposed owner, sharing and roles for **new** tenants.
- **Manage Remote deployment accounts** manages Splunk source/API connections and their account RBAC. **Manage Cribl connections** manages Cribl API credentials and scope.

- **Manage Email delivery accounts**, **Manage S3 export accounts** and **Manage Webhook accounts** manage the other integrations.
- An existing tenant's roles and owner are changed through its Virtual Tenant UI, as described below. These changes are separate from system-wide defaults.



See *Configuration* and *System settings*.

RBAC at tenant creation

RBAC and ownership are defined as part of creating a Virtual Tenant.

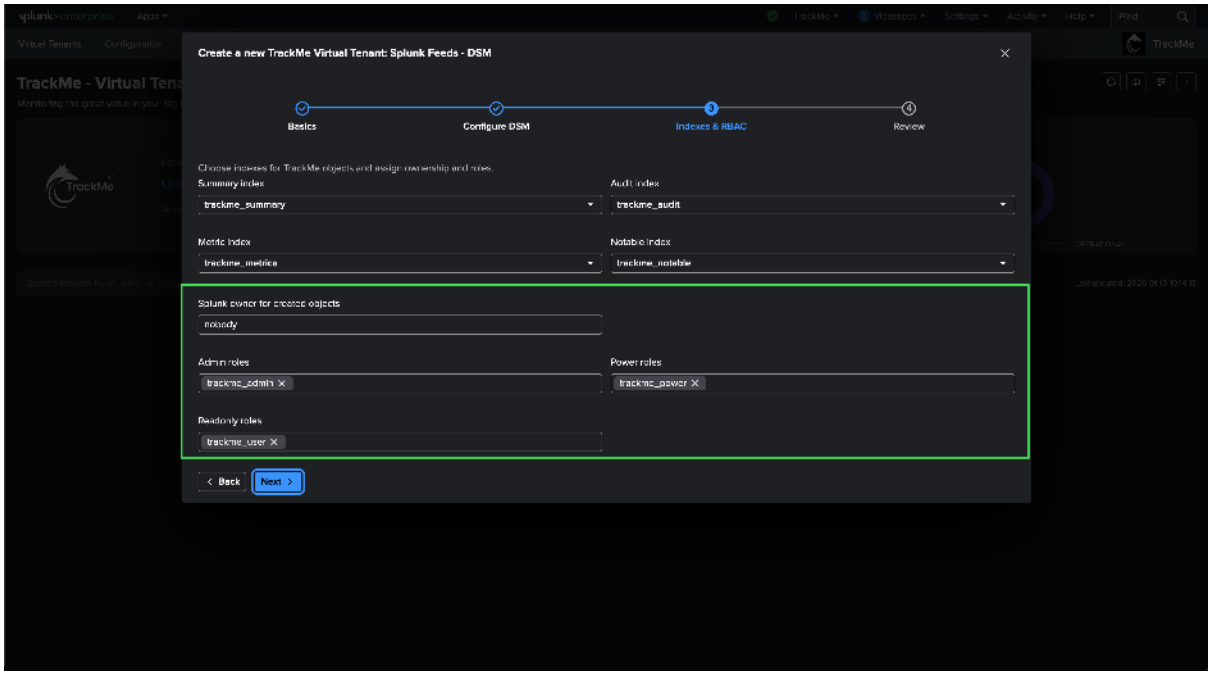
Hint

Preset the creation defaults

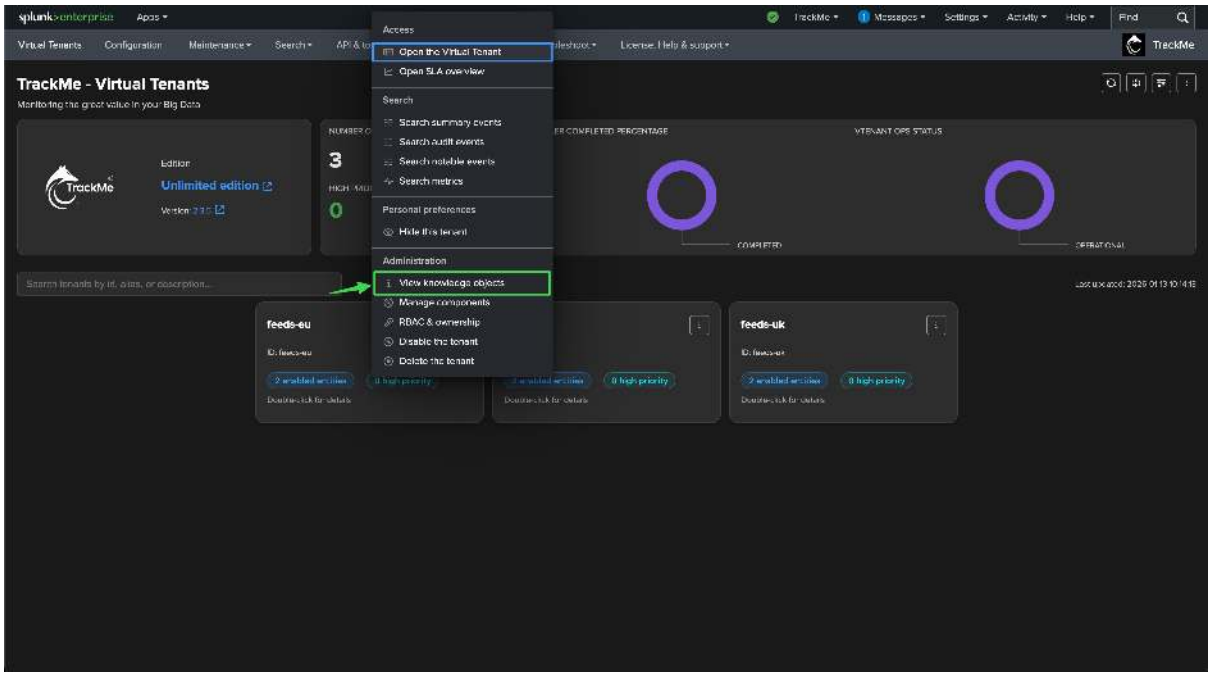
You can preset the proposed owner and roles for new tenants under **Configuration → System settings → General → Knowledge objects & RBAC defaults**.

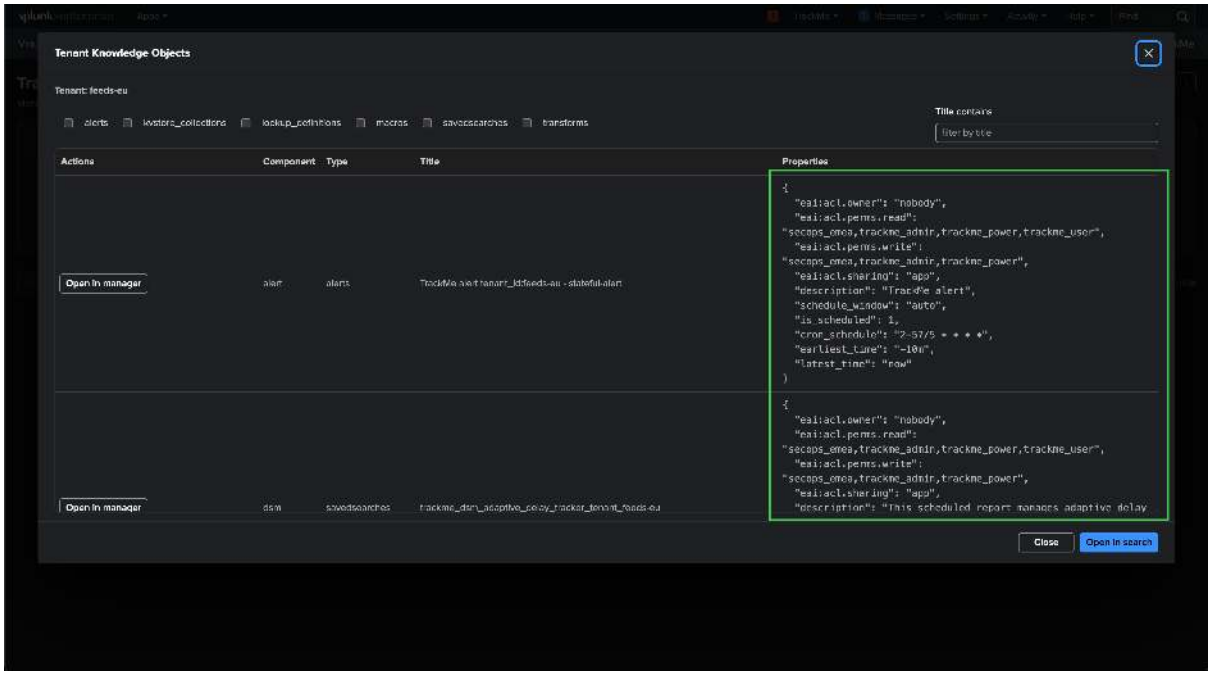
See *System settings* for the native configuration interface. These defaults do not change the permissions of existing tenants.

Defining RBAC while creating a tenant:



Once the tenant exists, you can review the permissions and ownership TrackMe applied:



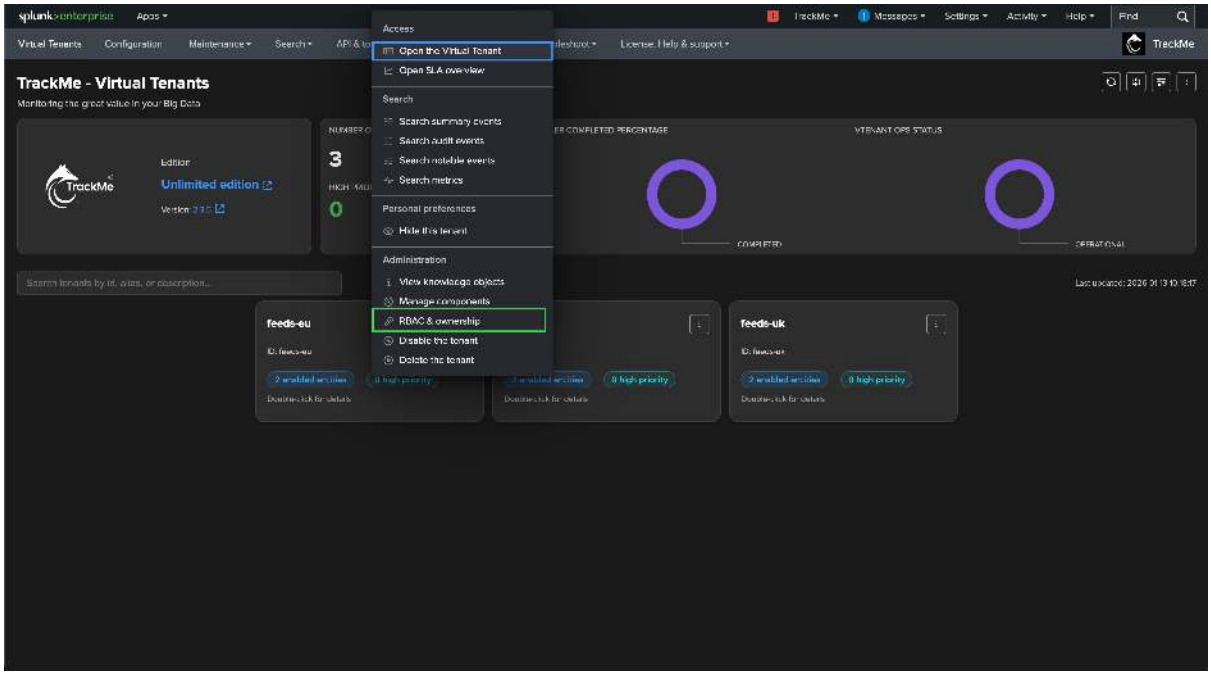


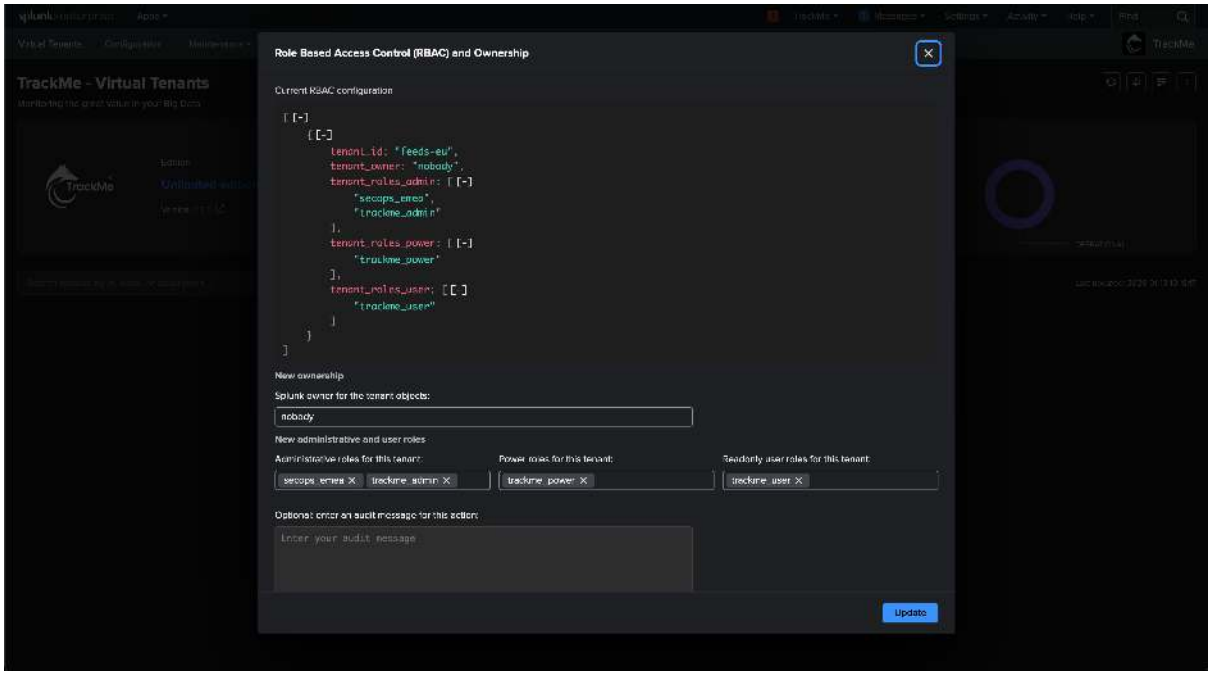
Worked example: per-team tenant access

This example shows how to scope access to Virtual Tenants by role. We have three tenants, each dedicated to a regional security-operations team:

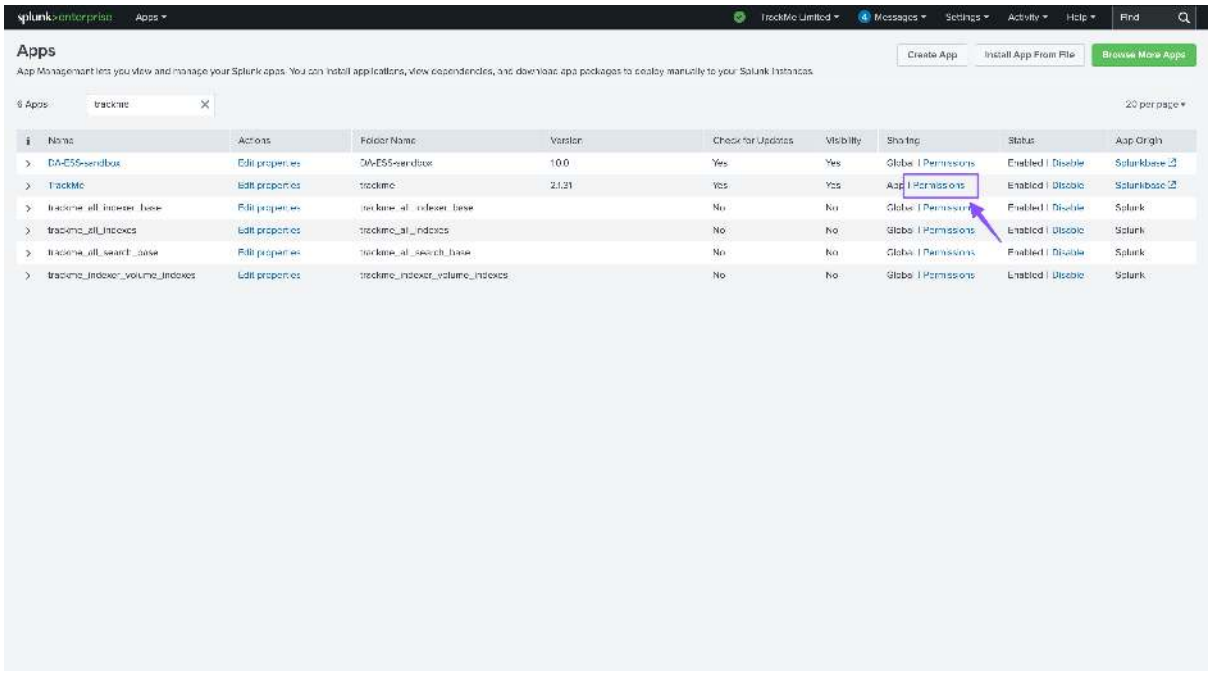
- `secops-emea` — EMEA team, Splunk role `secops_emea`
- `secops-amer` — Americas team, Splunk role `secops_amer`
- `secops-uk` — UK team, Splunk role `secops_uk`

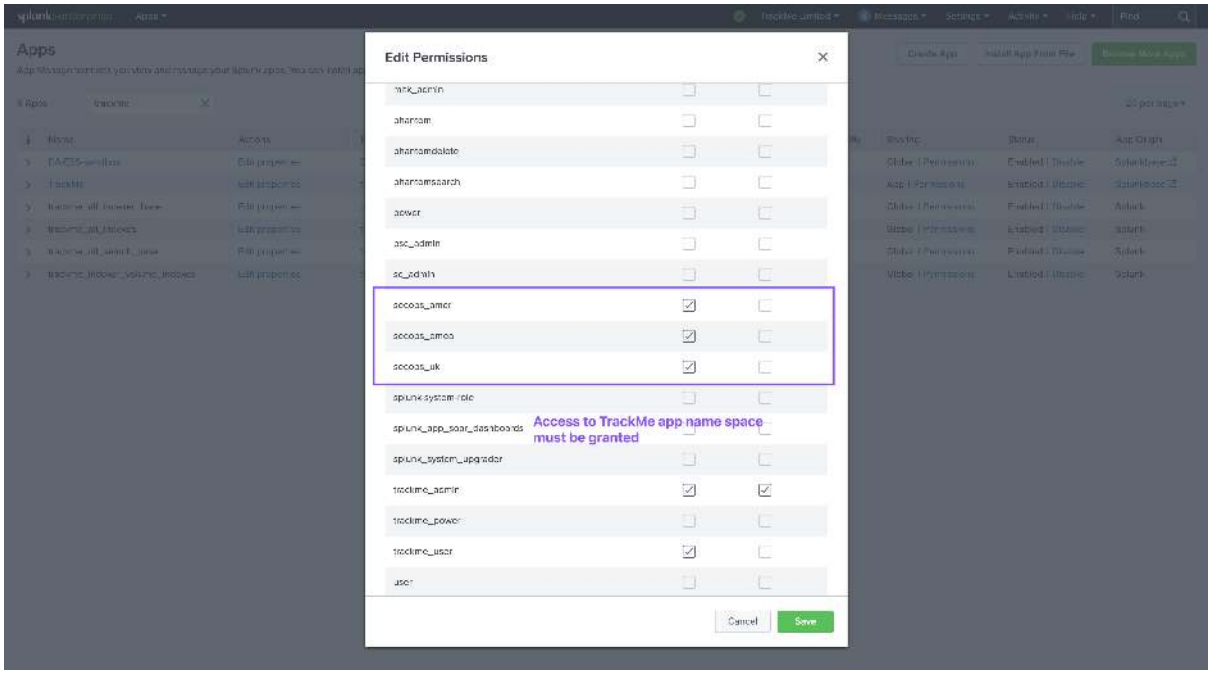
The administrator in this example is granted admin access to all three tenants. Each team receives its own scoped role for access:





Each role must also be granted access to the TrackMe application namespace:



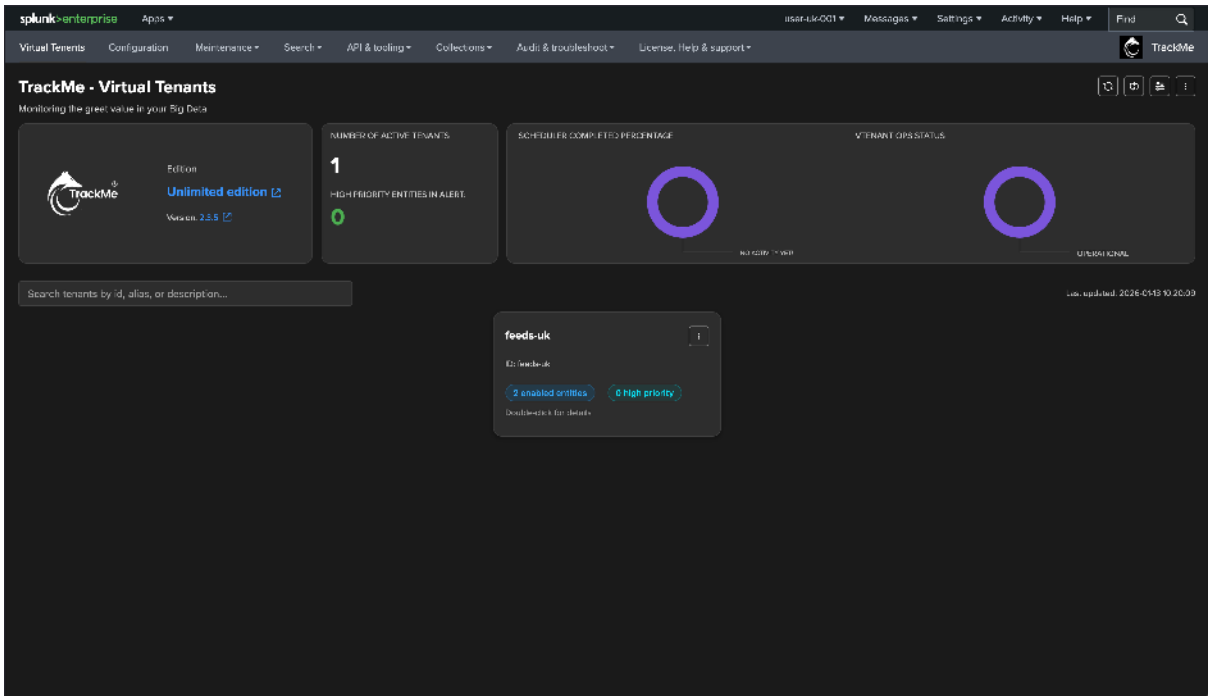


Warning

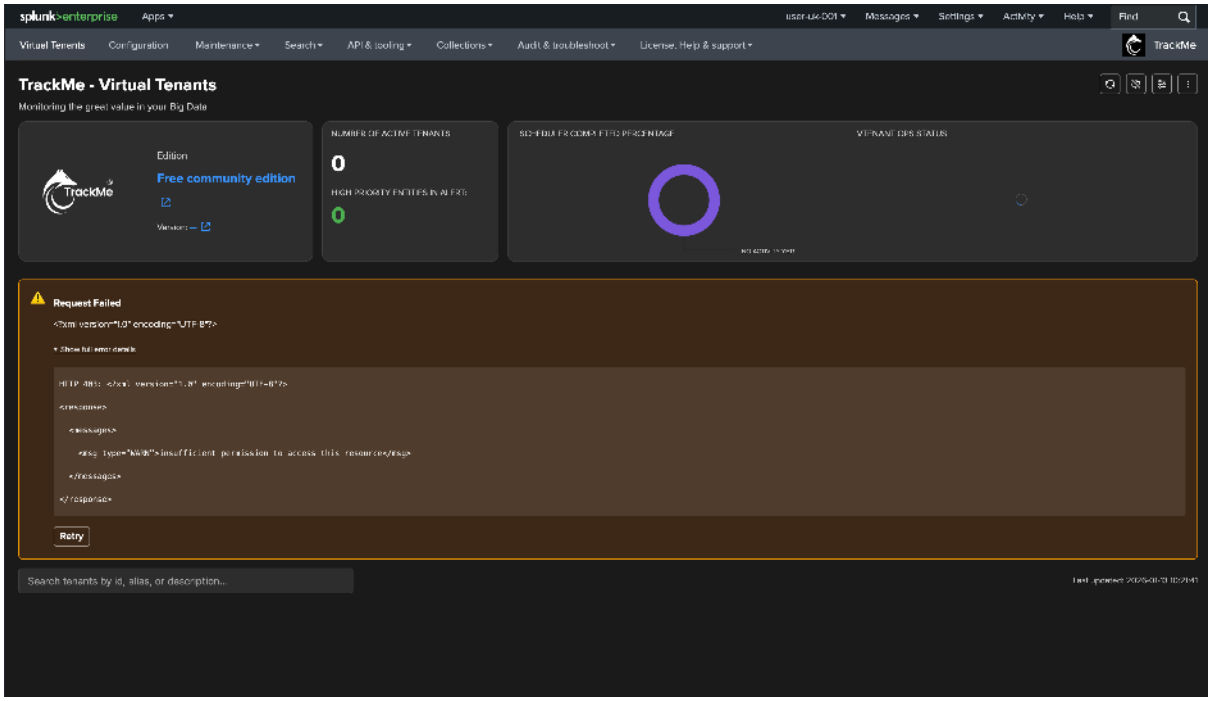
Inheritance can over-grant access

By default, a new tenant lists all three built-in roles in each RBAC category. So if the role you use for access **inherits** from one of the built-in roles and you leave that default in place, its members are granted access and will see **every** tenant. To scope access cleanly, either make the desired TrackMe capability **native** to the user's role, or remove the built-in roles from the tenant's RBAC configuration.

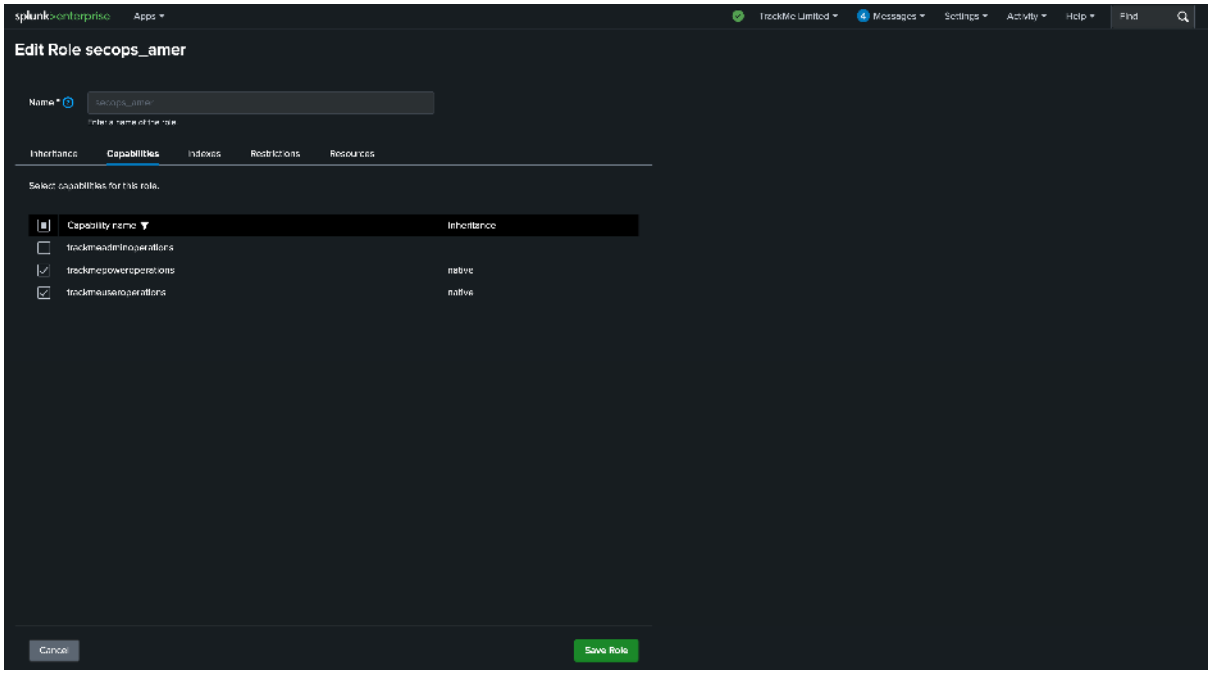
When a member of the configured roles connects, they see only the tenants they have access to:



If a user is granted TrackMe app access but lacks the required TrackMe capabilities, they get this error screen instead:



Here the roles carry the TrackMe capabilities natively, so the user can access the resources as intended:

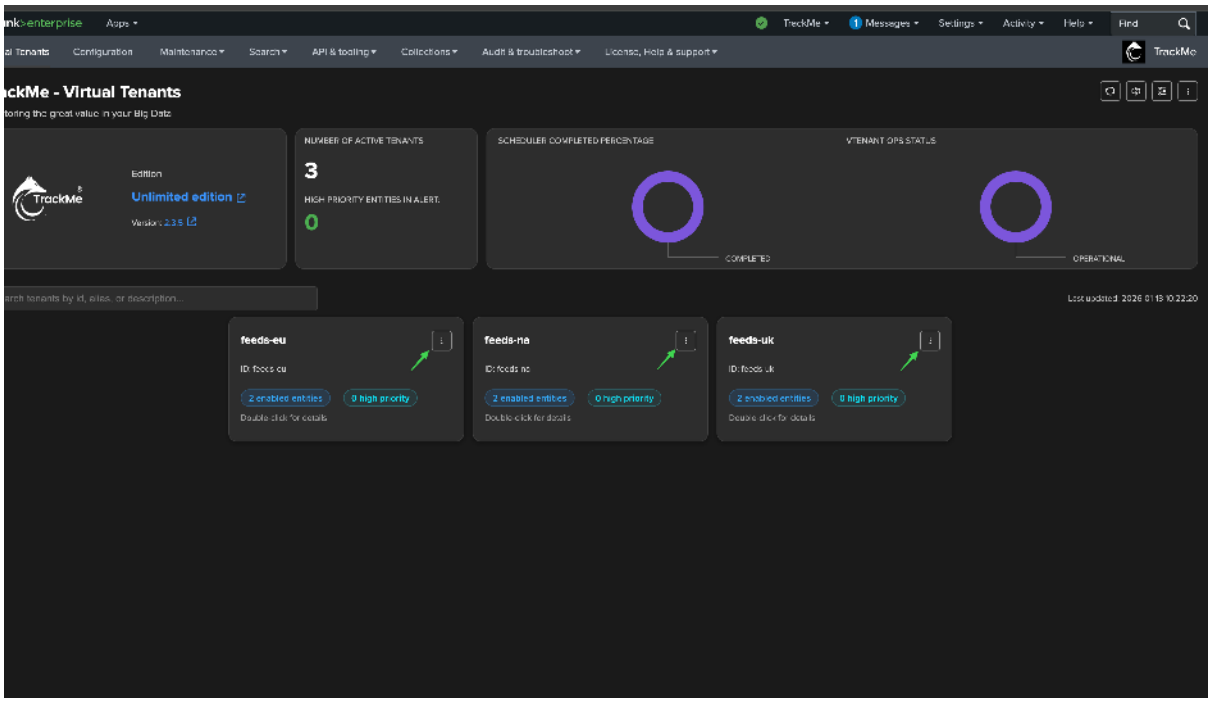


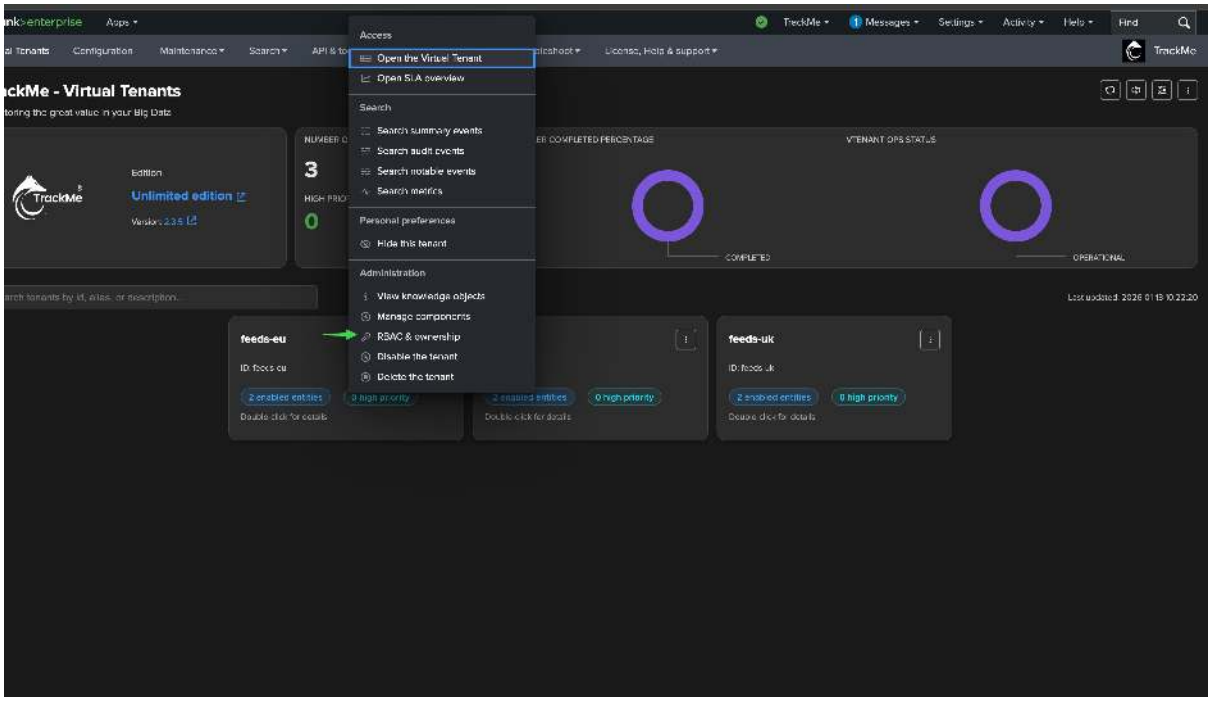
Updating RBAC for an existing tenant

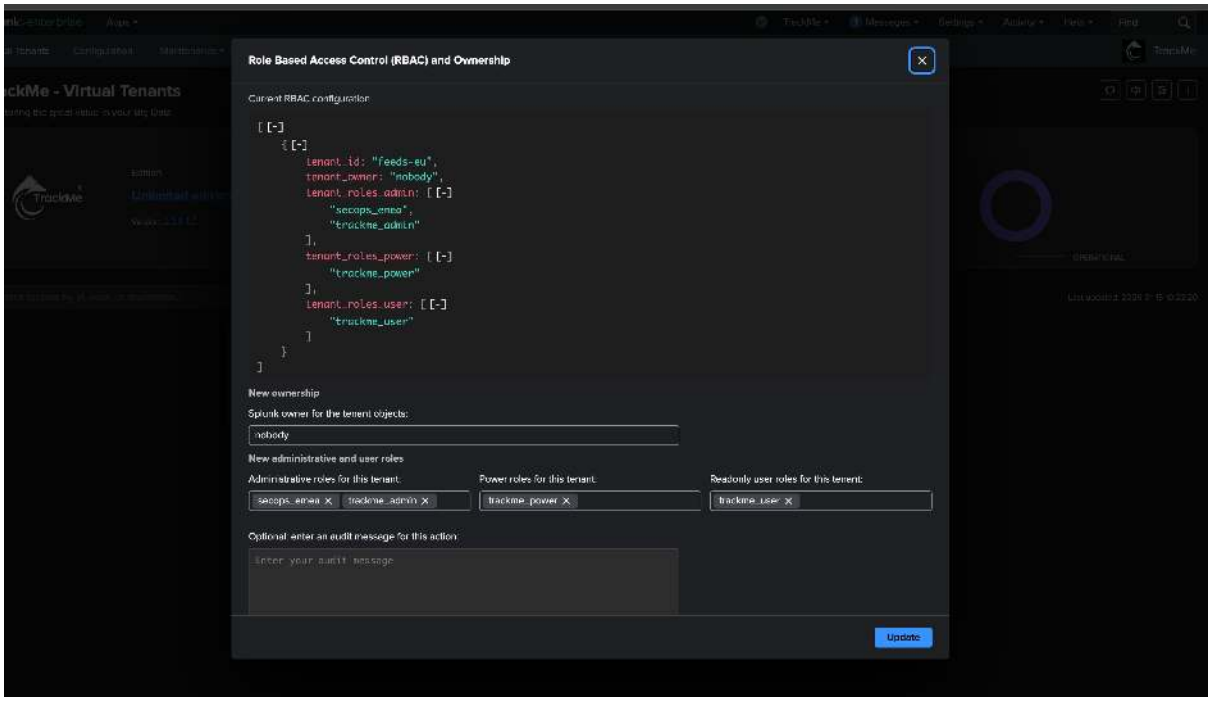
You can update a tenant's RBAC policies and ownership at any time — through the UI or the REST API.

Through the Virtual Tenant UI

Open the Virtual Tenants interface, double-click the tenant, and open its administration screen:



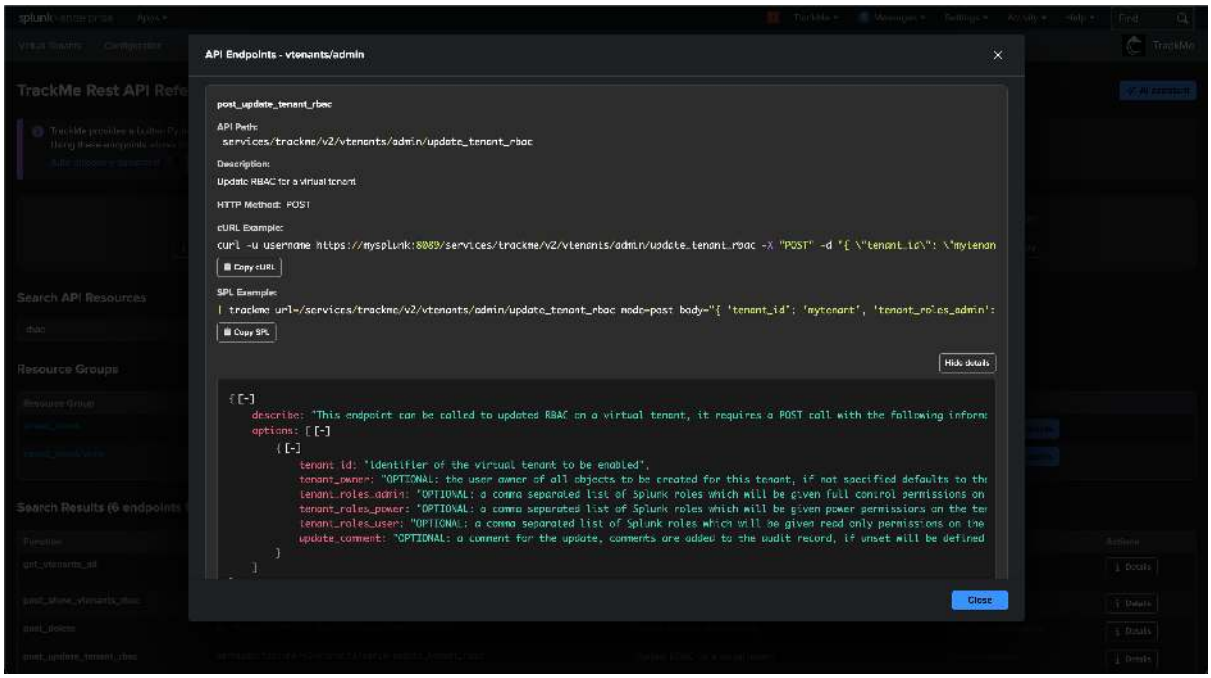




Update the ownership and/or RBAC policies carefully: TrackMe updates the tenant configuration and re-assigns all of its knowledge objects if needed, updating their permissions accordingly.

Through the REST API

The same update is available from the `update_tenant_rbac` endpoint. The best way to discover any endpoint's usage — its parameters, HTTP method, and ready-to-copy **curl** and **SPL** examples — is the built-in **TrackMe REST API Reference** UI (open it from **API & Tooling → TrackMe REST API Reference**), which documents every endpoint:



For instance, to add the `siem_users` role to the user access of the `siem-quality-control` tenant:

```
| trackme url=/services/trackme/v2/vtenants/admin/update_tenant_rbac mode=post
    body="{'tenant_id': 'siem-quality-control', 'tenant_roles_admin':
```

(continues on next page)

(continued from previous page)

```
↪'emea_siem_admin',
          'tenant_roles_power': 'emea_siem_power',
          'tenant_roles_user': 'emea_quality_control,siem_users',
          'tenant_owner': 'srv-trackme'}"
```

Restricting a tenant to specific users

On top of the role model, a tenant can be restricted to an **allowlist of Splunk usernames**. When the allowlist (`tenant_allowed_users`) is non-empty, only those users — plus the tenant **owner** — see the tenant in the Virtual Tenants UI and via `trackmeload`; other ordinary users do not, even with a granting role. `splunk-system-user` bypasses this filter so scheduled searches and alert actions keep working. The dedicated findings workspaces also retain the `admin` / `sc_admin` administrative bypass: this is not an isolation boundary against Splunk administrators. It is an extra restriction layered *over* RBAC, not a replacement — a listed user still needs a role that grants access. Clear the list to remove the restriction. Set it from the `vtenants/admin/update_tenant_visibility` endpoint:

```
| trackme url=/services/trackme/v2/vtenants/admin/update_tenant_visibility␣
↪mode=post
    body="{'tenant_id': 'siem-quality-control', 'tenant_allowed_users': 'alice,bob
↪'}"
```

8.2.7 Personal preferences

Each user can tailor the TrackMe interfaces to their own taste from the **Settings** panel. These preferences are **private**: changing them never affects anyone else, and they never change tenant data, access control or monitoring behaviour. Administrators set the **defaults** that apply until a user makes their own choice (see *Application-wide defaults* below).

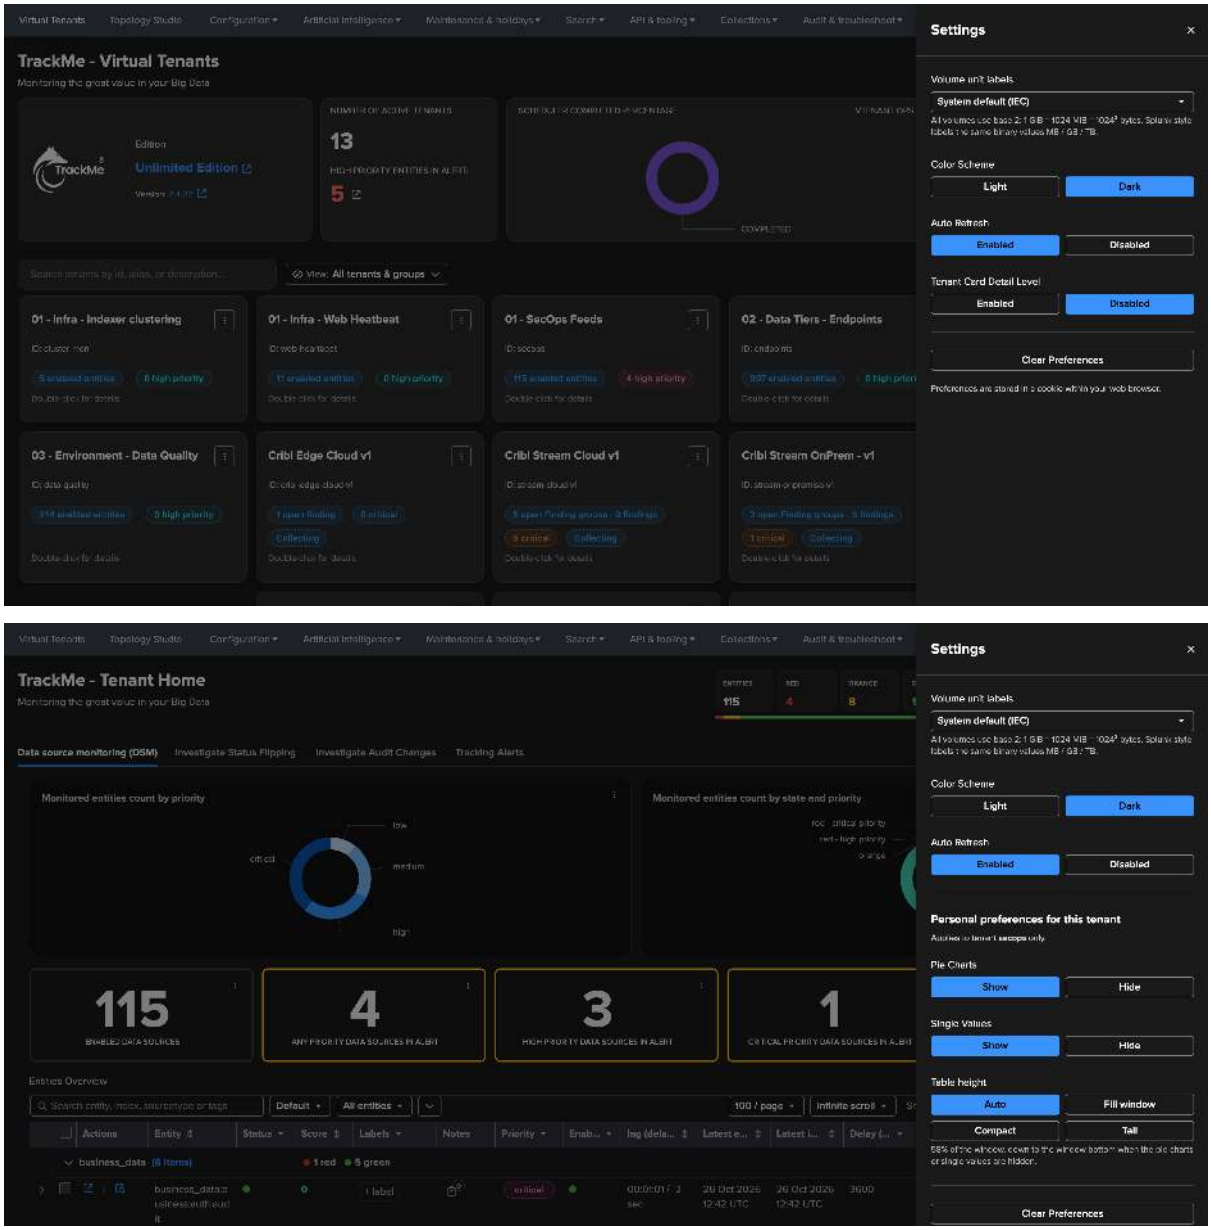
Note

One theme choice: Light or Dark

TrackMe's interfaces are native Splunk UI (React) components, and the colour scheme is a single **Light** or **Dark** choice. Earlier releases styled their entity tables with the Tabulator JavaScript library, which offered named table themes (*Dark Site*, *Dark Midnight*, *Light Site*, *Light Modern*) and a separate icon theme. That component and those preferences no longer exist, and neither does the old `trackme_theme_default` system setting: the application default is now `default_theme` (see below).

Opening the Settings panel

Click the **settings** icon (the sliders button, *Open settings*) at the top right of the **Virtual Tenants** page, of any **Tenant Home** or of **Topology Studio**. The panel slides in from the right and every change applies immediately — there is no Save button.



Left: the panel on the Virtual Tenants page. Right: the panel on a Tenant Home, with its per-tenant section.

What you can set

Preference	Where	Effect
Volume unit labels	Virtual Tenants, Tenant Home	How volumes are labelled: **System default**, **IEC (MiB / GiB / TiB)** or **Splunk binary (MB / GB / TB)**. Only the label changes: every volume is computed in base 2 (1 GiB = 1024 MiB = 1024^3 bytes), Splunk style simply labels the same binary values MB / GB / TB.
Color Scheme	All three	**Light** or **Dark**. The choice is global: it applies to every TrackMe interface, including embedded views, the AI assistant and notifications.
Auto Refresh	All three	**Enabled** or **Disabled**. Whether the page refreshes its data automatically (on Topology Studio, the live-status polling of the canvas). Until you choose, the system default applies.
Tenant Card Detail Level	Virtual Tenants	**Enabled** shows the priority breakdown (low, medium, high, critical) on each tenant card; **Disabled** keeps the compact cards.
Virtual Tenants visibility	Virtual Tenants	Appears once you have hidden at least one tenant (tenant menu → **Hide this tenant**). **True** shows your hidden tenants again; **False** keeps them out of your grid. Hiding is personal and never restricts access (see *Managing tenants*).

Personal preferences for this tenant

On a **Tenant Home**, the panel adds a section that applies to **that tenant only** (it names the tenant). The controls depend on the kind of tenant:

Tenant	Controls
Entity tenants (DSM, DHM, MHM, FLX, FQM, WLK, VOL)	**Pie Charts** and **Single Values** (Show / Hide) — the priority and state charts and the KPI tiles above the entities table. **Table height — Auto** (58 % of the window, down to the window bottom when the pie charts or single values are hidden), **Fill window**, **Compact** (40 %) or **Tall** (75 %).
User Activity Monitoring	**Collection monitors**, **Single stats** and **Charts** (Show / Hide) — see *User Activity Monitoring*.
Cribl Stream, Cribl Edge and Splunk HEC	**Workspace context**, **Single stats** and **Charts** (Show / Hide), and **Rows per page** (25, 50 or 100) for the workspace tables. Hiding a layer never stops collection, findings or safety warnings.

Other choices TrackMe remembers

A few selections made elsewhere in the interfaces are kept with your preferences too: the **Saved View** selected on the Virtual Tenants page (see *Saved Views*), the list of tenants you have **hidden**, the **display mode** of the Topology Studio views browser (see *Views browser and display modes*) and the **Policies** layout (cards, compact or list) of the UAM and Cribl workspaces.

Where preferences are stored

Preferences live in a single browser cookie, `trackme_user_preferences`, and are read and written by every TrackMe interface. As a consequence:

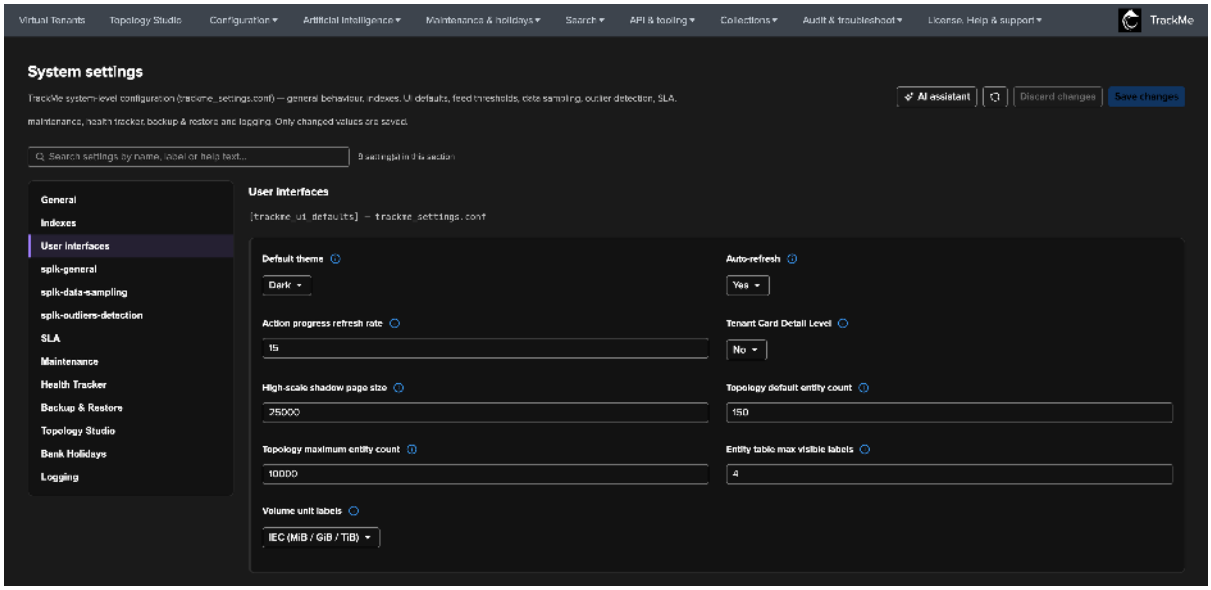
- they follow **your browser**, not your Splunk account: another browser or another device starts from the system defaults;
- the cookie holds UI state only — no personal data, no tenant data;
- deleting the site's cookies in your browser resets them.

Clearing your preferences

Clear Preferences, at the bottom of the panel, asks for confirmation, then deletes the whole cookie and reloads the page: every choice above — colour scheme, auto-refresh, unit labels, per-tenant layouts, hidden tenants, the selected Saved View — returns to the system defaults. A few views remember purely local display options (for example chart options in the VOL views) in the browser's local storage; Clear Preferences leaves those untouched.

Application-wide defaults

Administrators set the defaults for all users from **Configuration → System settings → User interfaces**, the `[trackme_ui_defaults]` stanza of `trackme_settings.conf`. Like every Configuration interface, this page is reserved for Splunk admins (see *Configuration*).

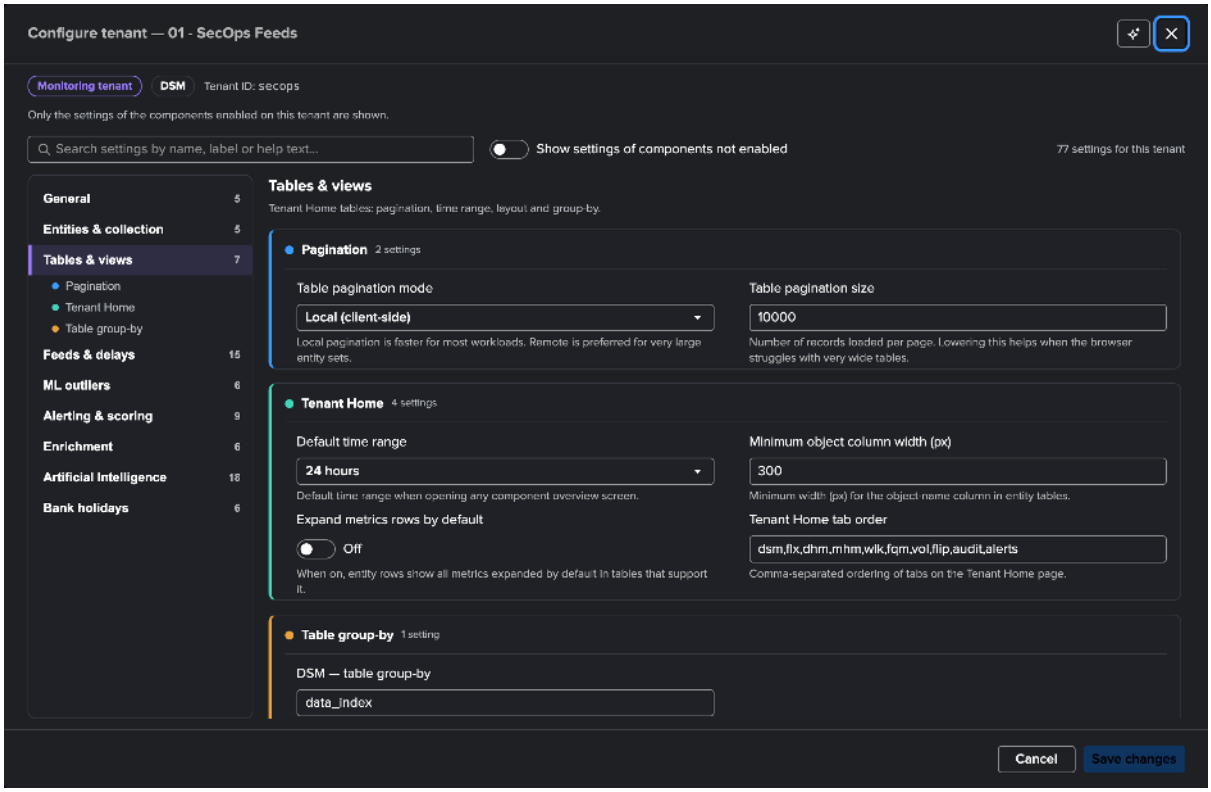


Setting	Key	Default	Notes
Default theme	`default_theme`	`dark`	`dark` or `light`. Users override it with **Color Scheme**.
Auto-refresh	`auto_refresh`	`1`	Auto-refresh on (`1`) or off (`0`) by default. Users override it with **Auto Refresh**.
Action progress refresh rate	`auto_refresh_inte:`	`15`	Seconds between progress refreshes while an action runs (creating a tenant, running a tracker, training models). 5–300; raise it on slow systems.
Tenant Card Detail Level	`vtenants_card_det:`	`0`	Show the priority breakdown on tenant cards (`1`) or not (`0`). Users override it.
High-scale shadow page size	`shadow_page_size`	`25000`	Records fetched per batch when large entity tables load from shadow collections. 5,000–50,000.
Topology default entity count	`topology_default_max_e:`	`150`	Member entity nodes drawn when the topology graph view opens. 10–10,000; analysts can adjust it per view.
Topology maximum entity count	`topology_max_entities`	`10000`	Ceiling on the member entity nodes an analyst can request. 100–100,000.
Entity table max visible labels	`table_labels_max_vi:`	`4`	Label chips shown per entity before the rest collapse into **+N**. 1–10.
Volume unit labels	`volume_unit_labels`	`iec`	`iec` (MiB / GiB / TiB) or `splunk` (MB / GB / TB); values stay binary either way. Users override it with **Volume unit labels**.

The precedence is always the same: a user's own choice wins, then the system default, then a built-in fallback. Changing a default affects users who have not made their own choice; it never overwrites a personal one. The deployment-wide default display mode of the Topology Studio views browser is set in the **Topology Studio** section of the same page.

Per-tenant table defaults

How a tenant's entity tables load and group is a **tenant setting**, not a personal one. Tenant administrators set it from the tenant menu → **Configure tenant** → **Tables & views** (see *Configuring a tenant*):



- **Pagination** — the table pagination mode (**Local**, client-side, the default; or **Remote**, server-side for very large entity sets) and size (`10000` records per page). New tenants inherit both from **System settings → General** (`pagination_mode`, `pagination_size`).
- **Tenant Home** — the default time range, the minimum width of the object column, whether metric rows open expanded, and the order of the Tenant Home tabs.
- **Table group-by** — per component, the field or fields the entities table is grouped by when it opens (for example `data_index` for DSM, `overgroup` for WLK, `group` for FLX and VOL). Users can still regroup on the fly with the table's **Group by** selector.

Note

The group-by settings keep their historical keys in `trackme_vtenants.conf` (`splk_dsm_tabulator_groupby`, `splk_flx_tabulator_groupby` and so on). The word *tabulator* in the key is a leftover of the former table component; the setting drives the grouping of today's entity tables.

8.3 Monitoring Components

Everything TrackMe tracks is an **entity**, and every entity belongs to one of seven **monitoring components**. The component decides *what* is measured and which tracking logic applies. This part introduces the shared model, gives each component its own page, then covers the advanced tracker types that extend them.

- **Overview —** the seven components at a glance, the shared entity lifecycle, and how to choose between them.
- **DSM, DHM, MHM —** the data-flow family ("is my data arriving?").
- **VOL —** is my license volume normal? Drops, spikes and silence on the licensed volume of every index, with a trend and a month projection.
- **FLX —** track anything you can express in SPL.
- **FQM —** is my data well-parsed and CIM-compliant?
- **WLK —** are my scheduled searches healthy?
- **UAM —** *Who is doing what on my Splunk?* A dedicated tenant type outside the seven entity components: the accounts, their scheduled searches, their activity and their resource usage, turned into findings.
- **Cribl Stream —** *Is my Cribl Stream deployment healthy?* A dedicated tenant type that monitors one Cribl Stream deployment from the Cribl metrics already in Splunk and the Cribl Leader API: Sources, Destinations, Pipelines, Routes and Workers, findings from a policy catalogue and traffic ML models.
- **Cribl Edge —** *Are my Cribl Edge Fleets healthy?* A dedicated tenant type that follows the Fleets of a Cribl Edge Leader and their Edge Nodes, Sources and Destinations, read in bulk from the Leader at any fleet size, with findings from a policy catalogue.
- **Splunk HEC —** *Are my HTTP Event Collector endpoints healthy?* A dedicated tenant type that monitors the HEC endpoints, pools and tokens of one Splunk deployment from the telemetry Splunk already writes (`_introspection` and `_internal`), with findings from a policy catalogue and traffic models.
- **Splunk S2S —** *Is every receiver accepting, and is my intermediate tier keeping up?* A dedicated tenant type that watches the receivers, intermediate forwarders and pools of one Splunk deployment, traces back pressure to its origin, and learns traffic ML models per pool.
- **Splunk UF Fleet —** *Which forwarding agents are connected, at any fleet size?* A dedicated tenant type that follows the forwarding agents and the Deployment Servers that manage them, with groups, expected agents and mass events as one finding.
- **Findings —** the model the dedicated tenant types share: policies, findings, Finding groups, notifications, findings actions and the AI Agents.
- **Hybrid & replica trackers —** advanced tracker types that feed entities into those components: build a tracker from your own SPL (local or remote), or mirror entities from another TrackMe deployment.

8.3.1 The seven components at a glance

A **component** is the kind of thing an entity is. It determines what TrackMe measures, which thresholds apply, and what "healthy" means. Every entity belongs to exactly one component, and the seven codes — DSM, DHM, MHM, VOL, FLX, FQM, WLK — appear throughout the interface, the metrics, and the REST API.

Code	Component	What it tracks	Use it to answer
DSM	Data Source Monitoring	`(index, sourcetype)` data feeds — delay, latency, volume, quality.	*Is my data flowing?*
DHM	Data Host Monitoring	Host × sourcetype activity per endpoint.	*Who is sending, and what?*
MHM	Metric Host Monitoring	Hosts sending metric data, by metric category.	*Are my metrics arriving?*
VOL	Volume Outliers	Licensed volume per index — drops, spikes, inactivity, trend and projection.	*Is my license volume normal?*
FLX	Flex Objects	Anything you can express in SPL, with custom KPIs.	*Is this custom thing healthy?*
FQM	Field Quality Monitoring	Field extraction quality and CIM compliance.	*Is my data well-parsed?*
WLK	Workload Knowledge	Scheduled-search execution health.	*Are my searches healthy?*

DSM, DHM, and MHM form the **Splunk Feeds** family and share a delay/latency model. FLX, FQM, and WLK share a **dynamic-thresholds + metrics** model. VOL stands on its own: one entity per index fed by the license usage logs, with ML outliers as its state.

Note

UAM — User Activity Monitoring is not an eighth entity component but a dedicated **tenant type**, outside the seven: it has no entities, no state and no scoring — it answers *who is doing what on my Splunk?* with **findings** about accounts and their scheduled searches, activity and resource usage. See *User Activity Monitoring*.

Cribl Stream is another dedicated **tenant type**: it monitors one Cribl Stream deployment — its Sources, Destinations, Pipelines, Routes and Workers — from the Cribl metrics already in a Splunk metric index and the Cribl Leader API, and raises **findings** from a policy catalogue and per-object traffic ML models. See *Cribl Stream and Cribl Edge*.

Cribl Edge, the third dedicated **tenant type**, follows the Fleets of a Cribl Edge Leader and their Edge Nodes, Sources and Destinations, and raises **findings** from a policy catalogue. See *Cribl Edge*.

Splunk HEC, the fourth dedicated **tenant type**, monitors the HTTP Event Collector endpoints of one Splunk deployment, the pools they form and the tokens senders use, from the HEC telemetry Splunk already writes, and raises **findings** from a policy catalogue. See *Splunk HEC*.

Splunk S2S and **Splunk UF Fleet**, the fifth and sixth dedicated **tenant types**, follow the forwarding of one Splunk deployment from what Splunk already writes: Splunk S2S watches the receivers, intermediate forwarders and pools of the S2S receiving side (see *Splunk S2S*), Splunk UF Fleet the forwarding agents and the Deployment Servers that manage them (see *Splunk UF Fleet*). The dedicated tenant types share one findings model: *Findings, Finding groups and findings actions*.

The shared entity model

However different the seven components look, every entity has the same shape and lifecycle.

An **entity** always has:

- an **object** — its canonical, unique key (what it identifies differs per component);
- an **alias** — an editable display name;
- a **state** — green / orange / red / blue (see *Entity State & Scoring*);
- a **score**, **thresholds**, anomaly fields, and a cache of its latest **metrics**.

And every entity goes through the same lifecycle each cycle:

```
DISCOVER  →  TRACK  →  EVALUATE  →  ALERT / LIFECYCLE
a tracker     each run    decision maker   stateful alerting,
enumerates    refreshes   sets state +     acknowledgment,
units and     metrics     score from       purge of inactive
creates       & times     thresholds       entities
entities
```

Note

Trackers are scheduled searches, usually running every five minutes. The freshness of a delay measurement is therefore only as precise as the tracker cadence — a five-minute schedule can report a delay up to five minutes after the fact. Entities can also be **declared before they exist** (see expected sources / hosts for *DSM* and *DHM*); a declared entity starts red until real data arrives.

Choosing a component

You want to track…	Use
The freshness and volume of an index + sourcetype feed	**DSM**
Which hosts are sending, and what sourcetypes, per host	**DHM**
Hosts sending data to a metrics index	**MHM**
The licensed volume of every index — drops, spikes, silence, trend, projection	**VOL**
Field parsing quality / CIM coverage	**FQM**
Scheduled-search execution health (skips, errors, delay, cost)	**WLK**
Anything else you can write a search for	**FLX**

What every component shares

These concerns apply to all seven and are documented once, in their own parts:

- **Classification** — priority, tags, labels, and SLA (*Classification & Protection*).
- **Protection** — logical groups, the disruption queue, and acknowledgments (*Classification & Protection*, *Alerting*).
- **Stateful alerting** — one state machine for all seven (*Alerting*).
- **Scoring** — one hybrid score; the per-anomaly weights differ per component (*Entity State & Scoring*).
- **ML outlier detection** — a natural fit for DSM and FLX, and the very purpose of VOL; less useful, and off by default, for DHM, MHM, FQM, and WLK (*Machine Learning*).
- **Topology graphs** — every component except VOL can render its entities as an interactive link / network graph (see *Topology graphs* below).

Where the components differ

A few capabilities are specific to certain components. Keep this map in mind:

Capability	Available for
Variable delay & lagging classes	DSM, DHM (MHM uses static thresholds)
Data sampling, elastic sources, lookup monitoring	DSM only
Expected-sources / hosts injection & coverage-gap analysis	DSM, DHM
Dynamic, time-sliceable metric thresholds	FLX, FQM
Versioning, orphan detection, app enablement, SVC cost	WLK
Free-form KPIs, template catalog, converging trackers	FLX
ML outliers as the primary state, detection direction per index (drops / spikes / both)	VOL
Inactivity policy (static or by day-of-week / hour-of-day), history backfill, month projection, Global license usage analytics	VOL

Topology graphs

Every component except VOL can render its entities as an interactive **topology graph** — open it from the graph icon in the **Tenant Home header** (the icon is contextual to the component tab you are viewing). The modal offers two views, a **Link graph** and a **Network graph**, and lays the tenant's entities out as a hierarchy:

Component	Hierarchy
DSM	tenant → index → entity
DHM	tenant → host → index → sourcetype (→ extras)
MHM	tenant → host → metric category
WLK	tenant → app → entity
FQM	tenant → data model → entity
FLX	plus dedicated *converging* and *use-case* graphs (tenant → service / group → members)

Note

VOL has no Tenant Home topology graph — one entity per index leaves no hierarchy to draw. VOL entities can still be placed in *Topology Studio* views like any other component.

Each node is coloured by status (/ / /), and a parent rolls up to the **worst** status among its descendants — so a single red leaf turns its whole branch red, letting you trace a problem from the tenant down to the offending entity at a glance. You can search the graph, filter to **All / Down / Up**, and cap the number of leaf nodes drawn (default 150) on large tenants.

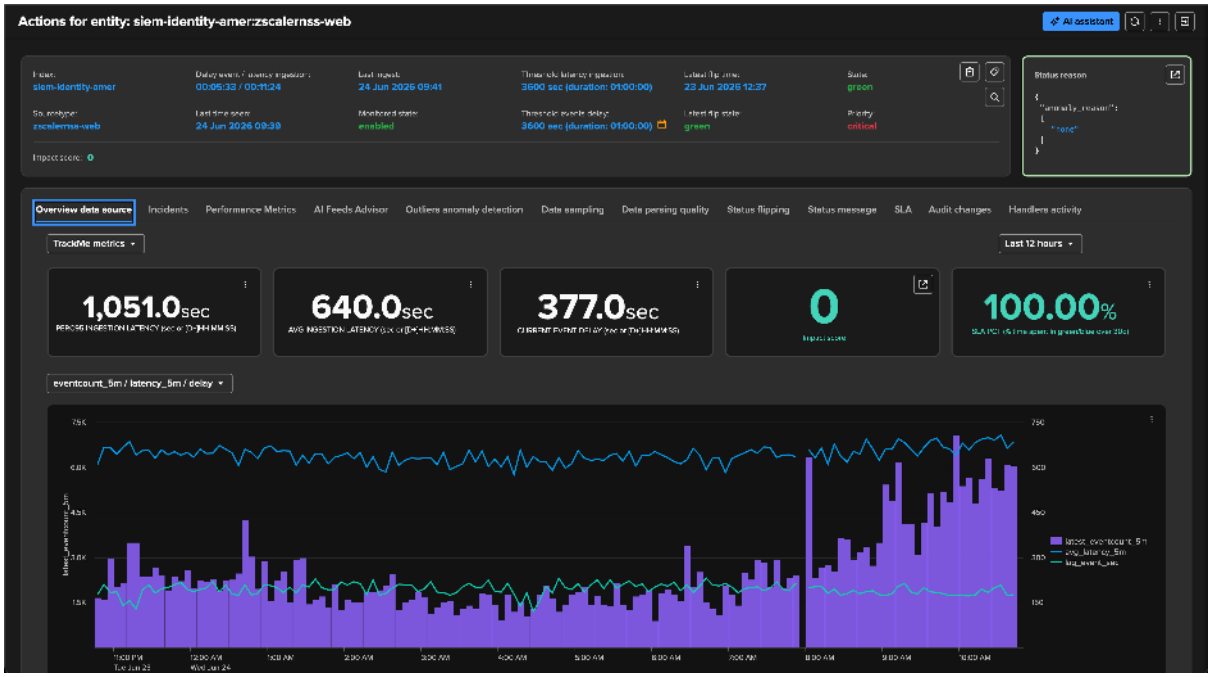
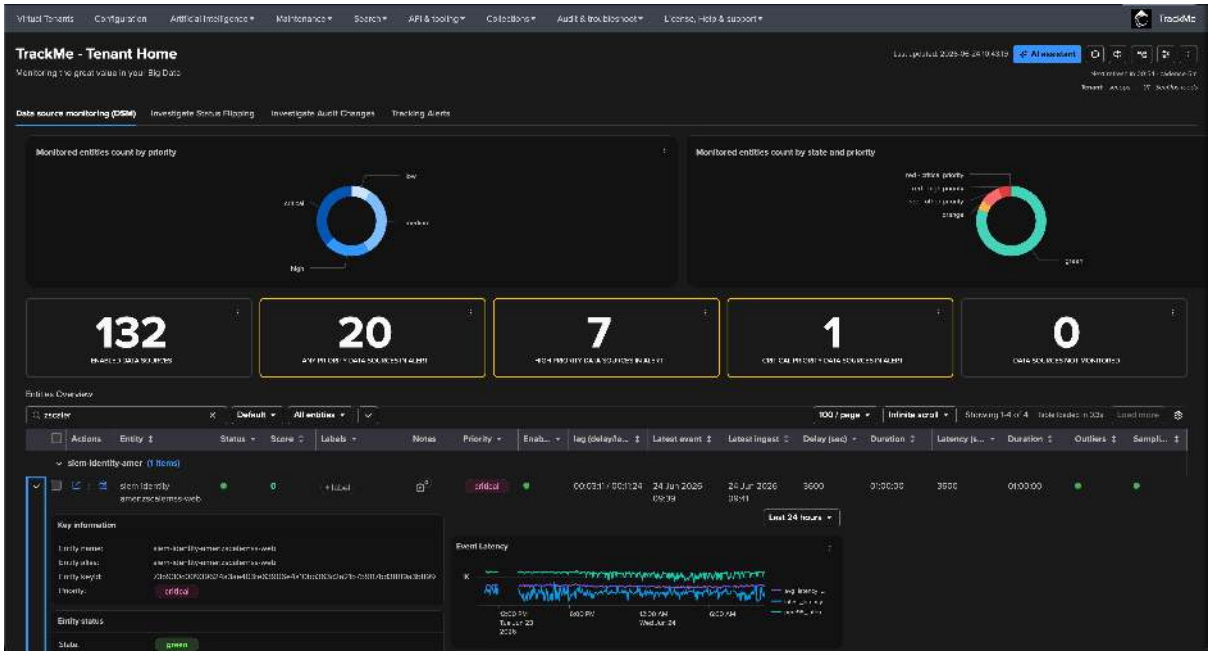
8.3.2 DSM — Data Source Monitoring

Data Source Monitoring is TrackMe's original and most fundamental component. Each entity is a **data feed** — an `(index, sourcetype)` combination, optionally split further by a *break-by* field — and DSM answers the first question of any healthy platform: **is my data still flowing, on time, in the expected volume, and well-formed?**





What DSM tracks

Signal	What it means
Delay	How old the most recent event is (`now - last_event_time`). Breached when the latest data is older than the **delay max** threshold (`data_max_delay_allowed`).
Latency	The lag between an event's timestamp and when Splunk indexed it (`_indextime - _time`). Breached above the **lag max** threshold (`data_max_lag_allowed`).
Volume outliers	Unusual event volume, detected by ML density-function modelling — a natural fit for DSM (see *Machine Learning*).
Future events	Events arriving with a timestamp in the future (beyond tolerance) — usually a time-zone or parsing problem.
Data quality	Unknown formats, mixed formats, and format drift, surfaced by **data sampling** (see below).

In an entity's overview you can switch the source of these figures between **TrackMe metrics** (fast, served from the metrics index) and **Splunk queries** (direct and exact, but slower and requiring index access).

Tip

Delay and **latency** are the two most-confused KPIs in TrackMe (people call everything "latency"). If the difference is not crystal clear, read *Delay vs latency: what they actually mean* — it is short, diagram-led, and worth five minutes.

Defining what gets tracked

- **Root constraint** — the base SPL filter that defines a tenant's data scope.
- **Allowlist / blocklist** — regex rules that include or exclude specific `index + sourcetype` combinations from automatic entity creation.
- **Break-by** — an optional extra field that splits one feed into finer entities.

Note

Sourcetype-explosion safeguard. If a single index produces more sourcetypes than the configured cap, bulk DSM creation is refused and an alert is raised. The fix is to blocklist the noisy sourcetypes and re-cover the index with a single `<index>:@all` aggregate entity.

Delay thresholds, in depth

DSM delay handling is rich, because "late" means different things at different times:

- **Static or variable delay.** A delay threshold can be a single fixed value, or a **variable** time-slot policy (day-of-week × hour-of-day) — tighter during business hours, relaxed overnight and at weekends.
- **Lagging classes** — named, reusable delay/lag rule sets by cadence (high-frequency, nightly batch, quarterly…). Assign a feed to a class for consistent thresholds.
- **Adaptive delay** — TrackMe can compute delay thresholds automatically from an entity's own history.
- **Threshold lock** — lock a feed's delay and lag thresholds so neither adaptive delay nor a lagging class can rewrite them; a red lock icon marks locked entities.

The full thresholds-and-scoring model lives in *Entity State & Scoring*.

Note

One authority manages delay per tenant. If the AI *Feed Lifecycle Advisor* is set to manage DSM delay, it takes over and the legacy adaptive-delay / variable-delay auto-review settings are disabled automatically. Turning the advisor back off does not re-enable them — re-toggle them by hand if you want them back. See the *Artificial Intelligence* section.

Elastic sources

Elastic sources are virtual DSM entities built from arbitrary SPL — `tstats`, `raw`, `mstats`, or `from` a data model or lookup — rather than from straightforward `index/sourcetype` discovery. One search defines one entity. They suit syslog collectors, data-model- or lookup-derived sources, and cases that rely on search-time fields. They come in two flavours: **shared** (one pooled, concurrency-capped tracker) and **dedicated** (an independent scheduled report). See *Elastic sources* for the full treatment.

Tip

For high-cardinality cases, *Hybrid trackers* have largely superseded elastic sources — but elastic sources remain the right tool for `from` / `raw` single-entity edge cases.

Lookup monitoring

DSM can track Splunk **lookups** (CSV and KV Store) as first-class entities — one entity per lookup — to detect whether a lookup is still being refreshed. Only the delay threshold applies (latency is not meaningful for a lookup). This is covered with the other integrations in *Integrations & Remote Deployments*.

Data quality: sampling

Data sampling periodically samples a feed's events and matches them against format models to detect unknown formats, multi-format feeds, and format drift. TrackMe ships out-of-the-box regex models, and you can add your own. Data sampling is configured under operations — see *Operations & Administration*.

Declaring feeds before they exist

You can declare feeds that **should** exist from a Splunk lookup — **expected sources injection**. For DSM both `index` and `sourcetype` are required. Injected feeds appear **red** until real data arrives, then their metadata auto-populates. Imports can be one-shot or recurring.

Coverage-gap analysis complements this: a read-only reconciliation of a reference (a lookup, or a live `tstats` / `raw` search) against the feeds TrackMe actually tracks, returning three downloadable lists — only in the reference, only in TrackMe, and in both.

Delayed and inactive entities

When a feed falls so far behind that it drops out of the tracker's search window, TrackMe does not lose track of it — two cooperating processes keep its delay metadata fresh (this behaviour is shared with *DHM*):

- **Health Tracker — the ``untracked_entities`` task.** The tenant's Health Tracker runs every **5 minutes**; its `untracked_entities` task detects entities no longer covered by any tracker and refreshes their calculated delay, stamping `tracker_health_runtime` on each entity it handled. Troubleshoot it with:

```
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth task=
↪"untracked_entities"
index=_internal sourcetype=trackme:custom_commands:trackmetrackerhealth␣
↪tenant_id="mytenant" component="splk-dsm" task="untracked_entities"
```

- **Delayed entities inspector.** A scheduled job named `trackme_<component>_delayed_entities_inspector_tracker_` runs the `trackmesplkfeedsdelayedinspector` command. It picks up the entities the Health Tracker flagged (via `tracker_health_runtime`) and runs one targeted search per entity to refresh its metadata, on a tiered cadence keyed to current delay — entities delayed **< 24h** every ~30 min, **< 7 days** hourly, and

beyond that once every 24 hours — until the entity reaches the tenant's auto-disablement period. Configure it per tenant under **Delayed entities inspector** in the tenant settings. The last inspection time is stored on the entity as `tracker_runtime` (epoch), shown human-readably in the entity's right-click contextual menu.

Each inspected entity logs a pair of lines — `Executing entity delayed tracking resulting search=` then `delayed_entity_search_results=`:

```
index=_internal␣
↪sourcetype=trackme:custom_commands:trackmesplkfeedsdelayedinspector tenant_id=
↪"mytenant" component="splk-dsm" object="myentity"
```

You can also follow the inspector (and TrackMe's other backend logics) in the **Handler events** tab — the `trackme:handlers` sourcetype in the tenant's summary indexes.

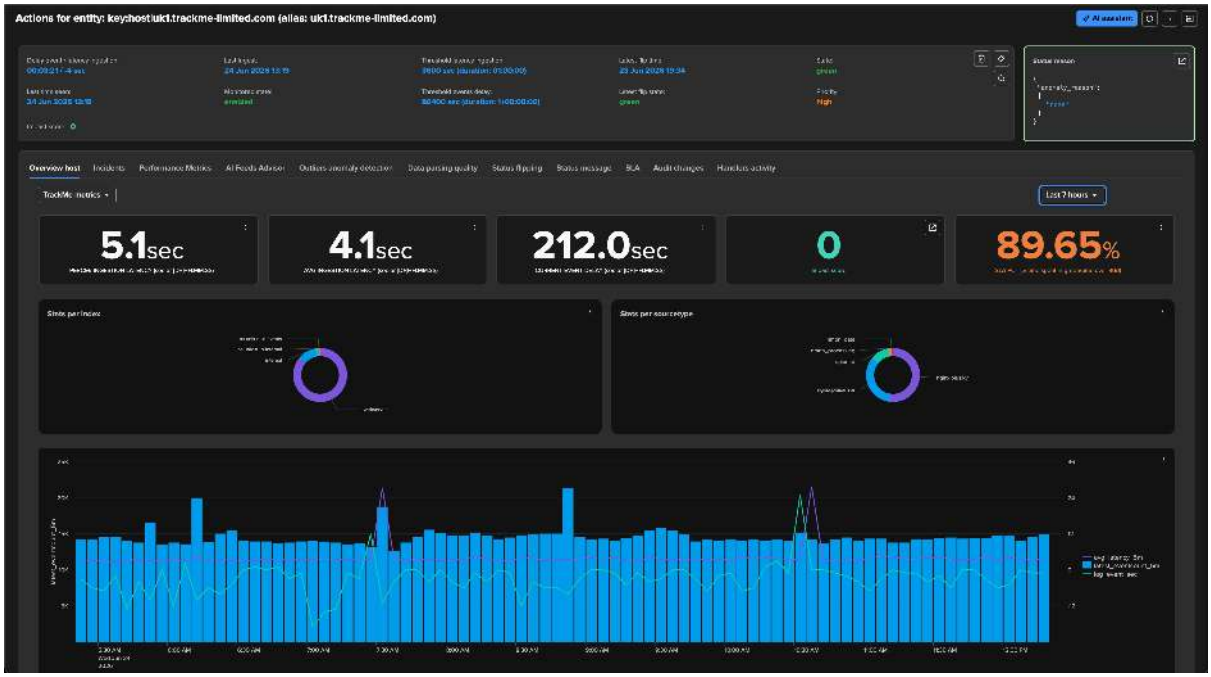
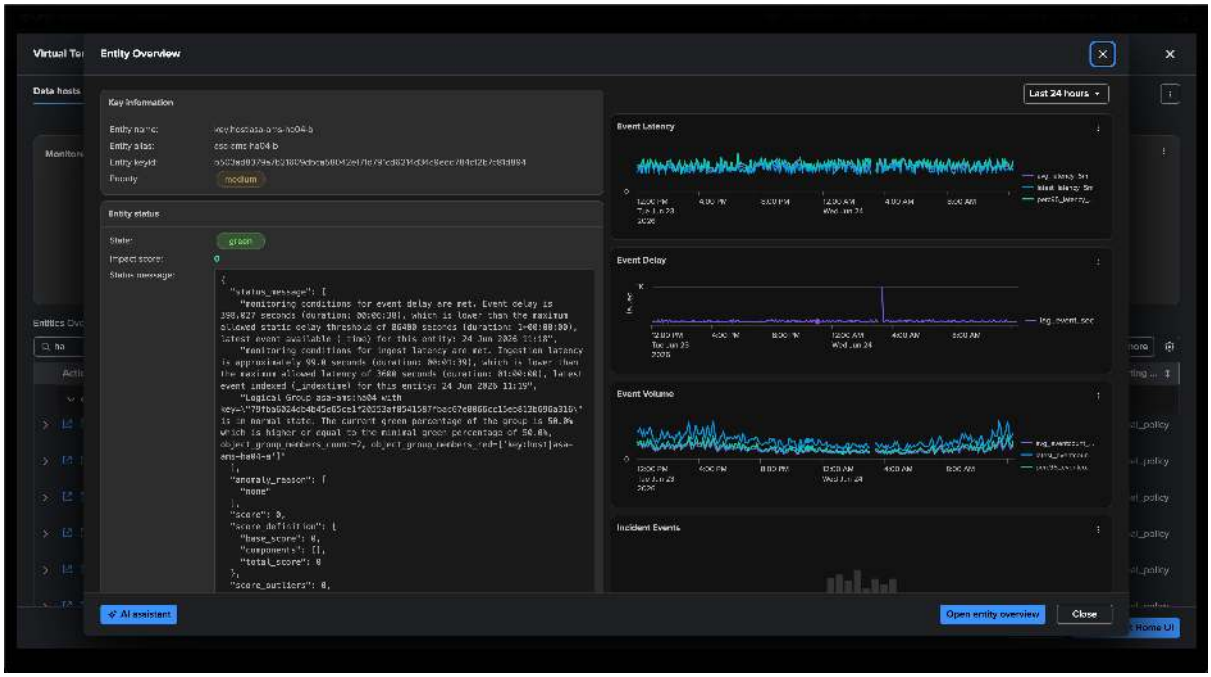
8.3.3 DHM — Data Host Monitoring

Data Host Monitoring tracks **host × sourcetype activity** — which hosts are sending data, and what they are sending. Where *DSM* watches feeds, DHM watches the *senders*, which makes it the natural component for forwarder fleets and for declaring the hosts that *should* be reporting.





What DHM tracks

Each entity is a **host**, carrying the index × sourcetype combinations it sends. DHM shares DSM's delay/latency model:

- **Delay** and **latency** against the configured thresholds.
- **Volume outliers** per host/sourcetype (off by default — host volume is noisy).
- **Future events** and **distinct-host drift**.

> **Note**
>
> **The asset field.** Each host also carries an `asset` field — a de-duplicated set of every known variation of the host name (canonical value, alias, short hostname, FQDN). TrackMe uses it to match short names against fully-qualified ones, so a host is not tracked twice as `web01` and `web01.corp.example`.

Per-host granularity

DHM lets you choose how finely a host is broken down, via the tracker's break-by mode:

Mode	Grain
Standard	Combos at `(index, sourcetype)`.
Merged	Sourcetype collapsed — `(index, all sourcetypes)`.
Custom	Keyed by any single field you choose (for example `cmdb_ci`), with up to five extra ordered metadata dimensions (such as `source`).

Declaring hosts that should be sending

DHM's signature feature is **expected-hosts injection** — telling TrackMe which hosts *ought* to be reporting, so a host that goes silent (or never starts) is visible as a problem rather than an absence.

- Declare hosts from a Splunk lookup (local or remote, CSV or KV Store). For DHM only the `host` field is required.
- The wizard previews the lookup, maps fields, and **simulates** the import (reporting how many rows are new, existing, or already tracked) before you commit. Imports can run once or on a recurring schedule.

- Injected hosts appear **red** until data arrives; their index/sourcetype placeholders fill in automatically — and clean up automatically — once the DHM tracker sees real data.
- Existing entities are never duplicated; the `asset` field makes the matching short-name/FQDN aware, and large lookups are batched automatically.

Host coverage-gap analysis complements injection: a read-only reconciliation of a reference host list (a CMDB lookup, or a `tstats` / `raw` search) against the hosts TrackMe tracks — returning the hosts only in your reference (the coverage gap), only in TrackMe, and in both.

Shared with DSM

DHM shares DSM's configuration model: root constraint, allowlist/blocklist, variable delay, lagging classes, adaptive delay, threshold lock, the AI Feed Lifecycle Advisor delay mutex, and the delayed/inactive-entity inspector. See *DSM — Data Source Monitoring* for those.

Note

DHM has **no data sampling and no elastic sources** — those are DSM-only. On large fleets (10k+ hosts), keep SLA thresholds moderate to avoid alert storms, and remember that inactive hosts are auto-disabled after the tenant's auto-disablement period.

8.3.4 Feeds thresholds (delay & latency)

For the splk-feeds family — *DSM* and *DHM* — the core question is *"is my data on time?"*. Two KPIs answer it, and each has a threshold an entity must stay under:

- **Delay** — how old the most recent event is (`now - last_event_time`); breached above `data_max_delay_allowed`.
- **Latency** — the gap between an event's timestamp and when Splunk indexed it (`_indextime - _time`); breached above `data_max_lag_allowed`.

Tip

New to these two, or not sure which is which? Start with *Delay vs latency: what they actually mean* — a plain-English, diagram-led explanation of the difference (and how they appear in the UI).

When discovered, every entity starts with a **1-hour** (3600-second) maximum for both. From there, TrackMe gives you several ways to set the *right* threshold for each feed — from a fixed value to fully automated, machine-learning-driven thresholds.

Ways to set a delay threshold

Approach	When to use it
Static threshold	A single fixed value — the default. Set it per entity, simulate it first, and read the two worked anatomy examples.
Lagging classes	Rule-based thresholds at scale — match entities by index, sourcetype or priority and apply a shared delay (and optional latency) threshold.
Adaptive delay (ML)	Let TrackMe learn each feed's normal lag from history and maintain the threshold for you.
Variable delay	Time-aware thresholds that change by day-of-week and hour-of-day — tight during business hours, relaxed at night and on weekends.

Who manages a threshold: the Threshold Lock and the AI Advisor

Two cross-cutting ideas decide *who* owns an entity's delay threshold.

The Threshold Lock. Setting thresholds used to mean answering two easily-confused per-entity questions — *"allow adaptive delay to auto-tune this?"* and *"should this entity override lagging classes?"* — that interacted in non-obvious ways and could each silently rewrite a value you had set by hand. A single per-entity **Threshold Lock** (a red , pinning delay *and* latency together) replaces both with one yes/no:

- **Locked** — *this value is mine.* TrackMe pins your manual thresholds and **every** background writer skips the entity: adaptive delay, variable-delay auto-review, and lagging-class management. A periodic reconcile even restores your pinned values (and, for a variable entity, your slot schedule) if anything drifts.
- **Unlocked** — *TrackMe, manage it.* Lagging classes and adaptive / variable adaptive delay are free to set and maintain the thresholds.

(The lock is the single control behind the older `allow_adaptive_delay` and `data_override_lagging_class` fields, which are now derived from it and no longer edited directly. Locking is governed per tenant by `delay_threshold_lock_enabled`.)

Important

The AI Feed Lifecycle Advisor takes precedence. When the AI *Feed Lifecycle Advisor* is enabled to cover DSM/DHM, it becomes the authority for delay thresholds: the legacy **adaptive-delay** and **variable-delay auto-review** mechanisms are automatically disabled (their per-tenant toggles are forced off and their trackers short-circuit at runtime). Turning the advisor back off does **not** re-enable them automatically — you re-toggle them by hand if you want them back. See the *Artificial Intelligence* section.

Delay vs latency: what they actually mean

People call everything "latency" — a feed is late, a dashboard is stale, an alert fired, and it all gets labelled *latency*. In TrackMe these are **two different measurements** that answer **two different questions**, and telling them apart is the single most useful thing you can learn about feeds monitoring. Get this right and the entities table, the thresholds, and the alerts all suddenly make sense.

Two timestamps

Every event in Splunk carries two moments in time:

- `_time` — **when the event happened** (the timestamp inside the event itself).
- `_indextime` — **when Splunk indexed it** (when it actually arrived and was stored).

Those two are never exactly equal, and the whole idea of delay and latency falls out of the gap between them and the gap to *now*:

- **Latency** = `_indextime - _time` — *"when an event arrives, how late is it?"* A measure of the **ingestion pipeline** (forwarding, queues, network, clock skew). It is a **per-event** property.

- **Delay =** `now - last_event_time` **—** *"how long since we last heard anything at all?"* A measure of **freshness**: is the feed still alive right now?

The mailbox analogy

Think of a feed as your postbox:

- **Latency** is how long a letter takes from the day it was **written** (the postmark — `_time`) to the day it **lands in your box** (`_indextime`). A letter postmarked Monday that arrives Thursday has three days of latency.
- **Delay** is how long since the **last letter of any kind** turned up. If nothing has arrived for five days, your delay is five days — the box has gone quiet.

The two are independent. Someone can drop a stack of old, week-old postmarked letters in today (**low delay, high latency** — fresh arrivals, but every one is stale). Or your reliable daily letter can simply stop coming (**high delay, low latency** — when letters *did* arrive they were same-day, but now there is nothing).

Why you can't collapse them into one

Because they are independent, a feed sits in one of four states — and the cause you go looking for is different in each:

The practical upshot: **an alert on latency and an alert on delay are telling you different things.** A latency breach points at your **ingestion path**; a delay breach points at the **source** (has it stopped?). Fixing one does nothing for the other.

How TrackMe measures each

- **Latency** is computed per event as `_indextime - _time`. On an entity, TrackMe surfaces the **current**, **average**, and **95th-percentile** latency over a recent window (so a single odd event does not dominate).
- **Delay** is computed as `now - last_event_time` — always relative to *this moment*, which is why a delay figure keeps climbing on its own while a feed is silent.

Each has its own threshold, and an entity turns red when it goes over:

- `data_max_delay_allowed` — the **delay max** (freshness ceiling).
- `data_max_lag_allowed` — the **lag max** (per-event latency ceiling).

New entities start with a 1-hour default for both. See *Feeds thresholds (delay & latency)* for the ways to set the *right* value per feed (static, lagging classes, adaptive, and variable).

Where you see them in the UI

In the **entities table**, each feed row shows:

Column	Meaning
lag (event / ingest)	A combined summary cell: the current **delay** (event) and **latency** (ingest), in that order.
Latest event	The newest event seen, by `_time` (drives **delay**).
Latest ingest	The newest event seen, by `_indextime`.
Delay max	The current delay threshold for the entity (`data_max_delay_allowed`).
Lag max	The current latency threshold for the entity (`data_max_lag_allowed`).

On an entity's own view, the KPI stat tiles read:

- **CURRENT EVENT DELAY —** `now - last_event_time`.
- **AVG INGESTION LATENCY / PERC95 INGESTION LATENCY** — the mean and 95th-percentile latency over the recent window.

All of these display in **seconds**, switching to a `[D+]HH:MM:SS` duration format (via Splunk's `tostring(…, "duration")`) once the value exceeds 60 seconds — so `4200` shows as `01:10:00` and a two-day-stale feed as `2+00:00:00`.

- *Entity State & Scoring* — how a breach feeds the entity state and impact score.

Delay & latency thresholds

This is the starting point for splk-feeds thresholds: how the two KPIs work, how to read an entity's current thresholds, how to set them by hand, and how to validate a value before you commit it. For the automated and rule-based options, see *lagging classes*, *adaptive delay*, and *variable delay*.

Delay and latency, briefly

TrackMe measures two independent things for every feed entity, and gives each its own threshold.

Delay — is the data fresh?
: How old the most recent event is: `delay = now() - max(_time)`, where `_time` is when the event happened *at the source*. It answers *"how long ago did the most recent event arrive?"* High delay means the source has stopped producing fresh data — it is silent, or only sending old, backlogged events.

Latency — how slow is the pipeline?
: How long an event took to travel from the source to Splunk's index: `latency = _indextime - _time`, where `_indextime` is when Splunk *indexed* it. It answers *"how delayed was the pipeline between the source and Splunk?"* High latency points to a forwarding, buffering, or queuing problem — the events exist, but they arrived late.

The two are **independent** — you can have one without the other, and each tells a different story:

Pattern	What it means
High latency, low delay	Events are arriving, but they were already old when they got there — the source is fine, the transport is slow (pipeline buffering).
High delay, low latency	Events are indexed promptly once they arrive, but the source has stopped sending fresh data (a gap or silence).
Both high	The source is sending delayed, backlogged events that *also* took a long time to transit — the most concerning pattern.

Because they mean different things, **tune them independently**. On every monitoring cycle TrackMe checks each against its own threshold — delay against the entity's delay policy (static or variable), latency against `data_max_lag_allowed` — and each breach contributes to the *impact score* that drives the entity's state. A new entity starts with a **1-hour** (3600-second) maximum for both; the rest of this page is about setting better values.

Reviewing current thresholds

An entity's active thresholds — and which delay policy is in force (static or variable) — are shown in the entities table (a two-value cell for delay and latency) and on the entity's own screen.

Setting a threshold per entity

To set thresholds by hand, open the entity, go to its threshold settings, and you can:

- set the maximum acceptable **latency**;
- set the maximum acceptable **delay**;
- choose whether to alert on **both** KPIs (the default) or only one;
- **lock** the threshold so neither a *lagging class* nor *adaptive delay* will overwrite your value (see *Who manages a threshold: the Threshold Lock and the AI Advisor*).

Tip

The **Threshold Lock** replaces the old per-entity "override lagging classes" checkbox. Lock a threshold when you have deliberately tuned it and want it left alone; leave it unlocked to let lagging classes or adaptive delay manage it.

Simulating a threshold before you apply it

Before committing a value, use **Simulate thresholds** to test it against the history TrackMe has already accumulated. Provide candidate latency and delay values and TrackMe replays them over the entity's summary events, returning one event per breach that *would* have occurred — so you can see whether a value is too tight before it pages anyone. For a provider that sends data once per hour but indexes it promptly, you would keep latency tight and allow a little over an hour of delay, confirm the simulation is quiet, then apply.

Worked example: an entity suffering from latency

Latency means events are indexed well after their event time — you may *also* see delay, but not necessarily; a feed can mix near-real-time events with late ones. The two measures will usually differ, which is expected.

When an entity breaches its latency threshold, the rising latency is visible in both the overview and Performance Metrics charts, the **status message** spells out the problem, and **Smart Status** adds an automated investigation. To review the offending events by hand — here, events indexed more than 15 minutes (900 s) late over the last 4 hours:

```
index=myindex sourcetype=mysourcetype _index_earliest="-4h" _index_latest="+4h"␣
↪earliest="-4h" latest="+4h"
| eval indextime=_indextime, latency=(_indextime-_time)
| where latency>900
| eval indextime=strftime(indextime, "%c")
| table _time indextime latency _raw
```

Once the root cause is fixed and latency returns to normal, TrackMe brings the entity back to green after a short while.

Worked example: delay without latency

Some feeds are perfectly on time when they *do* arrive, but arrive infrequently — batched data. A provider that emits one batch per day shows no latency but accrues delay between batches; TrackMe surfaces the current delay alongside the latest event (`_time`) and the latest ingested event (`_indextime`). The fix is to set a delay of a little over 24 hours while keeping latency low, after which the entity returns to green.

A feed that arrives once per hour is the more common case: the default 3600-second delay will alert if the provider runs even slightly late, and too tight a value (say 3000 s) produces constant delay alerts — so you settle on something like 4200 s (1 hour 10 minutes). As always, tolerating delay in *delivery* does not mean tolerating latency in *indexing* — tune the two KPIs independently.

See also

- *Lagging classes* — rule-based thresholds at scale.
- *Adaptive delay (ML)* — let ML maintain the delay threshold.
- *Variable delay* — time-aware thresholds.
- *Entity State & Scoring* — how a breach feeds the impact score and state.

Lagging classes

A **lagging class** is a rule that sets delay (and optionally latency) thresholds for every entity that matches it — the scalable way to manage thresholds without touching entities one by one. Define a class once for "all firewall syslog feeds" or "everything in the `sec_*` indexes", and matching entities pick up its thresholds automatically.

Lagging classes are **per component**: DSM, DHM and MHM each keep their own set (MHM matches on metric category rather than delay/latency). This page covers the splk-feeds (DSM/DHM) classes.

How a lagging class is defined

Each class is a matching rule plus the thresholds to apply:

Field	Meaning
name	The pattern to match against (an index name, a sourcetype, or a priority value).
level	What the pattern matches on: `index`, `sourcetype`, or `priority`.
match mode	How the pattern is compared: `exact`, `wildcard`, or `regex` (regex is a **full match**).
delay	The delay threshold to apply — either a single **static** value, or a full **variable** schedule (named time slots, see *Variable delay*).
latency *(optional)*	An optional latency (lag) override; leave it empty to not touch latency.

So a single class can apply a static delay, a time-aware variable delay, and/or a latency override, to any set of entities you can describe by index, sourcetype or priority.

How a class is matched to an entity

When several classes could apply, TrackMe resolves a single winner deterministically:

1. **By level**, most specific first: an `index` match beats a `sourcetype` match, which beats a `priority` match. The first level with any match wins.
2. **Within a level**, the most specific match mode wins — `exact` over `wildcard` over `regex` — with the oldest rule breaking any tie.
3. For multi-value entity fields (common in DHM), a class matches if **any** value matches.

You can preview which entities a class would match with the lagging-class **simulation** before saving it.

Note

An entity whose threshold is **locked** (see *Who manages a threshold: the Threshold Lock and the AI Advisor*) is skipped by lagging classes entirely — its manual value stands. Likewise, latency rules from a class apply independently of the delay policy, so an entity on *variable delay* still honours a class's latency override.

Example: a class for a firewall sourcetype

Here we define a class at the **sourcetype** level for `netscreen-firewall`, applying a delay of 2 hours (7200 s) and a latency of 10 minutes (600 s). Once the trackers have run at least once and the matching entities are active, their thresholds are set from the class automatically.

See also

- *Delay & latency thresholds* — per-entity thresholds and the Threshold Lock.
- *Variable delay* — the time-slot schedule a class can carry.
- *Priority* — the priority a `priority`-level class matches on.

Adaptive delay (ML)

Adaptive delay lets TrackMe **learn each feed's normal lag from history and maintain its delay threshold automatically** — so a feed whose natural cadence drifts over time keeps a sensible threshold without anyone re-tuning it. It is handled by a dedicated tracker, `trackmesplkadaptivedelay`, which inspects entities in a delay breach and, when the conditions are met, updates the delay threshold and records an audit trail.

The more history TrackMe has for an entity, the more accurate the computed threshold.

Important

When the AI **Feed Lifecycle Advisor** covers DSM/DHM, it owns delay management and adaptive delay is **disabled** automatically (the tracker short-circuits and its tenant toggle is forced off). See *Who manages a threshold: the Threshold Lock and the AI Advisor*.

How a run works

The adaptive-delay tracker runs **every 20 minutes** by default, as a **per-entity batch under a runtime budget** (900 seconds by default, never more than the schedule interval — see *batches under a runtime budget*). Each occurrence selects the entities that need review, processes as many as the budget allows, and resumes with the rest on the following cycle — so on a large tenant a multi-minute run simply means a large batch, not a stuck search.

Adaptive delay is also **self-limiting by design**: an entity only enters the review bucket when it is actually in a delay-breaching state, and it is further gated by the entity's SLA compliance — entities comfortably within SLA are skipped. The cost therefore scales with how much of the estate is *unstable*: the cleaner and more stable the environment, the fewer entities adaptive delay has to review.

How an entity is selected

Each run, an entity becomes a candidate only if **all** of these hold — otherwise it is skipped:

```
enabled  and  currently red
  └─ in a delay breach (delay_threshold_breached)
       └─ threshold UNLOCKED                  ── locked? → skip (your pinned value␣
↪stands)
            └─ current delay ≥ min_delay_sec  (3600 s by default)
```

(continues on next page)

(continued from previous page)

```
                └─ AI Feed Lifecycle Advisor not covering DSM/DHM
                                                  ── advisor covers? → skip (it owns␣
↪delay)
                     └─ ✓ candidate → compute & update the threshold
```

(See *Who manages a threshold: the Threshold Lock and the AI Advisor* for the lock and the AI Advisor gate.)

It also reviews entities it has already managed: an entity updated in the last 4 hours is left to settle; one updated 4–24 hours ago whose threshold was *increased* is re-checked; and beyond that, managed entities are reviewed on a rolling 7-, 15- or 30-day cadence (`review_period_no_days`) so a feed that has stabilised can have its threshold tightened back down.

How the threshold is computed

For a selected entity, TrackMe models the observed lag metric (`trackme.splk.feeds.lag_event_sec`) with its **native ML engine** (`trackmefit` — no Splunk MLTK dependency) to find an upper bound on normal lag, then rounds to the nearest hour and adds a one-hour safety buffer (the variable-delay path rounds up instead). In essence:

```
| mstats latest(trackme.splk.feeds.lag_event_sec) as lag_event_sec
    where `trackme_metrics_idx(mytenant)` tenant_id="mytenant"
    object_category="splk-dsm" object="myobject" by object span=5m
| trackmefit ...                          ``` native ML upper-bound on normal lag ```
| eval adaptive_delay = (round(UpperBound/3600, 0) * 3600) + 3600
```

When **re-reviewing** an entity after an earlier update, TrackMe runs the same logic over three windows — last 24 hours, 7 days and 30 days — and aggregates them, which lets it react faster when a feed returns to stability after an interruption rather than waiting for the long window to catch up. Every search and its result are logged.

Tracker arguments

The behaviour is tuned with per-tracker arguments (edit them in the tracker configuration):

Argument	Default	Effect
`min_delay_sec`	`3600`	Minimum current delay (seconds) for an entity to be considered.
`max_auto_delay_sec`	`604800`	Cap on the value the engine may set; a higher computed value is clamped to this (the entity then stays under review).
`max_changes_past_7days`	`10`	Maximum updates per entity in a rolling 7 days; once reached, the entity is left alone until the counter resets.
`min_historical_metrics_day`	`7`	Minimum days of accumulated metrics before the threshold may be updated.
`review_period_no_days`	`30`	Re-review window for already-managed entities (`7`, `15` or `30`).
`max_sla_percentage`	`100`	Skip entities whose current SLA % is at or above this — protecting a stable entity hit by a genuine one-off anomaly from being widened (defaults effectively to 90%).

Automatic updates and audit

When the command updates a threshold it writes an audit record (context: *automated adaptive delay update*). Review them with:

```
`trackme_audit_idx` tenant_id=* "automated adaptive delay update"
| table _time, tenant_id, object_category, object, action, comment
| sort - 0 _time | trackmeprettyjson fields=comment
```

A dedicated dashboard, **TrackMe - Adaptive delay threshold audit**, is available under **Audit & Troubleshoot**.

Automated summary notes

When the framework updates an entity's threshold, it also attaches a **Markdown summary note** to that entity (author `trackmesplkadaptivedelay`), making the change self-documenting. The note records the change **direction**, the **previous and new** values (as a duration and in seconds, e.g. *1h (3600s) → 4h (14400s)*), a short **reason**, and a **reasoning table** (95th-percentile, max and standard deviation of the observed lag plus the ML upper bound, per window), and flags when the value was capped at `max_auto_delay_sec`.

Find it under **Tenant Home → the entity → Notes**, or in the entity's **Audit changes** tab. Notes are controlled per tenant by the `adaptive_delay_notes` setting (*Feature Behavior*, enabled by default); a note is created only when a threshold actually changes, and note creation never blocks the update itself.

Activity logs

The tracker logs every entity it considered and the action taken:

```
index=_internal sourcetype=trackme:custom_commands:trackmesplkadaptivedelay␣
↪object="myobject"
```

Opting an entity or tenant out

To stop adaptive delay managing a **single entity**, **lock** its threshold (see *Who manages a threshold: the Threshold Lock and the AI Advisor*) — the lock pins your value and excludes the entity from automatic management. To disable adaptive delay for a **whole tenant**, turn off **Adaptive delay (auto-tune thresholds)** (`adaptive_delay`) in the tenant menu → **Configure tenant** → **Feeds & delays** (see *Configuring a tenant*). The toggle is locked while the AI Feed Lifecycle Advisor manages DSM/DHM on the tenant.

Disabling it at the tenant level also takes the backend off the Splunk scheduler: the tenant's health tracker **unschedules the adaptive-delay tracker** on its next cycle (and the tracker short-circuits at runtime in any case). The only effect is that thresholds are no longer auto-reviewed — they simply hold their current values, or whatever your policies and manual settings define. Adaptive delay is a convenience feature, valuable but entirely optional, which makes it the classic first lever in a *footprint review*.

Variable adaptive delay

Adaptive delay is no longer limited to the static policy — for an entity on the *variable delay* policy, the same `trackmesplkadaptivedelay` tracker (same `adaptive_delay` tenant setting, same per-entity management) also keeps the **slot thresholds** current. It **recomputes each slot's** `max_delay_allowed` **and the fallback** `variable_delay_default` from history, while **preserving your slot layout** — the slot names, days and hours you defined are kept; only the threshold values are refreshed.

This is different from the variable-delay *auto-review* reviewer (`trackmesplkvariabledelayreview`), which *regenerates* the slot layout. The two are independently opt-in and can both apply to a variable entity:

Mechanism	Opt-in	What it changes
Variable adaptive delay	`adaptive_delay` + entity managed (unlocked)	Refreshes per-slot thresholds + the default; **keeps your slot names/days/hours**.
Variable-delay auto-review	`variable_delay_auto_review_ena`	**Regenerates** the slot layout (`auto_slot_N`) when patterns shift.

A **locked** entity (*Threshold Lock*) is skipped by both, and its pinned slot schedule is restored if it ever drifts.

See also

- *Delay & latency thresholds* — manual thresholds and the Threshold Lock.
- *Variable delay* — time-aware thresholds.
- *Artificial Intelligence in TrackMe* — the AI Feed Lifecycle Advisor that supersedes this when enabled.

Variable delay

Variable delay lets an entity's delay threshold change by **day of the week** and **hour of the day**, instead of using one value around the clock. It solves a common problem: feeds have natural rhythms — a business application produces data through weekday office hours but little overnight or at weekends. A single static threshold must be loose enough for the quiet periods, which makes it too forgiving when the feed is busy. Variable delay fixes this by letting you define **named time slots**, each with its own threshold.

Variable delay applies to **splk-dsm** and **splk-dhm**.

Static vs variable delay

Aspect	Static (default)	Variable
Threshold	One fixed value at all times	Multiple values that change by day-of-week and hour-of-day
Configuration	A single number per entity	Named slots (days, hours, threshold) + a fallback default
Quiet periods	Must keep the value loose, reducing sensitivity when busy	Relax overnight/weekends, tighten during business hours
Anomaly reason	`delay_threshold_breached`	`variable_delay_threshold_breached`
Entity field	`variable_delay_policy="static"`	`variable_delay_policy="variable"`

Setting the tenant default

The **default** delay policy for new entities is set per tenant, separately for DSM and DHM — both at tenant creation (static, or variable with slot definitions) and afterwards from tenant management.

Setting variable delay on an entity

Per entity, variable delay is configured from the entity's lagging policy / variable-delay modal.

How slots work

Each slot specifies a **name**, the **days** it covers (`0` = Monday … `6` = Sunday), the **hours** it covers (`0–23`), and the **max delay allowed** (seconds). Evaluation is **first match wins**: slots are checked in order, the first whose day and hour match the current time is used, and if none match, the **fallback default** threshold applies.

```
{
  "slots": [
    {
      "slot_name": "business_hours",
      "days": [0, 1, 2, 3, 4],
      "hours": [8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19],
      "max_delay_allowed": 3600
    },
    {
      "slot_name": "weekends",
      "days": [5, 6],
```

(continues on next page)

(continued from previous page)

```
      "hours": [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18,␣
↪19, 20, 21, 22, 23],
      "max_delay_allowed": 86400
    }
  ]
}
```

Here weekday business hours allow 1 hour of delay, weekends allow 24 hours, and weekday nights fall through to the default. The UI ships **presets** — *business hours*, *weekday/weekend*, and a three-tier *business hours / nights / weekends* — for quick setup.

Auto-computation from history

TrackMe can propose slots from an entity's own history, using `trackme.splk.feeds.lag_event_sec`: it buckets 5-minute metrics by day-of-week × hour-of-day, applies a statistical function (`perc95` by default, or `perc99`), rounds each window up to the next hour plus a one-hour buffer (minimum 3600 s), groups adjacent hours with the same value into named slots, and applies a safety cap (default 604800 s = 7 days).

Auto-review

An optional review process keeps slots current as patterns shift. A scheduled report per tenant per component (DSM, DHM) runs daily — `trackmesplkvariabledelayreview` — recomputing thresholds from history and updating slots **only** when the largest deviation exceeds a configurable threshold (default **20%**). It can be enabled at the tenant level and per entity.

```
index=_internal sourcetype=trackme:custom_commands:trackmesplkvariabledelayreview
```

Note

The periodic reviewer regenerates slot layouts (`auto_slot_N`); the operator "honour" strategy and the adaptive-delay branch preserve your slot names.

Important

When the AI **Feed Lifecycle Advisor** covers DSM/DHM, variable-delay **auto-review** is disabled automatically (and does not auto-re-enable when the advisor is turned off). See *Who manages a threshold: the Threshold Lock and the AI Advisor*.

Interactions with other features

- **Adaptive delay.** Variable delay and *adaptive delay* are no longer mutually exclusive — adaptive delay also keeps variable-delay slot thresholds refreshed. Whether either mechanism may touch a given entity is governed by the *Threshold Lock*.
- **Lagging classes.** A *lagging class* can itself carry a variable-delay schedule; and a class's **latency** override still applies independently of the delay policy.
- **Monitoring time policy.** Independent — the monitoring policy controls *whether* an entity is monitored; variable delay controls *which threshold* applies when it is.
- **Bulk edit.** Variable delay can be applied to many entities at once from the bulk-edit actions.
- **Upgrades.** Existing entities default to `variable_delay_policy="static"` with no variable-delay record, so behaviour is unchanged until you opt in.

- *Adaptive delay (ML)* — ML-maintained delay thresholds.
- *Lagging classes* — rule-based thresholds, which can carry slots too.

8.3.5 Expected sources & hosts — in depth

Tip

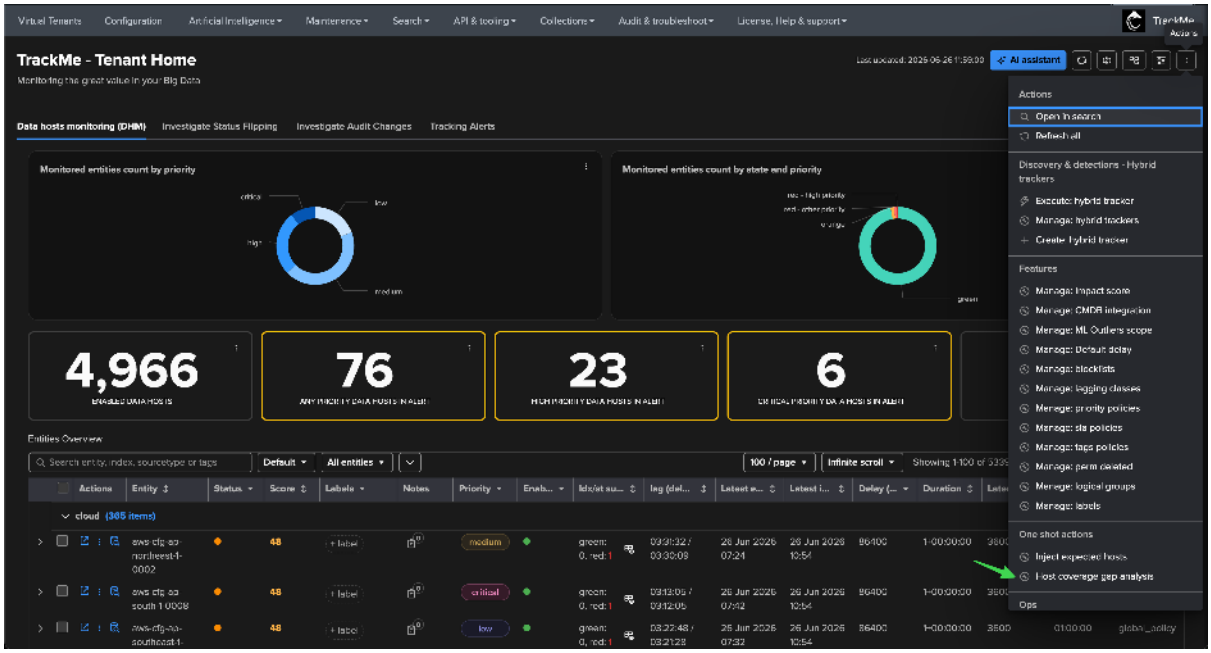
This is the **in-depth reference** for injecting *expected* data sources (DSM) and hosts (DHM) so TrackMe alerts on entities that have **stopped** sending — even ones it never auto-discovered. For the component basics, see *Data source monitoring* and *Data host monitoring*. This page covers **coverage gap analysis**, the guided injection wizard, the `trackmepushdatasource` command, entity-key formats, and the recurring-import mechanics.

Inject expected data sources or hosts from a Splunk lookup — with a guided wizard, simulation preview, and optional recurring schedule

- This guide walks you through the **Inject Expected Sources / Hosts** wizard, available directly from the Tenant Home actions menu.
- Use this feature to manually insert entities into TrackMe that have not yet been discovered, based on a CMDB, asset inventory, or any Splunk lookup table.
- When injected, these entities are added as if they were discovered by TrackMe under normal circumstances.
- If these entities are not yet sending data to Splunk, they will appear in a **red** state. As soon as real data arrives and the trackers run, the entities will be updated and their status will reflect the actual health of the data.
- The wizard supports both **one-shot injection** and **recurring scheduled imports**, so new entries added to the lookup over time are automatically picked up.
- Supported for **Data Source Monitoring (DSM)** and **Data Host Monitoring (DHM)**.
- This feature requires **TrackMe 2.3.19** or higher.

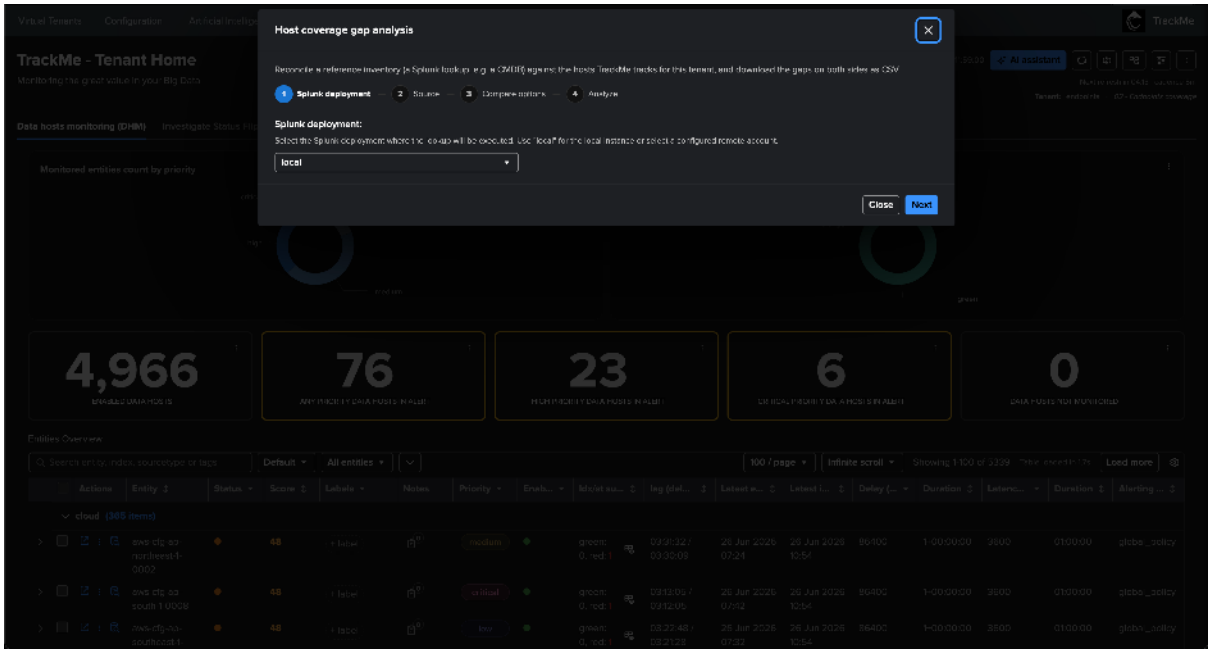
Coverage gap analysis

Before you inject anything, **coverage gap analysis** tells you *what* is missing. It is a **read-only** reconciliation of a **reference inventory** — a Splunk lookup such as a CMDB or asset table — against the entities TrackMe actually tracks for the tenant, returning the gaps on **both** sides as downloadable CSVs. Open it from the Tenant Home **three-dot menu → Ops**: **Host coverage gap analysis** (DHM) or **Data source coverage gap analysis** (DSM).

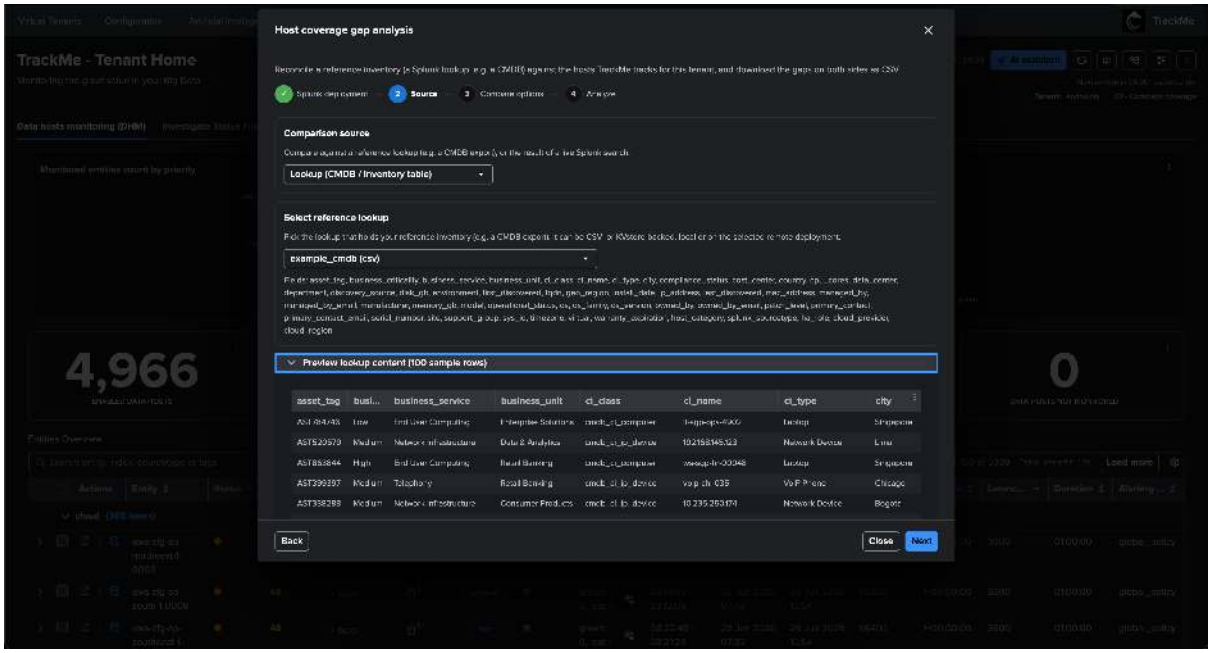


It runs as a four-step wizard.

Step 1 — Splunk deployment. Choose where the reference lookup lives: the local instance, or a configured remote account.

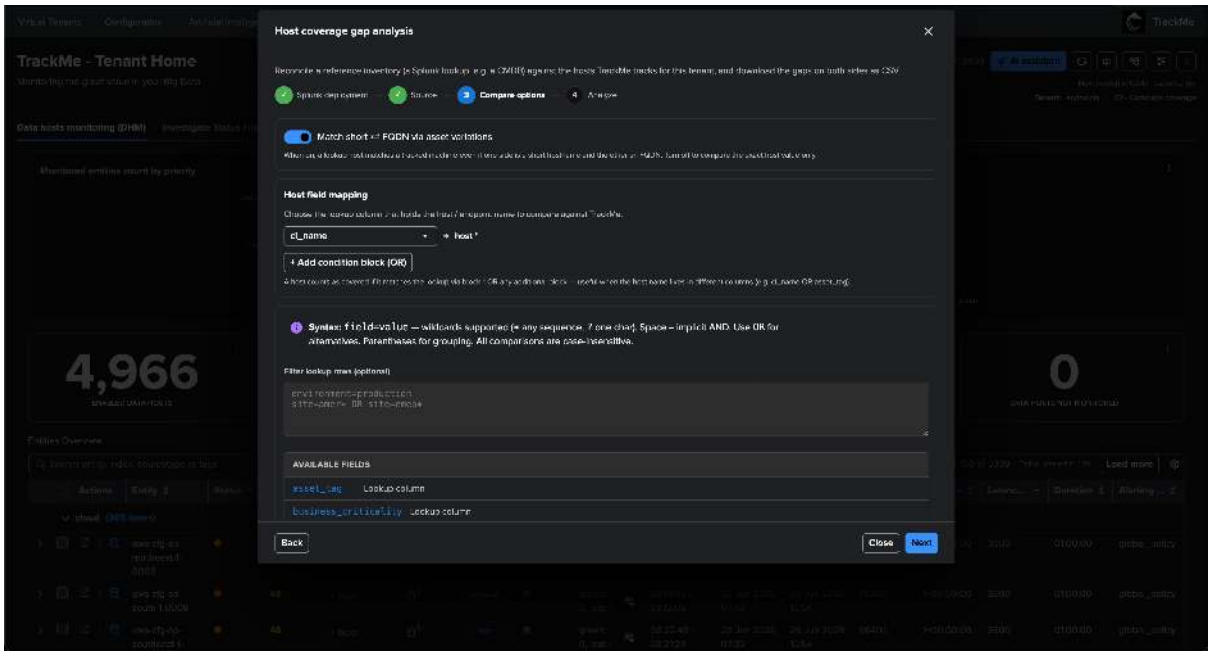


Step 2 — Source. Pick the comparison source — a reference **lookup** (CMDB / inventory table) or the result of a live Splunk search — and the wizard previews its content so you can confirm the right table and columns.



Step 3 — Compare options. Decide how a reference row is matched to a tracked entity:

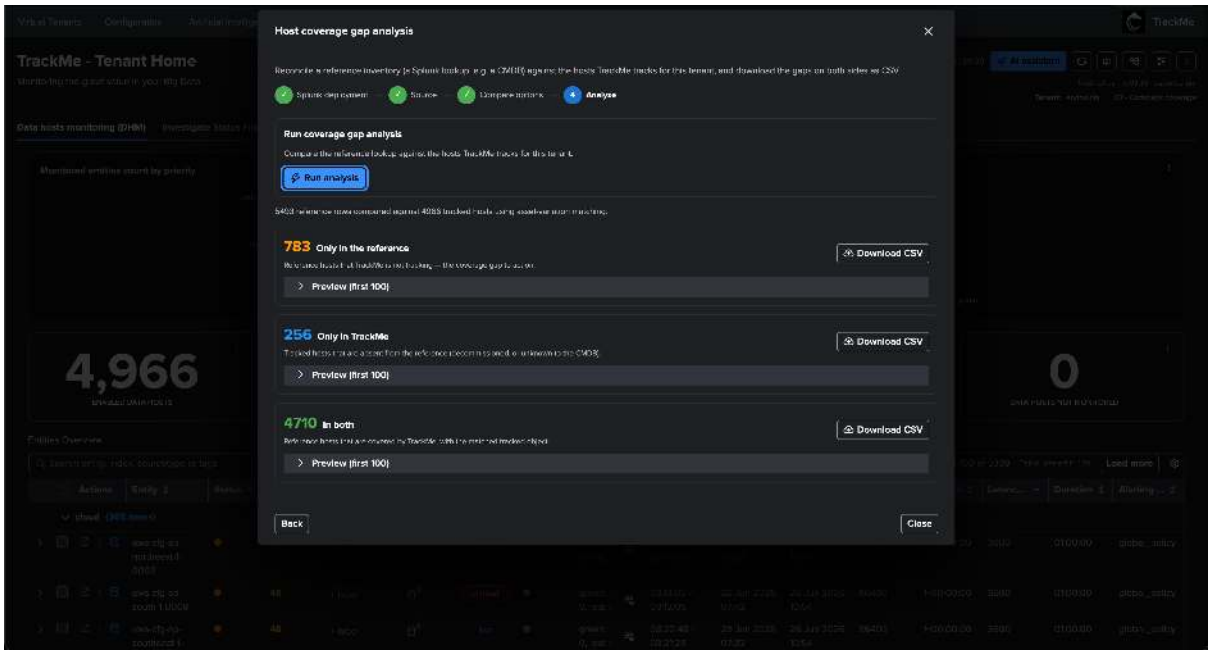
- **Match short ↔ FQDN via asset variations** *(DHM)* — when on, a short hostname matches its FQDN form (and vice-versa); turn it off to compare the exact host value only.
- **Host field mapping** — choose the lookup column that holds the host / endpoint name. Add an **OR condition block** when the name can live in more than one column (for example `ci_name` OR `asset_tag`). *(For DSM you map the index and sourcetype columns instead.)*
- **Filter lookup rows** *(optional)* — restrict the reference with a simple expression: `field=value`, wildcards `*` (any sequence) and `?` (one character), space = implicit AND, `OR` for alternatives, parentheses for grouping; all comparisons are case-insensitive — e.g. `environment=production site=ams* OR site=emea*`.



Step 4 — Analyze. Run the analysis. TrackMe compares the reference rows against the tracked entities and returns three buckets, each previewable and downloadable as CSV:

- **Only in the reference** — entities in your inventory that TrackMe is **not** tracking: the coverage gap to act on.
- **Only in TrackMe** — tracked entities **absent** from the reference (decommissioned, or unknown to the CMDB).

- **In both** — covered entities, with the matched tracked object.



Tip

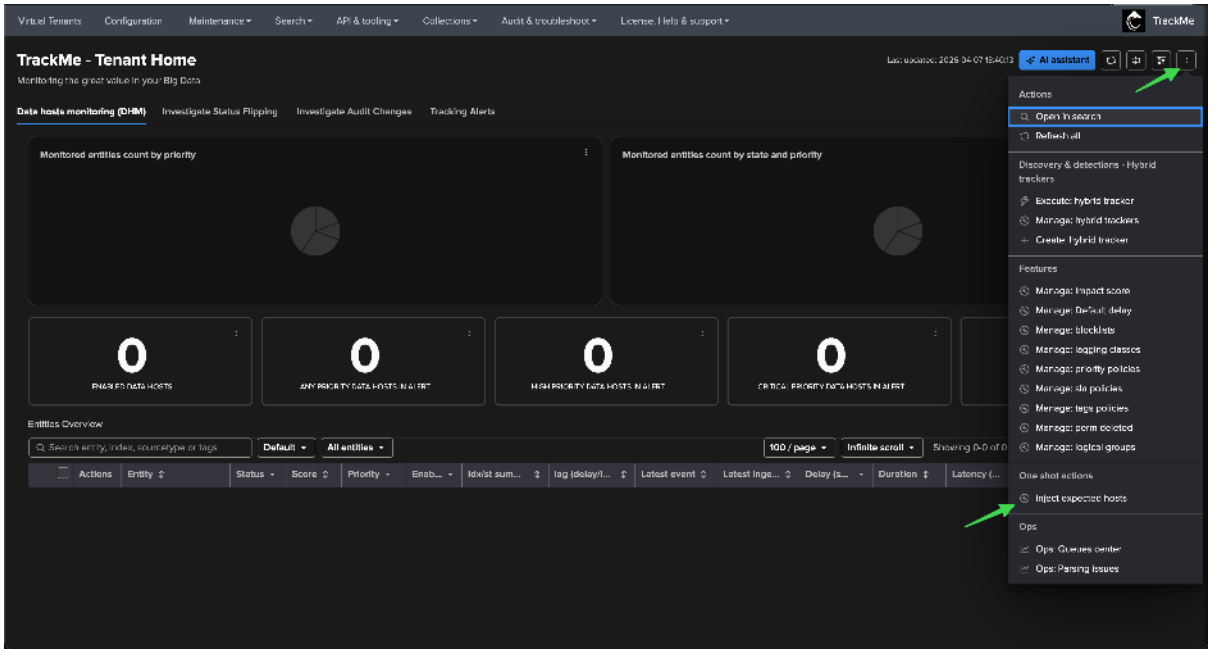
Gap analysis and injection are a pair: run the analysis to find the **Only in the reference** set, then inject those expected entities (below) to start monitoring them and close the gap.

Injecting expected data hosts (DHM)

In this example, we inject 400 expected hosts from a lookup into a DHM tenant. The lookup contains a `host` field with the hostnames we expect to see in Splunk.

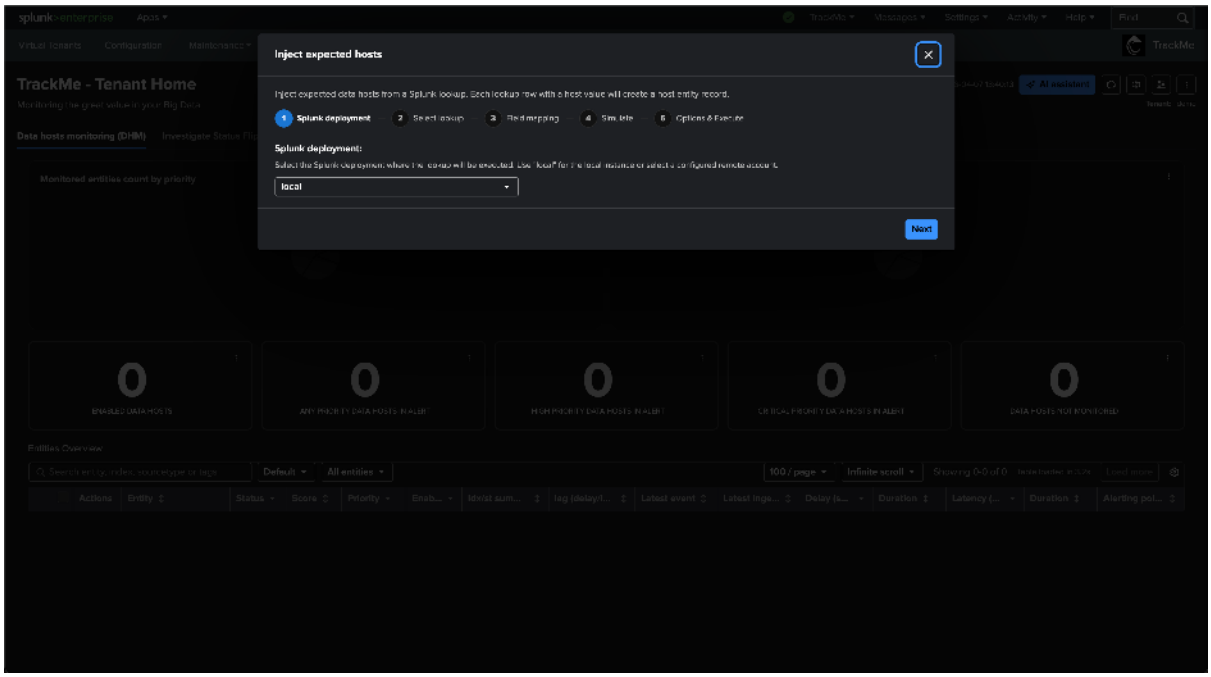
Step 1 — Open the wizard

From the Tenant Home for a DHM tenant, click the **three-dot menu** (top-right) and select **Inject expected hosts** under the **One shot actions** section:



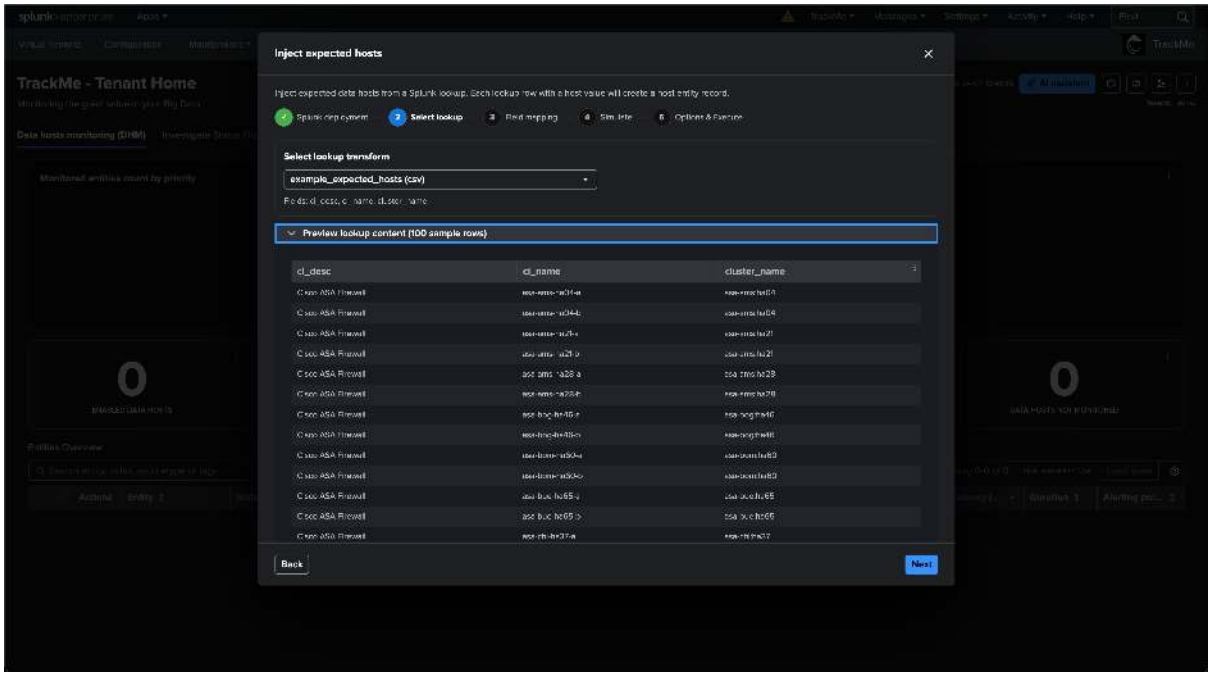
Step 2 — Select the Splunk deployment

The wizard opens. The first step lets you choose the Splunk deployment where the lookup resides. Select **local** for the local instance, or pick a configured **remote account** if the lookup lives on a different Splunk deployment:



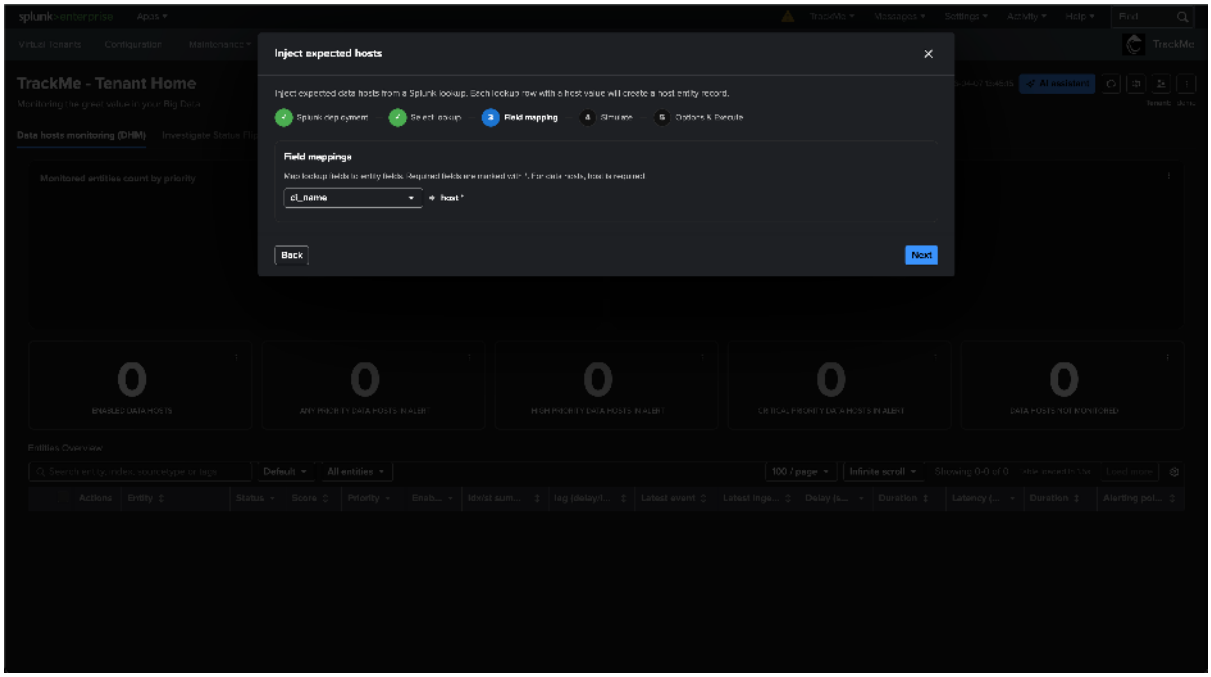
Step 3 — Select the lookup and preview its content

Select the lookup transform from the dropdown. The wizard loads the lookup fields and displays a **preview table** showing sample rows, so you can verify the content before proceeding:



Step 4 — Map lookup fields to entity fields

Map the lookup fields to the required entity fields. For DHM, the **host** field is required. The wizard auto-detects matching field names — if your lookup has a column called `host`, it will be pre-selected automatically:

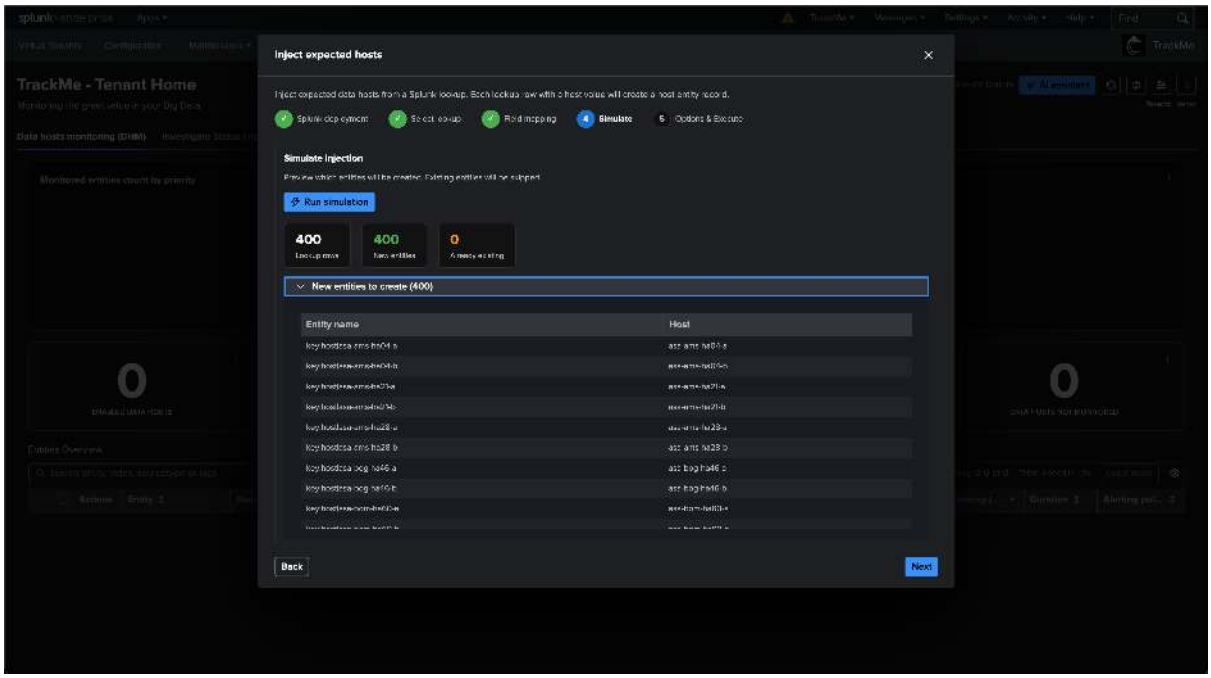


Step 5 — Simulate the injection

Before executing, run a **simulation** to preview exactly what will happen. The simulation checks each row against the existing KV store and reports:

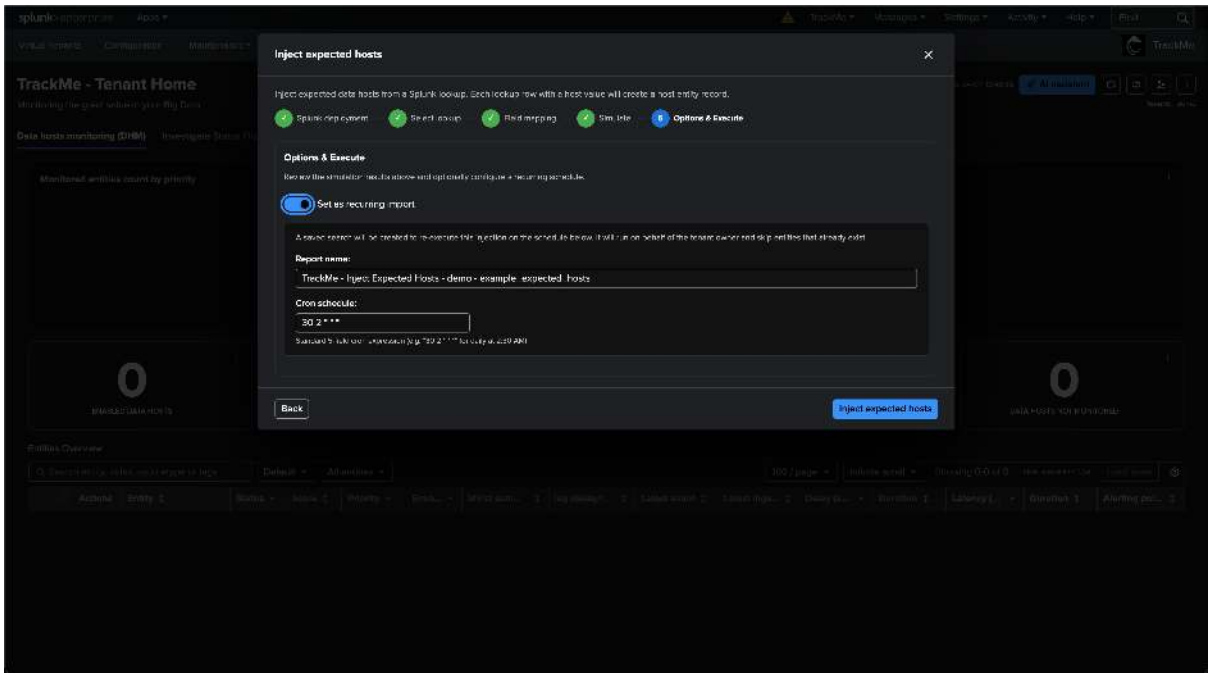
- **Lookup rows** — total rows in the lookup
- **New entities** — entities that will be created (not yet in TrackMe)
- **Already existing** — entities that already exist and will be skipped

A collapsible table shows the full list of new entities to be created, with their object name and host value:

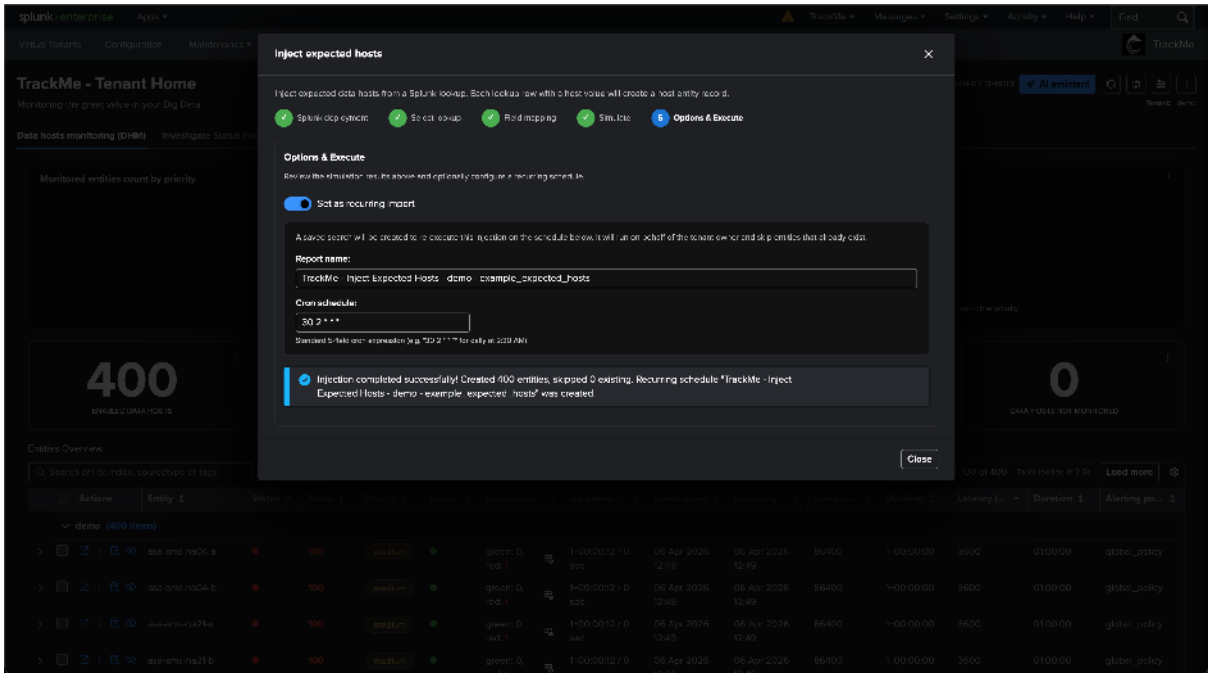


Step 6 — Configure options and execute

The final step lets you optionally enable a **recurring import** before executing. When toggled on, a saved search is created to re-execute the injection on the configured schedule. You can customize both the **report name** and the **cron schedule**:

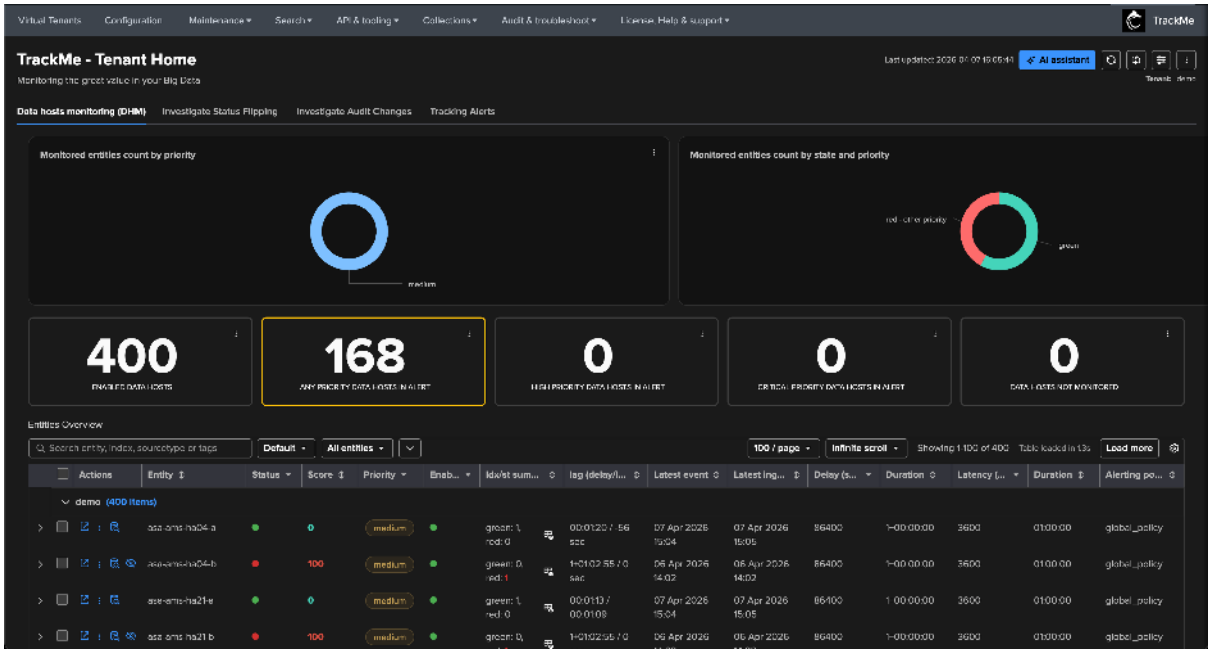


Click **Inject expected hosts** to execute. The wizard reports the results — entities created, entities skipped, and whether the recurring schedule was created:



Result — Entities visible in Tenant Home

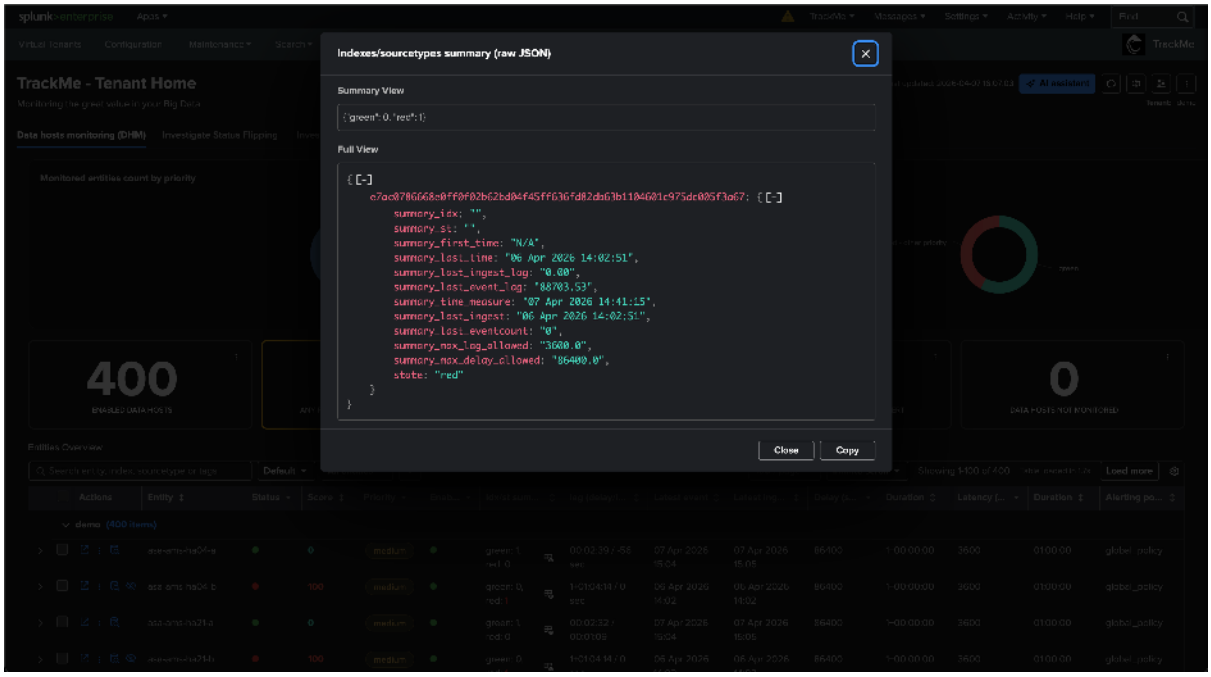
After closing the wizard and refreshing, the 400 injected hosts are now visible in the Tenant Home. Entities that are not yet actively sending data to Splunk appear in a **red** state, which is expected:



Hint

For DHM entities, the index and sourcetype fields will initially appear empty for hosts that have not yet sent data to Splunk. This is normal — once real data arrives and the DHM tracker runs, these fields are automatically populated and the empty placeholders are cleaned up.

Clicking on an entity that has not yet sent data shows the indexes/sourcetypes summary with empty placeholder values. Once the host starts sending data, these values are automatically replaced with the real indexes and sourcetypes:



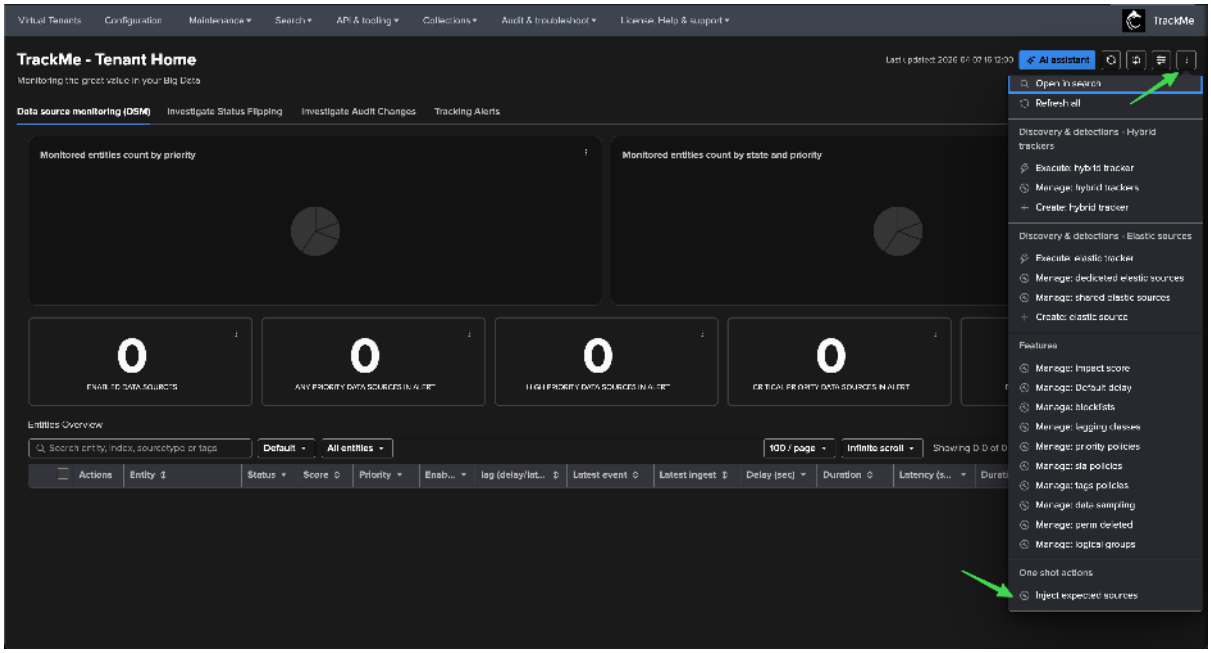
As soon as trackers are executed and the hosts start sending data to Splunk, the entities will transition to a **green** state and their metrics will be fully populated.

Injecting expected data sources (DSM)

The process for data sources is very similar, with the key difference that DSM requires both an **index** and a **sourcetype** field from the lookup.

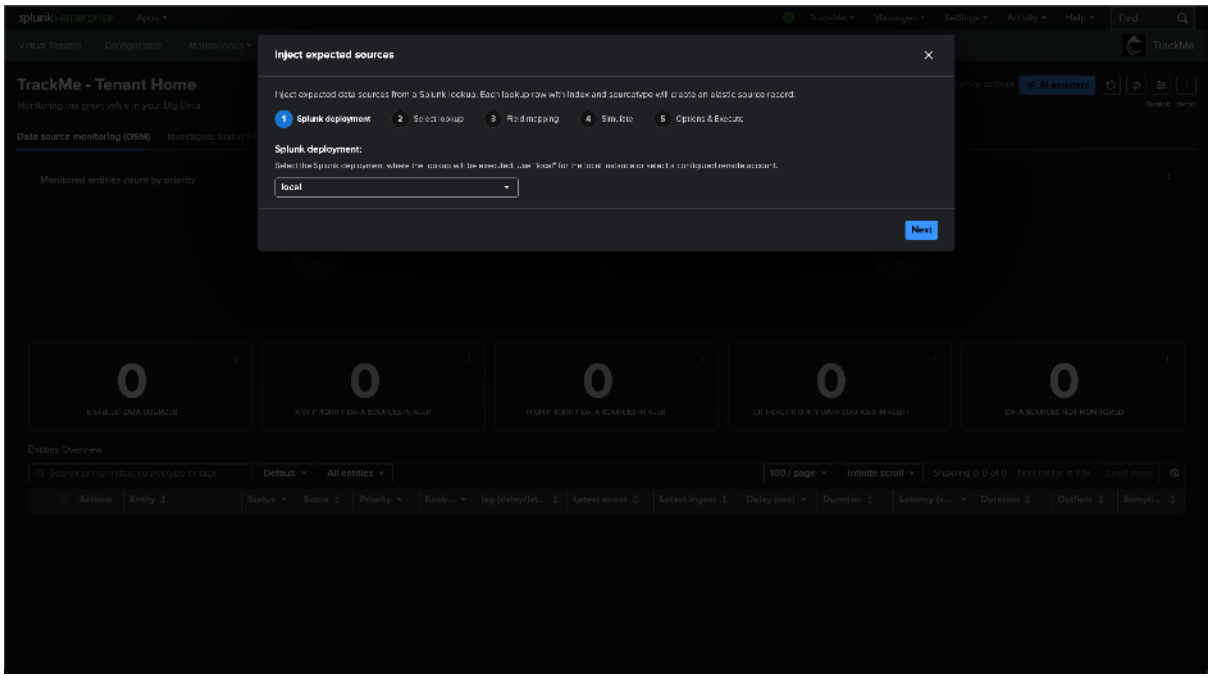
Open the wizard (DSM)

From the Tenant Home for a DSM tenant, click the **three-dot menu** and select **Inject expected sources** under the **One shot actions** section:



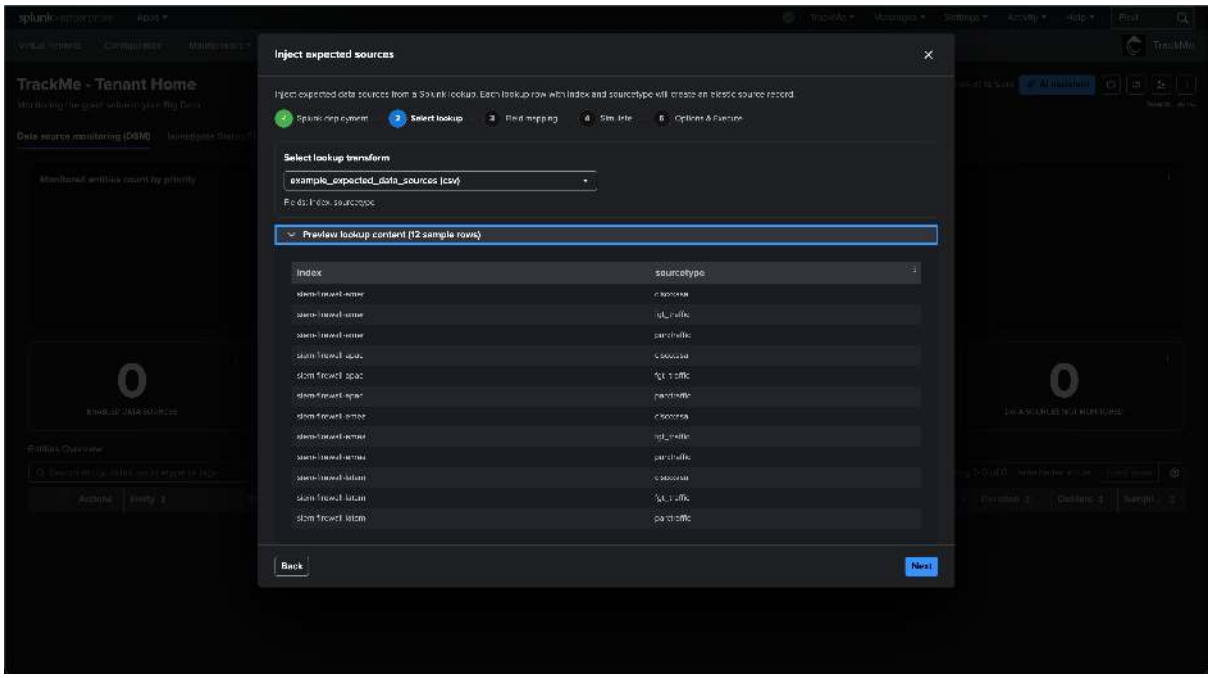
Select the Splunk deployment (DSM)

Choose the Splunk deployment where the lookup resides:



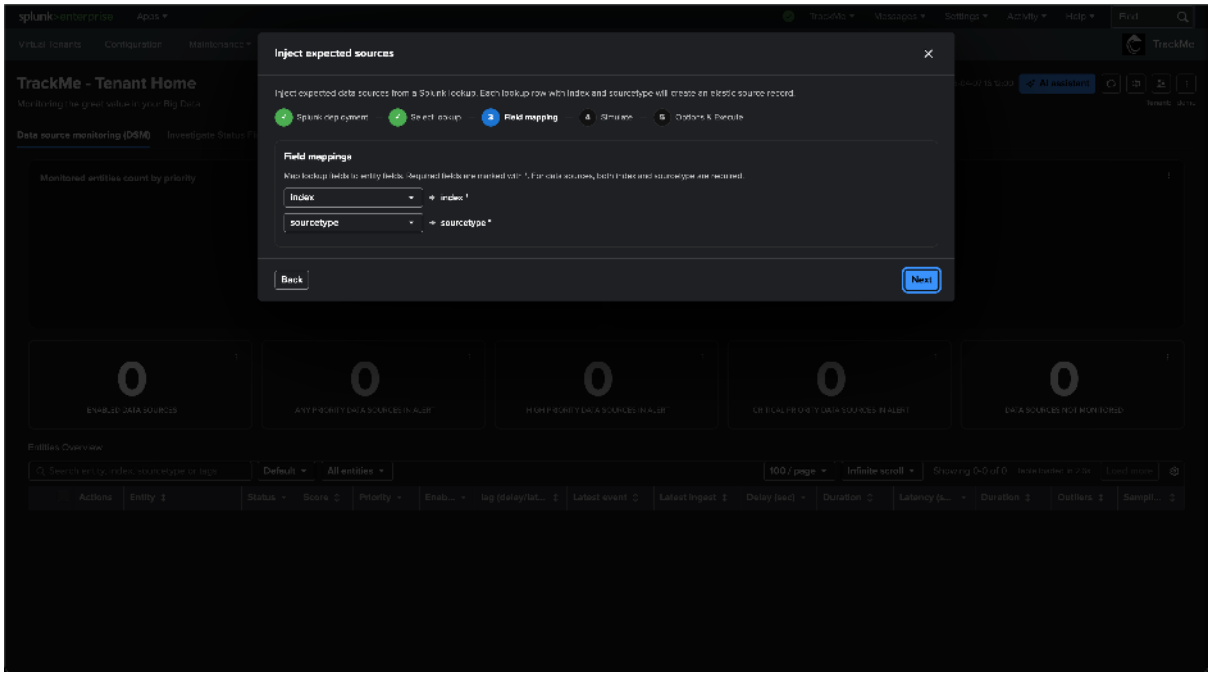
Select the lookup and preview (DSM)

Select the lookup transform. The preview table shows the index and sourcetype columns from the lookup:



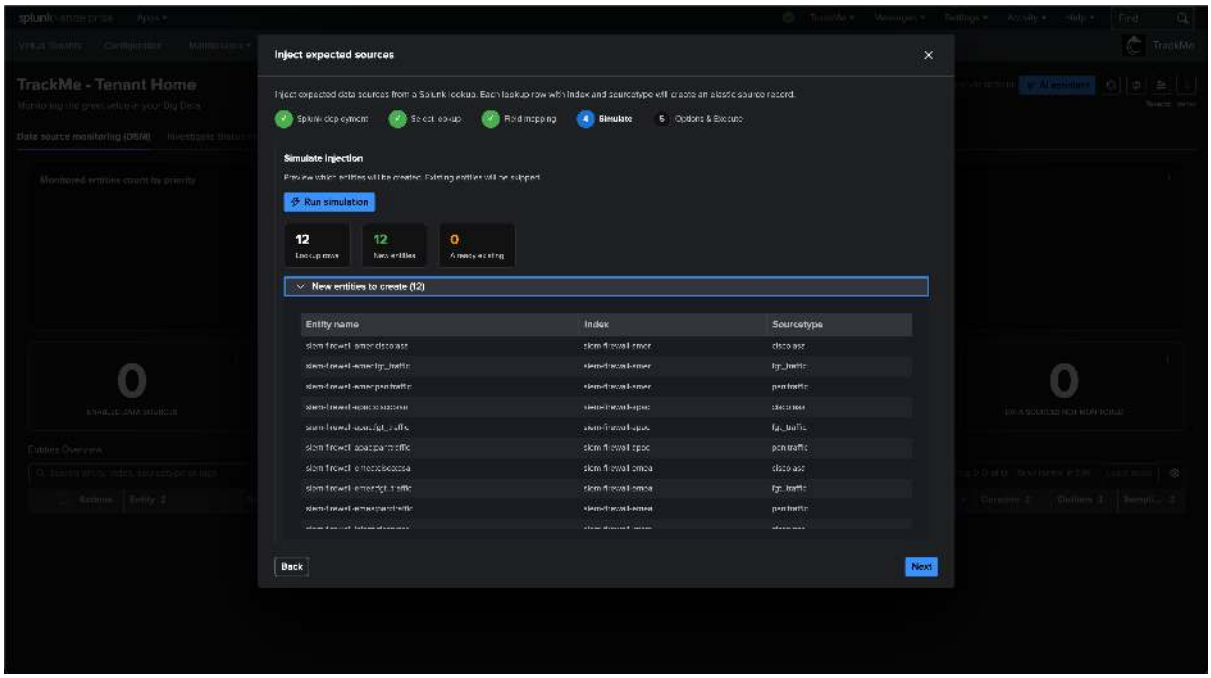
Map lookup fields (DSM)

For DSM, both **index** and **sourcetype** mappings are required. The wizard auto-detects matching field names:



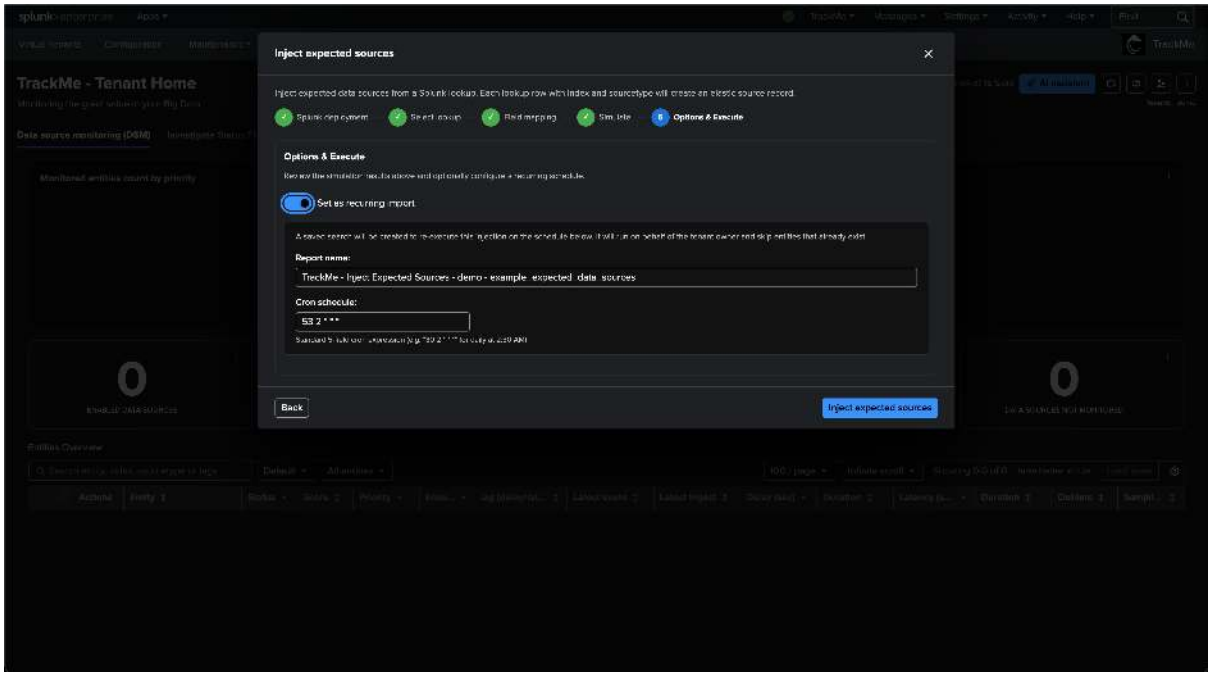
Simulate the injection (DSM)

Run the simulation to preview the results. In this example, 12 new data source entities will be created:

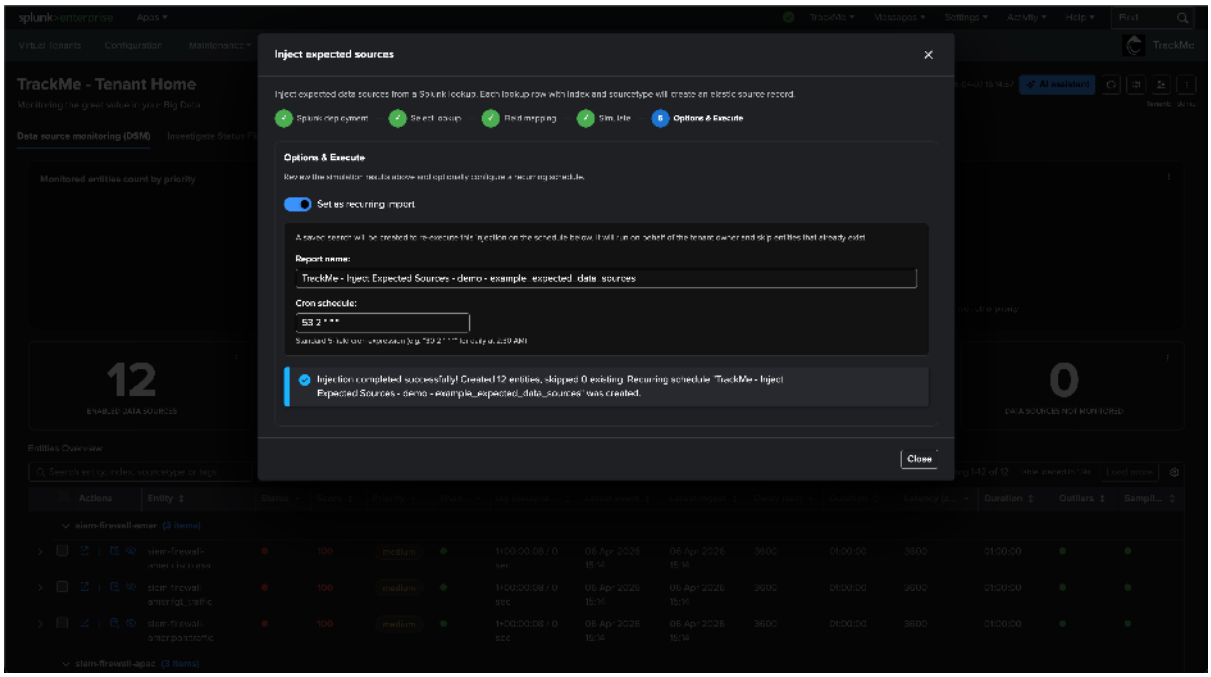


Configure options and execute (DSM)

Enable the recurring import if desired, customize the report name and cron schedule, then click **Inject expected sources**:

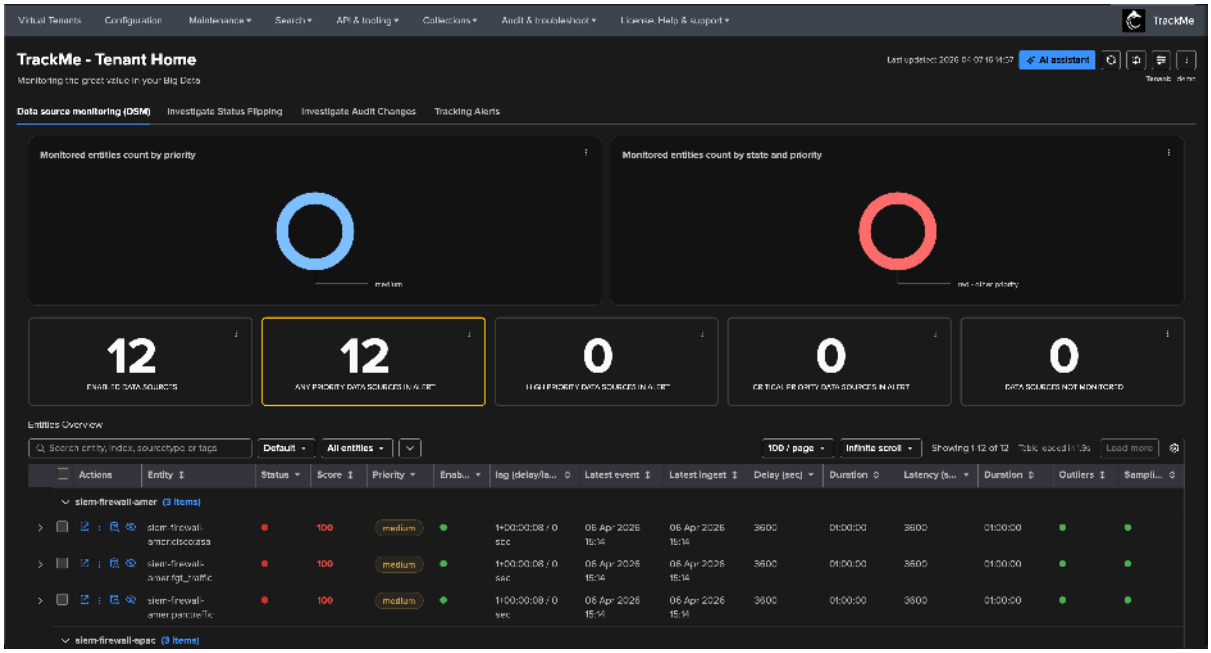


The wizard confirms the injection was successful and the recurring schedule was created:

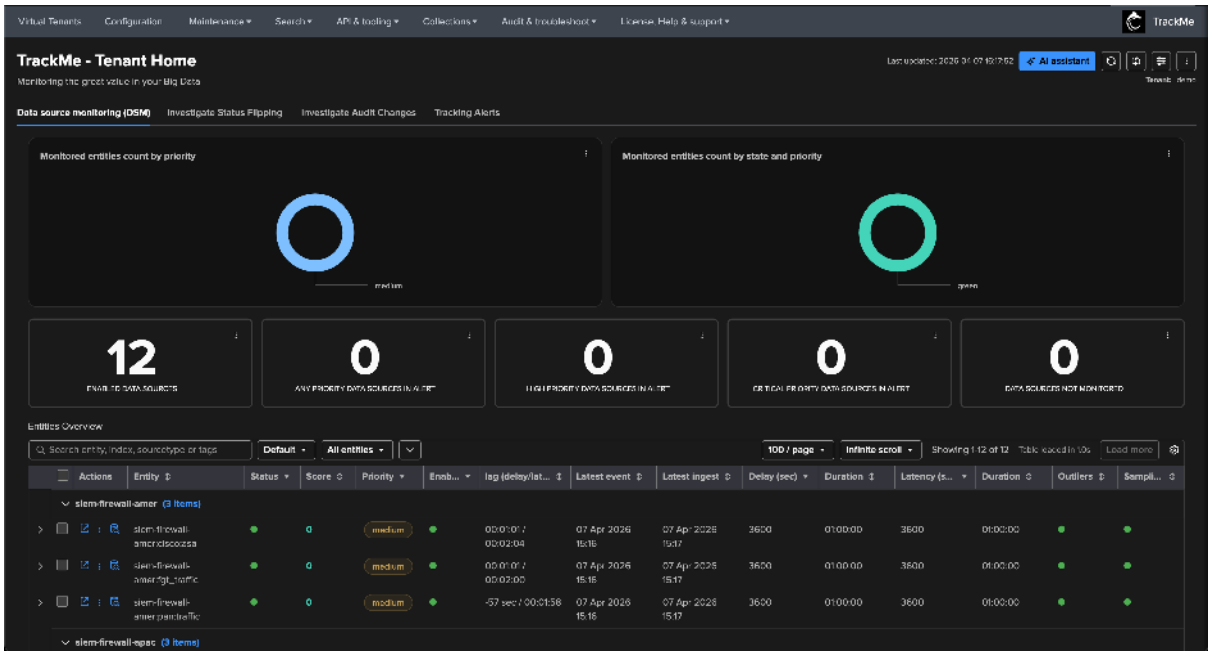


Entities visible in Tenant Home (DSM)

The 12 injected data sources are now visible in the Tenant Home. Entities not yet covered by the tracker scope appear in red:



As soon as the trackers are executed and the data sources become active within their scope, the entities transition to a **green** state:



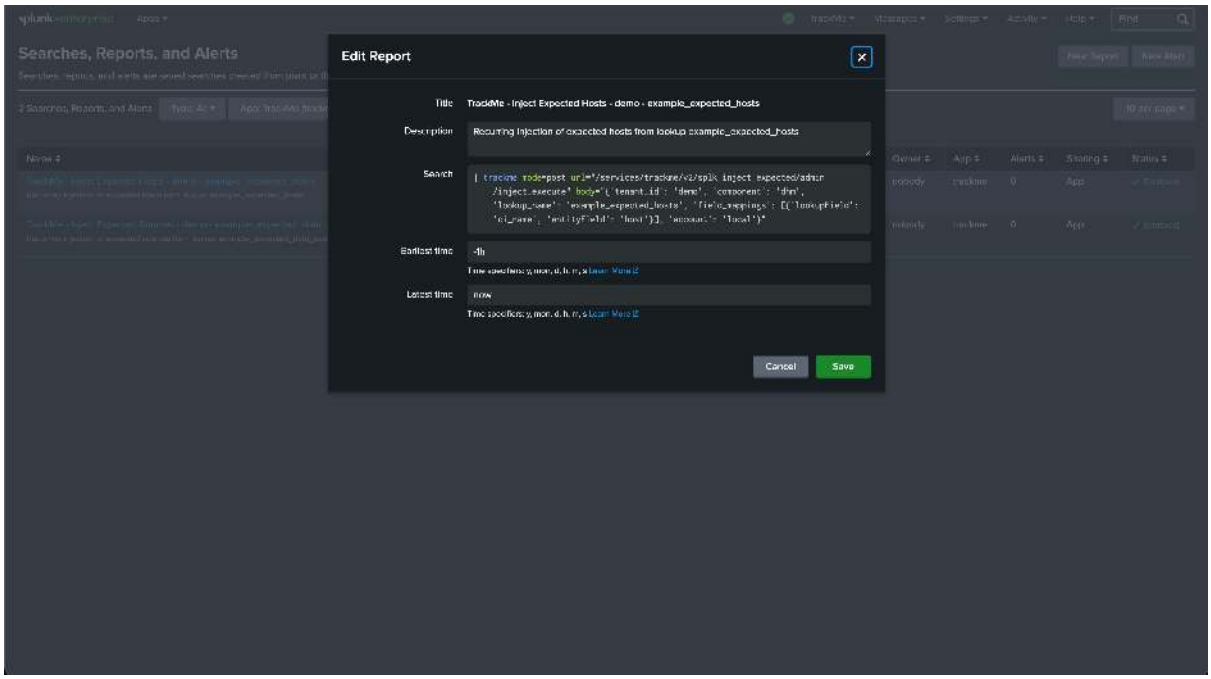
Recurring imports

When you enable **Set as recurring import** in the wizard, a Splunk saved search is created with the specified name and cron schedule. This saved search:

- Runs on behalf of the **tenant owner** (automatically re-assigned)
- Reads the lookup on each execution and injects any **new** entities not already in TrackMe
- **Skips** entities that already exist — no duplicates, no overwrites
- For recurring runs where nothing new is found, **no audit event** is recorded and no searches are executed (the pre-filter detects that all entities already exist and short-circuits)

You can also create a recurring schedule **after** the initial injection by toggling the recurring import switch and clicking **Create schedule** in the footer.

The recurring schedule can be managed from Splunk's **Settings > Searches, Reports and Alerts** page. Look for reports with the naming convention `TrackMe - Inject Expected {Sources|Hosts} - {tenant_id} - {lookup_name}`:



How it works under the hood

The inject wizard leverages the `trackmepushdatasource` streaming command, which is the same mechanism used by the TrackMe push API. This ensures injected entities are created with all required fields properly initialized — delay/latency statistics, timestamps, and other metadata that the decision maker expects.

For **DSM**, each lookup row with an index and sourcetype produces a data source entity with the format `{index}:{sourcetype}`.

For **DHM**, each lookup row with a host value produces a host entity with the format `key:host|{hostname}`. The raw hostname is stored as the entity's **alias** for display purposes.

Key behaviors

- **Existing entities are never overwritten.** The wizard checks against the KV store before injection and skips any entity that already exists.
- **Empty placeholder cleanup for DHM.** Injected hosts start with empty index/sourcetype values. Once real data is detected by the DHM tracker, these empty placeholders are automatically cleaned up — no manual intervention required.
- **Batching for large lookups.** Lookups with more than 500 entities are automatically processed in batches to stay within Splunk's SPL query length limits.
- **Remote deployment support.** The lookup can reside on a different Splunk deployment. Select the configured remote account in the first step of the wizard.

Troubleshooting

If you encounter issues with the injection, check the following logs:

Inject expected REST handler logs:

```
index=_internal sourcetype=trackme:rest_api source=
↪"*trackme_rest_api_splk_inject_expected*"
```

trackmepushdatasource command logs:

```
index=_internal sourcetype=trackme:custom_commands:trackmepushdatasource
```

Advanced usage with the trackmepushdatasource command

The inject wizard uses the `trackmepushdatasource` streaming command under the hood. For advanced use cases, you can call this command directly in SPL.

Command arguments

Argument	Required	Default	Description
tenant_id	Yes	None	The tenant identifier
component	Yes	None	The component to use (`dsm` or `dhm`)
search_type	Yes	None	The type of search to perform (`tstats` or `raw`)
show_search_query	No	False	If true, includes the search query in the summary output
show_search_results	No	False	If true, includes the search results in the summary output
pretend_latest	No	-24h	Relative time value in Splunk format for data_last_time_seen

Example — Pushing expected data sources via SPL

```
| inputlookup example_expected_data_sources.csv
| trackmepushdatasource search_type=tstats tenant_id=demo show_search_query=True␣
↪show_search_results=True pretend_latest="-24h" component="dsm"
```

Example — Pushing expected hosts via SPL

```
| inputlookup example_expected_hosts.csv
| trackmepushdatasource search_type=tstats tenant_id=demo show_search_query=True␣
↪show_search_results=True pretend_latest="-24h" component="dhm"
```

Controlling the break-by logic for DSM

For expected data sources, if the TrackMe tracker logic includes a specific break-by logic, you can submit the value for the object accordingly:

```
| inputlookup ds_expected.csv
| fields index, sourcetype, cribl_env
| eval object = index . ":" . sourcetype . ":" . "|key:cribl_env|" . cribl_env
| trackmepushdatasource search_type=tstats tenant_id=secops show_search_query=True␣
↪show_search_results=True pretend_latest="-24h" component="dsm"
```

Controlling the host metadata key for DHM

For expected hosts, you can control the metadata key for the host:

```
| inputlookup dh_expected.csv
| fields host
| eval host = "key:forwarder|" . host
| trackmepushdatasource search_type=tstats tenant_id=endpoints␣
```

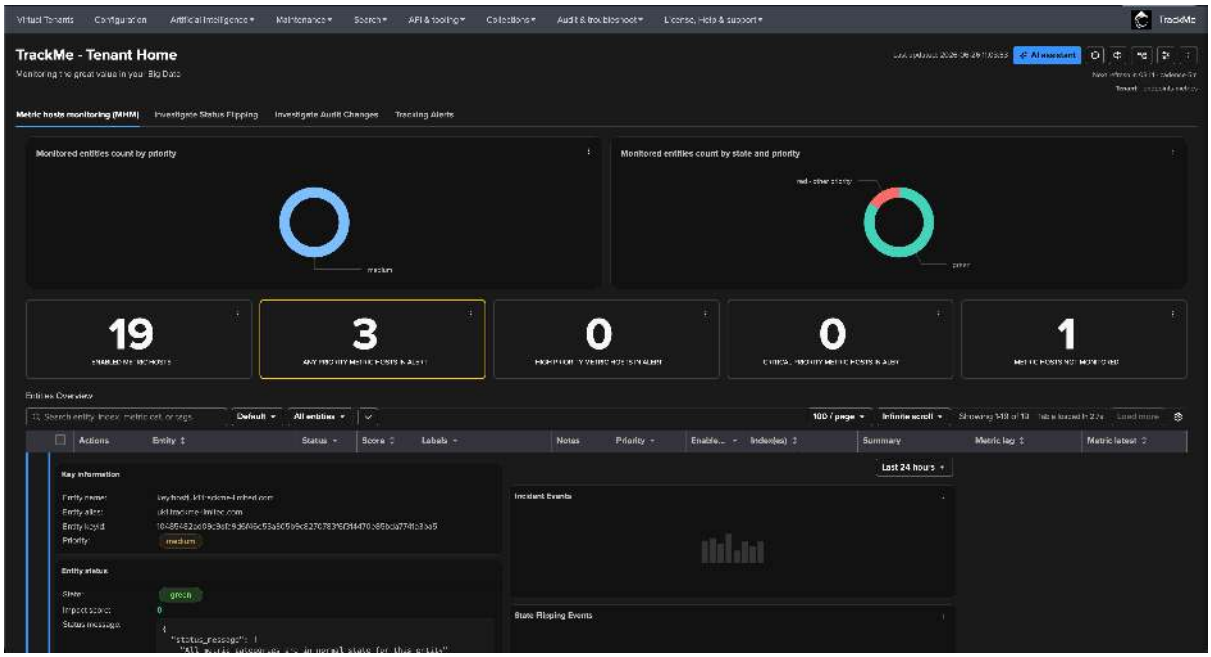
(continues on next page)

(continued from previous page)

```
↪show_search_query=True show_search_results=True pretend_latest="-24h" component=
↪"dhm"
```

8.3.6 MHM — Metric Host Monitoring

Metric Host Monitoring is the metric-index counterpart of *DHM*. It tracks **hosts sending metric data**, grouped by metric category, answering "are my metrics still arriving for every host that should be emitting them?"

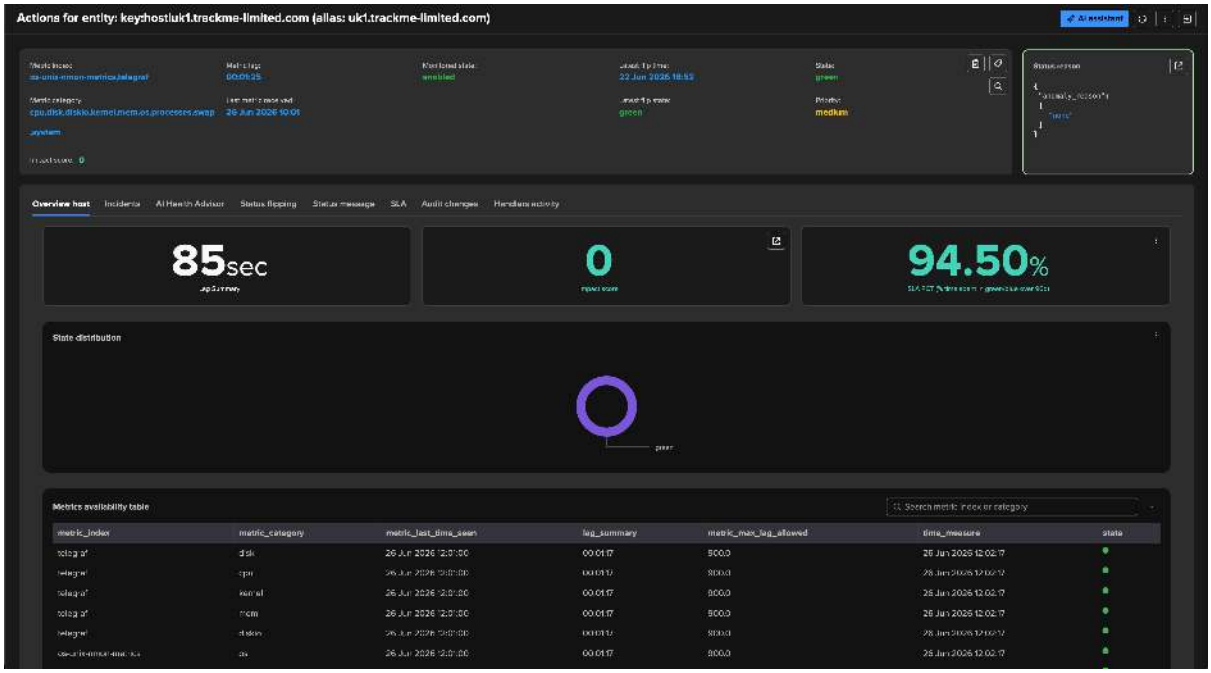


What MHM tracks

Each entity is a **host × metric category** pair (for example `os.cpu` or `os.mem`). The host is the group; its categories inherit the host's state. MHM watches:

- **Metric lag per category** — the freshness of each category.
- **Inactivity** — a host or category that has stopped sending.
- **Missing expected categories** — a host no longer emitting a category it used to.

MHM is scoped to a **metrics index** and queries it with `mstats`. The creation wizard enumerates the hosts in that index, groups their metric categories, and lets you choose which to track. A host's **Overview** tab summarises its lag, impact score and SLA, and the **metrics availability table** lists every metric category with its last-seen time, lag, and state:



How MHM differs

Important

MHM is deliberately simpler than DSM/DHM:

- **Static thresholds only** — no variable delay, no lagging classes.
- **No data sampling, no elastic sources.**
- **Outlier detection is not available** — unlike the other components, MHM does not support the native ML outlier engine at all (see *Outlier detection*).

Tip

Many infrastructure metrics report on an irregular cadence, which produces "metric lag" false positives. If a host legitimately emits a category intermittently, raise its lag threshold or disable that entity.

See also

- *DHM — Data Host Monitoring* — the event-data host-centric component.
- *Entity State & Scoring* — thresholds and scoring.
- *Classification & Protection* — priority, tags, and SLA.

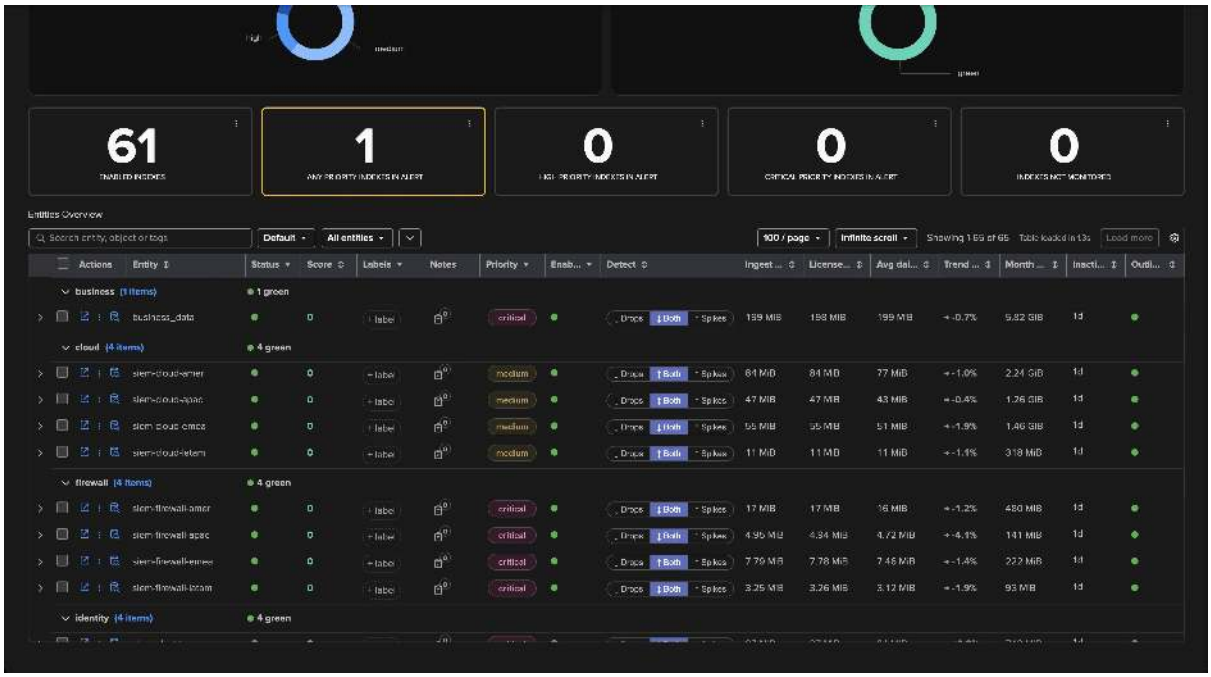
8.3.7 VOL — Volume Outliers

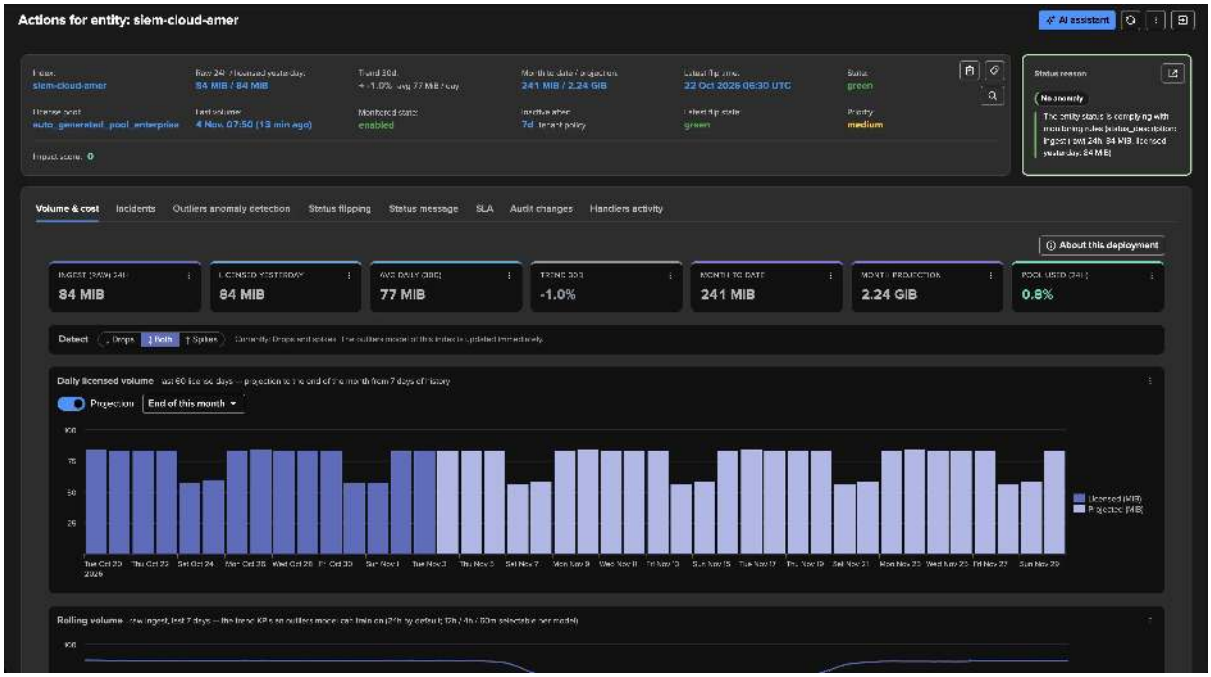
Volume Outliers tracks the **licensed volume of every Splunk index** — the volume you pay for — and answers a question the other components leave open: **is my license volume normal?** Each entity is one **index**; its state comes from **ML outlier detection** on the rolling volume (abnormal drops and / or spikes) and from **inactivity** (an index that silently stops consuming license). On top of the detection, VOL records the **daily licensed volume** per license day, a **30-day trend** and a **month projection**, per index and for the whole environment.

Where DSM watches feeds arrive on time, VOL watches *how much* arrives, from one source that is authoritative,

cheap to read and identical on every Splunk deployment: the **license usage log**. One tenant covers a whole Splunk deployment — local or remote, Splunk Enterprise or Splunk Cloud — in a few clicks, with the history **backfilled automatically**: detection and the cost trend are usable as soon as the replay completes, not weeks later.

Volume detection has always been part of TrackMe: per feed with the DSM volume models, per index with the Flex Objects license usage templates. VOL is its **standardised, first-class form at scale**: one entity per index, the licensed volume read incrementally, outliers on drops and spikes, and a purpose-built UI. It is the seventh monitoring component, next to DSM, DHM, MHM, FLX, FQM and WLK, and on top of the detection it answers the license questions people otherwise build dashboards for: who consumes, how the trend goes, how the month will end, which days went over quota, what a working day costs and which team pays for what.





What VOL tracks

Signal	What it means
Volume outliers	Each index has its own ML model on its **rolling 24-hour licensed volume** (the shorter windows — 60 min, 4 h, 12 h — can be modelled too). A value outside the learned range is a **drop** (lower bound) or a **spike** (upper bound). The **detection direction** — drops, spikes, or both — is chosen per index; the tenant sets the default. Outliers are the *state* of the component, not an option.
Inactivity	An index whose last licensed volume is older than the threshold in force turns **red**. The threshold is a tenant policy — static, or **variable** by day of week and hour of day (by default 1 day during working hours, 7 days for nights and week-ends) — and can be overridden per index.
Daily licensed volume	The volume of each **license day** (the day rolls at the license manager's local midnight, whatever your search head's time zone), the figure your license is measured on. Reported per index and summed for the environment.
Trend and projection	A 30-day trend, the month-to-date volume and a **month projection** that follows the weekday pattern of the index — recomputed every 5 minutes, per index and for the whole environment. Both are built on medians, so a one-off spike or outage does not dominate them.
Pool usage	On Splunk Enterprise, the share of the license pool consumed over the last 24 hours; the entity's *group* is its license pool. On Splunk Cloud a pool has no limit, so no pool usage is reported.

Every index is a regular TrackMe entity: priority, tags, labels, SLA, logical groups, the disruption queue, acknowledgments, notes, maintenance, stateful alerting and the AI Assistant all apply. VOL has **no thresholds** to configure and no delay / latency — there is nothing to tune before it delivers value.

How it collects

One tracker per tenant runs every 5 minutes and reads **only the new events** of the license usage log — one bounded search, whatever the number of indexes — into **5-minute buckets** per index. The rolling KPIs, the daily volumes and the projection are derived from those buckets, never by rescanning `_internal`. The tracker writes the `trackme.splk.vol.*` metrics with explicit bucket timestamps, so the charts and the ML models see a continuous, regular series.

At creation the tenant **backfills** its history: 30 days by default, a choice from 7 to 90 days, or **Custom…** for any number of days up to **400** (13 calendar months, enough for a year of chargeback statements), always bounded by the retention of the license usage log. The backfill replays the same collection over the past, one license day at a time, and writes the daily licensed volume of every day it covers, so the license view, the daily chart and the projection are complete when it finishes; the outliers models train as soon as it completes. Progress is visible on the tenant card, in the Tenant Home header and in the *Manage: volume collection* screen. See *Backfill* for the details.

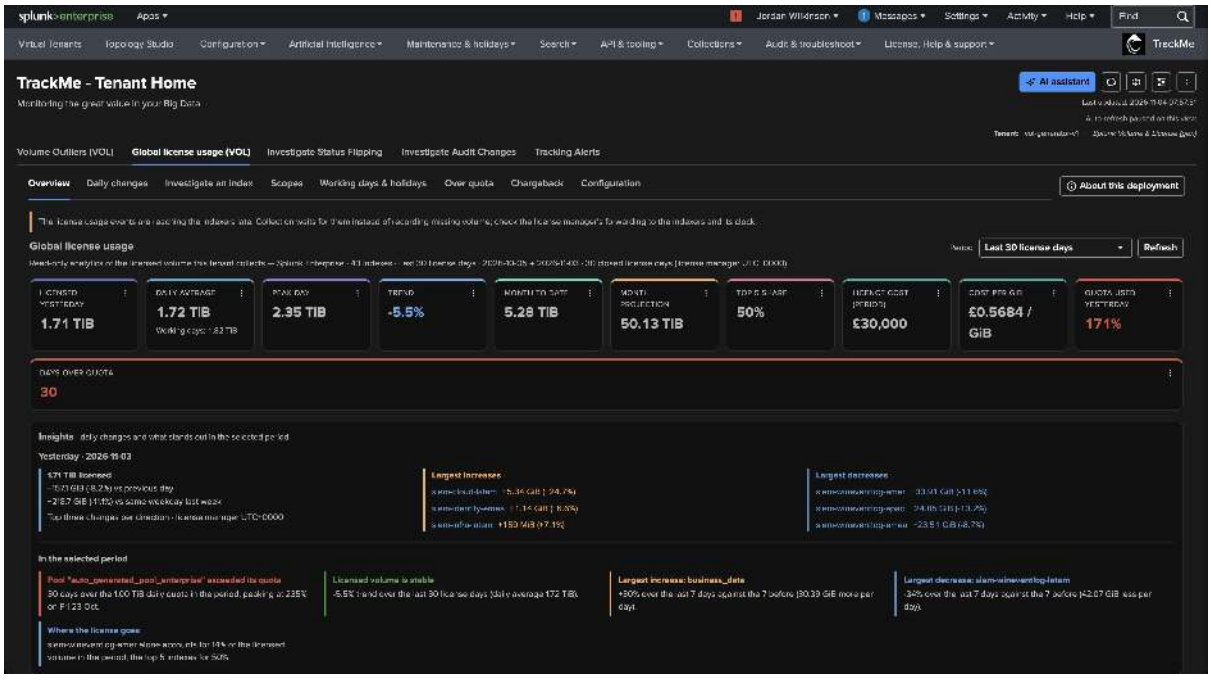
Global license usage

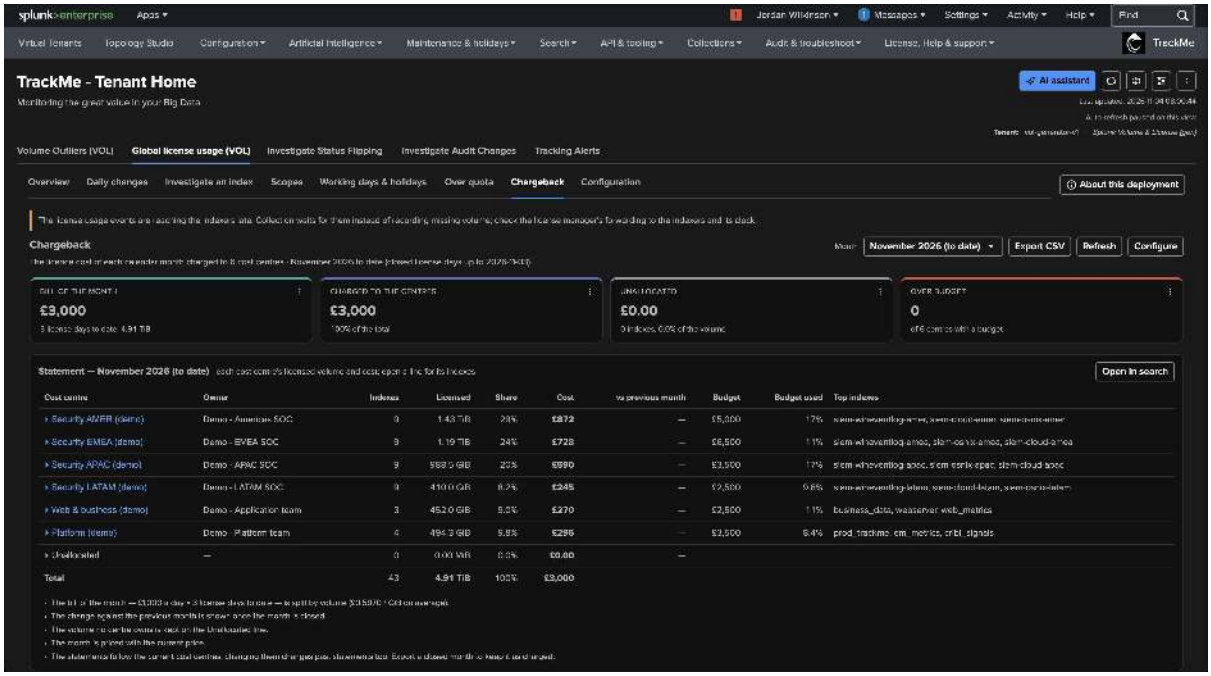
Next to the VOL component tab, Tenant Home offers the **Global license usage (VOL)** tab: the license consumption of the whole environment, the dashboards people otherwise build by hand. It reads what the tenant already collected, so it adds no search on the license usage log, raises no alert and works the same on a remote deployment. It covers closed license days only, over a period of 30, 60 or 90 days, and every tenant user can open it.

The view has six sub-tabs:

Sub-tab	What it answers
Overview	The key figures (licensed yesterday, daily average and working-day average, peak day, trend, month to date, month projection, top 5 share), insights in plain words, the daily volume stacked by top consumers with the quota line, the whole environment per day with its projection, the consumers table, the week-over-week movers and the license pools. With costs on, the cost of the period, the cost per GB and the unused capacity; with a quota, the days over quota.
Scopes	One tab per **named scope**: a set of indexes analysed together, such as a team, a use case or the indexes of Enterprise Security. A scope is defined by index patterns or follows the CIM datamodel index macros. Each tab shows the scope's share of the license (or its cost), its daily average, its peak day, the last 7 days against the 7 before, its month projection and its indexes.
Working days & holidays	Weekends and public holidays pull a daily average down. This tab shows the working-day, weekend and holiday averages, the average per weekday, and the top consumers and pools on a working day. Holidays come from the *Bank Holidays* calendars.
Over quota	The days a license pool went over its daily quota, over 3, 6 or 12 months: per day against the quota, per calendar month and over a rolling 60 days. **What made the day** shows, for any day you pick, the pool's largest indexes against their usual day.
Chargeback	A monthly statement of the license cost per **cost centre**, over 13 calendar months: the bill of the month, what each centre is charged, its budget, the unallocated volume, the unused capacity, a 13-month trend and a CSV export.
Configuration	The scopes, the working days, a daily quota per pool, the cost centres and the costs with their price history, saved together.

Everything beyond the overview is **opt-in**: nothing is priced, scoped or charged until a power or admin user of the tenant configures it. The **AI Assistant** of Tenant Home switches to this view while it is open: it knows the sub-tab and the figures on screen, and with your consent it can change the configuration for you through the Concierge.





Creating a VOL tenant

1. **Create a tracking tenant** and pick the **Splunk Volume (Outliers)** card.
2. **Basics** — the tenant identifier, alias and description.
3. **Volume** — the target environment (this Splunk, or a remote account), the default **detection direction**, the **backfill history** (up to 400 days with **Custom…**), which priorities are in scope for outliers, the minimum history a model needs before its confidence is *normal*, and the default **outliers KPIs**. *Advanced* holds the license search constraint and the settle margin.
4. **Inactivity** — the tenant's inactivity policy (static, or variable by day and hour).
5. **Indexes & RBAC** — the TrackMe indexes, the roles and the owner, as for every tenant.
6. **Review** and create. The first collection runs at once; the backfill follows on its own schedule.

The wizard is walked step by step in *Creating a splk-vol tenant*, and end to end — from creation to the first alert — in the *Volume Outliers white paper*.

Tip

Foundation customers get it too. VOL is part of the **Foundation** edition, next to DSM, DHM and MHM — a Foundation deployment can monitor its license volume out of the box, without Flex Objects. Enterprise and Unlimited include it as well.

Note

Replaces the Flex Objects license-usage recipes. Before 2.4.18, volume outliers on the license usage were delivered with Flex Objects templates (`splk_license_usage_per_index_*`) and, per feed, with the DSM volume models. VOL packages that recipe as a first-class component: cheaper to run, backfilled, with a purpose-built UI. The templates remain available for custom needs.

8.3.8 Volume Outliers — in depth

Tip

This is the **in-depth reference** for the Volume Outliers (splk-vol) component. For the readable overview of what VOL is and when to use it, start with *VOL — Volume Outliers*; for a guided, end-to-end walkthrough on a live deployment, read the *Volume Outliers white paper*. This page covers the collector, license days and time zones, the closed-day reconciliation, the backfill, the outliers and inactivity policies, the projection, the Global license usage view and its configuration (scopes, working days, daily quotas, costs, chargeback), alerting, the REST endpoints, the metrics and troubleshooting.

The entity model

- An entity is one Splunk **index**: `object` is the index name, `object_category` is `splk-vol`, and the entity's **group** is its license **pool** (a single-pool deployment has one group; on Splunk Cloud, where a pool has no limit, the group is `default`). An index reported under several pools follows its **primary pool** — the one carrying most of its bytes in the window — with hysteresis: it keeps that pool up to 24 hours while the pool reports it, and moves only when another pool carries twice its volume.
- The state is **green by default**: collection never turns an index orange or red on its own. The state comes from **ML outliers** (a lower-bound breach is a *drop*, an upper-bound breach a *spike*) and from **inactivity**, through the same hybrid impact scoring as every component (*Entity State & Scoring*). The tenant impact keys are `impact_score_vol_outliers` and `impact_score_vol_inactive` (default 100: an inactive index turns red).
- Per index the analyst chooses the **detection direction** — *Detect drops*, *Detect spikes*, or both — with the inline **Detect** toggle of the VOL table, in bulk edit, or in the entity's *Volume & cost* tab. The direction is stored on the index's outliers model (`alert_lower_breached` / `alert_upper_breached`); the tenant default is `vol_default_direction` (`both`).
- Everything generic applies: priority, tags, labels, SLA, logical groups, disruption queue, acknowledgments, notes, maintenance, monitoring time, enable / disable, deletion. An index deleted *temporarily* keeps its bucket history when it had licensed volume in its last 24 hours (it comes back with its true rolling volume); a *permanent* deletion drops it and the index is never collected again.

The collector

One report per tenant, `trackme_vol_tracker_tenant_<tenant_id>`, runs every 5 minutes through the standard tracker executor (execution summary, licensing checks and the scheduled-time anchor come with it). Each run:

1. **Loads the checkpoint** of the tenant — the `cursor` (the end of the last finalized 5-minute bucket), the validated history start, the license manager's UTC offset and the deployment type.
2. **Establishes the license writer** — the one host writing `type=Usage` over the last 3 days — and scopes every license search to it. No writer, or several (two license managers in one license search, a test stack forwarding its log to the same index), holds the collection with the `VOL_LICENSE_WRITER_UNKNOWN` / `VOL_MULTIPLE_LICENSE_WRITERS` diagnostic rather than summing licences: the cursor does not move,

the history is kept, and the license view and the *Manage: volume collection* screen say so. Scope `vol_license_search` with `host=<license manager>` to resolve it; after a license manager is replaced, collection resumes by itself once the previous host has written no `Usage` for 3 days.

3. **Computes the window** `[cursor, floor(min(now, watermark) - settle))`, aligned on 5-minute boundaries. The **source watermark** (2.4.22) is how far the writer has delivered: the newest `_internal` event of the writer host, which travels the same forwarding path as the license usage log (for a custom license search, the earlier of that and the newest license event). The window waits for a late source instead of closing on events that have not arrived; the **settle margin** (`vol_settle_seconds`, default 300 s) still leaves the time to write every `Usage` event of a bucket before it is read. A run catches up at most 6 hours at a time; a gap above 24 hours re-seeds the history (see *Validated history* below).

4. **Runs one bounded search** on the license usage log, local or on the tenant's remote account, starting `vol_late_overlap_seconds` (default 1800 s) before the cursor so stragglers of the previous buckets are read again:

```
search (index=_internal source="*/license_usage.log" host=<writer>) type=Usage␣
↪idx=* earliest=<cursor - overlap> latest=<end>
| bin _time span=300s
| eval effective_bytes=b*coalesce(licensed_weight,1)
| stats sum(b) as b, sum(effective_bytes) as effective_b, latest(poolsz) as␣
↪poolsz by _time, idx, pool, host
```

   plus, once a day (and on every run around the license manager's midnight), a cheap indexed probe on the `RolloverSummary` event that returns the license manager's UTC offset and the deployment type. `b` is the **raw ingest**; `effective_b` the **licensed volume** — data Splunk licenses at a reduced weight carries a `licensed_weight` on its `Usage` rows (2.4.22). The 5-minute buckets and the rolling values the outliers models train on stay raw ingest; the daily figures (yesterday, month to date, trend, projection and the whole *Global license usage* view) are licensed volume, and the raw ingest is shown next to *Licensed yesterday* when the two differ.

5. **Updates the ring** of each index — the last 288 buckets (24 hours) kept in the tenant's KV store: appends the new buckets (a bucket with no event is 0), recomputes the rolling sums at each bucket end, accumulates the current license day and closes any license day that ended. A bucket read again through the overlap is **raised** to the re-read total, never lowered (license events are never removed, so a re-read cannot take volume away); the difference goes to the ring and to the open or closed day it belongs to, and the 5-minute and rolling points already written are not written twice.

6. **Writes the metrics** with explicit bucket timestamps, then advances the cursor — the cursor moves only once the metrics and the rings are persisted, so a run that dies mid-way is replayed, never skipped.

7. **Emits one entity row per known index**, carrying the latest rolling values, the daily figures (yesterday, month to date, 30-day average, trend, projection), the pool usage on Splunk Enterprise, the detection direction, the effective inactivity policy and the **hold** the run measured on the source (see *Late license events* below).

8. **Reconciles closed days** — after 03:00 license-manager time, up to two of the last seven closed license days are reread from the license usage log, repaired if needed and compared with the license manager's own daily summary (see *Closed-day reconciliation*).

Note

Why a ring instead of querying the metrics index. The rolling volume must not depend on the metrics pipeline's own indexing latency: a blocked queue would read as a drop and raise false lower-bound outliers. The rolling values are computed from the buckets TrackMe holds and *then* written as metrics.

Integrity rules

- **Validated history.** Every ring and the tenant checkpoint carry the time from which the history is continuous. A rolling KPI is emitted only once its whole window lies inside the validated history, and a license day is reported only when it was observed from its start — the first run's 24-hour seed writes the 5-minute volumes

for every bucket, but the 24-hour trend only from the last seed bucket. No ramp-up or gap ever reaches the series the models train on.

- **Search errors fail the run.** An error from the usage search — or a warning saying the results are incomplete (a peer down, a search process ended prematurely) — stops the run before anything is written; the cursor does not advance and the missing volume is never recorded as a drop.
- **One collecting run at a time.** A lock protects the collection; an overlapping run (for instance *run the tracker now* during the schedule) rebuilds the entity rows from the stored rings without writing any metric point. A run that meets the lock of a tenant being seeded waits for it (up to 4 minutes) and then collects normally.
- **A new source re-seeds.** Changing the target environment (`vol_account`) or the license search constraint discards the rings and the checkpoint and re-seeds 24 hours from the new source, emitting only the points *after* the previous source's cursor — a series never holds two points for the same bucket. The previous source's indexes stop being updated, turn inactive and can be deleted.
- **Fail-closed reads.** The rings, the per-index directions and the permanently deleted indexes are read without a fallback: a failed read fails the run instead of resetting a direction or resurrecting a deleted index.
- **Squashed rows keep the index.** When the license manager squashes `Usage` rows (`squash_threshold`), it drops the host and source, never `idx` — squashing never reads as a drop.
- **One license writer.** Every search is scoped to the host established as the `Usage` writer; a held collection (no writer, several writers) never sums volumes and never moves the cursor.

Late license events

The license usage log reaches the indexers through the license manager's own forwarding. A blocked output queue on the license manager, an indexer restart or a license manager clock behind the indexers used to turn into a sudden, lasting drop on **every** index at once while the events were all there, just late. Since 2.4.22 three layers keep the figures exact whatever the latency:

- **The window waits for the source** — it ends at the writer's watermark (step 3 above), so on an in-order forwarding path every bucket the collector reads is complete.
- **The late overlap** — each run rereads the last `vol_late_overlap_seconds` before its cursor (default 30 minutes, 0 disables, up to 4 hours) and raises the buckets it finds short, never lowers one.
- **The closed-day reconciliation** — a straggler that arrives after its license day closed is repaired in the day's figures by the reconciliation (next section).

A window held 15 minutes or more behind the wall clock raises the `VOL_LICENSE_SOURCE_DELAYED` diagnostic in the license view: the collection is waiting for the events instead of recording missing volume — check the license manager's forwarding to the indexers and its clock. The hold each run measures is written on every index and **discounted from the inactivity clock**, up to 4 hours, so a late source does not turn every index red; a source delivering nothing for more than 4 hours is an outage and does. The measure is the run's, not "now minus the cursor": a tracker that stops running keeps its last measure and the inactivity clock keeps running.

License days and time zones

Splunk measures the license on **license days** that roll at the **license manager's local midnight**, whatever the time zone of your search heads or of your Splunk user. VOL follows the license manager:

- The daily probe reads the license manager's UTC offset from the `RolloverSummary` event (its raw timestamp carries the offset, and its time is the true day boundary). On a deployment younger than a license day no rollover has been logged yet: the offset is then read from the raw timestamp of the latest `Usage` event (every line of the license usage log carries it) and the *Manage: volume collection* screen says so. UTC is assumed only when there is no license event at all, and the open day is voided when the real offset turns out to differ.
- The probe runs on every run between 22:00 and 03:00 license-manager time, so a **daylight-saving transition** is caught within the run that follows it. The buckets between the old and the new day boundary move to the day they belong to, and a corrected closed day is re-emitted (a fall-back day lasts 25 hours, a spring-forward day 23 hours).

- The `daily_volume_mb` metric of a license day is stamped in the middle of that day, so a chart binned by day places it on the right date whatever the viewer's time zone.

The **daily figures** (`yesterday`, `month to date`, the trend and the projection) refer to license days, and the *Volume & cost* tab says which license date "today" is for the collector.

Closed-day reconciliation

The live collection reads each 5-minute bucket once, shortly after it ends. A `Usage` event that reaches the indexers later than the settle margin (a blocked forwarding queue on the license manager, an indexer restart) would be missing from the day's figure, and Splunk's own daily summary — the `RolloverSummary` event the license manager writes at its midnight — can itself differ from the sum of the detailed `Usage` records. Since 2.4.22 the tracker therefore **reconciles every closed license day** against the license usage log and says what it found.

How it runs

- The reconciliation is a phase of the 5-minute live tracker, under the collection lock: a run that collects (one `Usage` writer identified, no diagnostic hold) checks at most **two closed days** among the **seven most recent** the tenant holds, in due-time order, so a day that keeps failing never starves the others.
- A closed day becomes due at **03:00 in the license manager's time zone** of the following day, leaving late events and the rollover itself the time to be indexed. A verified day is checked again every day at 03:00 while it stays in the seven-day window (a late redistribution between indexes is caught); a day that could not be read, or whose totals disagree, is retried **every hour**.
- Each attempt reads the day's `RolloverSummary` (the day's exact bounds come from the two adjacent rollovers and their UTC offsets, so a 23-hour or 25-hour day is read as such), then rereads the **whole day per index** from the `Usage` records — the same source and the same remote account as the live collection, under the tenant's license search constraint.
- A reread that answers **repairs the stored figures** of the day: the raw ingest and the licensed volume of every index of that day, including an index that stopped consuming (its day is zeroed, never left at a stale value) — never an index first seen on a later day, never a permanently deleted index. The repair happens whether or not the rollover agrees: the detailed `Usage` records are the measurement.
- A repaired day is re-emitted: one corrected daily point per index (`daily_volume_mb`, `daily_ingest_mb`), stamped later than the original point inside the same license day and carrying the `license_day` and `reconciliation_revision` dimensions (`r1`, `r2`…). The entity searches read the daily series with `latest()`, so a corrected point replaces the original one in every chart and figure without summing the two; the stored daily figures the license view reads carry the same snapshot.
- Nothing is invented: when the rollover or the `Usage` records of the day are no longer available (retention), the day boundaries cannot be established, or the search fails, the previous figures are kept untouched and the attempt is retried an hour later. A day that leaves the seven-day window without a successful reread keeps its figures and is marked as outside the automatic window; it is never set to zero.

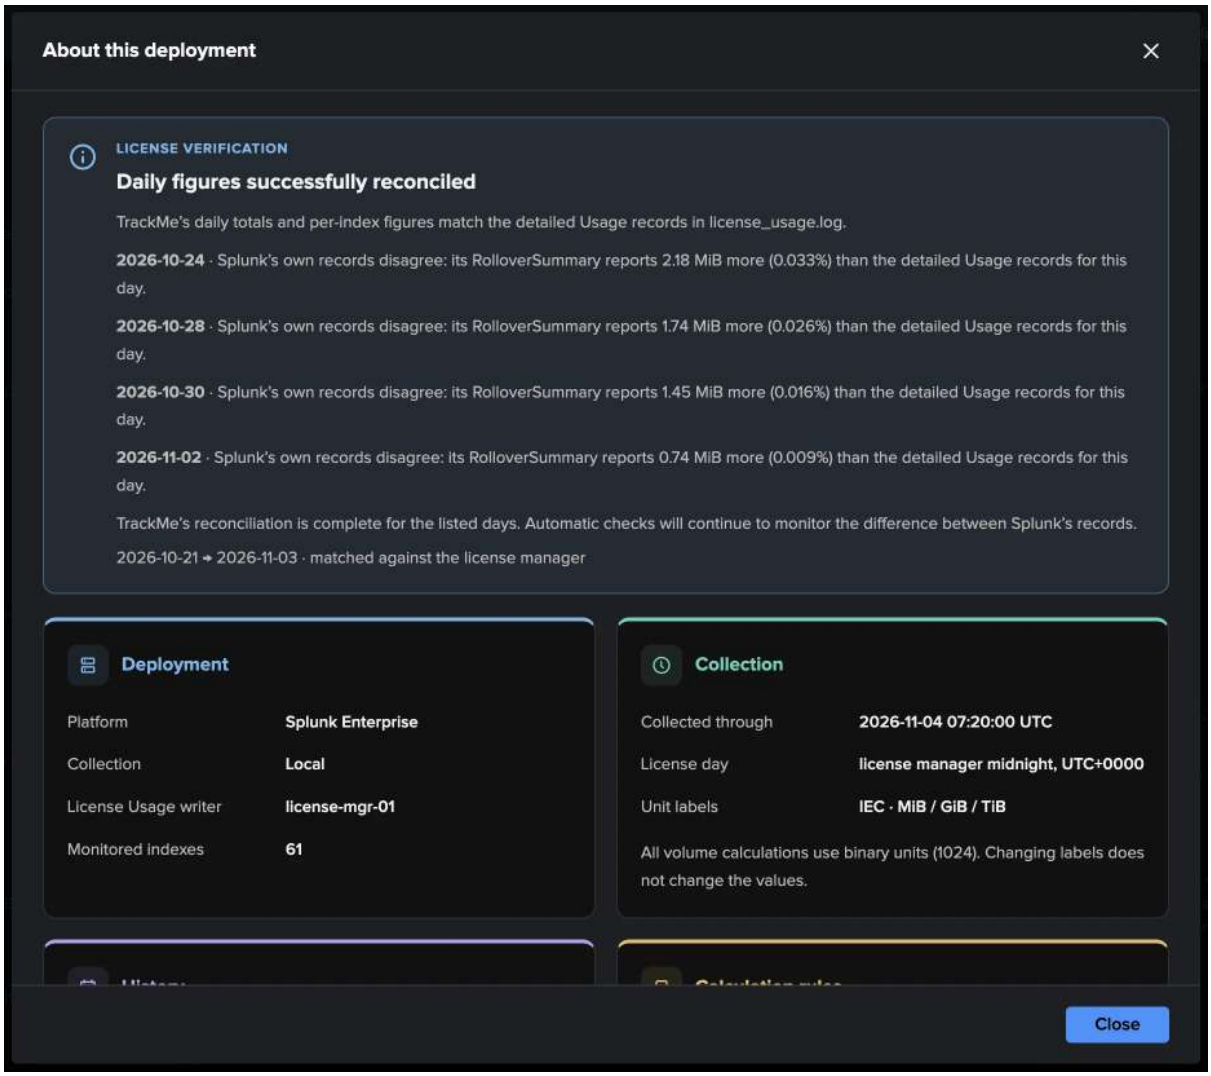
Verified, or reconciled with a difference

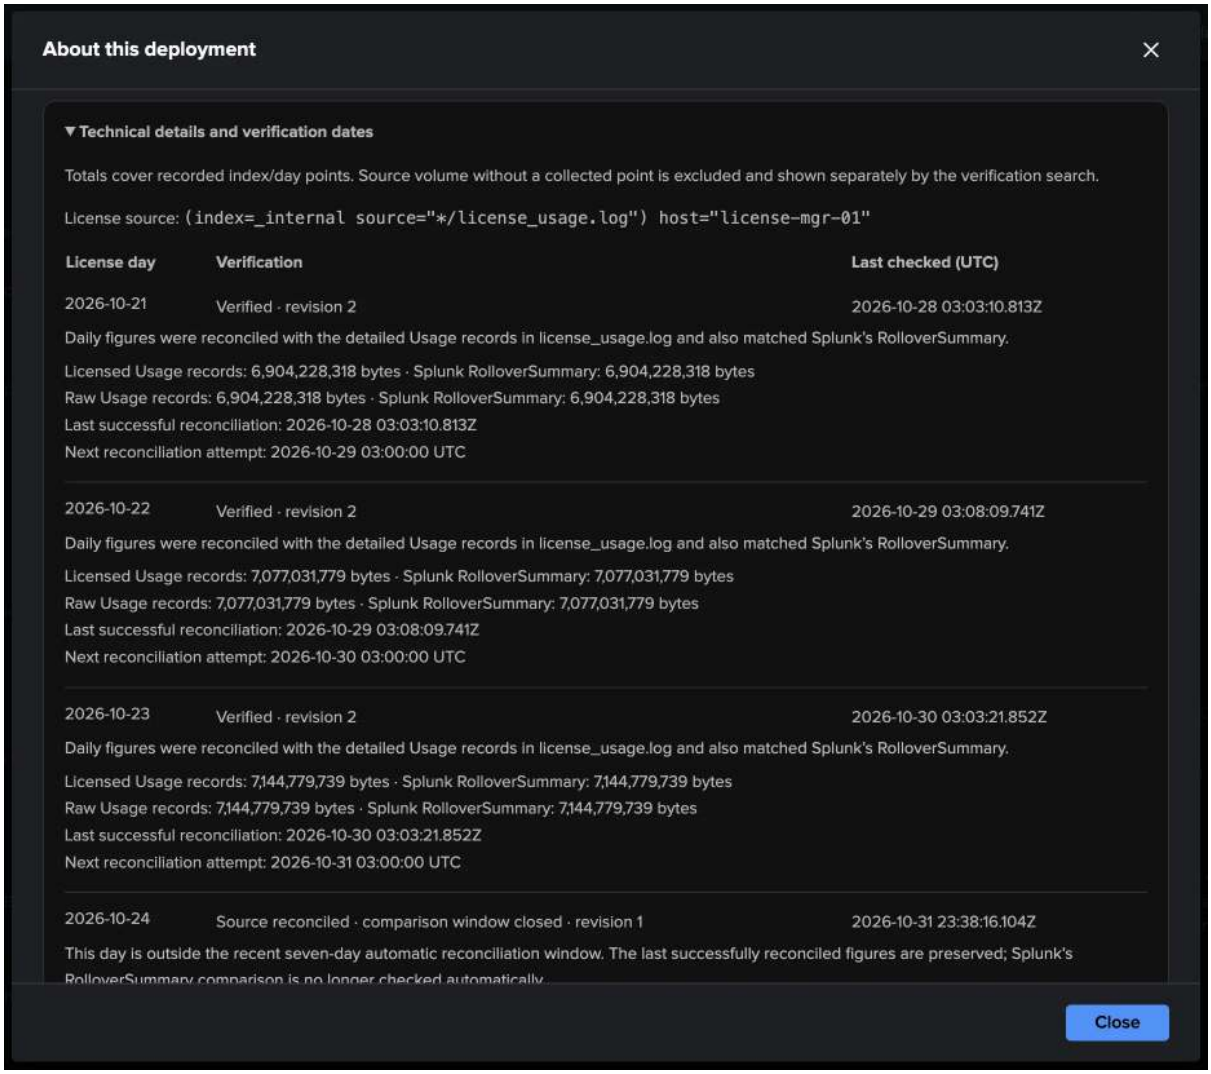
Repairing the figures and agreeing with the license manager are two different things. Once the day is reread, its raw and licensed totals are compared with the `RolloverSummary` totals to the byte (8 bytes of tolerance, independent of the displayed rounding):

- **Verified** — the `Usage` records and the rollover agree (*Verified for collected scope* when permanently deleted indexes are excluded from the comparison).
- **Source reconciled · summary differs** — TrackMe matches the detailed `Usage` records, but Splunk's own `RolloverSummary` reports more or less than those records. The card gives both totals, the difference in MiB and in percent of the summary, and the next comparison check. This is information, not an alert: TrackMe's reconciliation is complete, the figure is the one the `Usage` records measure, and the comparison keeps running while the day stays in the window.
- **Reconciliation incomplete** — the day could not be reread (the reason and the last attempt are on the card) and keeps its previous figures; the retry is automatic.

Where to see it

About this deployment — the button at the top of the *Global license usage* tab, and the same card on the *Manage: volume collection* screen — leads with the verification state: *N closed license days verified*, *Daily figures successfully reconciled* with one line per day whose summary differs, or *Collection or verification needs attention* with the days to look at. *Technical details and verification dates* lists every day of the window with its status, revision, last check, both byte totals and the next check. The cards of the *Global license usage* views whose figure comes from the license usage log offer **Verify against license_usage.log** in their menu: the search that sums the `Usage` records of that exact day and scope, so you can confirm the figure yourself.





Note

After an upgrade to 2.4.22. Nothing to request and nothing to wait for: the closed days are those the tenant already holds, so the first collecting runs after the upgrade reconcile the last seven of them, two per run. There is no manual reconciliation request; **Run tracker now** on the *Manage: volume collection* screen runs the same tracker at once, under the same rules — it cannot pick a day, nor reconcile a day before 03:00 license-manager time the day after it closed.

Backfill

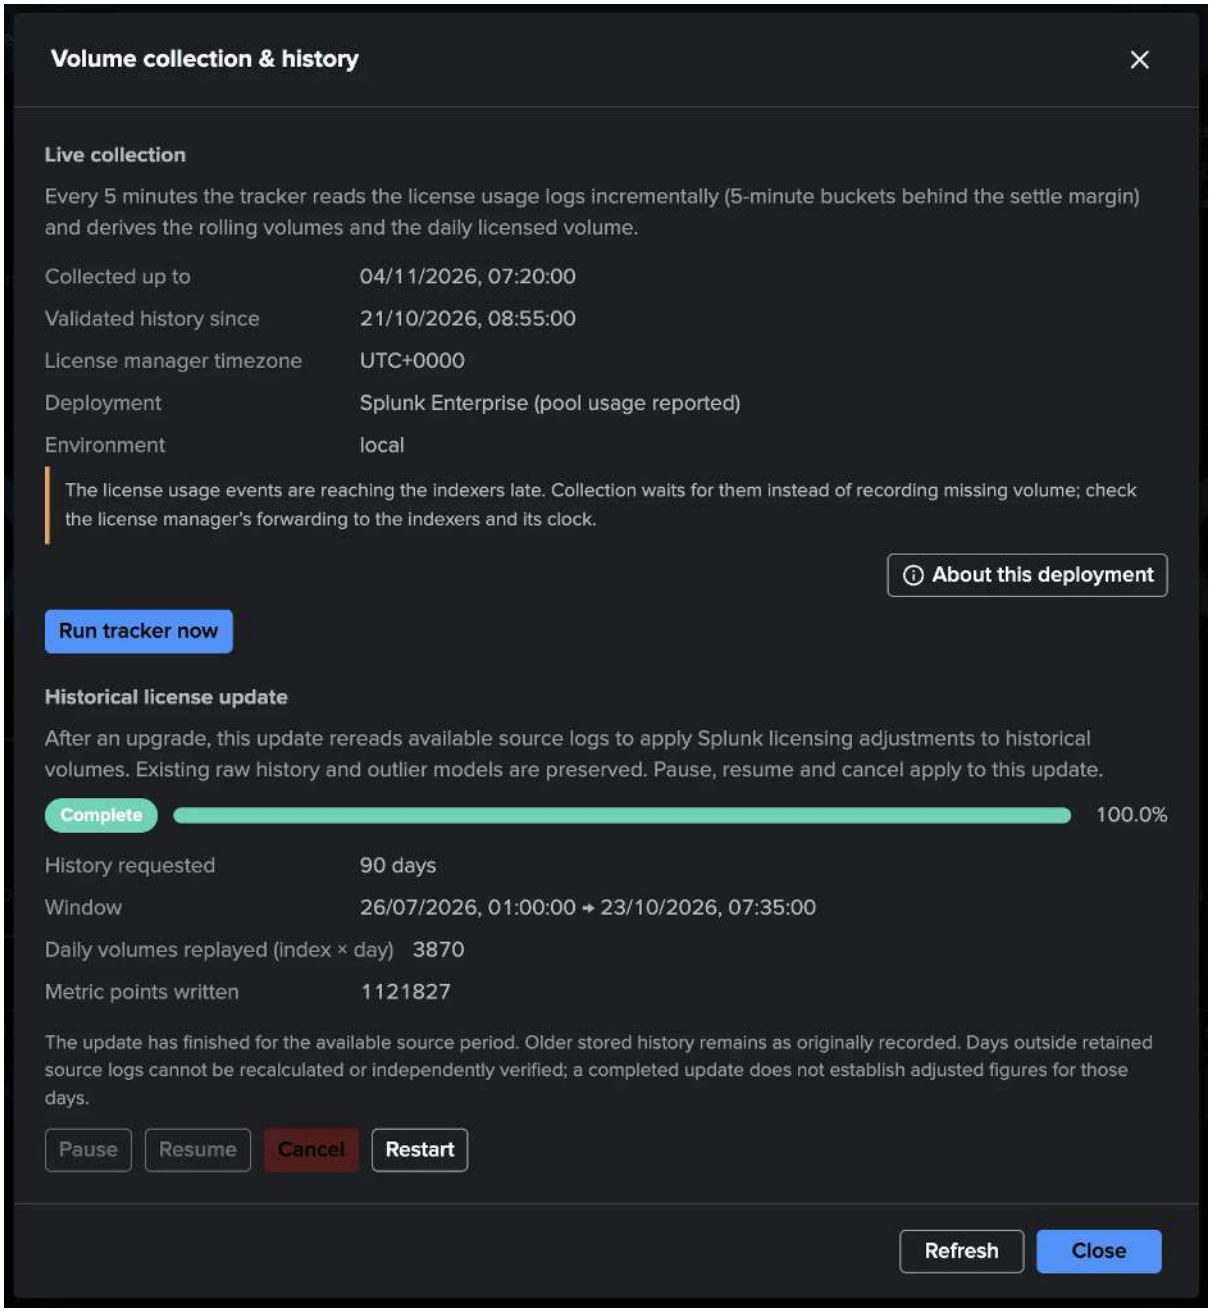
At creation the tenant requests a **backfill** of its history (`vol_backfill_days`, default 30) so the outliers models train as soon as it completes and the daily history, the trend and the month projection are complete. The wizard offers **No backfill**, 7, 14, 30, 60 or 90 days, or **Custom…** for any whole number of days up to **400** — 13 calendar months, the depth of the chargeback statements. It caps the depth to the retention of the license usage log it can reach, shows the reachable span, and shows the estimated cost in metric points before you confirm.

- The backfill is a separate report, `trackme_vol_backfill_tracker_tenant_<tenant_id>`, scheduled **hourly** while a plan is open and un-scheduled once complete. It walks **forward** in time (every rolling value needs the 24 hours before it) in day-sized chunks, each chunk replaying exactly the live collection with historical timestamps, and runs for at most 50 minutes per slot.
- The backfilled range ends where the live collection started: the live tracker and the backfill **never overlap** and no point is written twice. The first backfilled day is aligned on a license-day start, so it is complete; every complete license day of the range emits its `daily_volume_mb`.

- The live collection emits a rolling value only once its whole window lies in its own history, so the **first live day** has no 24-hour value (and no 12-hour, 4-hour or 60-minute one for its first hours). About 24 hours after the live start, the hourly backfill job replays that day and writes the missing rolling values; until then the *Manage: volume collection* screen reads *First live day trends: pending* and the rolling chart shows a gap at the seam.
- Daylight-saving transitions inside the range are replayed with the offset in effect at the time, from the `RolloverSummary` history.
- On completion the backfilled days are merged into each index's live history (the entity figures reflect them at once), the seam day around the live start is completed, and a **training of every VOL model** is requested, so outliers are usable without waiting for the next training cycle.

Progress is visible in three places — the tenant card on the Virtual Tenants page (`Backfilling 42 %`), the vignette in the Tenant Home header band, and the **Manage: volume collection** screen (live cursor, validated history, license-manager offset, deployment type, the backfill progress with **pause / resume / cancel / restart**, and *run the tracker now*). From the creation until the backfill job's first hourly run, the three read **Backfill pending** with the requested depth and the job's next run.

An upgrade to 2.4.22 runs a **Historical license update** through the same job: the reachable source history is reread once to apply the licensed weight to the stored daily volumes (*Updating history* on the vignette, *Historical license update* on the collection screen, with the same pause, resume and cancel). The raw rolling history and the outlier models are untouched; a day whose source has expired keeps its raw value, and the *Adjusted history from* date on the screen says where the licensed history starts.



Note

A **restart** re-plans only the history *before* the earliest point already written: it extends the history backward and never rewrites it. A change of the target environment or of the license search constraint while a plan is open cancels the plan (the new source is re-seeded first); restart it once the live collection runs on the new source.

The license search constraint (advanced)

Every license search of the tracker, the backfill and the probes is formed from one tenant-level constraint, `vol_license_search`. Its default targets the license usage log of the deployment the tenant collects from:

```
index=_internal source="*/license_usage.log"
```

You normally never change it. The **Advanced** section of the wizard's *Volume* step (and the *Configure tenant* form afterwards) lets you point the tenant at another data set holding events in the `license_usage.log` format — for

instance a copy of the license usage events forwarded to a dedicated index, or a deployment where `_internal` is not reachable under that name. The constraint is a plain base search on indexed fields:

- no pipe, subsearch (square brackets), macro (backtick), line break, `earliest` or `latest` — the tracker sets the time range;
- it must name an **index** as a real search term (`index=` inside a quoted value does not count), and not every index: a bare wildcard (`index=*`) is refused, `index=lic*` is fine;
- every `OR` alternative must be index-scoped (`index=a OR index=b` is fine, `index=a OR source=x` is refused) and parentheses must balance.

The wizard validates the constraint as you type, and it is validated again at every save.

Important

The data behind a custom constraint must have the `license_usage.log` key=value fields extracted at search time — `type`, `idx`, `b`, `pool`, `poolsz` — since the tracker filters on `type=Usage idx=*` and sums `b`. The real `license_usage.log` in `_internal` (`sourcetype=splunkd`) is extracted out of the box; a copy stored under a sourcetype with `KV_MODE = none` (`stash`, for instance) needs a `props.conf` stanza with `KV_MODE = auto` for its source, or the tracker reads no usage row at all.

Changing the constraint on a running tenant re-seeds the collection from the new source (see *Integrity rules* above) and cancels an open backfill plan.

Outliers

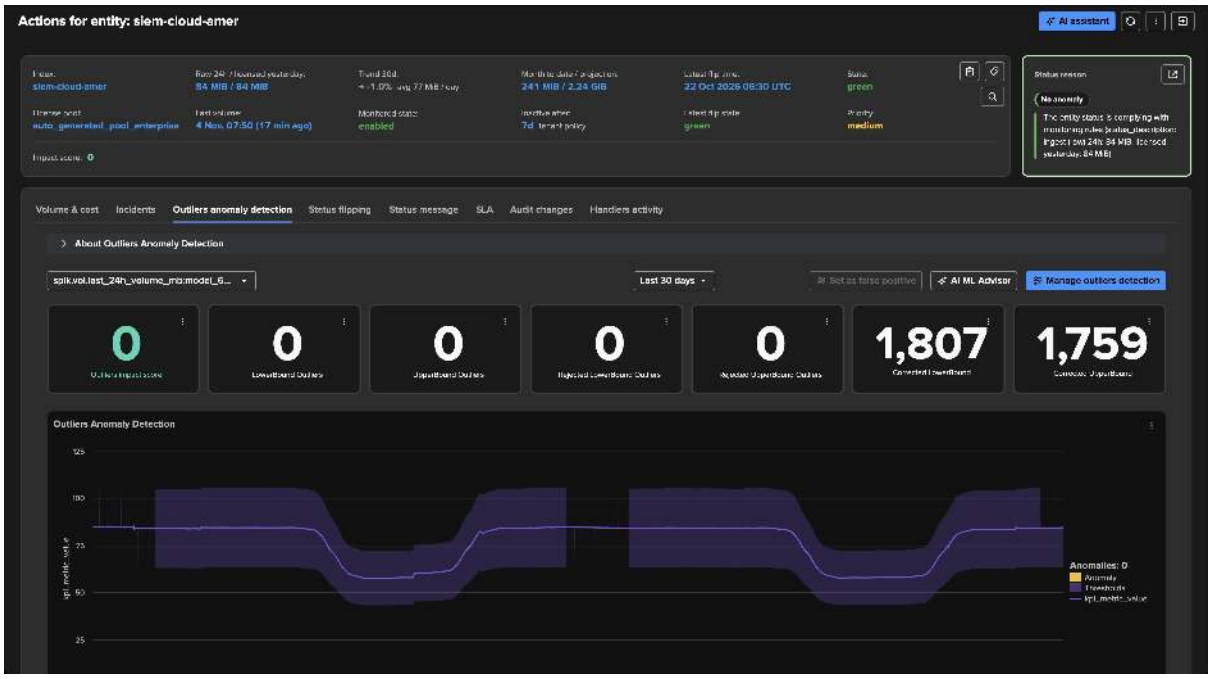
VOL rides TrackMe's native outliers engine (*Machine Learning*, *Outlier detection — in depth*) with component-specific defaults:

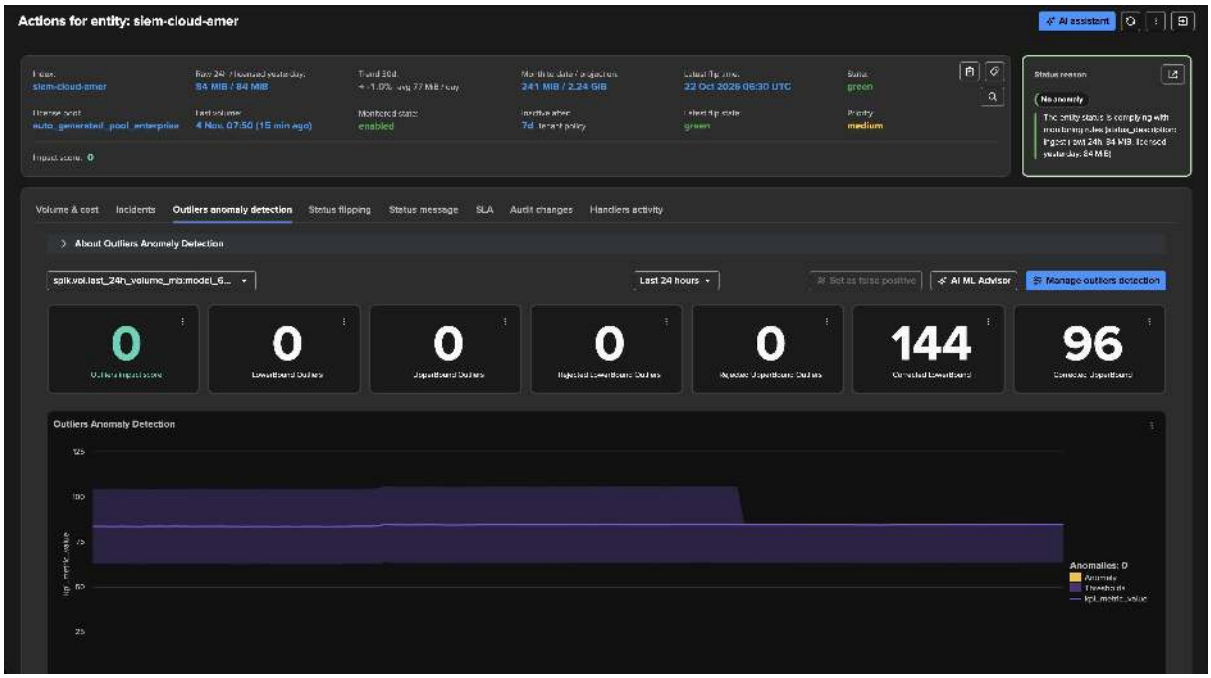
- **Every new index gets one model per default KPI** — `vol_outliers_kpis`, default `last_24h_volume_mb`, any subset of the four rolling KPIs. The rolling 24-hour volume follows the daily pattern and is the proven choice; the shorter windows (12 h, 4 h, 60 min) react faster to a sudden drop or spike and are noisier. One model per index is the deliberate default: several models per index multiply the noise. The models use the day-of-week × hour-of-day time factor over a 90-day calculation period.
- The default KPIs are set in the wizard and changed later in Tenant Home (*Manage: Outliers default KPIs*), with an opt-in **apply to the existing indexes** that adds the models of newly selected KPIs and removes the models of deselected rolling KPIs — models of kept KPIs and of non-rolling metrics are untouched. A model can also be added on, or switched to, any of the four KPIs from the entity's Outliers tab.
- **Direction** — a drop is a lower-bound breach, a spike an upper-bound breach; the per-index detection direction enables one or both bounds on the model.
- **Scope** — VOL has its own scope: `vol_mloutliers_priority_filter` (default: every priority — volume outliers are the point of the component) and `vol_mloutliers_filter_expression` (the TrackMe filter DSL on `object`, `priority`, `tags`, `labels` and `pool`). The tenant-wide `mloutliers_priority_filter` and `mloutliers_filter_expression` do **not** apply to VOL entities. The *Manage: ML Outliers scope* modal edits the VOL pair on a VOL tenant, and the table's Outliers column shows *out of scope* with the reason for an excluded index.
- **Minimum history** — the wizard exposes the tenant override of `splk_outliers_min_days_history` (15 days on a VOL tenant by default, against a system default of 30) and tells you whether the requested backfill covers it: with 30 days of backfill, the models reach *normal* confidence once the replay completes.
- **Reading a model** — the entity's *Volume & cost* tab draws one outliers chart per enabled model, each with its own **History** slider, from 24 hours (the default) to 90 days. The chart reloads once, when you release or leave the slider, and its subtitle gives the number of **anomaly windows** over that range with their points (for instance *5 anomaly windows (36 points)*: consecutive anomalous points form one window, as the chart's legend counts them) and the model's confidence.
- ML is **always on** for VOL. A tenant where ML is off for the other components because it only runs DHM / MHM keeps ML on for VOL alone (`mloutliers_allowlist=vol`).

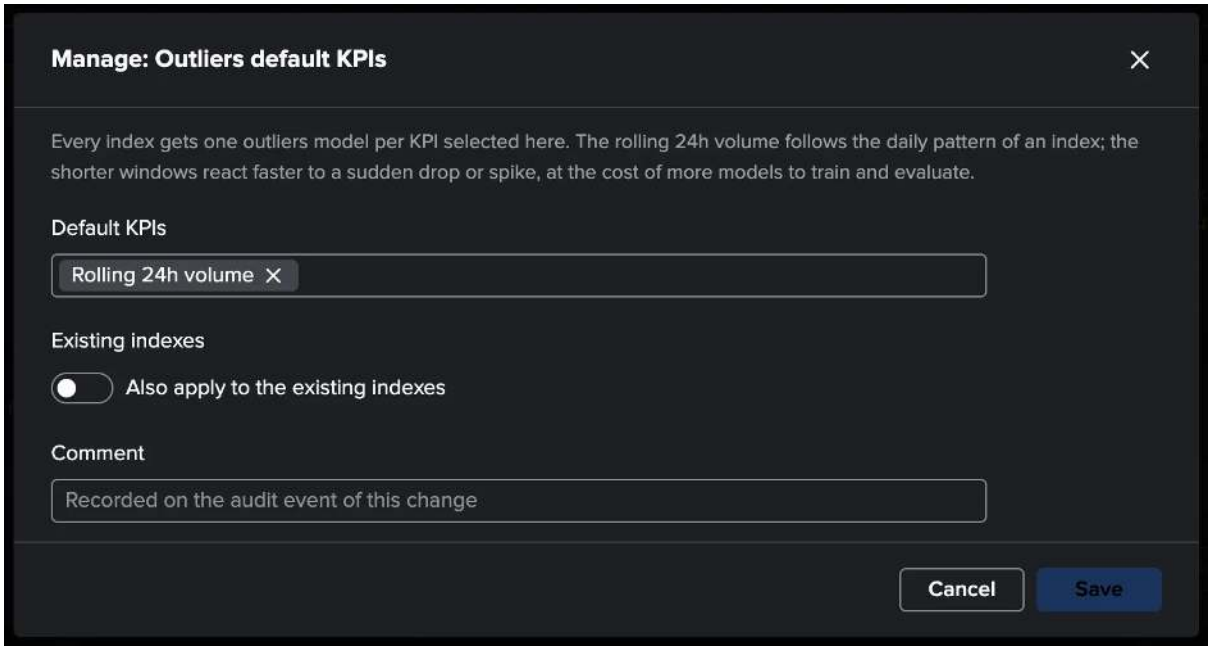
- The **AI ML Advisor** — interactive and its automated batch — covers VOL models like any other (*AI ML Advisor*).

Note

A one-off spike right after a short backfill. The models use the day-of-week × hour time factor over a 90-day period. Trained on a short history, a model learns a single spike as a weekly pattern: its bounds widen on that weekday and hour until the day ages out of the calculation period. To remove it sooner, add a **period exclusion** on the entity's Outliers tab and retrain, or let the **AI ML Advisor** in act mode do it.







Inactivity policy

An index whose last licensed volume is older than the threshold **in force** turns red (`anomaly_reason=inactive`, `impact_score_vol_inactive`). Two policy shapes exist:

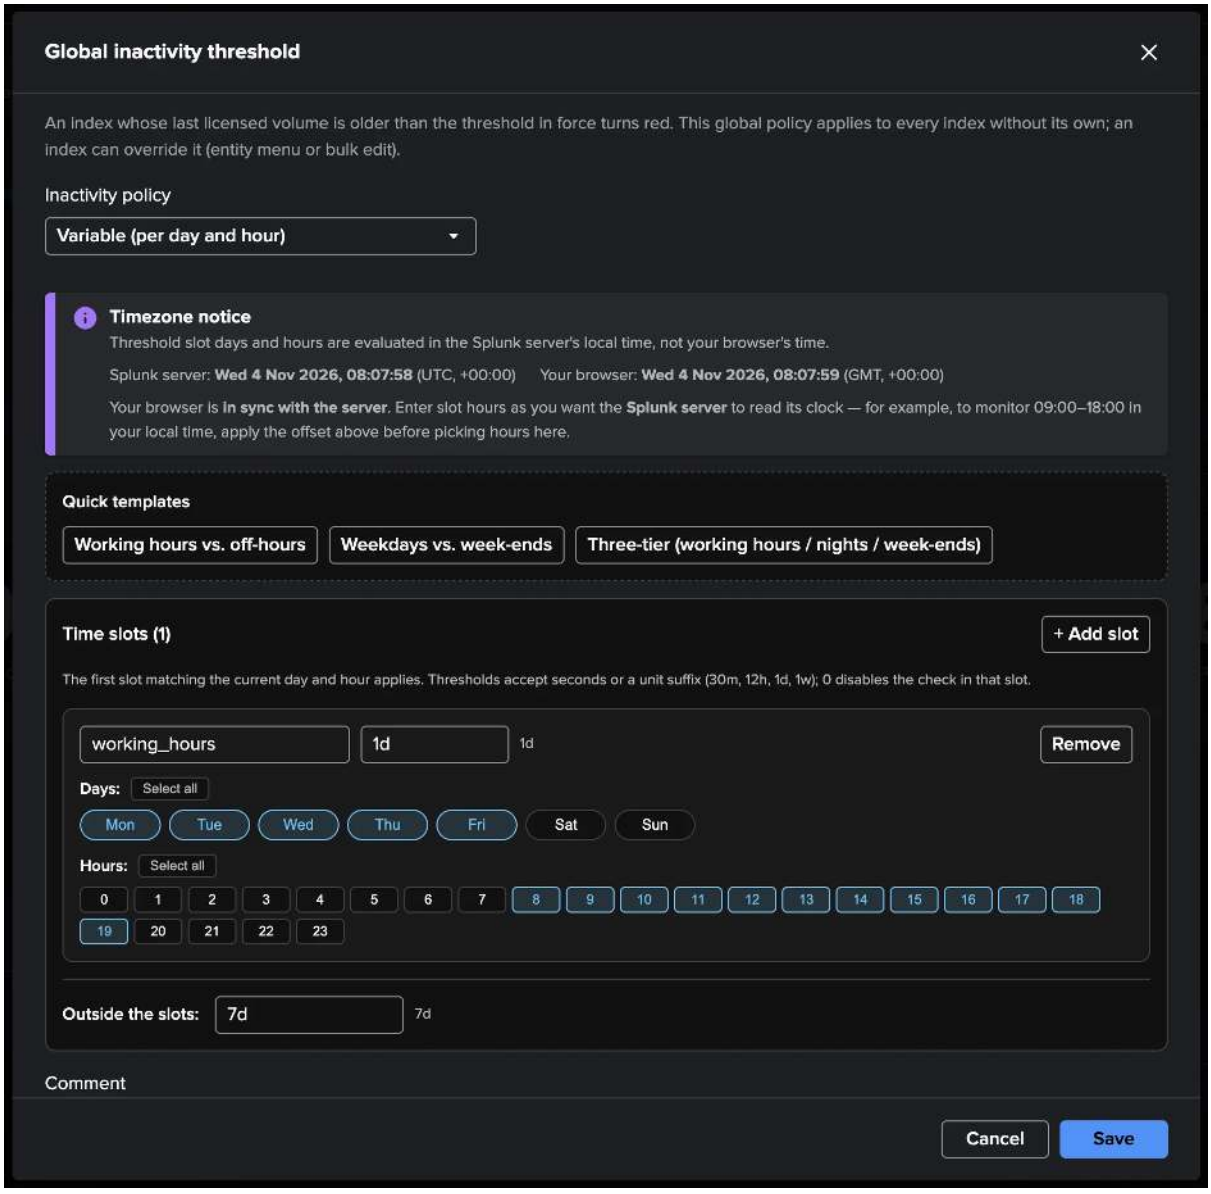
- **static** — one threshold (`vol_max_sec_inactive`, default 7 days);
- **variable** — slots by day of week and hour of day, the DSM / DHM variable-delay model: `{slot_name, days (0 = Monday .. 6), hours (0-23), max_sec_inactive}`; the **first matching slot** applies, the default (`vol_inactive_default`) outside every slot.

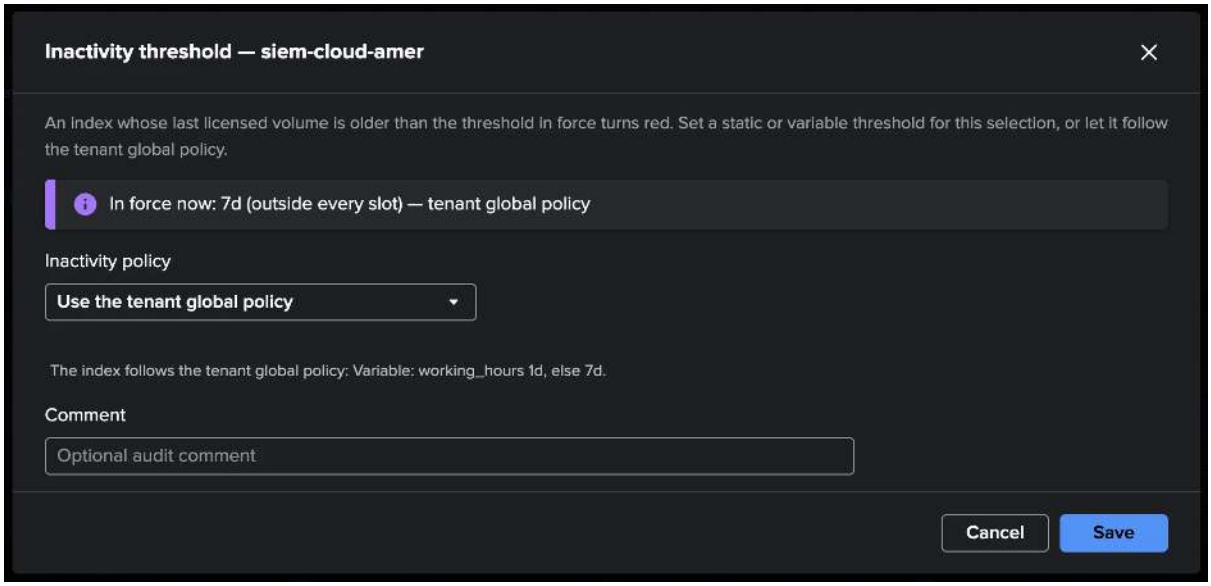
The tenant policy (`vol_inactive_policy`, **variable by default: 1 day during working hours, Monday to Friday 08:00–19:59, and 7 days for nights and week-ends**) applies live to every index without its own override. A **per-index override** — static or variable — is set from the entity menu (*Modify → Inactivity threshold*), from the bulk edit category *Inactivity Threshold*, or by clicking the **Inactivity** column, and can be sent back to the tenant policy. A threshold of 0 disables the check (the whole static policy, or one slot); otherwise it runs from 300 seconds to 90 days. Durations accept seconds, a unit suffix (`30m`, `12h`, `1d`, `1w`) or `[D+]HH:MM:SS`.

Note

The slot clock is **splunkd's system time zone** — the frame the editor's hour grid is drawn in (the editor shows the server time and converts your browser hours). It is not the time zone of the user running the tracker or viewing the page, so the scheduled tracker, a Tenant Home refresh and an inactivity save all pick the same slot.

The red status message names the slot in force (and says *set for this index* when an override applies); the table's compact *Inactivity* column shows the threshold in force, with the slot and the source in its tooltip.



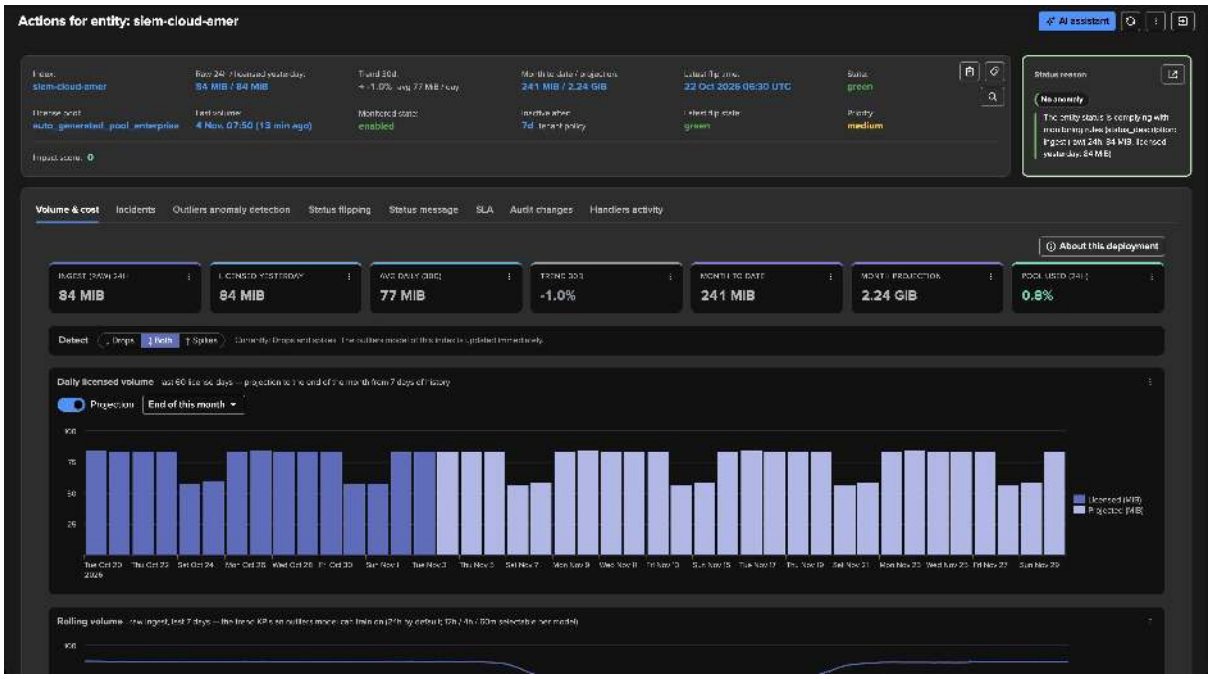


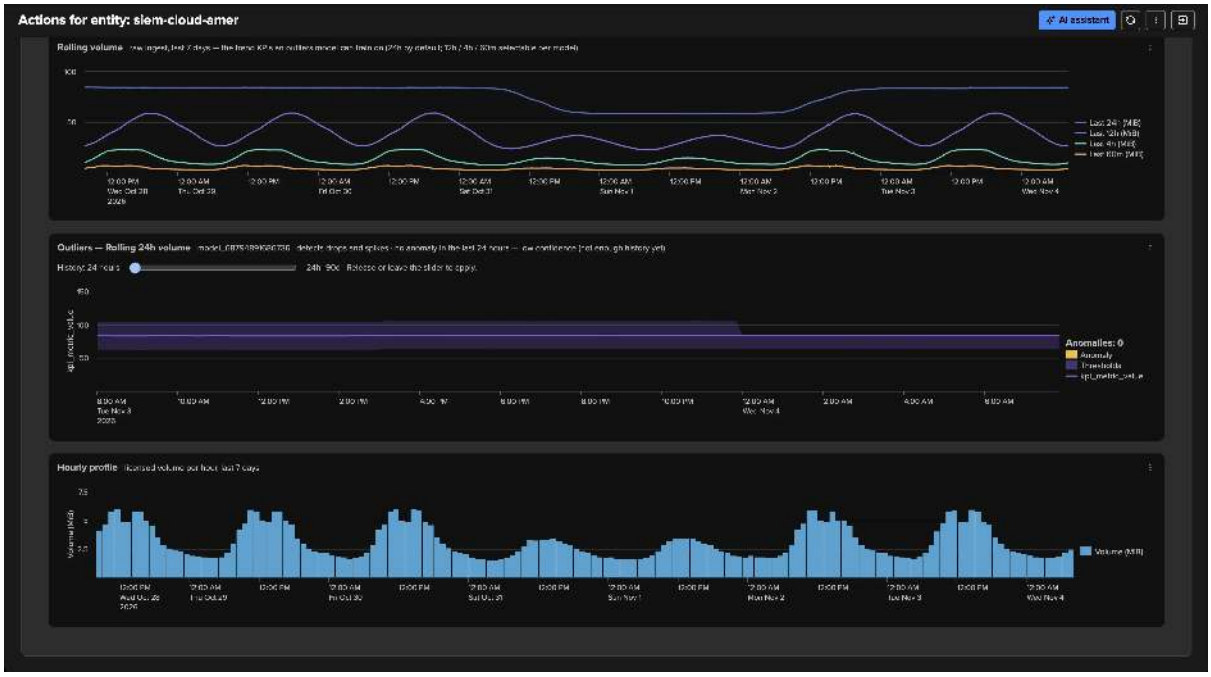
Trend and projection

The collector computes, per index and on every run, from the closed license days it holds:

- `yesterday_volume_mb`, `mtd_volume_mb` (month to date), `avg_daily_30d_mb`;
- `trend_30d_pct` — a **robust (Theil–Sen) slope** over the last 30 closed days (the median of the slopes between every pair of days), as a percentage of their **median**, never below −100 % (a volume cannot fall by more than all of it), from 7 days of history;
- `projected_month_mb` — the month to date plus, for each remaining day, its expected rate: the **median** of the same weekday over the last 28 license days once two samples exist, else the mean of the last 7 days. The open day counts for the larger of its volume so far and its expected rate. **No projection before 7 closed license days**: a day or two of history gives no sensible monthly estimate. A day missing *inside* the index's history (a collector outage past the catch-up) is estimated at its rate; the days before the index's first recorded day are not.

Both figures use medians on purpose: a **single outlier day cannot dominate them**. A one-off spike or outage inside the 28 days is not repeated on every remaining same weekday of the month, and does not turn a flat index into a steep trend. With only two samples of a weekday, the median is their mean.





The *Volume & cost* tab draws the daily licensed volume of the last 60 days with the per-day projection to the **end of this month** or **of next month** (a switch remembered per viewer), scaled to the collector's figure so the chart and the card agree; **Open in search** carries the same rule in SPL. There is deliberately no `predict`: a weekday-weighted rate is what the license bill follows.

Global license usage (VOL)

A Tenant Home tab next to the VOL component tab: the license consumption of the whole environment, with an opt-in configuration layer (named scopes, working days, daily quotas, costs and chargeback). It reads what the tenant already keeps (one daily point per index and closed license day, and the entity figures), so there is **no monitoring, no alerting and no search on the license usage log**: a few `mstats` searches, the same for a remote deployment. It is as deep as the tenant's history, live collection plus backfill.

Principles

- **Closed license days only**, in the license manager's time zone. Today, the open day, is never in a chart; the month figures (month to date, month projection) come from the entities.
- **One value per index and license day**, placed in the middle of the day, so any viewer within 12 hours of the license manager sees it on its own date.
- **Analysis period**: every view has its selector — rolling 7, 14, 30, 60 or 90 closed license days, 6 or 12 calendar months, the current or previous week, or the year to date (Overview opens on 30 days, *Daily changes* on 14, *Investigate an index* on 90). A banner says when a backfill is still filling the history in, or where the history starts when it is shorter than the period.
- **Binary units, IEC labels.** Every volume is computed in base 2 (1024) and labelled **MiB / GiB / TiB** by default (2.4.22). The system setting `[trackme_ui_defaults] volume_unit_labels = splunk` (*System settings → User interfaces*) switches the whole app to Splunk's own MB / GB / TB labels for the same values, and each user can pick either style, or the system default, in the settings panel of Tenant Home and Virtual Tenants; the values never change, only the labels. Every chart draws in one unit picked from its largest value; tables and tiles follow the same rule.
- **Exact dates, stated frame.** *Licensed yesterday* and the pool meters show the last closed license day or **Not recorded** (the last recorded day is named separately), never an older day under that label; every sub-tab states the license-day frame (license manager midnight and its UTC offset) and names the collection scope — a custom license source, permanently deleted indexes, missing or partial days.

- **No auto-refresh.** Tenant Home's auto-refresh is paused while the license view is open, so an analysis or a configuration draft is never reloaded under you; **Refresh** reloads.

Sub-tabs and deep links

Two rows of sub-tabs: the views on the first — **Overview**, **Daily changes**, **Investigate an index**, **Scopes**, **Working days & holidays**, **Over quota**, **Chargeback**, **Configuration** — and, under **Scopes** only, a second row with **All scopes** and one tab per enabled scope (tabs while they fit, a filterable selector beyond, up to 50 scopes). Each view has a deep link:

```
TenantHome?tenant_id=<tenant>&component=vol&tab=license_usage&view=<view>
```

where `<view>` is `overview` (the default), `daily-changes`, `investigate-index`, `scopes`, `scope-<scope id>`, `working-days`, `over-quota`, `chargeback` or `configuration`. A link to a scope that no longer exists, or is disabled, opens the overview. *Daily changes* and *Investigate an index* keep their selection in the link — `vol_index=<index>`, `vol_day=YYYY-MM-DD` and `vol_compare=weekday` (the previous-day comparison is implicit) — so a dated drilldown can be shared; without a date, a link opens on the last closed day against the previous day.

Overview

- **Key figures —** Licensed yesterday, Daily average (with the working-day average once working days are classified), Peak day, Trend (the 30-day rule of the entities, over the environment), Month to date, Month projection (the sum of the per-index projections, with the number of indexes that have one), Top 5 share. With costs on: the **Licence cost** or the **Cost of the volume** of the period (see *How costs are computed*), the **Cost per GB**, and the **Unused capacity** (or **Over the licence**). With a quota in force: the **Quota used yesterday** and the **Days over quota** of the period.
- **Insights** in plain words, most important first: a **Yesterday** block (the licensed volume of the last closed day, its change against the previous day and against the same weekday last week, the top changes per direction), then days over quota and pools close to it, the trend, the largest increase and decrease, indexes that stopped consuming, new consumers, the concentration, the weekly pattern and the licensing model.
- Every card's menu offers **Refresh**, **Open in search** (the `mstats` search behind the figure) and, for a figure measured in the license usage log, **Verify against license_usage.log** (see *Closed-day reconciliation*).
- **Licensed volume per day —** stacked by top consumers, with a **Top consumers** slider from 5 to 100 (remembered per viewer; the rest is *All others*) and the daily quota as an overlay line when a quota is in force.
- **The whole environment per day —** the daily total with the projection to the end of this month or of next month, the same rule as the entity chart.
- **Top consumers —** every index, sortable and filterable: rank, share, total, average, peak, the last 7 closed days against the 7 before, pool, projection and 30-day trend, plus the cost columns when costs are on. A click opens the entity.
- **Movers —** rising, falling, new consumers and stopped consuming, last 7 closed days against the 7 before. They need 14 recorded days: on a young tenant the card says so instead of calling every index new.
- **License pools —** one card per pool with its meters (yesterday, average, peak day), the number of recorded days over quota and the headroom; *(configured)* marks a quota set in the configuration. Each pool's quota is read from the pool's own rows, and the view lists the pools configured now: a pool the license manager has not reported for 4 days leaves the quotas (the card says so after a day without report — a pool fed on weekdays only reads so every weekend) while its recorded days stay in the charts under its name.

Daily changes

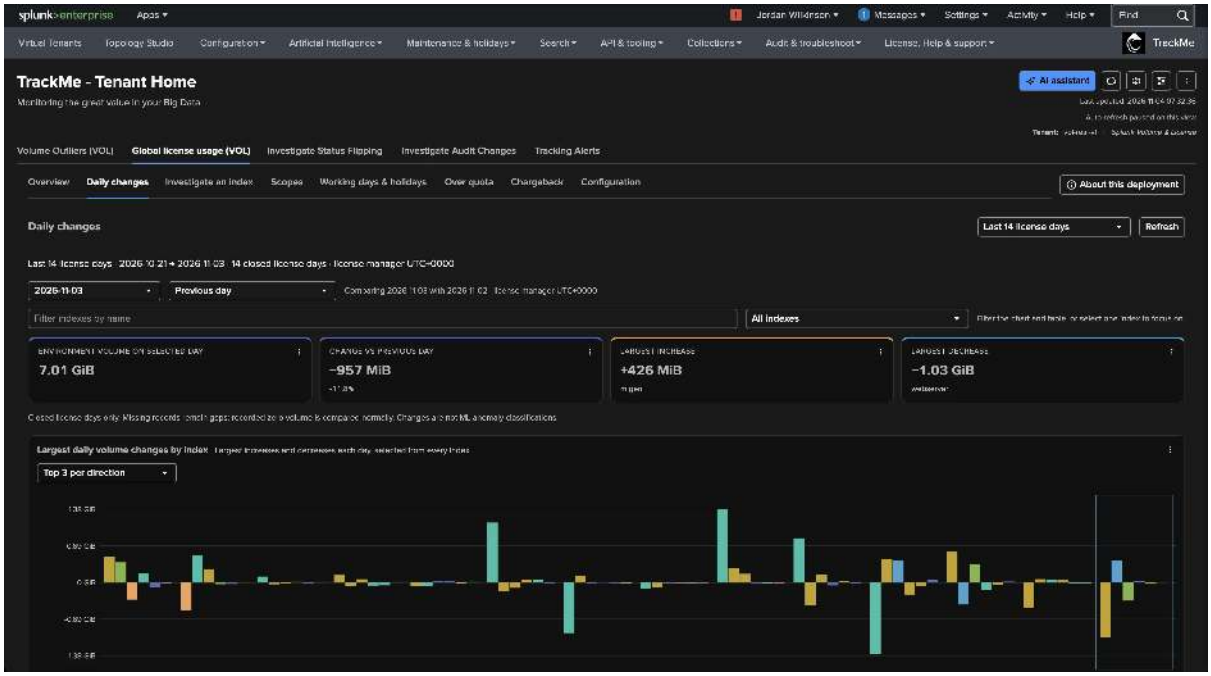
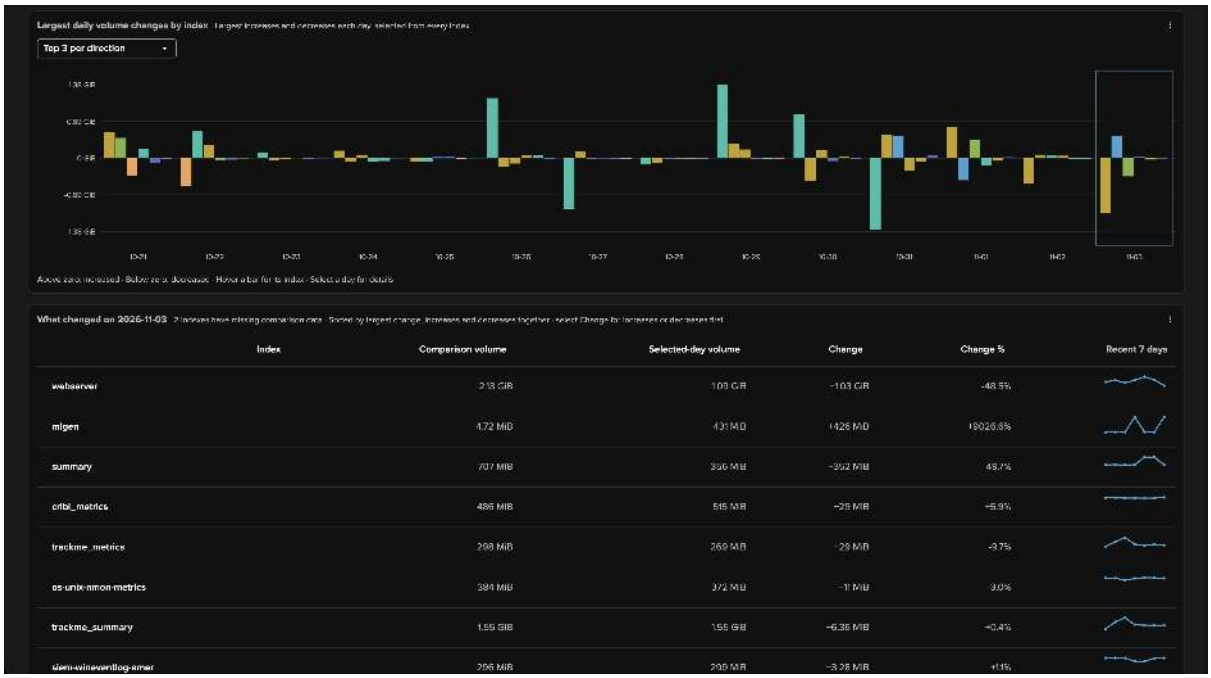
Which indexes moved, day by day. Each closed license day of the analysis period is compared with the **previous day** (the default) or with the **same weekday last week**:

- **Cards —** the environment volume on the selected day and its change against the comparison day, then the **largest increase** and the **largest decrease** of that day, each naming its index.
- **Largest daily volume changes by index —** one bar per mover and day, above zero for an increase and below for a decrease: the top 3, 5 or 10 per direction, chosen each day from every index (never only the Overview's top consumers). Hover a bar for its index and percentage; click a day to select it.
- **What changed on <day> —** every index of the selected day: comparison volume, selected-day volume, change, change in percent and the recorded volume of the last 7 days as a sparkline; sortable (the **Change** header cycles largest change → increases first → decreases first) and paged by 25. A row opens *Investigate an index* on that index and day.
- **Filter indexes** narrows the chart and the table by name, and the index selector next to it focuses the cards and the chart on one index, without the ranking cap.

Missing days stay gaps and a recorded zero is compared as zero: a change needs a recorded volume on both days, and an index with none on the comparison day reads *No prior volume*. These are changes, not outlier classifications.

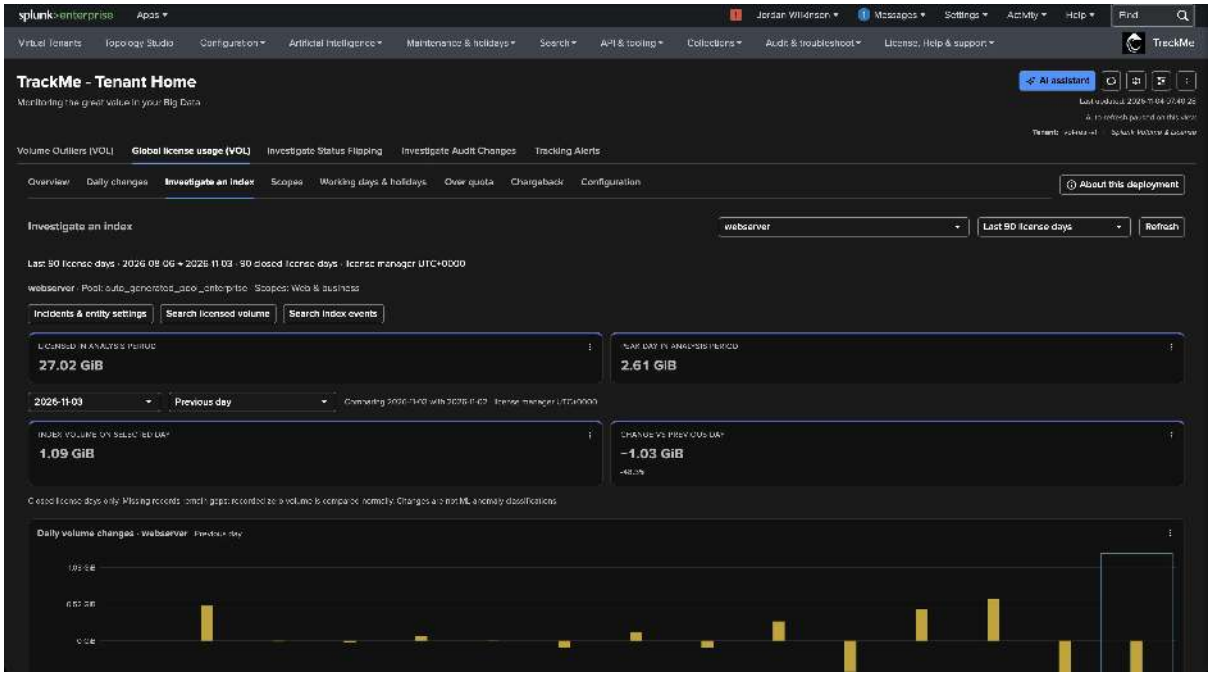




Investigate an index

Everything the tenant knows about one index, read-only. Pick it in the selector (every tracked index, including one without a closed day yet) or arrive from a row of *Daily changes*, from the Overview's top consumers, or from a deep link:

- The index's **pool** and the **scopes** it belongs to, with **Incidents & entity settings** (the entity's own modal, where the detection and inactivity settings live), **Search licensed volume** and **Search index events**.
- **Licensed in analysis period**, **Peak day in analysis period** and, with costs on, **Cost in analysis period**.
- The daily-change explorer of *Daily changes* for this index alone: the selected day and its comparison, the index volume and change cards, the daily bars and the selected-day comparison.
- The entity's own charts on their own windows — the daily licensed volume with its projection, the rolling volumes and their history, the outliers model and the hourly profile — as on the entity's *Volume & cost* tab.

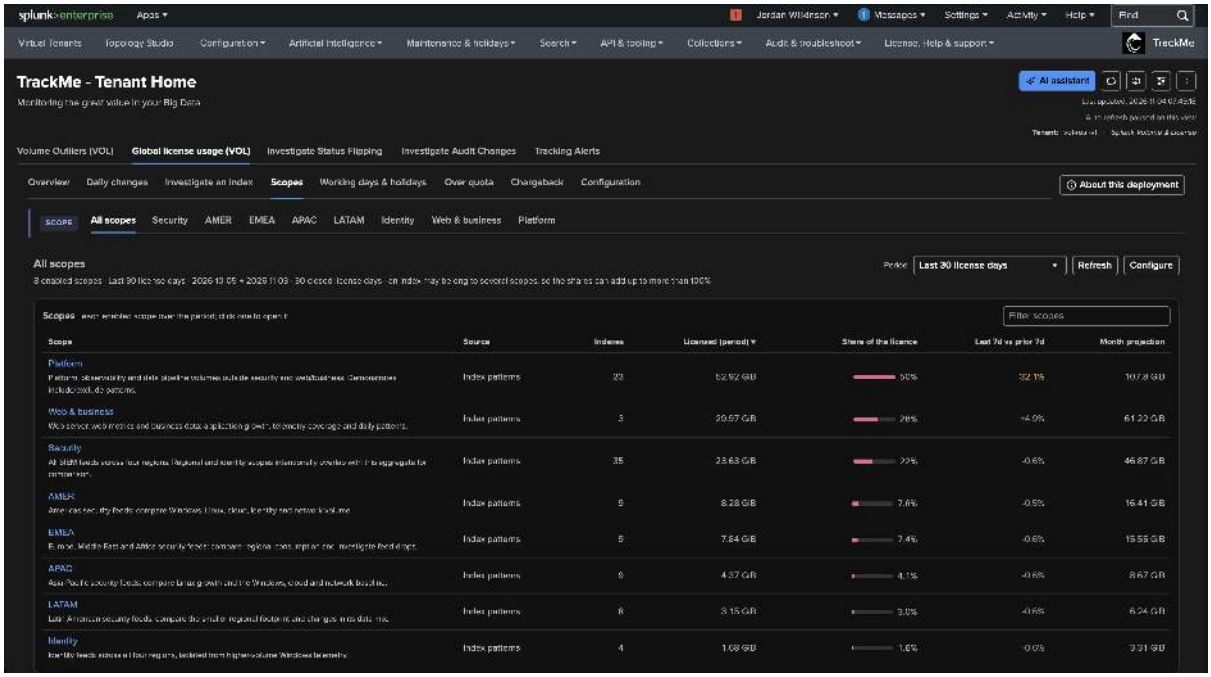


Scopes

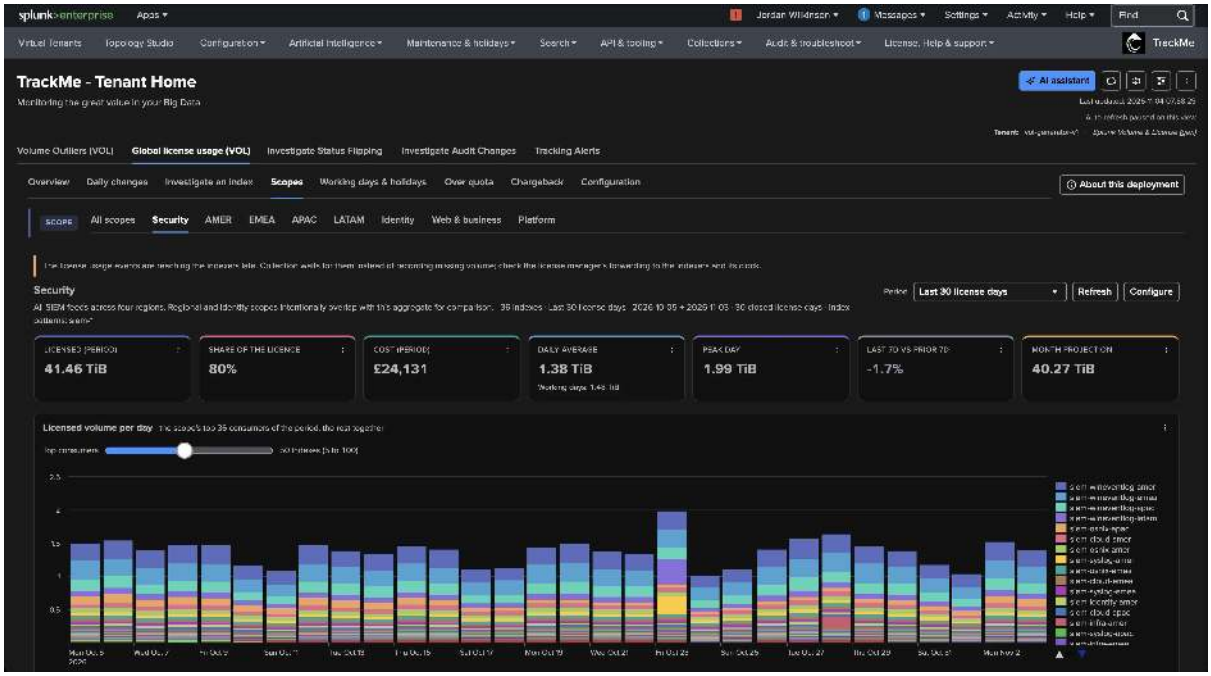
A **named scope** is a set of indexes analysed together: a team, a use case, the data of Enterprise Security. Up to 50 scopes; an index may belong to several (overlaps are allowed and shown). Two sources:

- **Index patterns** — include and exclude patterns, `*` and `?` as the only wildcards, case-insensitive.
- **CIM datamodel macros** — the scope follows the `cim_<datamodel>_indexes` macros, read where Enterprise Security configures them (**Read macros from**, per scope): this search head, the default, or a TrackMe remote account — the Enterprise Security search head tier when TrackMe runs on its own monitoring search head — as the caller, with the account's role restrictions. A remote source that cannot be read is reported as the scope's own error, never replaced by this search head's macros. A macro left at its default `()` is **unconstrained** and is left out, never read as every index; a macro that is not a plain list of index terms joined by `OR` is **unreadable** and left out too. Datamodels can be excluded, and exclude patterns apply on top. When every macro is at its default the scope is empty and the tab says so.

All scopes (`view=scopes`) compares every enabled scope side by side: its source (with the read error when unavailable), its indexes, **Licensed (period)**, **Share of the licence** or **Cost (period)**, the last 7 days against the 7 before and the month projection — sortable, filterable by name, a row opens the scope. It is computed from the per-index search the view already runs, so there is no daily average or peak here.



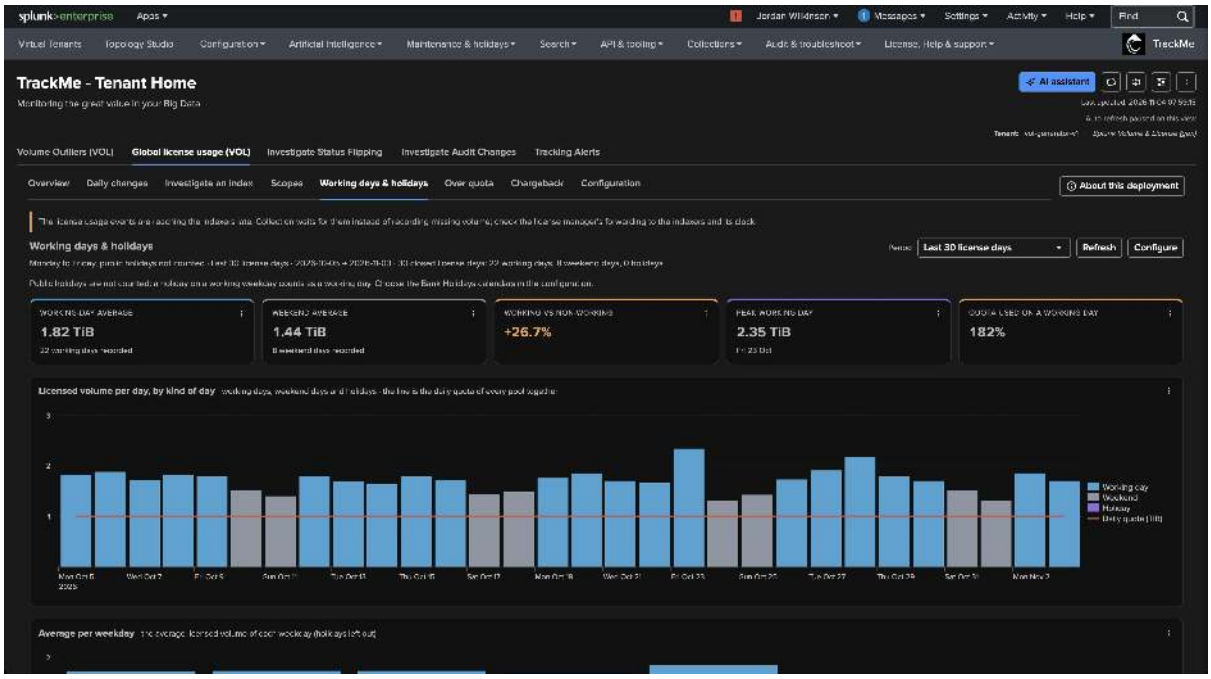
A scope tab shows **Licensed (period)**, **Share of the licence** (or **Cost (period)**), **Daily average**, **Peak day** (the peak of the scope's own daily series, not the sum of its indexes' peaks), **Last 7d vs prior 7d** and **Month projection**; the daily volume stacked by index with its own top consumers slider (50 by default); the scope per day with its projection; and its **Indexes** table.



Working days & holidays

Weekends and public holidays pull a daily average down, so the view gives a working-day average everywhere and a dedicated sub-tab: **Working-day average**, **Weekend average**, **Bank holidays** (the license days of the period that fall on a holiday, shown when holiday calendars apply), **Holiday average**, **Working vs non-working**, **Peak working**

day and **Quota used on a working day**; the daily volume coloured by kind of day; the average per weekday (holidays left out); the top consumers and the license pools on a working day; and the holidays of the period.



A license day is a **holiday** when its date is covered by a holiday of the calendars in use, else a **working** day or a **weekend** day from the working weekdays (Monday to Friday by default). The holidays are either not counted (default), those of the tenant's *Bank Holidays* calendars, or those of calendars you select. Only the holidays that count in a calendar are used, with their exact date every year (Easter Monday, Thanksgiving…). Working days follow the tenant's calendars, not the four Bank Holidays effects.

Over quota

The days a license pool went over its daily quota. It needs a quota in force: the license manager's pool size (Splunk Enterprise) or a **daily quota** configured per pool (any deployment, Splunk Cloud included). Without one, the tab offers *Configure the daily quota*.

- **Window —** 3, 6 (default) or 12 calendar months, ending with the last closed day.
- **Tiles —** In the window, This month, Last month, Rolling 60 days and Worst day.
- **Licensed volume per day against the quota —** one column per day, blue within the quota, red over it, with the quota line; a pool selector when several pools have a quota (the one most often over by default).
- **What made the day —** pick a day with the date selector or **Previous day / Next day** (a badge says *Over quota +N%* or *Within quota*): the pool's 10 largest indexes that day against their **usual day**, the average of their previous recorded days (up to 30). Each index links to its entity. Clicking a column of the chart presets the selector.
- **Days over quota —** the list, with the three largest indexes of each day and their change; **Per calendar month**; and **Splunk license warnings** for context.

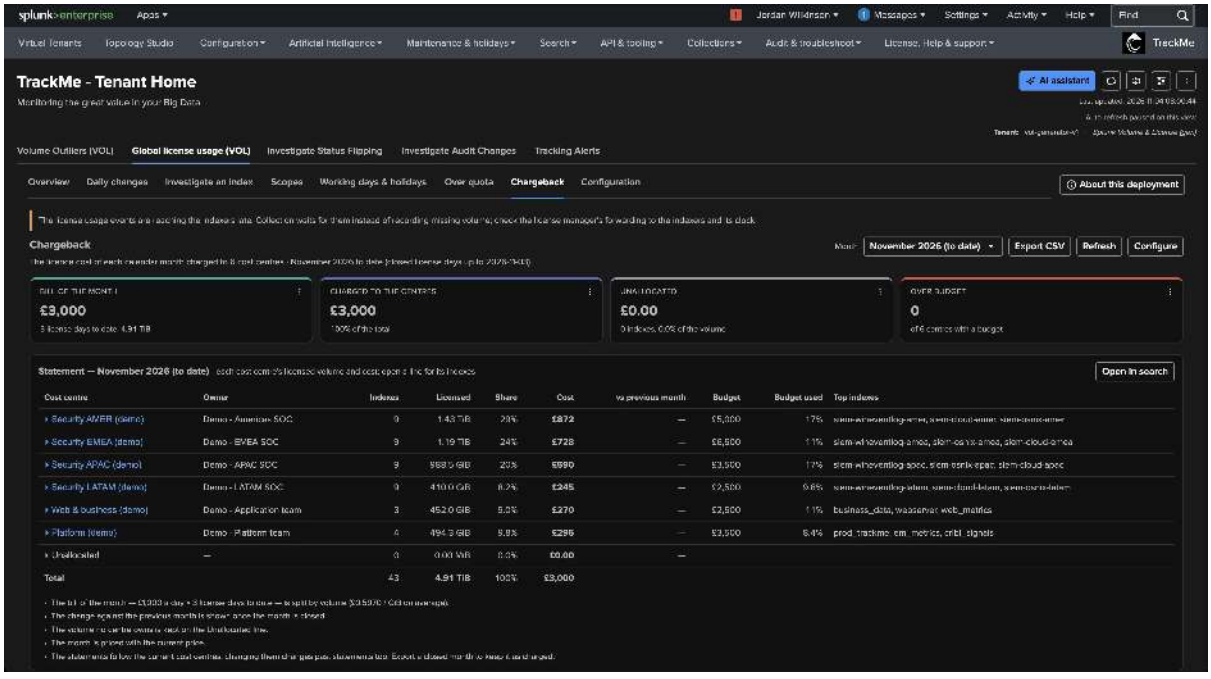
Note

Days over quota are not Splunk license warnings. Splunk counts one warning per pool and license-manager day over the pool's quota. A stack under 100 GB/day has search disabled for a pool after 45 warnings in a rolling 60 days; from 100 GB/day, warnings are issued but search is not disabled. TrackMe does not know the size of the stack (a pool is a slice of it), so the view states both rules and never claims which applies. Its warning count uses the license manager's quota only: a configured quota never raises one. Past days are measured against today's quota.

Chargeback

The license cost of each **calendar month**, charged to **cost centres**. It needs costs (a price) and at least one centre; otherwise the tab says what to configure.

- **Partition —** the centres are an ordered list, each with include and exclude index patterns. An index belongs to the **first** centre that matches it, so every GB is charged once; the configuration shows the indexes an earlier centre already took, so you can check the order. Indexes no centre matches form the **Unallocated** line, or are **spread** across the centres in proportion to their volume.
- **Statement —** for the month you pick among the last 13: the **Bill of the month** (the calendar days of the month; the closed days so far for the current month, marked *to date*), **Charged to the centres**, **Unallocated**, **Unused capacity** or **Over the licence**, and **Over budget**. Per centre: volume, share, cost, budget used and the change against the previous month, shown only between two complete months. Each line opens on its indexes. A 13-month trend chart and **Export CSV** complete it.
- **Prices with an effective date —** a renewal does not reprice the past: each previous price applies up to the month you give it, on its own basis (annual or per GB).
- A collection gap never shrinks the bill: the days are flagged and the rules under the statement say how each basis treats them.



Important

Statements are computed live from the **current** cost centres and price history: no statement is frozen. To keep the statement of a closed month as it was, export it to CSV.

Configuration

The **Configuration** sub-tab holds five sections, saved together with **Save configuration** (an optional comment goes to the audit trail), with live previews as you type. The sub-tab keeps an unsaved draft while you visit the other sub-tabs; **Reload saved** discards it.

Section	What you set
Scopes configuration	Add, remove, enable or disable a scope; its name, description, source (**Index patterns** or **CIM datamodel macros**), include and exclude patterns, excluded datamodels. The preview lists the indexes each scope resolves to.
Working days configuration	The working weekdays and the holidays: **Not counted**, **The tenant's calendars** or **Selected calendars** (with this year's holidays of each). The preview classifies the last 30 license days.
Daily quota configuration	One row per pool with the license manager's quota and an optional daily volume in GB. A configured quota becomes the view's reference (or gives a Splunk Cloud stack the volume it was sized for); it never changes Splunk's own warnings. Pools no longer reported stay listed so you can clear them.
Chargeback configuration	Enable the chargeback, choose what happens to unallocated indexes (**Its own line** or **Spread across the centres**), then the ordered cost centres (**Up / Down**) with a name, an owner, a monthly budget, a description and the patterns. **Seed from scopes** creates one centre per enabled pattern scope. The preview shows the partition.
Costs configuration	Enable the costs; the basis (**Annual licence cost**, with the licensed volume per day, or **Cost per GB**); the currency (ISO code, USD by default); the allocation (**By rate** or **By share of the bill**); the display (**Next to the percentages** or **Instead of the percentages**); and the **Price history**: **Record a price change** copies the saved price to last month before you enter the new one, **Add a previous price** enters an older one.

The configuration is one document per tenant with a revision: a save based on an older revision is refused, so two people editing at once never overwrite each other silently. It is backed up with the tenant. Nothing is configured by default.

Import / Export (an inner tab of *Configuration*, 2.4.22) moves the whole document between tenants and deployments. **Export** downloads the saved configuration — the five sections, the price history included, never unsaved edits — as a JSON file of format `trackme.vol.license-configuration`. **Import** reads such a file (up to 2 MiB), validates it on the server, shows the summary and the JSON, and **Replace configuration** replaces the destination's whole document after a confirmation that names the tenant: no merge (an empty section removes what was there), the destination's loaded revision must still be current, and unsaved edits or read-only access block it. Remote CIM accounts and Bank Holidays calendars are referenced by name, not exported: they must exist on the destination.

How costs are computed

Every figure uses one **effective rate per GB**:

- **Annual licence cost, by rate** — the annual cost divided by 365 and by the licensed GB per day (the configured value, else the pools' quota in force). Each GB costs the contract rate, and the **Unused capacity** is the bill of the recorded days minus the cost of the volume used (negative: **Over the licence**).
- **Annual licence cost, by share of the bill** — the bill of the recorded days split across the indexes by volume, so the costs add up to the bill. It needs no licensed volume per day: the natural choice on Splunk Cloud.
- **Cost per GB** — that cost, always by rate.

Amounts are never rounded, so a small per-GB price never turns into zero.

Permissions

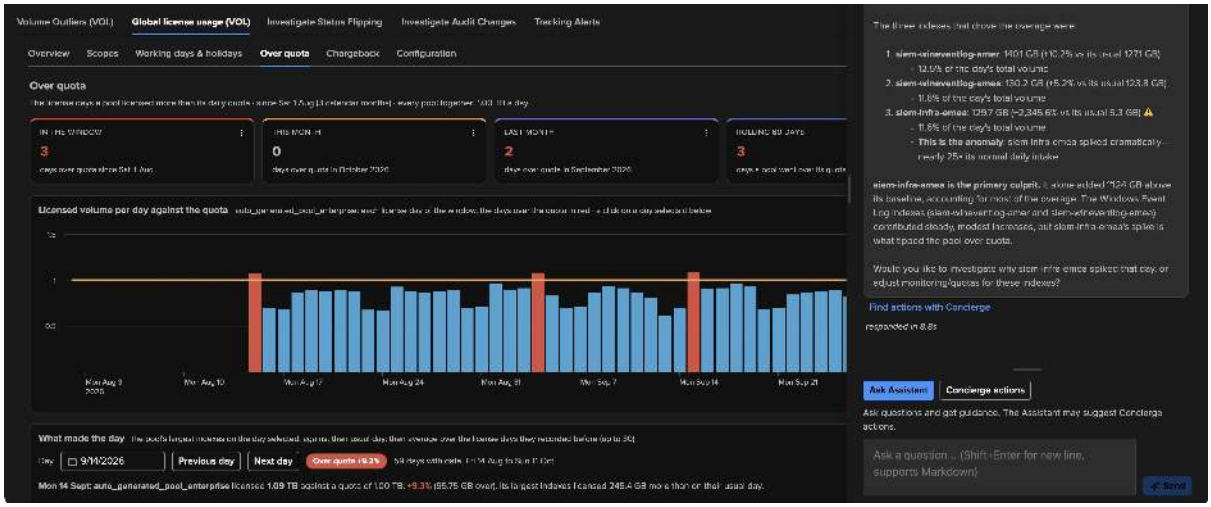
Action	Who
Open the tab and every sub-tab	Every TrackMe user who can open the tenant (`trackmeuseroperations`); the searches and the reads run with the user's own session.
Change the configuration (in the page or through the AI Assistant)	`trackmepoweroperations` **and** a power or admin role on the tenant. Otherwise the Configuration sub-tab is read-only. Changes are refused while the TrackMe license is read-only.

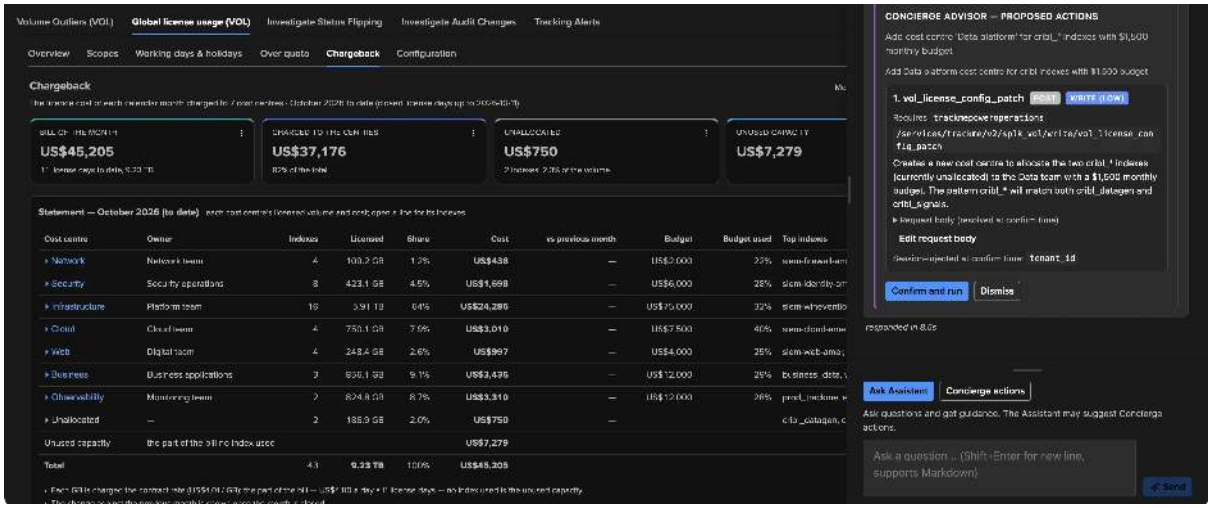
Every saved change is audited (`update license view configuration`).

AI Assistant on the license view

While the Global license usage tab is open, the Tenant Home **AI Assistant** works on this view: it knows the view, its configuration and the figures of the sub-tab on screen (the period, the day selected in Over quota, the statement month…), offers suggested questions per sub-tab, and keeps one conversation across sub-tabs.

With your consent it can **change the configuration** through the *Concierge*: add, change, remove or reorder scopes and cost centres, set the costs, record a price change or edit the price history, set the working days, set or clear a pool's quota, enable the chargeback. Each change is applied to the latest saved configuration, audited, and the view reloads it (an unsaved draft of your own is kept). The same permissions apply as in the page.





Known limits

- As deep as the recorded history: live collection plus backfill, up to 400 days within the retention of the license usage log. The movers need 14 recorded days, a month projection 7 closed days per index.
- Past days are measured against **today's** quota (there is no quota history).
- Statements follow the current cost centres and prices (see above).
- CIM scopes read the macros of the search head TrackMe runs on.
- The periods (30 / 60 / 90 days), the over-quota windows (3 / 6 / 12 months) and the chargeback depth (13 months) are fixed choices.

Alerting

VOL entities flow through *stateful alerting* like every component. What is VOL-specific:

- The **Create Alert** wizard offers the `SPLK-VOL` technical alert type (a filter on `object_category=splk-vol`); the outliers trigger stays on by default, the outliers being the VOL state. VOL is selectable in the stateful email component filter and in the SLA breaches alert.
- **Stateful alert emails** embed the rolling volume charts (24 h / 12 h / 4 h / 60 min over the alert's chart window), the outliers chart of each model, and a **daily licensed volume** bar chart over the last 30 license days.
- **AI status reports** run the ML outliers investigation for the index.
- Auto-acknowledgment, notable events, the free-style REST call, maintenance mode, CMDB and alert enrichment (`splk_general_vol_cmdb_search`, `splk_general_vol_alert_enrichment_search`)

and the drilldown (`TenantHome?component=vol&keyid=…`) need nothing special.

See *Alerting — in depth* for the alert types and the email anatomy.

REST endpoints

Resource group `splk_vol` (browse it with **API & tooling → TrackMe REST API Reference**, every endpoint supports `describe=true`):

Endpoint	Purpose
`POST /trackme/v2/splk_vol/vol_get_table`	The VOL entity table of a tenant.
`POST /trackme/v2/splk_vol/vol_entity_info`	One index: its figures, direction, inactivity policy in force and the entity searches.
`POST /trackme/v2/splk_vol/vol_get_state`	The collector state (cursor, validated history, license-manager offset, deployment type) and the backfill progress.
`POST /trackme/v2/splk_vol/vol_license_overview`	The Global license usage context and searches (`period_days` 30 / 60 / 90, `top_n` 1 to 100, `over_quota_months` 3 / 6 / 12), with the license verification context: the `Usage` writer, the effective coverage and the per-day `reconciliation` receipts (also carried by `vol_license_config` and `vol_entity_info`).
`POST /trackme/v2/splk_vol/vol_license_config`	The license view configuration with its resolved scopes, cost-centre partition, calendars and working-days preview, and whether the caller can change it; with a `draft`, the draft validated section by section and previewed.
`POST /trackme/v2/splk_vol/write/vol_license_config_update`	Save the whole configuration (`revision` of the document it is based on, `config`, optional `update_comment`). A stale revision is refused (HTTP 409).
`POST /trackme/v2/splk_vol/write/vol_license_config_patch`	Targeted changes on the latest saved configuration (`operations`, 1 to 50, all applied or none): `scope_upsert` / `scope_remove` / `scope_move`, `centre_upsert` / `centre_remove` / `centre_move`, `chargeback_set`, `costs_set`, `price_change`, `price_history_upsert` / `price_history_remove`, `working_days_set`, `quota_set`. The AI Assistant uses this endpoint.
`POST /trackme/v2/splk_vol/write/vol_set_direction`	The detection direction of one or more indexes (`object_list` or `keys_list`).
`POST /trackme/v2/splk_vol/write/vol_set_inactivity`	The inactivity policy of one or more indexes: `policy` `tenant` / `static` / `variable` with `max_sec_inactive` or `slots`.
`POST /trackme/v2/splk_vol/write/vol_backfill_control`	`action` `pause` / `resume` / `cancel` / `restart`, optional `run_now`.
`POST /trackme/v2/splk_vol/write/vol_bulk_edit`, `vol_update_priority`, `vol_monitoring`, `vol_delete`, `vol_update_wdays`, `vol_update_hours_ranges`, `vol_update_monitoring_time`, `vol_update_manual_tags`, `vol_update_sla_class`	The generic entity operations, as for every component.
`POST /trackme/v2/vtenants/admin/update_tenant_vol_inactivity_policy`	The tenant inactivity policy (dispatches the tracker so the indexes apply it within a minute); read it in the `vol` block of `GET vtenants/tenant_default_delay_config`.
`POST /trackme/v2/vtenants/admin/update_tenant_vol_outliers_kpis`	The default outliers KPIs, with the opt-in reconcile of the existing indexes.

The tenant is created with `tenant_vol_enabled` (see *Creating a tenant*); every `vol_*` option below can be set in the same call.

Tenant options

Stored in the tenant's `vtenant_account` and editable from *Configure tenant*:

Option	Default	Meaning
`vol_account`	`local`	This Splunk, or the remote account the license usage is collected from.
`vol_license_search`	`index=_interna source="*/license_usag log"`	The license search constraint (advanced, see above).
`vol_settle_seconds`	`300`	Settle margin (60–3600 s) before a 5-minute bucket is read.
`vol_late_overlap_seconds`	`1800`	How far before its cursor each run rereads the license usage log for late events (0 disables, max 14400).
`vol_backfill_days`	`30`	Days of history replayed at creation (0 disables, max 400).
`vol_default_direction`	`both`	Default detection direction of new indexes: `both` / `lower` (drops) / `upper` (spikes).
`vol_outliers_kpis`	`last_24h_vol`	The rolling KPIs every new index gets a model on.
`splk_outliers_min_days_hist`	`15`	Minimum history before a model's confidence is *normal* (the wizard's value on a VOL tenant; the system default is 30).
`vol_mloutliers_priority_filt`	every priority	Priorities in scope for outliers.
`vol_mloutliers_filter_expres`	empty	Filter expression restricting the indexes in scope.
`vol_inactive_policy`	`variable`	The tenant inactivity policy shape.
`vol_max_sec_inactive`	`604800`	Static policy threshold (7 days).
`vol_inactive_slots`	working hours	Variable policy slots (Mon–Fri 08:00–19:59 at 1 day).
`vol_inactive_default`	`604800`	Variable policy threshold outside every slot (7 days).
`impact_score_vol_inactive`	`100`	Impact score of an inactive index.

The Global license usage configuration (scopes, working days, quotas, costs, chargeback) is not a tenant option: it lives in its own document, edited in the view's **Configuration** sub-tab or through `vol_license_config_update` / `vol_license_config_patch`.

Metrics

Written to the tenant's metric index under `trackme.splk.vol.*` (`object_category=splk-vol`, dimensions `tenant_id`, `object`, `object_id`):

Metric	Meaning	Unit
`trackme.splk.vol.volume_5m_mb`	Licensed volume of the 5-minute bucket (the base series; the hourly profile is `mstats sum(…) span=1h`).	MB
`trackme.splk.vol.last_60m_volume_mb`, `last_4h_volume_mb`, `last_12h_volume_mb`, `last_24h_volume_mb`	Rolling volume ending at the bucket end — the outliers inputs.	MB
`trackme.splk.vol.last_24h_pool_pct_used`	Share of the license pool over the last 24 hours (Splunk Enterprise only).	percent
`trackme.splk.vol.daily_volume_mb`	Licensed volume of a closed license day, stamped mid-day. Since 2.4.22 it carries the effective license weight (`daily_effective_mb` is written alongside as the marker; an older point without it holds the raw ingest). A point corrected by the *closed-day reconciliation* is stamped later in the same day with the `license_day` and `reconciliation_revision` dimensions, so `latest()` selects it.	MB
`trackme.splk.vol.daily_ingest_mb`	Raw ingest of the closed license day, before the license weight (2.4.22).	MB
`trackme.splk.vol.volume_5m_ingest_mb`, `volume_5m_licensed_mb`	The 5-minute bucket as raw ingest and as licensed volume (2.4.22; `volume_5m_mb` stays the raw series the outliers models train on).	MB
`trackme.splk.vol.status`	Decision-maker status.	status code

Every point costs 150 bytes of metric-index licensing: about 288 buckets × 5 measures per index per day live (≈ 216 KB per index per day); the backfill writes the same series over the requested depth, and the wizard shows that estimate before you confirm.

The entity searches (*Open in Search* on every chart) read those metrics:

```
| mstats latest(trackme.splk.vol.daily_volume_mb) as daily_volume_mb
    where index=<metric_index> tenant_id="<tenant>" object="<index>" span=1d
| timechart first(daily_volume_mb) as daily_volume_mb span=1d
| eval daily_volume_gb=round(daily_volume_mb/1024, 3)
```

Troubleshooting

Symptom	What to check
The tracker succeeds but the tenant has no entity	The license search returns no `Usage` row: on a custom constraint, the `type` / `idx` / `b` fields are not extracted (add `KV_MODE = auto` for the source); on a remote account, the account's roles cannot read `_internal` on the remote deployment.
The daily chart shows no bar, or a bar a day early	No closed license day yet (a day sits mid-day; the entity overview chart carries its own 30-day window) — or your Splunk user's time zone differs from the license manager's: the daily point is placed on its license date, check the user preferences.
Every index turned red at once	Inactivity in force: the collection stopped (a failed usage search, the tracker disabled, a remote account failing) — the *Manage: volume collection* screen shows the cursor; the execution summary shows the run errors. Fix the source, the next run catches up 6 hours at a time.
No projection on the *Volume & cost* tab	Fewer than 7 closed license days, or the backfill has not merged its days yet (wait for the plan to complete).
The movers card says it needs 14 recorded days	Expected on a young tenant: the week-over-week comparison needs both weeks recorded.
A CIM scope is empty	The `cim_<datamodel>_indexes` macros are at their default `()` on the search head TrackMe runs on: configure CIM Setup there so the macros list the indexes.
Over quota is empty on Splunk Cloud	A Splunk Cloud pool has no quota: set a daily quota per pool in the **Daily quota configuration** section.
The Chargeback tab only explains what to configure	Costs are off, or no cost centre is defined.
Saving the configuration is refused	Someone saved since your draft started (reload, then reapply your change), you have no power or admin role on the tenant, or the TrackMe license is read-only.
Collection is held: *Usage was found from multiple license writers* / *No Usage writer could be established*	Two hosts write `type=Usage` into the license search (two license managers, a test stack forwarding its log to the same index), or none does yet. Scope `vol_license_search` with `host=<license manager>`; after a license manager replacement, collection resumes by itself 3 days after the old host stops writing. Nothing is lost meanwhile: the cursor waits.
The license view says the license usage events are reaching the indexers late	The collector's window is held behind the wall clock (15 minutes or more) because the writer's own events have not arrived; it waits rather than recording missing volume, and the hold is discounted from inactivity up to 4 hours. Check the license manager's forwarding to the indexers and its clock.
Licensed yesterday reads *Not recorded*	The last closed license day has no figure yet: it closes at the license manager's midnight and is recorded by the next collecting run, or the collection is held (see above). The last recorded day is named under the tile; an older day is never shown under that label.
About this deployment says a license day needs reconciliation attention	The day could not be reread: its `RolloverSummary` or `Usage` records are no longer searchable (retention of the license usage log, a remote account that cannot read it), the day boundaries could not be established, or the search failed. The previous figures are kept and the tracker retries every hour while the day stays in the seven-day window; the card gives the reason and the next attempt.
A day reads *Source reconciled · summary differs*	Not an error: TrackMe matches the detailed `Usage` records and Splunk's own `RolloverSummary` reports a different total for that day. Both totals and the difference are on the card; the comparison keeps running daily.
Yesterday's figure changed after the fact	The closed-day reconciliation repaired it (late `Usage` events, or the first reconciliation after an upgrade); the day's revision is on the card and the corrected point carries `reconciliation_revision`.
A backfill plan is *cancelled (live_history_reset)*	The live collection re-seeded (a gap above 24 hours, a source change) while the plan was open; **restart** the backfill from the *Manage: volume collection* screen once the live cursor advances again.

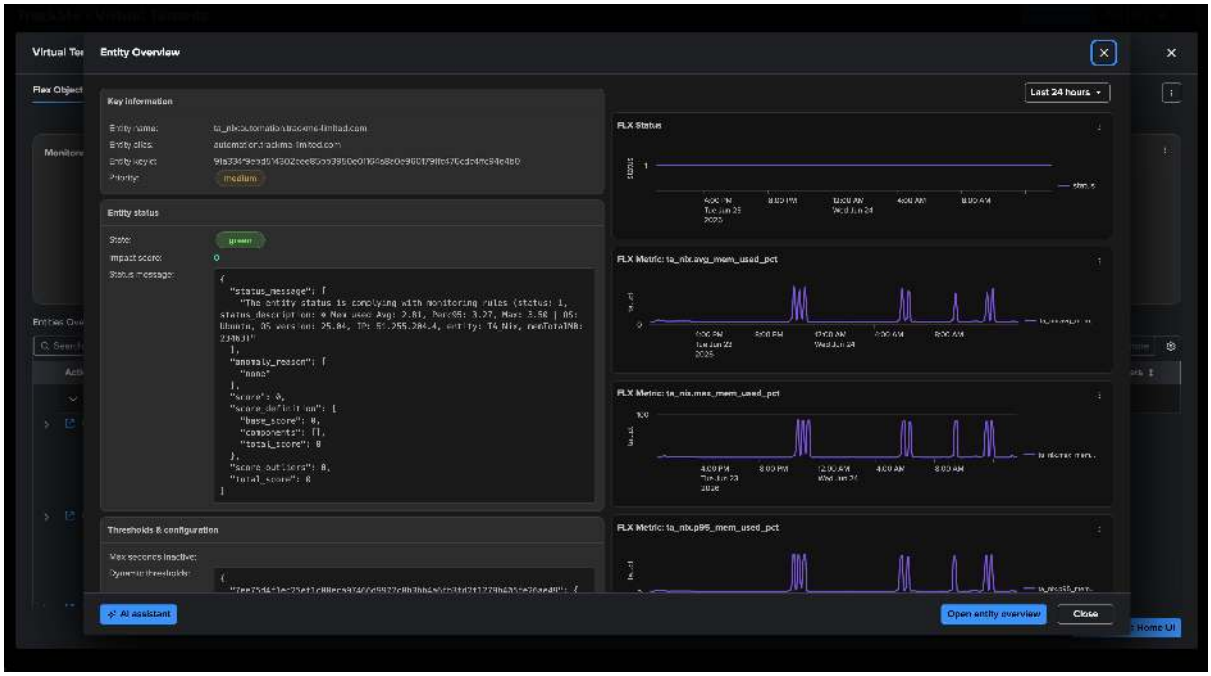
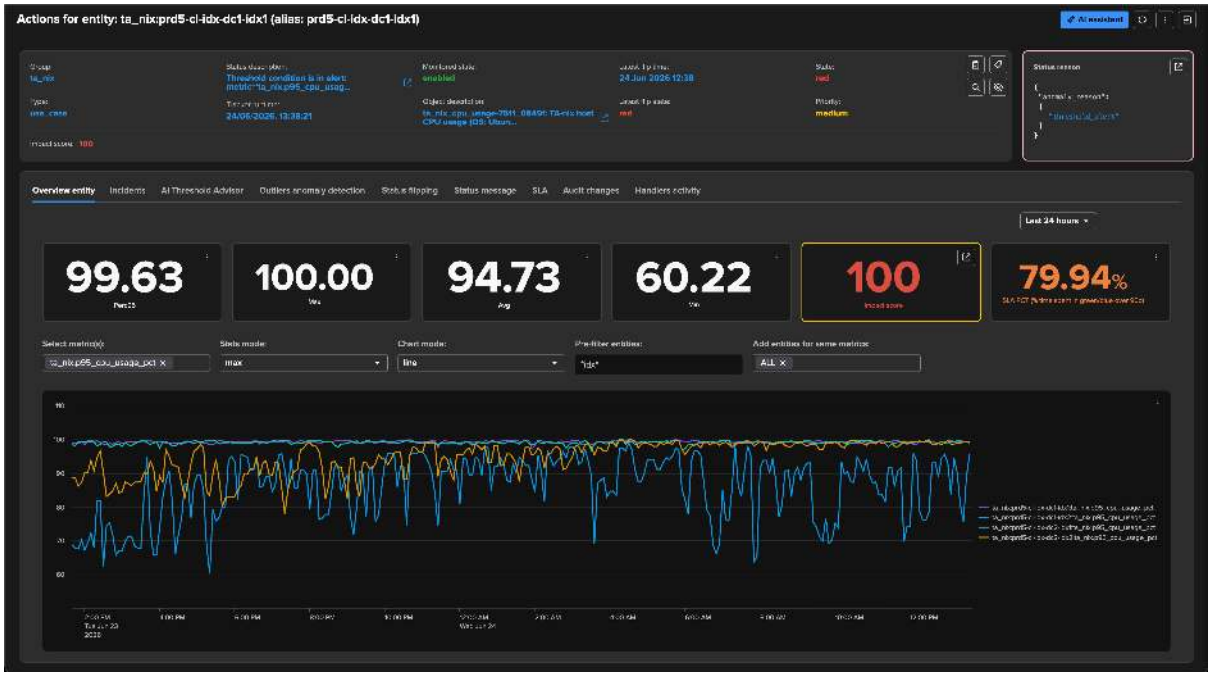
8.3.9 FLX — Flex Objects

Flex Objects turn the result of **any Splunk search** into fully tracked, scored, and alertable entities, with KPIs and thresholds you define. If you can write the search, TrackMe can monitor it. FLX is the most flexible component — and, with a 60+ template catalogue, often the fastest to get value from.

Note

Flex Objects are an **Enterprise / Unlimited Edition** capability.





The Flex search contract

A Flex tracker is a search whose **each result row becomes one entity**. TrackMe reads meaning from specific field names in that output:

Field	Required	Meaning
`object`	yes	The unique entity identifier (any ASCII string).
`status`	yes	The entity state: `1` green, `2` orange, `3` red, `0` unknown.
`group`	no	A logical grouping (defaults to the tracker name); an entity should belong to one group.
`metrics`	no	A JSON object of KPIs — one numeric value per key.
`outliers_metrics`	no	Per-metric ML outlier rules.
`alias`, `object_description`, `status_description`	no	Display name and human-readable context.
`max_sec_inactive`, `default_metric`, `default_threshold`	no	Inactivity window and default KPI / threshold.

Each metric you emit is stored on the entity **and** ingested into the metrics index (prefix `trackme.splk.flx.`), so your KPIs are immediately queryable with `mstats` for your own dashboards.

Dynamic thresholds

You set per-metric threshold rules (an operator and a value) entirely through the UI — no need to edit the SPL. Thresholds can be **time-sliced** (day-of-week × hour-of-day) for tighter limits during business hours. An entity's state is driven by threshold breaches, inactivity, outliers, and metric-shape drift.

The template catalogue

Rather than start from a blank search, load one of **60+ pre-built templates** from the **Flex Objects Library**, organised by vendor and category — Splunk infrastructure, data collection & quality, license management, Splunk Cloud / SVC, SOAR, Cribl, host monitoring, and more. Each template ships a complete search, pre-configured KPIs and outlier rules, a recommended schedule, and inline guidance. Load it, adapt the SPL to your environment, simulate, and create.

Tip

FLX is the most powerful component, and the steepest. Its value depends on the author's SPL skill — so start from a template whenever one fits. See also the *Use Cases* for worked examples.

Creating a Flex tracker

1. **Name & deployment** — local, or a remote account (connectivity is validated).
2. **Define the SPL** — from a template or from scratch.
3. **Time ranges** — short (for example `-5m` for `| rest`) or longer for `tstats` / `stats`.
4. **Simulate** — preview the discovered entities with their parsed metrics and outliers.
5. **Schedule & create.**

Outlier detection

FLX is, with DSM, the natural home for ML outlier detection. Per metric you can enable upper/lower breach alerting, with optional seasonality (hour, day-of-week) and a training window. Allow at least a week — ideally a month — of history before relying on outlier alerts. See *Machine Learning*.

Working at scale

A single tracker can manage from a handful to tens of thousands of entities. Use the `group` field deliberately to scope thresholds and SLA and to keep large trackers organised — a common convention is `object = group + ":" + host`. Prefer `tstats` over raw events and keep time ranges narrow.

Converging trackers

A **converging tracker** is a Flex flavour that aggregates the up/down state of many member entities — possibly across several tenants and components — into a single object with a **percentage-availability** KPI (for example "Authentication service: 98.5% available"). It is created from its own wizard, and a searchable inspector lists its members with a link back to each member's own tenant. Membership scope, the *orange-as-up* toggle, and the minimum-green percentage are editable in place; the object name and group are fixed once created.

Managing trackers

Warning

Manage a tracker's lifecycle only through TrackMe — do **not** manually delete its reports or lookups. Deleting a tracker removes its knowledge objects but does **not** remove entities it already discovered; those simply stop being maintained. Tune `max_sec_inactive` so entities that naturally go quiet do not raise false inactivity alerts.

8.3.10 Flex Object trackers — in depth

Tip

This is the **in-depth reference** for Flex Object (splk-flx) trackers. For the readable overview of what FLX is and when to use it, start with *Flex Objects*. This page covers the full tracker library, the search contract and KPI/metrics JSON, the creation wizard, outlier detection, high-scale grouping, converging trackers, and managing trackers.

Introduction

The splk-flx component (Flex Objects) allows you to turn the results of any Splunk search into fully tracked, monitored, and alerted entities within TrackMe.

- Flex trackers are scheduled backend jobs that orchestrate entity discovery, KPI tracking, and lifecycle management
- A Flex tracker can monitor anything you can query in Splunk: modular input statuses, Data Model Acceleration, host availability, infrastructure health, IoT devices, or any custom use case
- The component ships with a **library of 60+ pre-built use case templates** organized by vendor and category, ready to deploy in minutes
- A single tracker can discover and manage a few or many entities according to the needs
- **Enterprise Edition & Unlimited Edition** feature

Hint

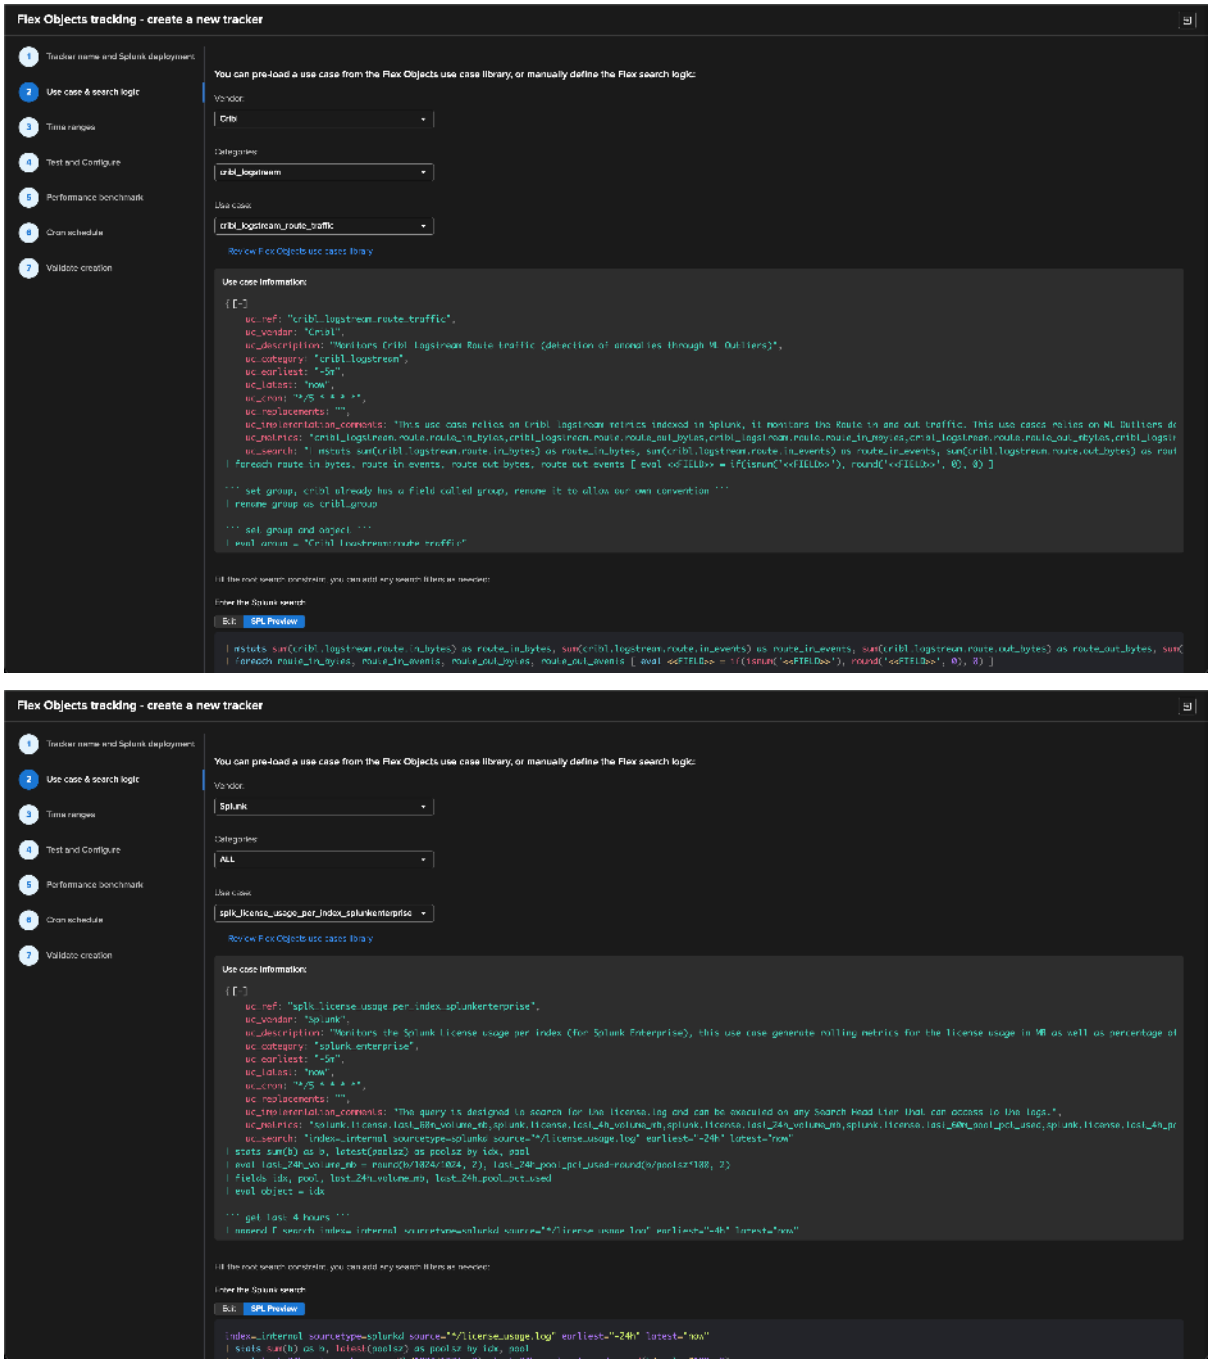
For a high-level overview of Flex Objects concepts and real-world use cases, see *Flex Objects - Adapt TrackMe to any monitoring use case (splk-flx)*.

The Flex Objects Library

One of the biggest challenges with a component as flexible as Flex Objects is knowing where to start. The **Flex Objects Library** solves this by providing 60+ pre-built use case templates that you can deploy in minutes.

Each template includes:

- A complete Splunk search with best-practice field definitions
- Pre-configured KPIs and metrics
- Outlier detection rules where applicable
- Recommended scheduling and time ranges
- Implementation comments and guidance



The Flex Objects Library with vendor and category filters. Select a use case to view its full definition including the search logic, metrics, and configuration.

Available categories

The library organizes use cases by vendor and category:

Category	Count	Examples
Splunk Infrastructure	17	KVstore status/size, cluster health, SHC status, CPU/memory usage, queue filling, HEC errors, bundle size, log level variations
Data Collection & Quality	10	Host tracking, deployment server clients, UF version tracking, dynamic sourcetype detection, volume variations, events drop detection, fields quality
License Management	5	Pool usage, global enterprise/cloud usage, per-index usage tracking
Splunk Cloud	4	SVC usage (global, per-app, per-consumer service), storage usage
Data Model Acceleration	1	DMA completion, size, runtime, and bucket monitoring
SOAR (Splunk Automation)	10	Asset health, service health, concurrent playbooks, infrastructure load/memory, action/playbook failures, automation brokers, Splunk forwarding
Cribl LogStream	8	Input/output health, CPU usage, destination pressure, pipeline metrics, route traffic, total traffic
Host Monitoring	4	Linux/Windows CPU usage, Linux/Windows memory usage (via TA-nix and TA-windows)

Hint

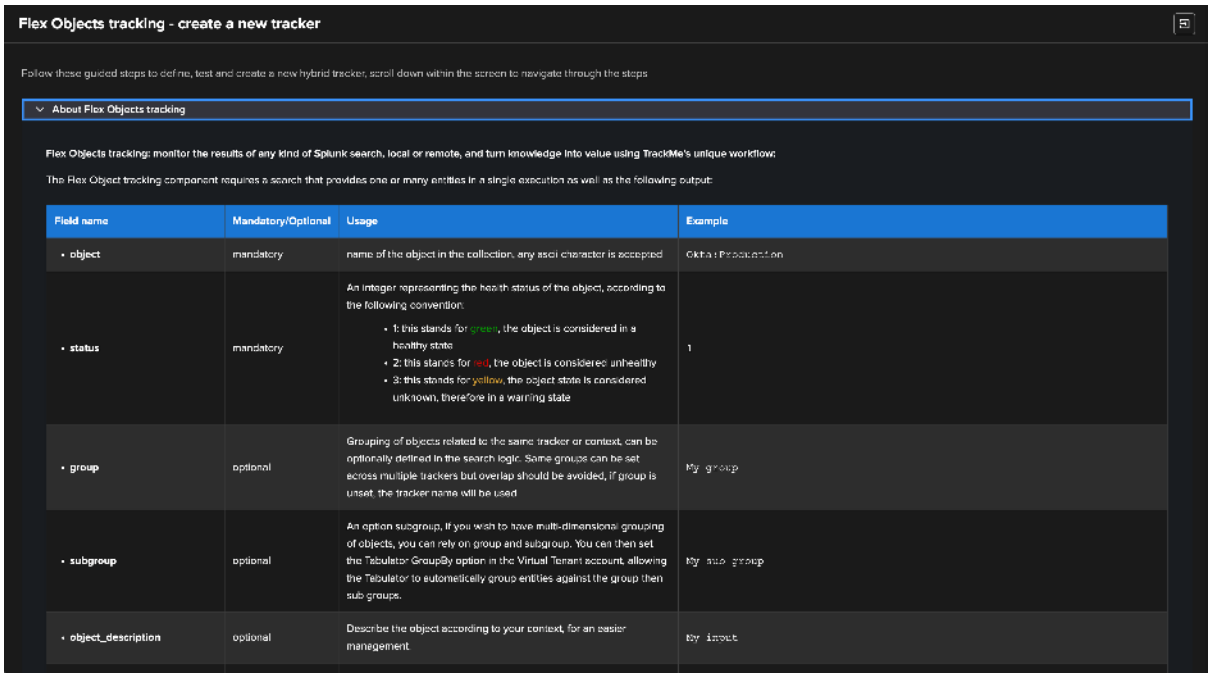
Loading a use case from the library

When creating a new Flex tracker, select "Vendor" and "Category" to filter the available use cases. Once you select a use case, its full definition is displayed including the search logic, expected metrics, and implementation comments. You can then customize the search to match your environment before deploying.

The Flex Search Contract

At the heart of every Flex tracker is a Splunk search that produces entities. This search must follow a simple contract: each result row represents one entity, and specific field names carry specific meanings.

This is what makes Flex Objects both powerful and approachable - if you can write a Splunk search, you can create a Flex tracker.



The Flex Objects field contract showing required and optional fields with their descriptions and examples.

Required fields

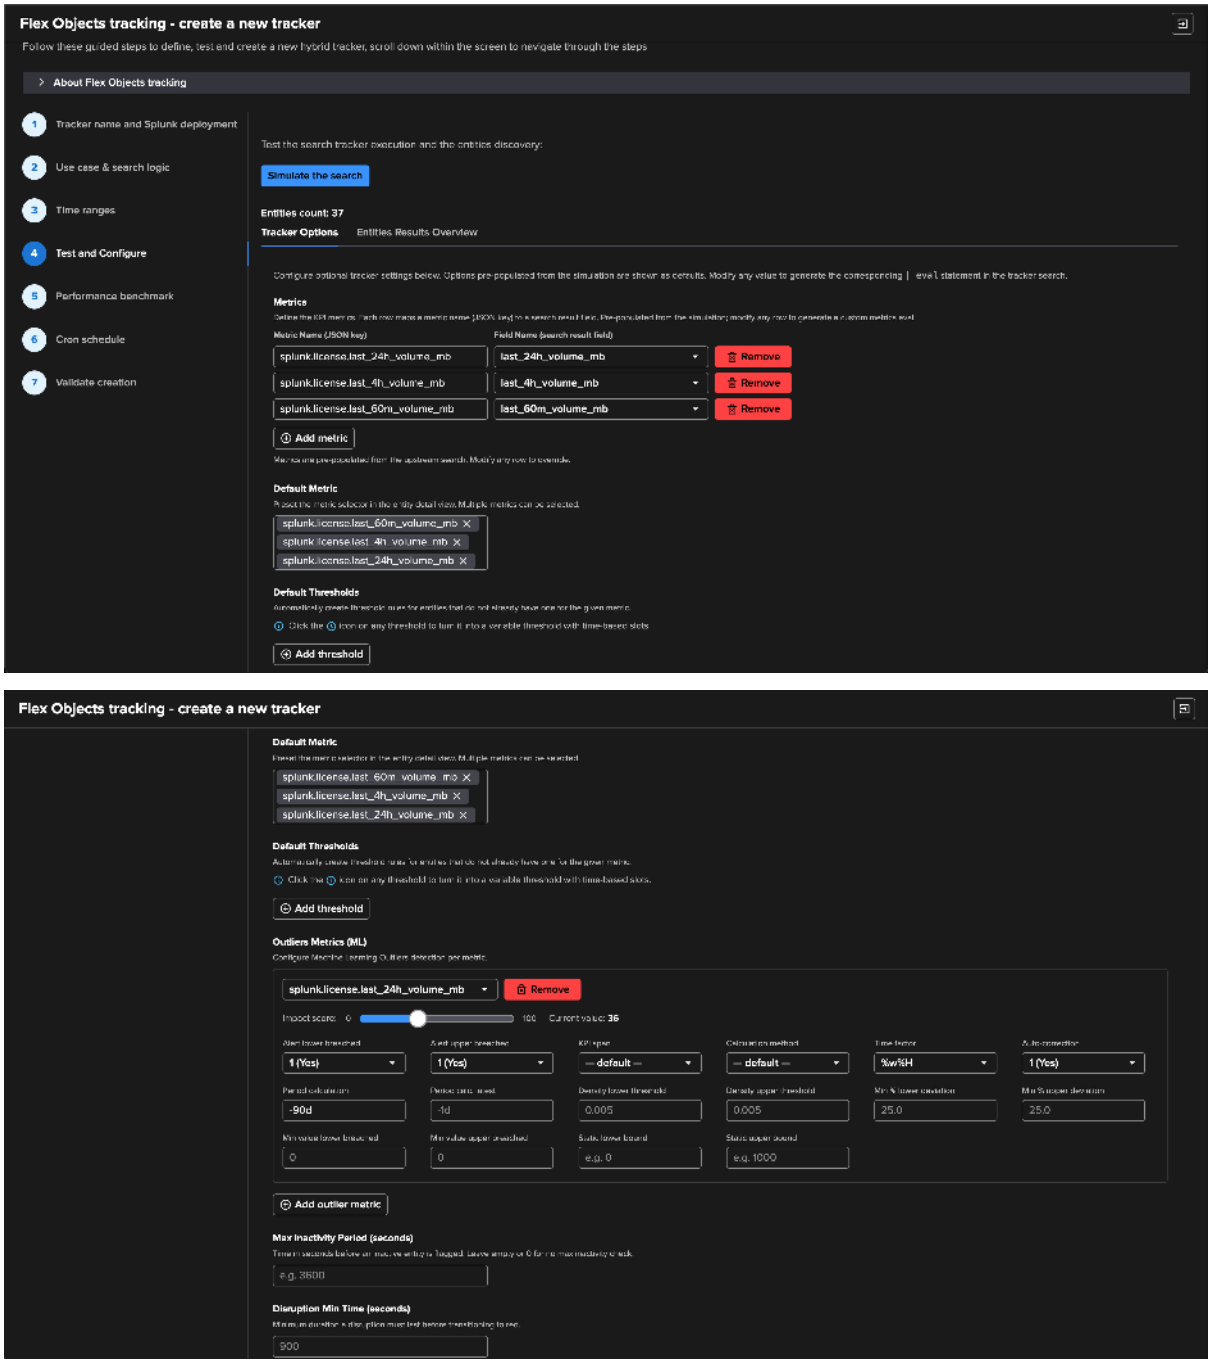
Every Flex search **must** produce these two fields:

Field	Type	Description
`object`	String	The unique identifier of the entity. Any ASCII character is accepted. This is the primary key that TrackMe uses to track the entity over time. Example: `Okta:Production`, `my_index`
`status`	Integer	The health status of the entity: **1** = green (healthy), **2** = orange (warning), **3** = red (critical). If set to **0**, the entity state is considered unknown.

Optional fields

These fields enrich the entity with metadata, KPIs, and anomaly detection:

Field	Type	Description
`group`	String	Logical grouping of entities. Groups can span multiple trackers but overlap should be avoided. If not set, the tracker name is used as the group.
`alias`	String	A human-readable display name for the entity, shown in the UI.
`object_descriptior`	String	Describes the entity for easier management. Example: `Datamodel: Authentication, app: Splunk_SA_CIM, retention days: 7.0`
`status_description`	String	Explains the current status condition. Example: `acceleration is completed`, `Input is enabled`
`metrics`	JSON String	A JSON object containing one or more Key Performance Indicators (KPIs). Example: `{'dma.complete_pct': 100.0, 'dma.size_mb': 136.55}`
`outliers_metrics`	JSON String	A JSON object defining Machine Learning Outlier detection rules per metric. Example: `{'dma.runduration_sec': {'alert_lower_breached': 0, 'alert_upper_breached': 1}}`
`max_sec_inactive`	Integer	Maximum number of seconds an entity can be inactive before turning red. Set to `0` to disable inactivity alerting.
`default_metric`	String	The primary metric to display in the entity table. Example: `dma.complete_pct`
`default_threshold`	JSON String	A threshold rule applied to the default metric for status determination.



Metrics, thresholds, and ML Outliers configuration - fully UI-driven for effortless setup.

Hint

Fully UI-driven configuration

Starting with TrackMe 2.3, the configuration of **metrics**, **thresholds**, and **ML Outliers detection** is entirely managed through the user interface. While the search contract fields remain available for programmatic definition, you can now configure every aspect of your KPIs and anomaly detection directly from the tracker UI - making it easier than ever to fine-tune your monitoring without editing SPL.

Understanding the metrics JSON

The `metrics` field is a JSON object where each key is a metric name and each value is a numeric measurement:

```
| eval metrics = "{'dma.complete_pct': " . complete_pct . ", 'dma.size_mb': " .␣
↪size_mb . ", 'dma.runduration_sec': " . round(runDuration, 2) . "}"
```

When metrics are provided:

- A metric object is automatically created in the Splunk metrics index for each KPI
- Metric names are prefixed with `trackme.splk.flx.` in the metrics index
- You can query these metrics with `mstats` for dashboards, reports, and further analysis

Understanding the outliers_metrics JSON

The `outliers_metrics` field defines which metrics should be monitored for anomalies using Machine Learning:

```
| eval outliers_metrics = "{'dma.runduration_sec': {'alert_lower_breached': 0,
↪'alert_upper_breached': 1, 'time_factor': 'none'}}"
```

Each metric entry contains:

- `alert_lower_breached`: Set to `1` to alert when the metric drops below the lower threshold (e.g., event count drops)
- `alert_upper_breached`: Set to `1` to alert when the metric exceeds the upper threshold (e.g., runtime spikes)
- `time_factor` *(optional)*: Defines the seasonality model for the ML algorithm:
  - `none` or omitted: No seasonality, the model uses the full history
  - `%H`: Hour of day (e.g., "traffic is normally lower at 3 AM")
  - `%H%M`: Hour and minute granularity
  - `%w%H`: Day of week + hour (e.g., "Monday mornings are different from Friday afternoons")
  - `%w%H%M`: Day of week + hour + minute for the finest granularity
- `period_calculation` *(optional)*: How far back to look for the ML model training. Example: `-90d` for 90 days of history.

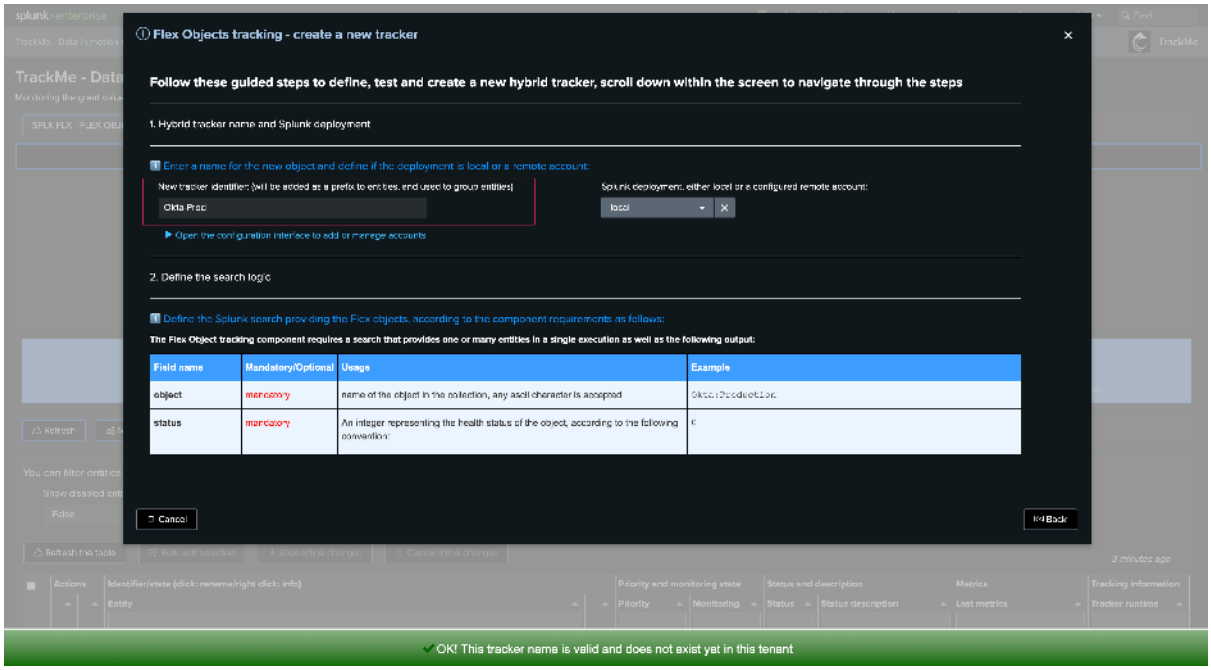
Creating a Flex Tracker

TrackMe provides a guided wizard that walks you through the entire creation process. You can either start from a library template or define a custom search from scratch.

Step 1: Name and deployment

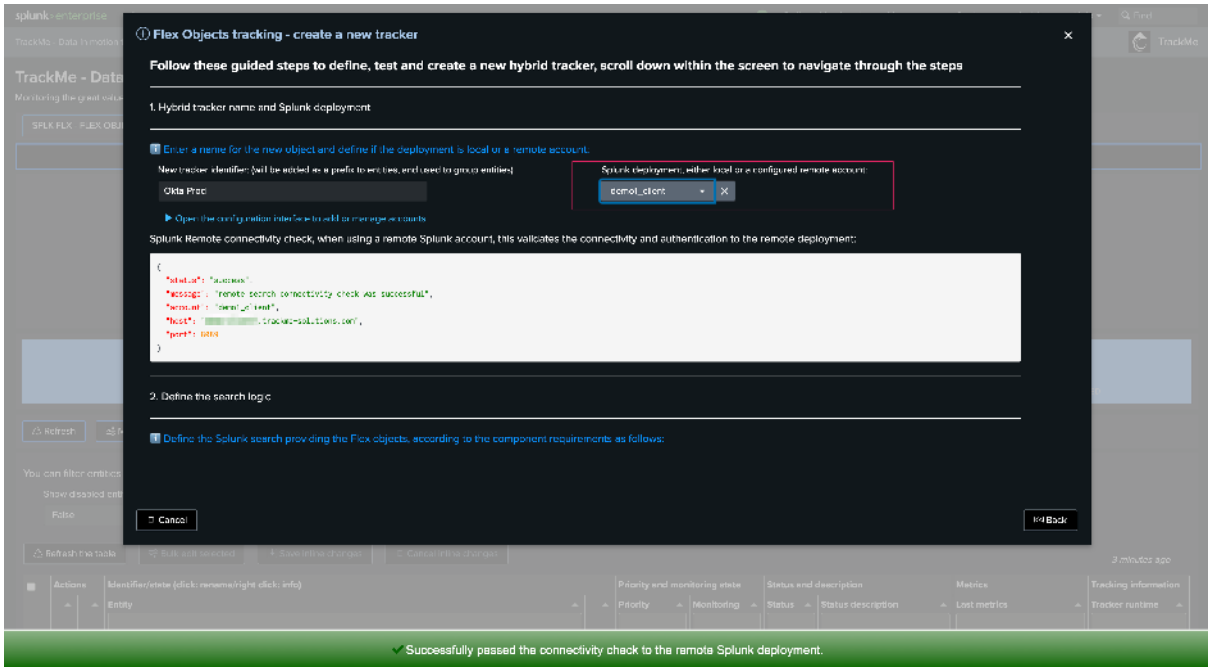
Choose a name for your tracker identifier and select the Splunk deployment (local or a configured remote account).

The tracker name is used as a prefix for entity grouping and must be unique within the tenant.



Step 1: Enter the tracker name and select the deployment. The name is validated for uniqueness.

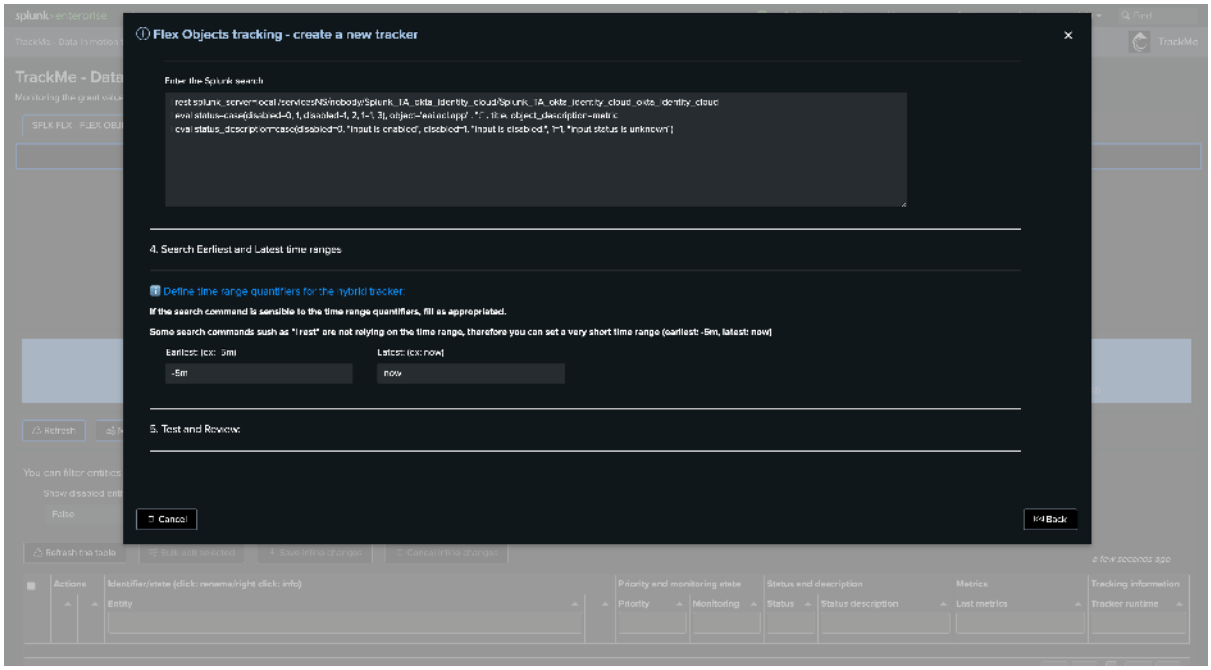
When using a remote deployment, TrackMe automatically validates the connectivity to the remote Splunk instance:



Remote deployment connectivity check showing a successful connection to the remote Splunk instance.

Step 2: Define the search logic

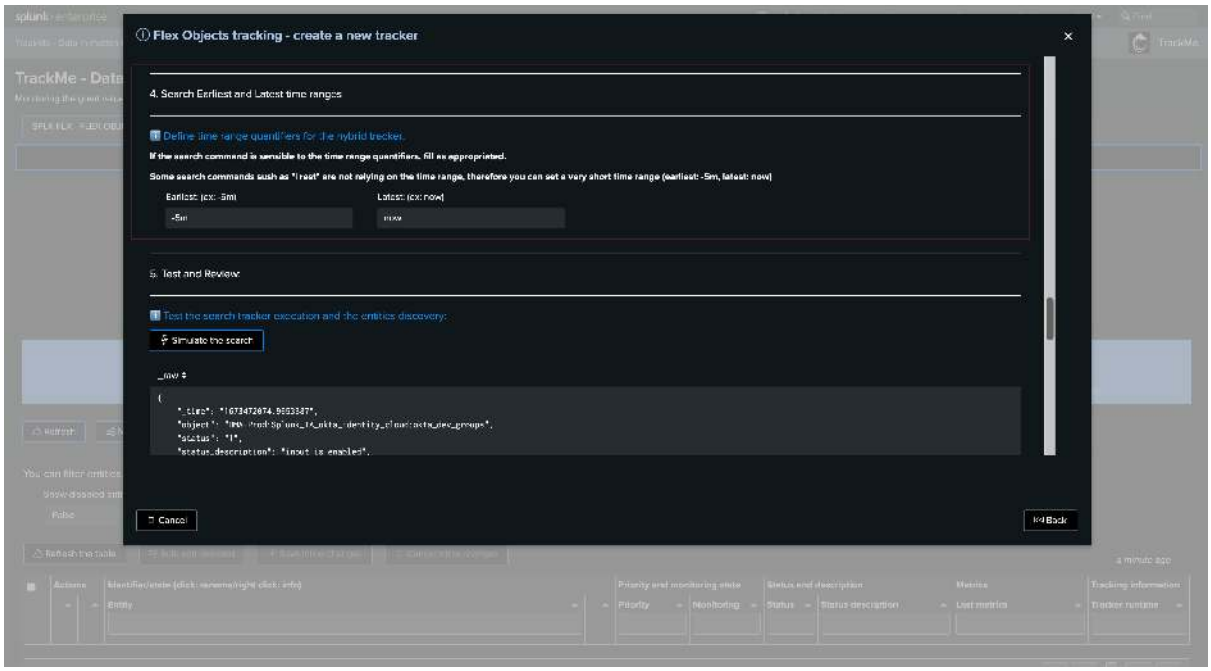
Enter your Splunk search or load one from the library. The search must produce at least the required fields (`object` and `status`).



Step 2: Enter or paste your Splunk search logic. The wizard displays the field requirements and examples for reference.

Step 3: Set time ranges

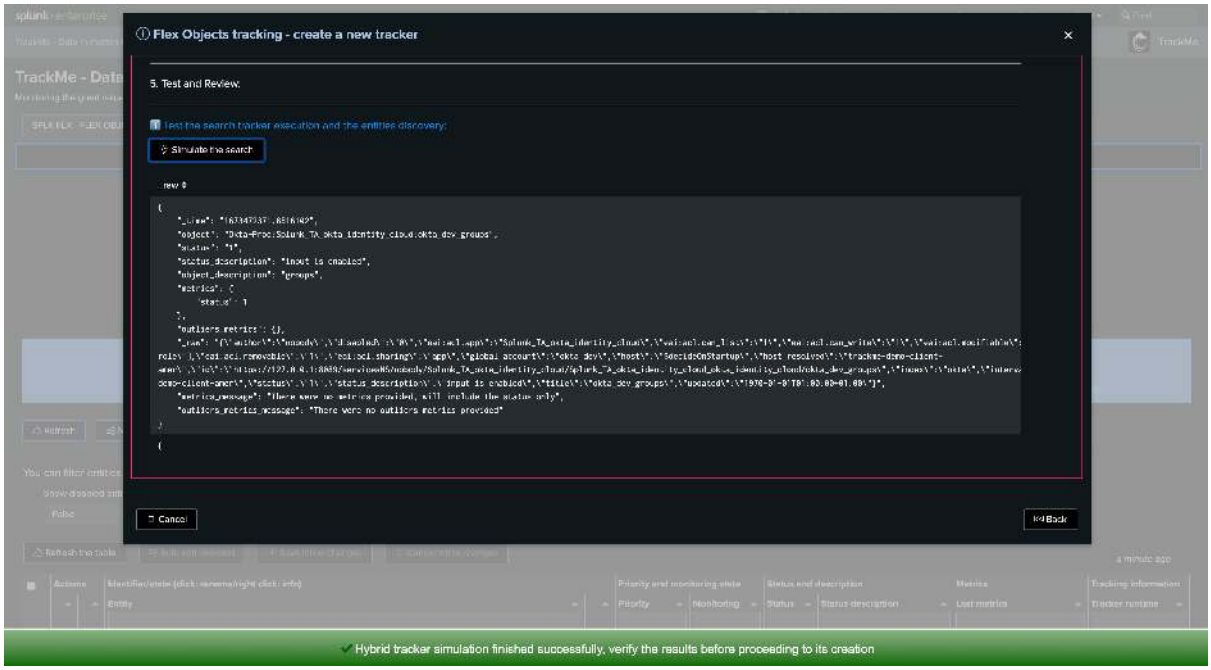
Define the earliest and latest time ranges for the search. Some searches (like those using `| rest`) don't rely on time ranges, in which case you can set a very short window.



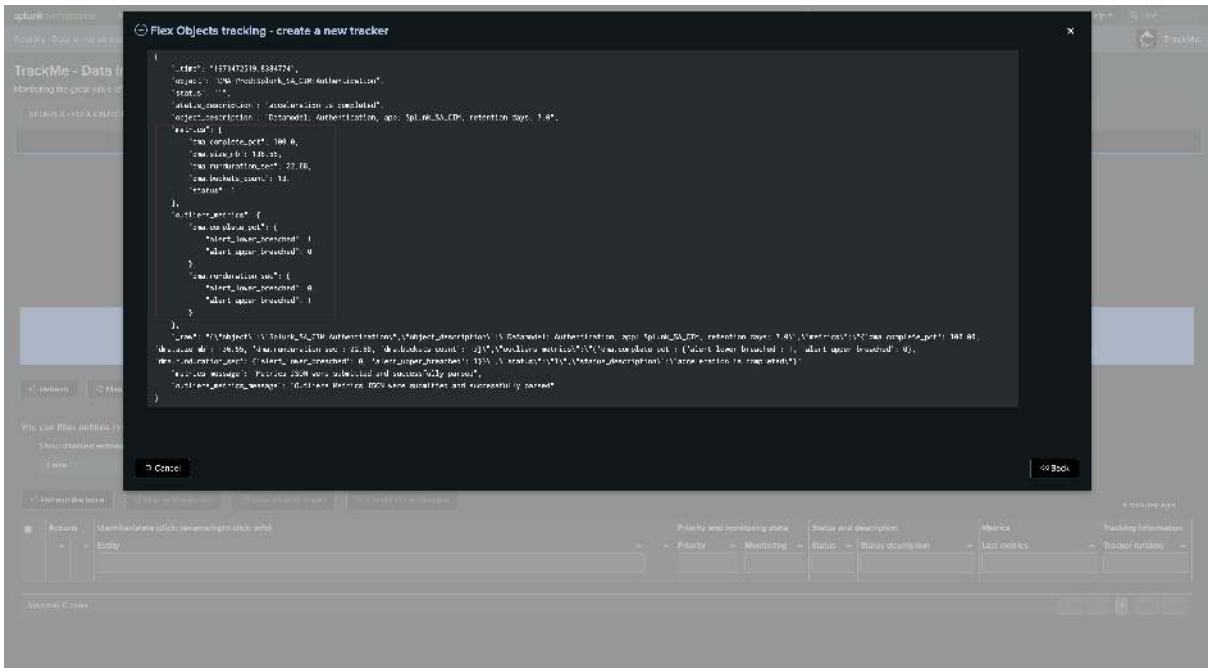
Step 3: Configure the search time range. Use short ranges like -5m for REST-based searches, or longer ranges for tstats/stats-based searches.

Step 4: Test and review

Before creating the tracker, simulate the search to verify the results. The simulation shows the raw JSON output for each discovered entity, including the parsed metrics and outliers:



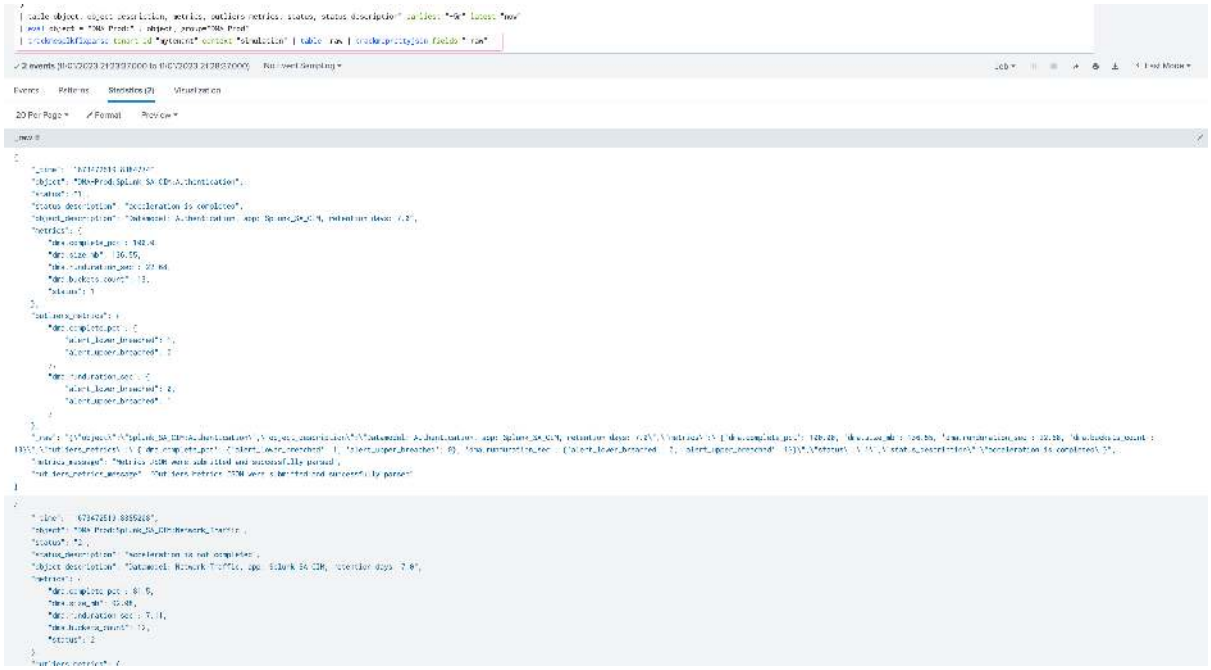
Step 4: Simulate the search. Click "Simulate the search" to preview the entities that will be discovered.



The simulation results showing discovered entities with their metrics and outliers_metrics successfully parsed.

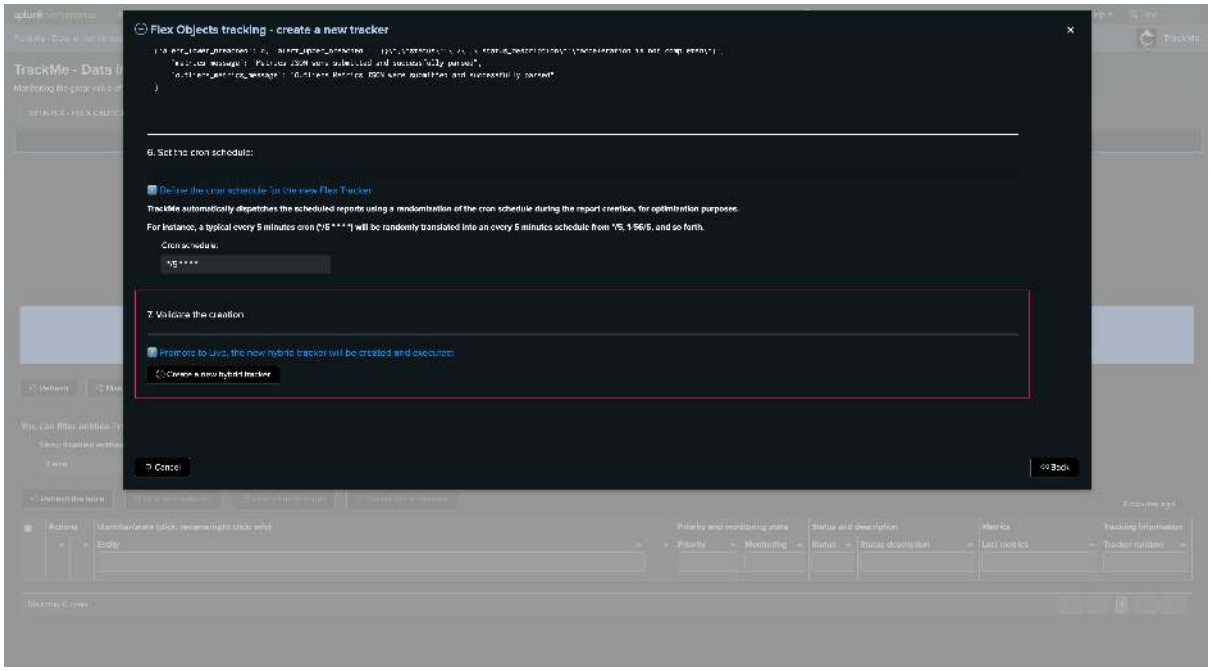
Step 5: Schedule and create

Set the cron schedule for the tracker execution. TrackMe automatically randomizes the schedule to distribute load across your environment.

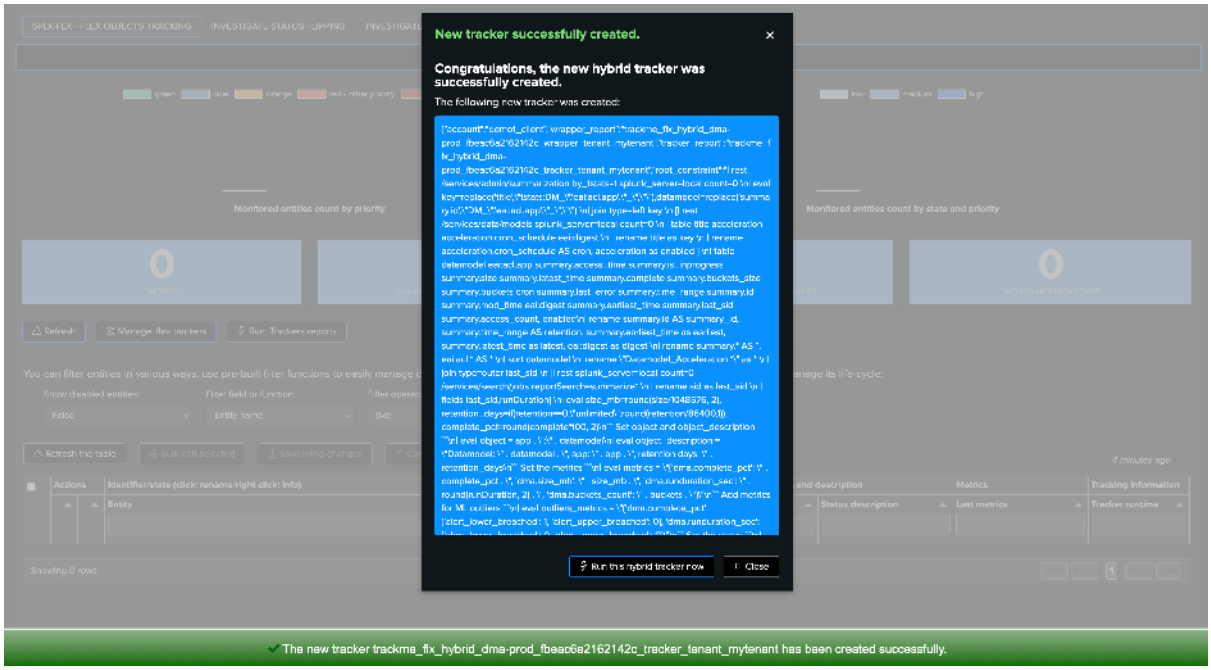


Step 5: Define the cron schedule. A typical every 5 minutes schedule is randomly distributed for optimization.

Finally, validate and create the tracker:



Promote to Live and create the new Flex tracker.



Success! The new tracker has been created with all its associated knowledge objects (reports, macros, lookups).

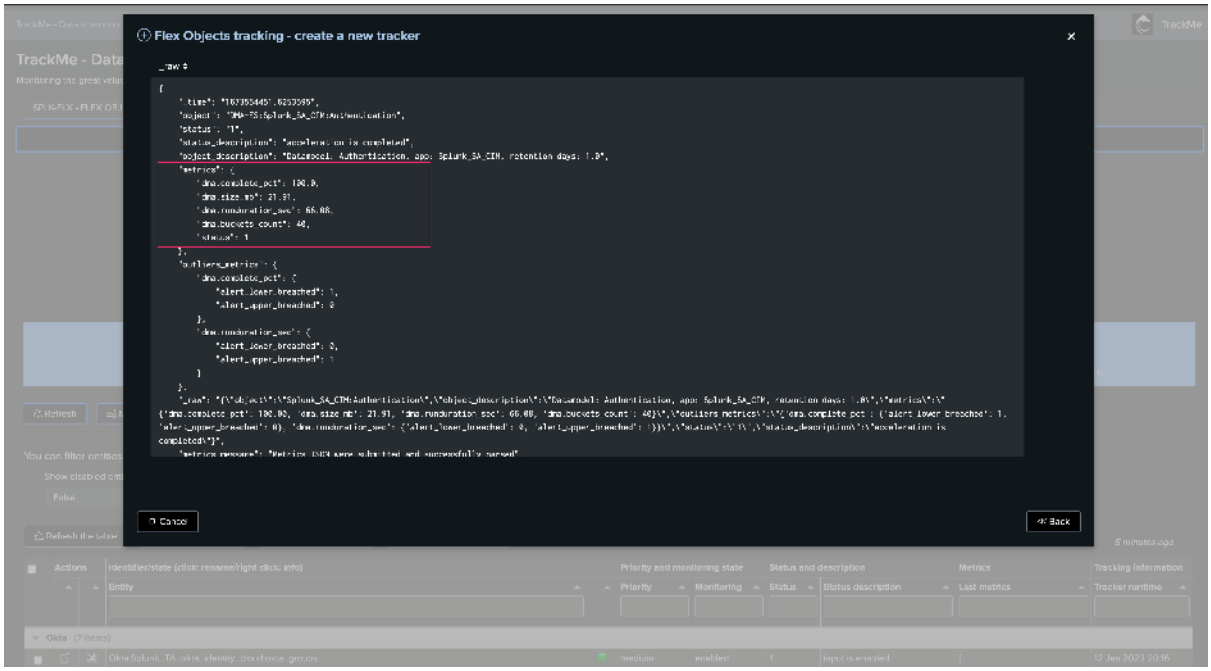
KPIs and Metrics

When your Flex search defines the `metrics` field, TrackMe automatically:

1. **Stores the KPIs** as part of the entity record for display in the UI
2. **Ingests metrics** into the Splunk metrics index (`trackme_metrics`) for trending and analysis
3. **Sets a default metric** for the entity table view if `default_metric` is defined

Viewing KPIs in the entity detail

Click on any Flex entity to open its detail view. The **Overview entity** tab shows the current status, description, and key metrics:



Entity detail view showing a CIM Data Model Acceleration entity with its metrics (dma.complete_pct: 99.30%) and status information.

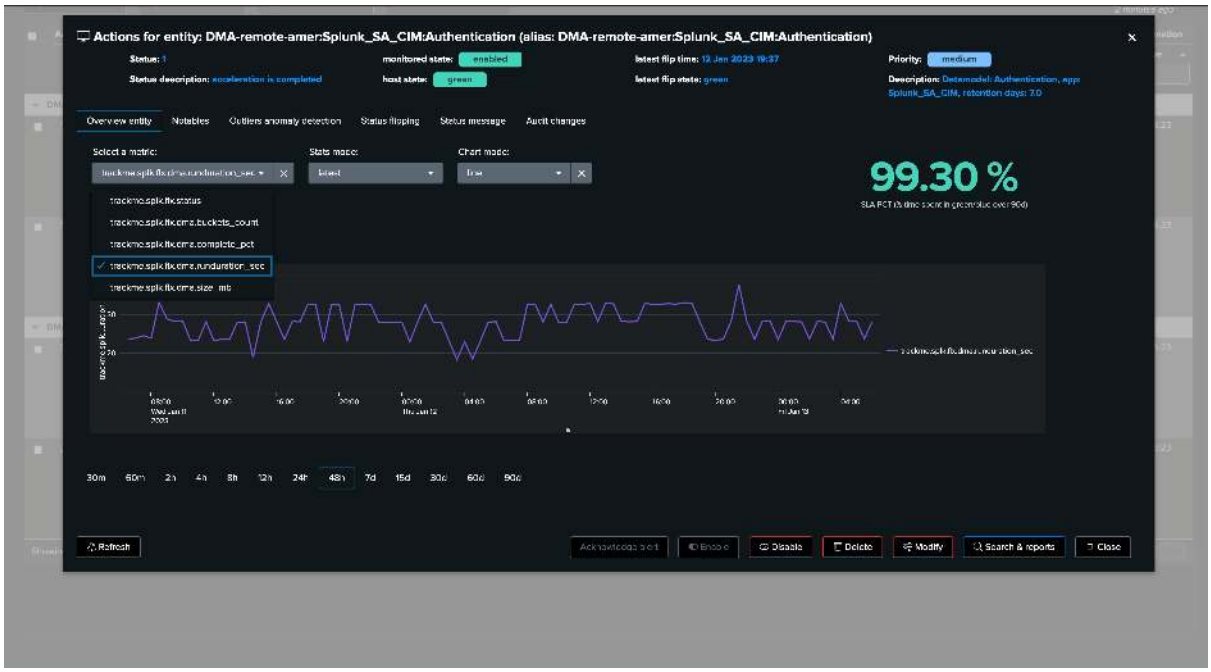
Querying Flex metrics

All Flex metrics are available in the `trackme_metrics` index with the prefix `trackme.splk.flx.`. You can query them with `mstats` for dashboards and reports:

```
| mstats avg(trackme.splk.flx.dma.complete_pct) as avg_complete,
    max(trackme.splk.flx.dma.size_mb) as max_size
where index=trackme_metrics tenant_id="my-tenant" object_category="splk-flx"
by object span=1h
```

Exploring metric events

You can also explore the raw metric events ingested by TrackMe for your Flex entities:



Splunk search showing Flex metric events in the trackme_metrics index with individual metric fields extracted.

Machine Learning Outlier Detection

Flex Objects integrates with TrackMe's Machine Learning Outlier detection to automatically identify anomalies in your KPIs. This is particularly powerful for use cases where you cannot define a static threshold - like event count variations that follow seasonal patterns.

How it works

When you define `outliers_metrics` in your Flex search, TrackMe:

1. **Builds an ML model** for each metric, learning the normal behavior over time
2. **Calculates dynamic thresholds** (upper and lower bounds) based on historical patterns
3. **Detects anomalies** when the current value falls outside the expected range
4. **Triggers alerts** based on your configuration (lower breach, upper breach, or both)

The `time_factor` parameter is key to accuracy: it tells the ML model about the seasonality of your data. For example, if your event counts are naturally lower on weekends, using `%w%H` (day of week + hour) ensures the model doesn't flag normal weekend dips as anomalies.

Viewing outlier detection

The **Outliers anomaly detection** tab in the entity detail shows the ML model's predictions alongside actual values:

Outlier detection view showing the ML model's predicted range (blue band) and actual values over time. The "0 outliers" indicator confirms no anomalies were detected in this window.

The chart displays:

- The **actual metric values** as a line chart
- The **predicted normal range** as a shaded band (upper and lower bounds)
- The **number of outliers** detected in the current time window
- A time range selector to zoom in or out on the data

You can manage the ML models, select which metric to visualize, and fine-tune the detection parameters directly from this view.

Hint

Outlier detection best practices

- Start with `time_factor: 'none'` for metrics without clear seasonality (e.g., DMA completion percentage)
- Use `time_factor: '%w%H'` for metrics with weekly patterns (e.g., event counts, search activity)
- Use `time_factor: '%H'` for metrics with daily patterns but no weekly variation
- Allow sufficient training time (at least 7 days, ideally 30+) before relying on outlier alerts
- Use `period_calculation: '-90d'` to limit the ML training window and adapt faster to changes

High Scale and Custom Grouping

Flex Objects is designed to handle high-scale environments with thousands of entities. Here are key strategies for managing large deployments effectively.

Custom grouping strategies

The `group` field in your Flex search determines how entities are organized. Smart grouping helps you:

- **Scope monitoring** - Different groups can have different alert thresholds and SLA policies
- **Organize at scale** - Group entities by function, environment, tier, or business unit
- **Avoid overlap** - Each entity should belong to exactly one group to prevent duplicate tracking

For example, in a Splunk infrastructure monitoring scenario, you might create separate groups for:

```
| eval group = case(
    tier=="indexers", "infra-indexers",
    tier=="search_heads", "infra-search-heads",
    tier=="heavy_forwarders", "infra-hf",
    1=1, "infra-other"
)
```

Entity naming conventions

The `object` field is the unique identifier for each entity. A common best practice is to prefix the object name with the group:

```
| eval object = group . ":" . host
```

This produces entity names like `infra-indexers:idx01`, `infra-search-heads:sh01`, making it easy to identify entities at a glance.

Performance considerations

- **Optimize your search** - Use `tstats` over raw searches when possible, as it's orders of magnitude faster for large datasets
- **Tune the time range** - Keep the search window as narrow as possible (e.g., `-5m` for REST-based searches, `-30m` to `-2h` for tstats)
- **Schedule wisely** - A 5-minute cron schedule is typical, but less critical use cases can use longer intervals (e.g., `*/15 * * * *`)
- **Use max_sec_inactive** - Set appropriate inactivity thresholds to avoid false positives for entities that naturally go quiet
- **Batch processing** - TrackMe automatically uses batch KVstore operations and parallel processing for optimal performance at scale

Converging Trackers

While standard Flex trackers (use_case type) create entities from a Splunk search, **converging trackers** take a different approach: they aggregate the status of multiple existing Flex entities into a single availability metric.

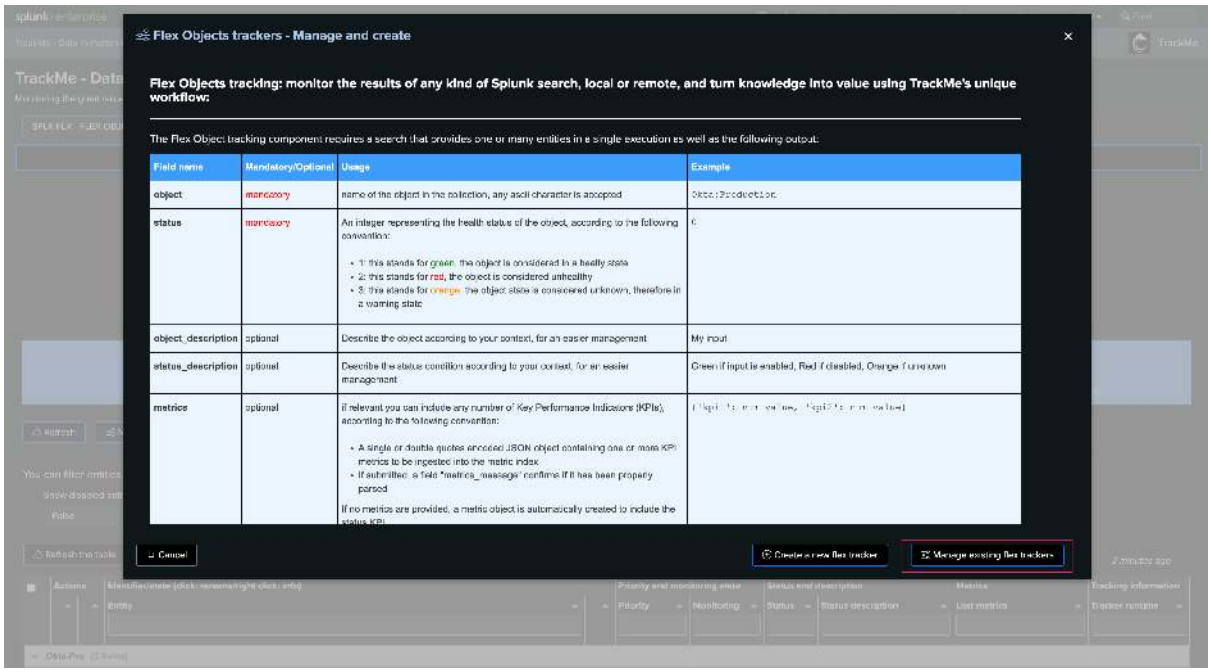
This is particularly useful for:

- **Service-level monitoring** - Aggregate the health of all components of a service into a single entity (e.g., "Authentication Service: 98.5% available")
- **Executive dashboards** - Provide a high-level view of complex multi-entity monitoring
- **SLA tracking** - Measure overall availability across a group of entities

A converging tracker calculates the percentage of entities in a healthy state within a specified group, providing a single aggregated status and availability metric.

Managing Flex Trackers

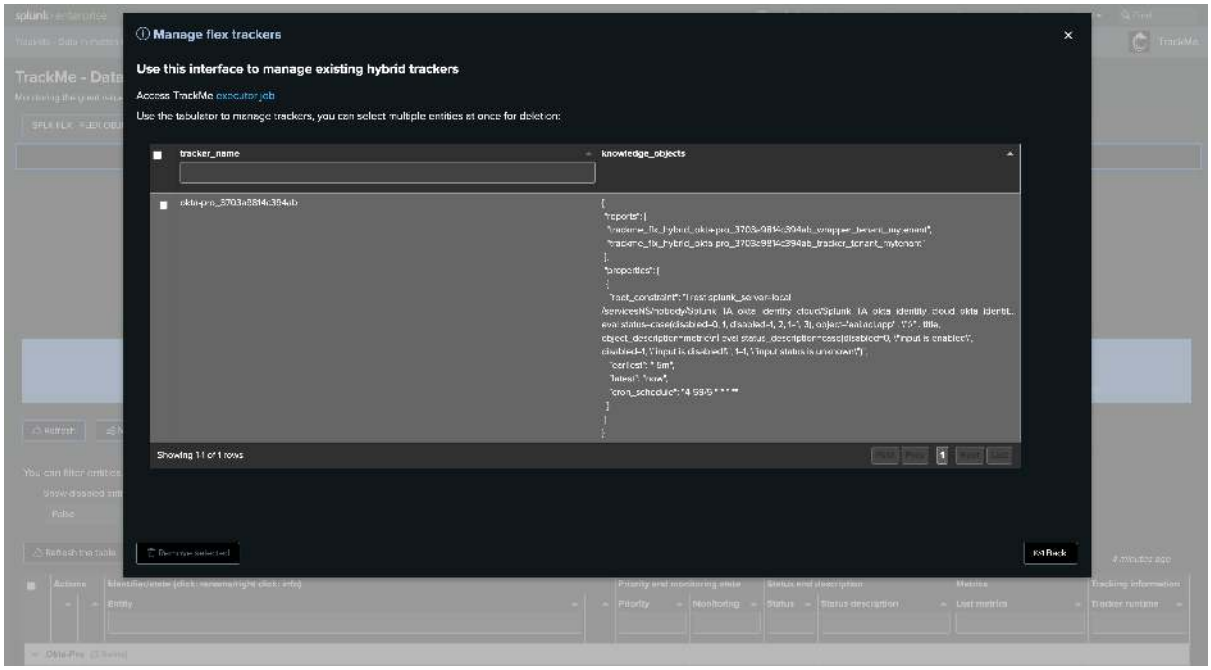
The **Manage existing flex trackers** interface allows you to view, inspect, and delete Flex trackers:



The Manage flex trackers interface showing existing trackers with their knowledge objects (reports, properties, schedule).

From this interface you can:

- **View tracker properties** - See the root constraint, cron schedule, time ranges, and associated reports
- **Select trackers for deletion** - Use the checkboxes to select one or more trackers for removal
- **Access the executor job** - Monitor the TrackMe executor job for tracker operations



Selecting trackers for deletion. Multiple trackers can be selected and removed at once.

Important

TrackMe keeps records of all knowledge objects related to a tracker. You must manage the tracker lifecycle through TrackMe - do not manually delete scheduled reports or lookups outside of the interface.

When a tracker is deleted, its associated knowledge objects are purged. However, entities previously discovered by the tracker are **not** automatically removed - they will simply no longer be maintained.

Deleting a Flex Tracker through REST

You can also delete a tracker programmatically via the REST API:

```
| trackme mode=post url="/services/trackme/v2/splk_flx/admin/flx_tracker_delete"␣

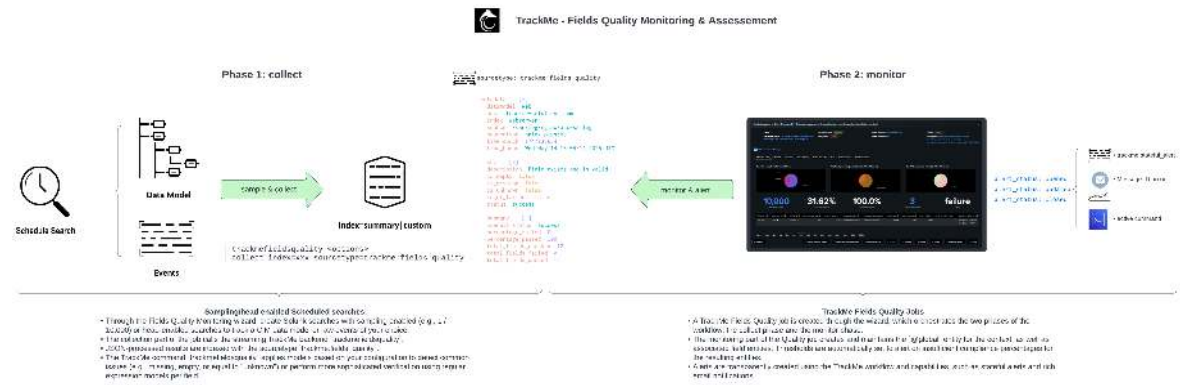
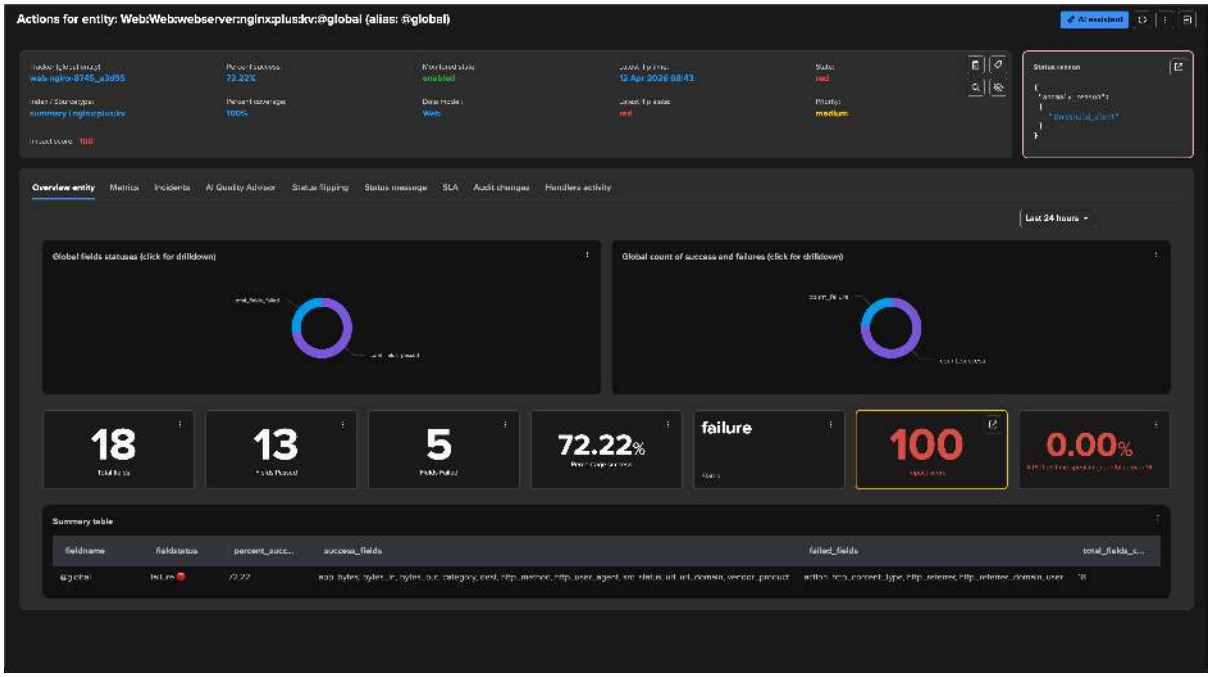
```

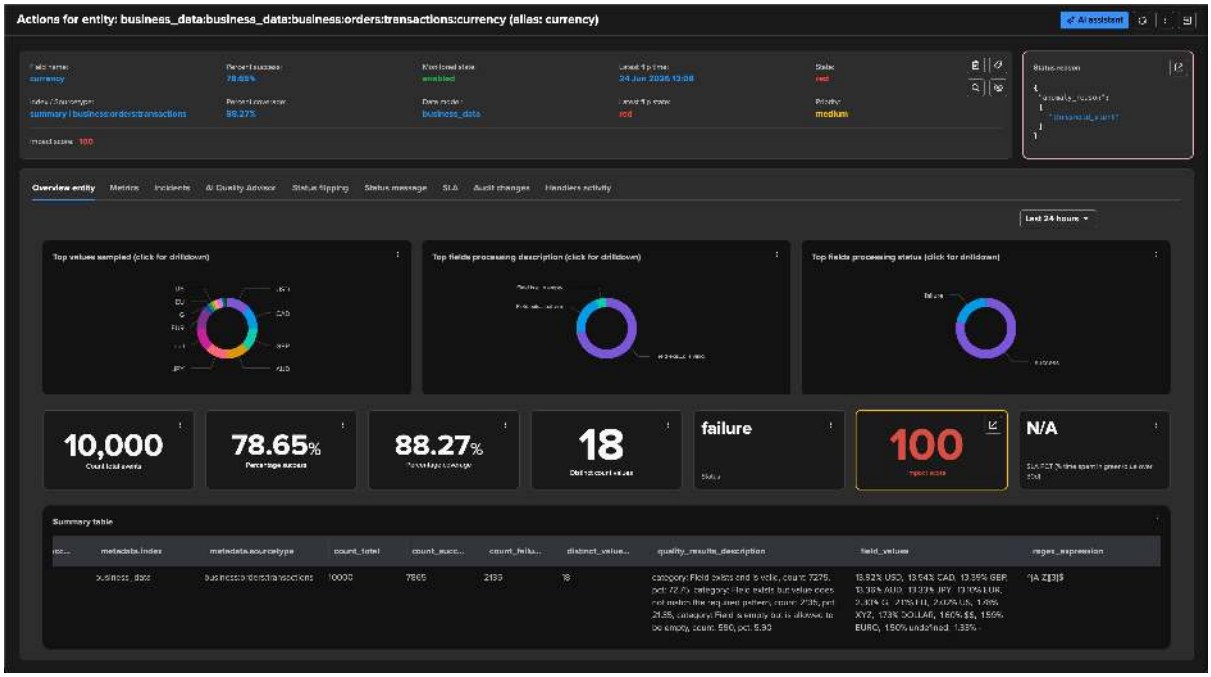
8.3.11 FQM — Field Quality Monitoring

Field Quality Monitoring tracks whether your data is **well-parsed**: how completely and correctly fields are extracted, and how compliant a sourcetype or data model is with the Splunk **Common Information Model (CIM)**. Where the feeds components ask "is the data arriving?", FQM asks "is the data *usable*?"

Unlike the other components, FQM works in **two phases**: a `collect` job samples and scores your events, and a `monitor` job then turns those results into TrackMe entities and alerts.







What FQM tracks

Each entity is the **extraction quality of one field** — typically one entity per `(data model, dataset, field)`, or per a custom SPL pattern. FQM measures:

Metric	Meaning
Coverage %	The share of events in which the field is present / extracted.
Success %	The share in which the field's value is valid / well-formed.
CIM compliance	Drift against CIM-specific expectations.
Inactivity	The dataset has stopped producing data.

You set coverage and success thresholds per metric — the same dynamic, optionally time-sliced threshold model as *FLX*.

Creating an FQM tracker

1. **Pick the source** — a CIM data model and dataset, or a custom SPL pattern.
2. **Choose the fields** to evaluate.
3. **Set thresholds** — coverage % and success %.
4. **Review and create.**

FQM leans on the Common Information Model: standard CIM lookups provide ready-made field patterns, while custom SPL covers non-CIM fields.

Tip

Aim for a realistic bar. 95% coverage is a common, healthy target — insisting on 100% will generate noise. Outlier detection is supported but **not recommended** for FQM, as field-quality metrics are slow-moving.

See also

- *Field quality use cases* — worked examples.

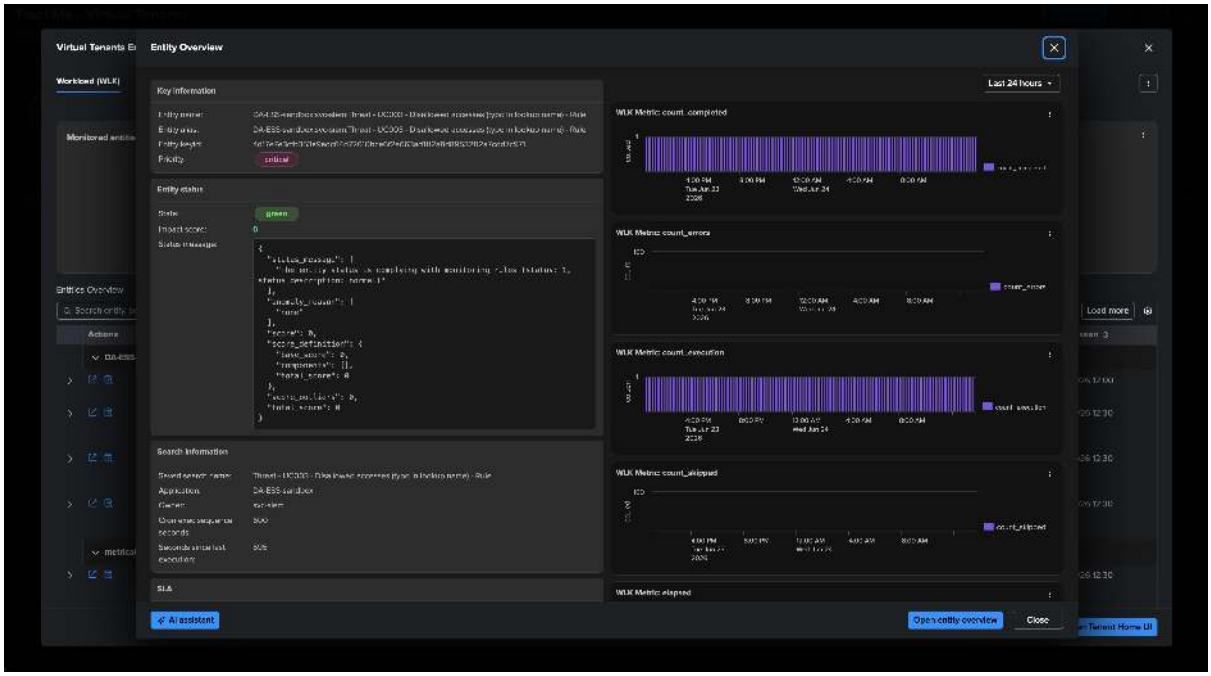
- *FLX — Flex Objects* — the shared dynamic-threshold model.
- *Entity State & Scoring* — thresholds and scoring.

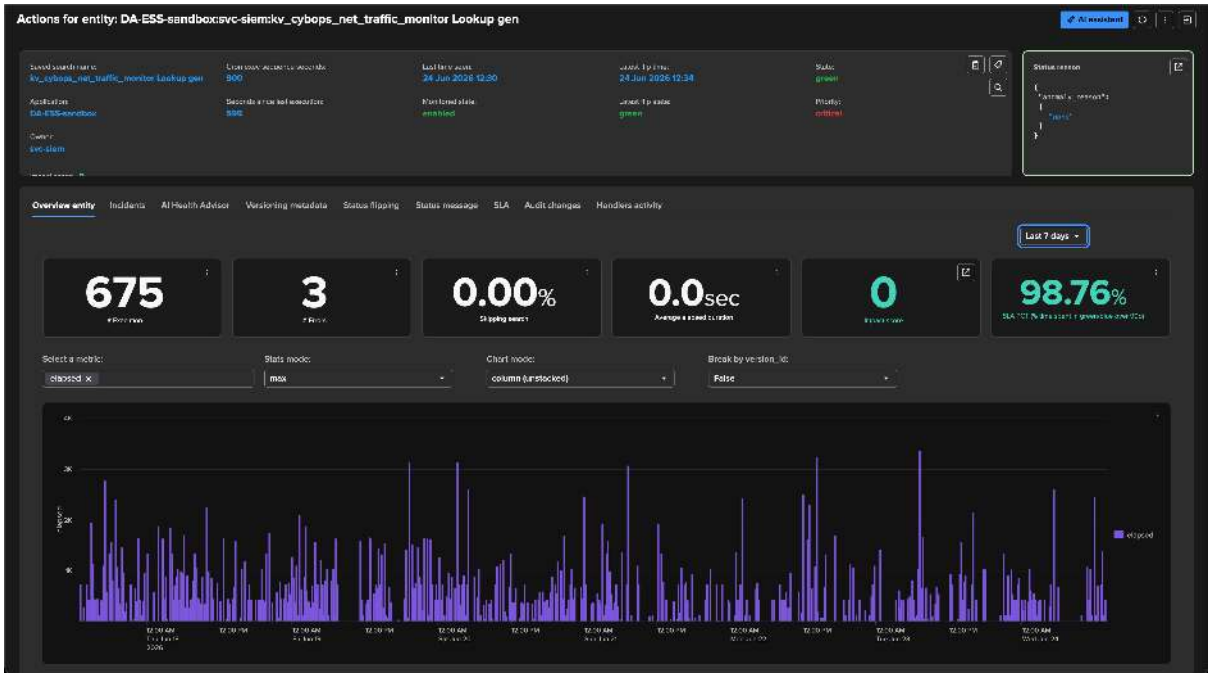
8.3.12 WLK — Workload Knowledge

Workload Knowledge tracks the **execution health of your scheduled searches** — are they running on schedule, completing without errors, not skipping, and not quietly costing more than they should? It turns Splunk's own scheduler activity into tracked, scored entities.

Note

WLK is a licensed / restricted component.





What WLK tracks

Each entity is **one scheduled search in one context** — its app, owner, and saved-search name together. The state is driven by these anomaly reasons:

Anomaly	Meaning
Skipping searches	The scheduler is skipping runs. Orange below 5%, red at or above 5% by default.
Execution errors	The scheduler reported execution errors.
Execution delayed	The search has not run on its cron schedule (within a grace period).
Orphan search	The search's owner is no longer valid, so it cannot run.
Runtime / cost outliers	An ML-detected spike in run time or cost.
Versioning drift	The search definition changed.
App disabled	The parent app is disabled, so its scheduled searches do not run.

The KPIs behind these include execution / completed / skipped / error counts, run time (`elapsed`), CPU and memory percentages, scan count, and — on Splunk Cloud — **SVC consumption** per search, for cost visibility.

Versioning

WLK can fingerprint each saved search's definition and flag when it **changes** — recording a versioning event and, when the change was made through Splunk Web or the API, a **diff** plus who changed it and when. This is invaluable for correlating a sudden jump in run time, cost, or skip rate with an edit to the search. Versioning is opt-in per app.

The tenant default threshold

WLK has a special tenant-wide fallback: a **default threshold row** that applies to any entity without its own per-entity threshold, so you can set sensible limits once and override only where needed.

Setup notes

- The creation wizard auto-builds the trackers it needs (scheduler, metadata, orphan, introspection, and — on Splunk Cloud — SVC).
- Entities are grouped by **app**, or by a custom **overgroup** if you want to host several search-head tiers in one tenant.
- On Splunk Cloud, point WLK at a remote deployment targeting the relevant search-head tier (see *Integrations & Remote Deployments*).

Tip

Dedicate a Workload tenant per search-head tier, and use an overgroup only when you deliberately want to combine tiers. Outlier detection is not recommended for the scheduler counters (too discrete), but it *is* useful for run-time and cost trends.

8.3.13 Workload monitoring — in depth

Tip

This is the **in-depth reference** for Workload (splk-wlk) monitoring. For the readable overview, start with *Workload monitoring*. This page collects the full administration and usage detail: Splunk Cloud setup, status-macro internals, the overgroup procedure, metadata versioning, the anomaly-reason and metrics tables, and the discovery / investigation workflow.

Introduction to the Workload component

The TrackMe workload component (splk-wlk) is a licensed users restricted component which tracks the activity from any kind of scheduled search in your Splunk deployment, from reports to alerts and Data Model Acceleration. (DMA)

The Workload component tracks various use cases such as execution errors which can slightly affect the consistency of your Splunk use cases, providing powerful features to detect issues and track the performance of the Splunk scheduling activity.

For the User Guide, consult: *WLK — Workload Knowledge*

Note

Grouping in the Workload component: group and overgroup

- By default, the Workload component groups entities by `app` which represents the Splunk application namespace hosting the scheduled report or alert.
- When creating the tenant and also later on when creating trackers manually, since TrackMe 2.0.70, you can optionally override this behaviour by setting up an `overgroup` value.
- By doing so, the Workload will group entities based on a custom term instead of applications, this can be useful if for instance you want to have multiple Search Head tiers in the same tenant.
- Refer to the *Creating a Workload tenant to host multiple Search Head tiers with overgroup* section for more information.

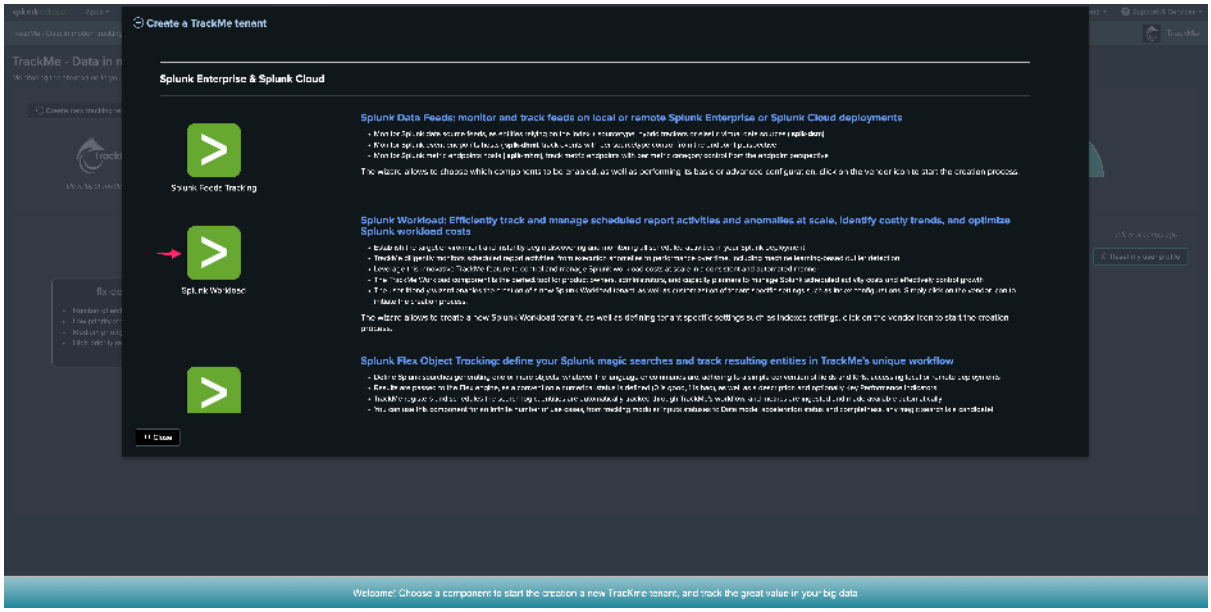
Note

Data collection enhancements in TrackMe v2.0.75

- Since TrackMe 2.0.75, the Workload components has been enhanced to automatically support data collection overlap between execution, relying on the tracking of the last known metrics for a given account/group and type of metrics.
- This allows TrackMe to look at multiple slices of times when tracking the Workload activity (scheduler, introspection, etc) and avoids missing any data point in case of Splunk delaying the execution of the workload trackers. (Splunk skew parameter, time_window and/or over busy scheduler)
- This process is fully automated and transparent, the last seen metadata are stored in a KVstore called `trackme_wlk_last_seen_activity_tenant_<tenant_id>`.

Creating and configuring a Workload Tenant

The creation and configuration of a Workload Tenant is guided through the wizard, click on the “create new tenant” and choose the associated component to start the configuration process:



Workload component in Splunk Cloud

Generally, in Splunk Cloud have two or more Search Head layers:

- The ad-hoc Search Head tier, where TrackMe should be used (standalone or SHC)
- The premium app Search Head tier, running Enterprise Security or ITSI (standalone or SHC)

In a nutshell, the configuration path is the following:

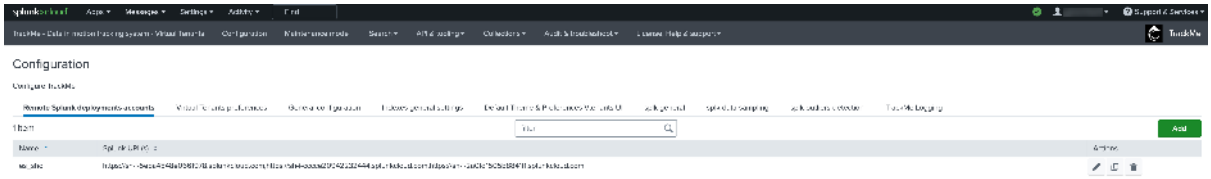
- configure a TrackMe Splunk Remote Deployment which targets the premium app Search Head tier (this is required notably for the versioning tracking of scheduled searches, even through both Search Head tiers access the same indexing tier)
- following these instructions to identify the Search Head tiers names as automatically defined per Splunk Cloud summary data, and recycle this information using a simple subsearch (see in the next sections)
- create and configure the Workload tenant in TrackMe

Step 1: configure the remote Splunk Deployment

For more information about TrackMe's Splunk Remote Deployments capabilities and configuration, consult: *Remote Splunk deployments*

Proceed as following:

- Create a bearer token in the premium app Search Head tier, it is good practice to associate the bearer token with a service account dedicated for that purpose



- Identify the Splunk Cloud label per Search Tier, we will use this logic as a subsearch when creating the Workload tenant/trackers:

```
index=summary source="splunk-svc-consumer" earliest=-7d latest=now
| stats values(usage_source) as members by search_head_names
```

Hint

Using the search_head_names label with a subsearch to dynamically restrict the hosts

- In Splunk Cloud, use the following subsearch technique to assign dynamically the list of Search Heads for that given Search Head tier
- If Search Head members are re-created, the subsearch will automatically pick up the new hosts and you have no changes to perform yourself

for instance, if the target Search head tier is called "es" (Enterprise Security), we will use the following subsearch to filter out the hosts dynamically:

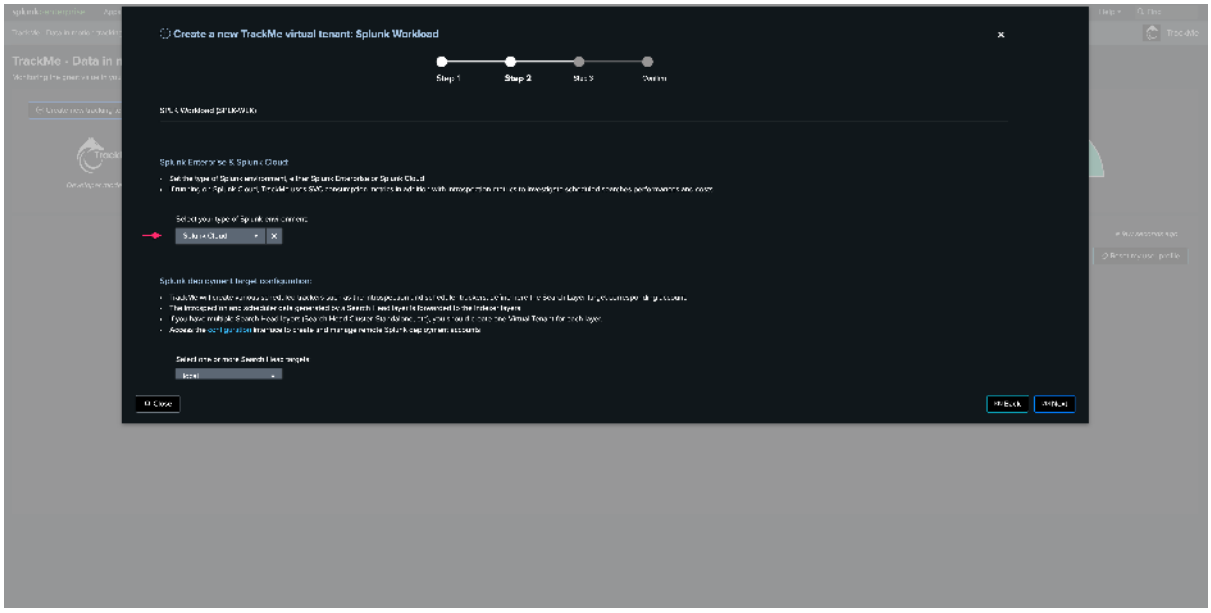
```
[ search index=summary source="splunk-svc-consumer" search_head_names="es"␣
↪earliest=-24h latest=now | stats count by usage_source | table usage_source |␣
↪rename usage_source as host | format | eval search = if(search="NOT ()", "host=*
↪", search) ]
```

Once you have validated the connectivity, you can continue and start the configuration of the Workload tenant.

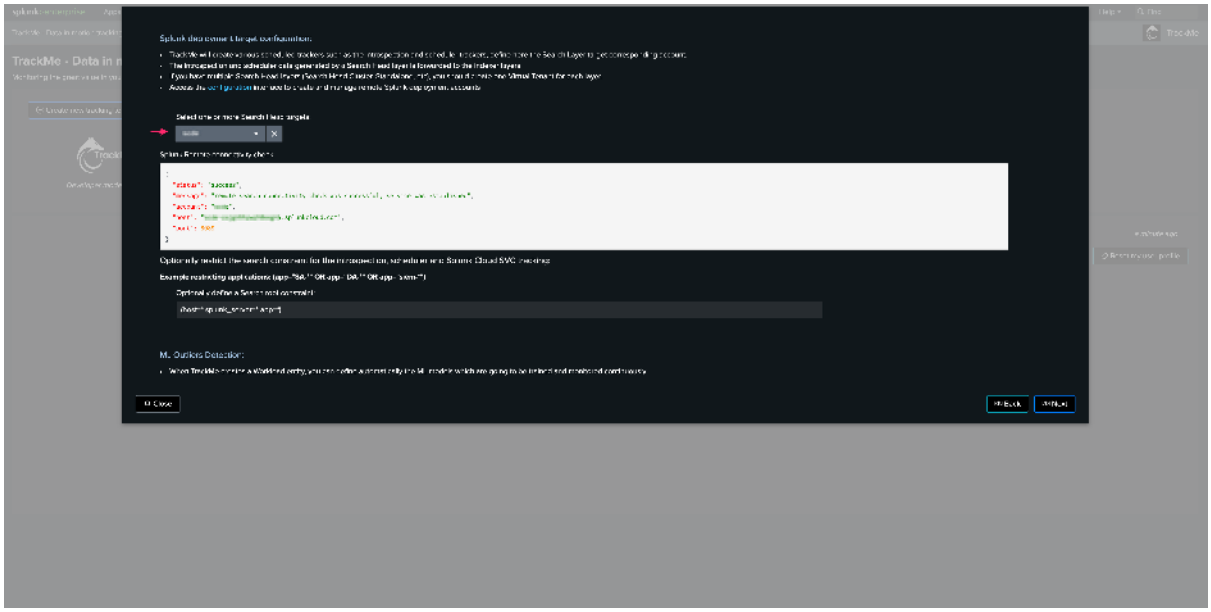
Step 2: create and configure the Workload tenant

Open the assistant wizard, and proceed as follows:

- Select "Splunk Cloud" in the Splunk environment dropdown:



- Select the Remote deployment target:

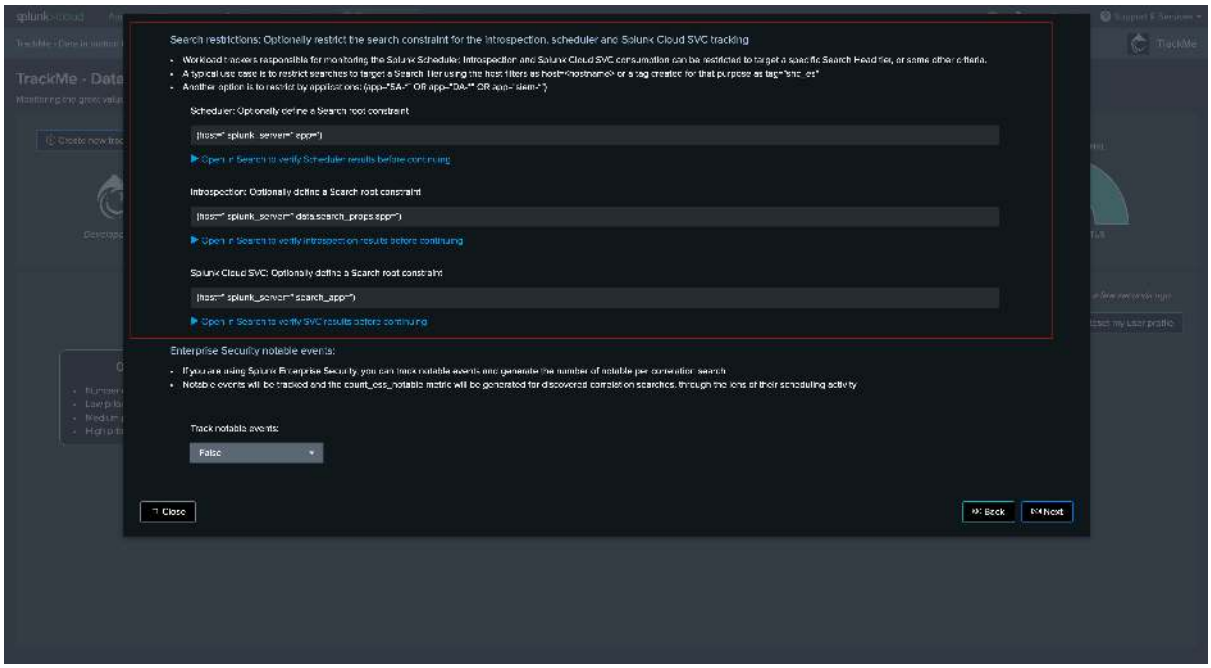


- Set the search restrictions:

Hint

Search restrictions per Workload component

- Since the release 2.0.57, you can define the search restrictions per component, to ease and improve the configuration process
- You can directly validate that the search will return results by clicking on the search preview link
- This opens a pre-populated search interface, it also sets the restrictions and calls splunkremotesearch if the search has to run against a remote Search Head tier



Complete the rest of the setup, it can take up to 5 minutes before entities start to be visible in the Workload tenant.

Workload component in Splunk Enterprise

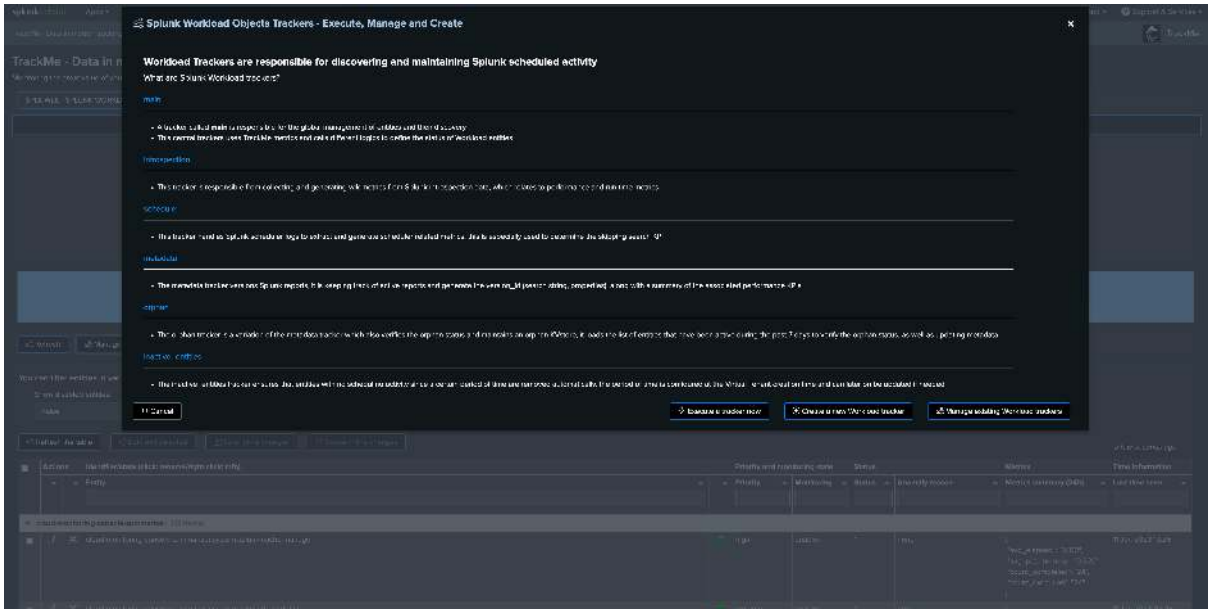
If you are running Splunk Enterprise, then the setup slightly depends on your deployment:

- If you have multiple Search Head tiers, you can use the same tag approach as documented in the Splunk Cloud setup above
- You can also create a custom indexed or search time field on the Search Head tier level, which automatically identifies the Search Head tiers to be targeted
- Use different combinations up to your preference

Managing Workload Trackers

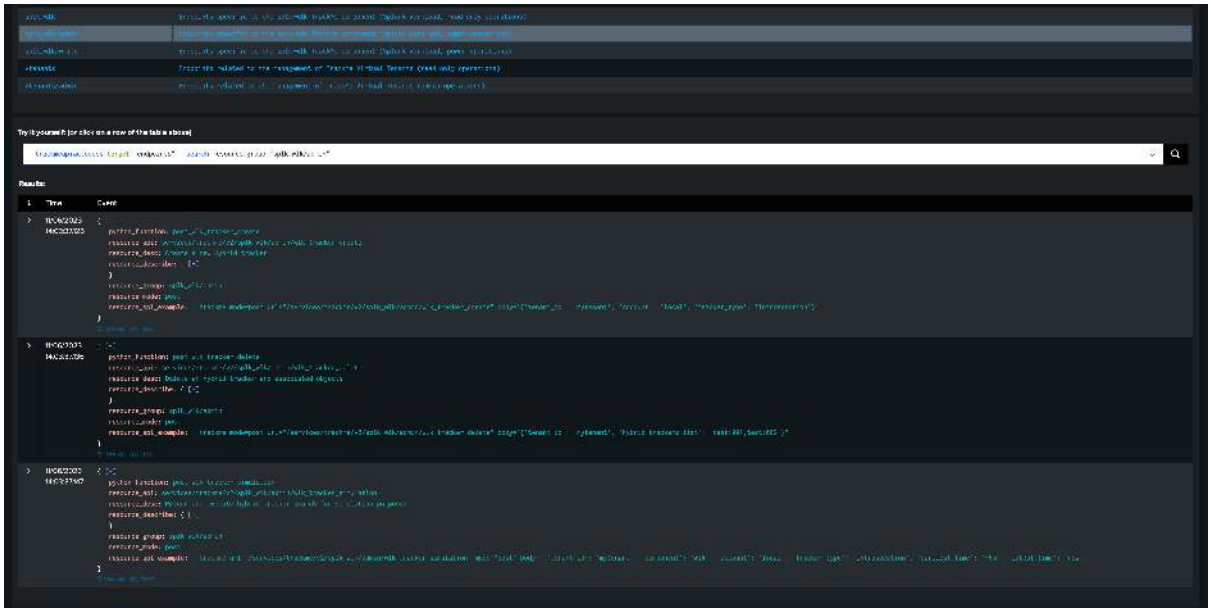
There are a certain number of Workload trackers which are created automatically by the wizard, depending on your Splunk environment.

Through the trackers management user interface, you can eventually add new trackers if needed, either if you want to re-create the trackers or extend the tracking to additional context:



However, the general recommendation is to dedicate a Workload Tenant to a given Search Head tier.

The REST API UI also allows you to manage all types of Workload trackers:



Managing Workload detection

When a Workload Virtual Tenant is created, TrackMe automatically creates a macro which defines the main status definition behaviour for that tenant.

The macro is named as follows:

- `trackme_wlk_set_status_tenant_<tenant_id>`

You can update this macro to modify how TrackMe defines the status of Workload entities, for instance these lines define the grace time period for the detection of delayed entities:

```
``` Calculate the delta in sequence between now and the last execution compared␣
↪against the requested cron schedule sequence, add 1h of grace time, detect if␣
↪the execution has been delayed ```
| eval status=if(cron_exec_sequence_sec>0 AND ( now()-last_seen >␣
↪(cron_exec_sequence_sec + 3600) ), 2, status)
```

This also defines the level of skipping searches (percentage) which leads entities to turn orange or red:

```
``` If there are skipping searches, define two levels of alerting, less than 5% is␣
↪3 (orange), more is 2 (red) ```
| eval status=case(skipped_pct>0 AND skipped_pct<5, 3, skipped_pct>0 AND␣
↪skipped_pct>=5, 2, 1=1, status)
```

The macro is part of the life cycle of the tenant's knowledge objects, therefore it will be removed automatically if the tenant itself is deleted.

This macro is executed by the "main" tracker, which naming convention is the following:

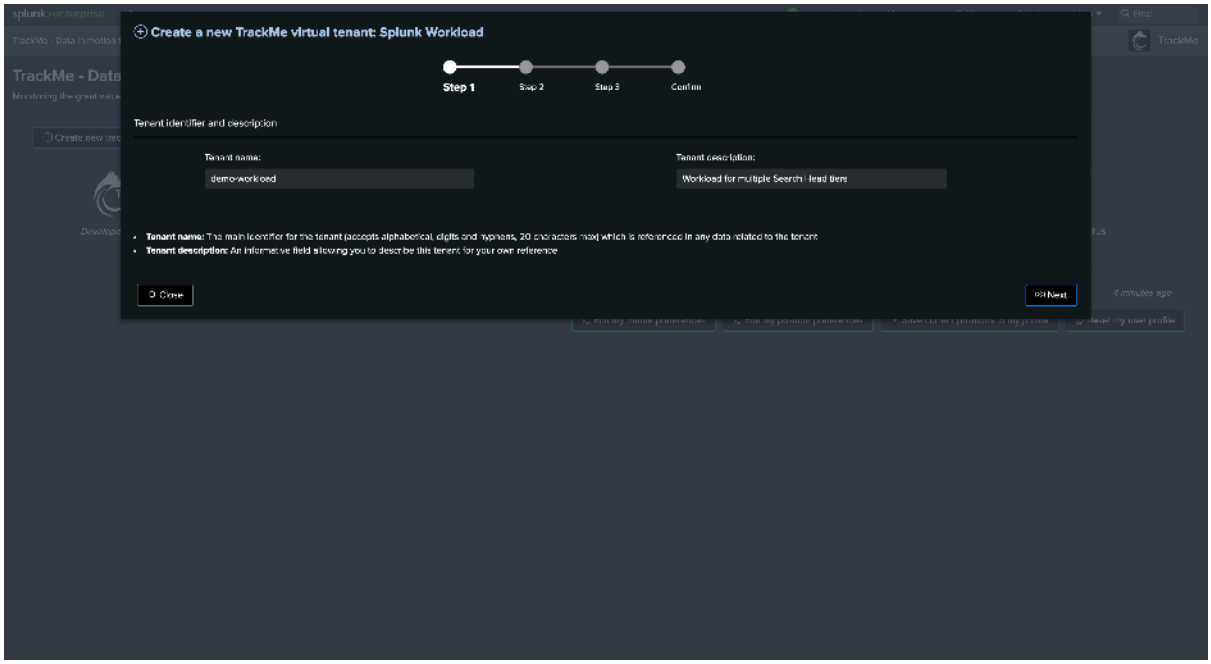
- `trackme_wlk_hybrid_main_ce555e75db1643a_wrapper_tenant_<tenant_id>`

Creating a Workload tenant to host multiple Search Head tiers with overgroup

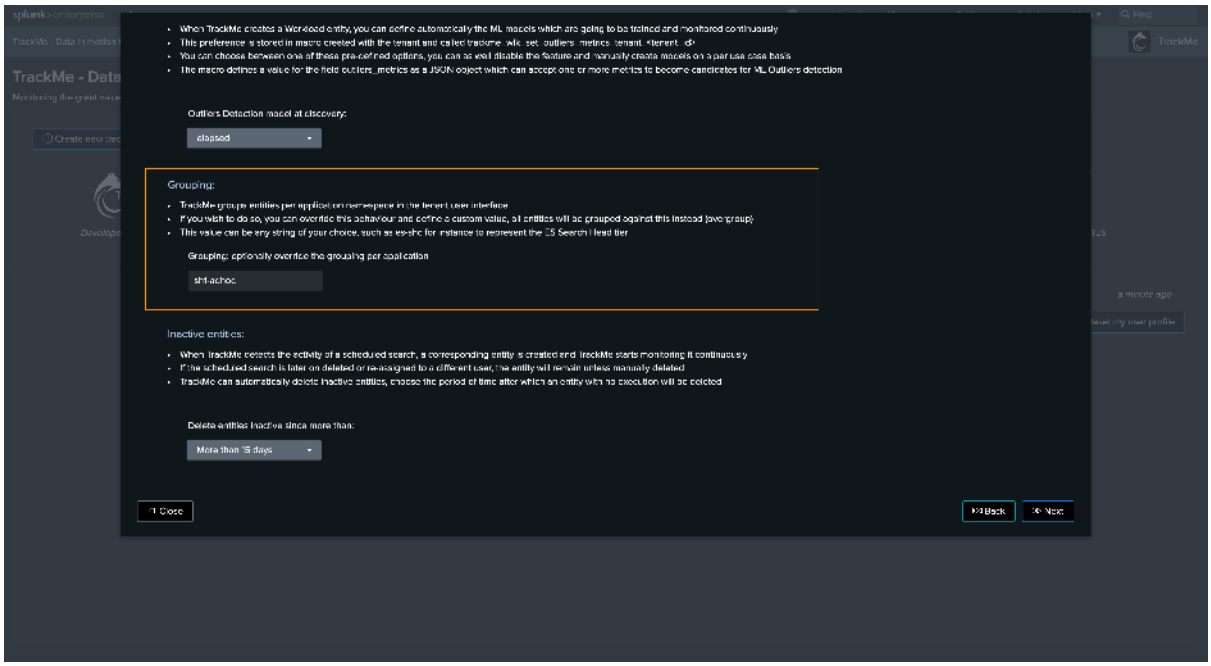
To create a tenant which hosts multiple Search Head tiers, you can use the overgroup feature, follow the steps below:

Step 1: Create the tenant with a first Search Head tier and the corresponding overgroup

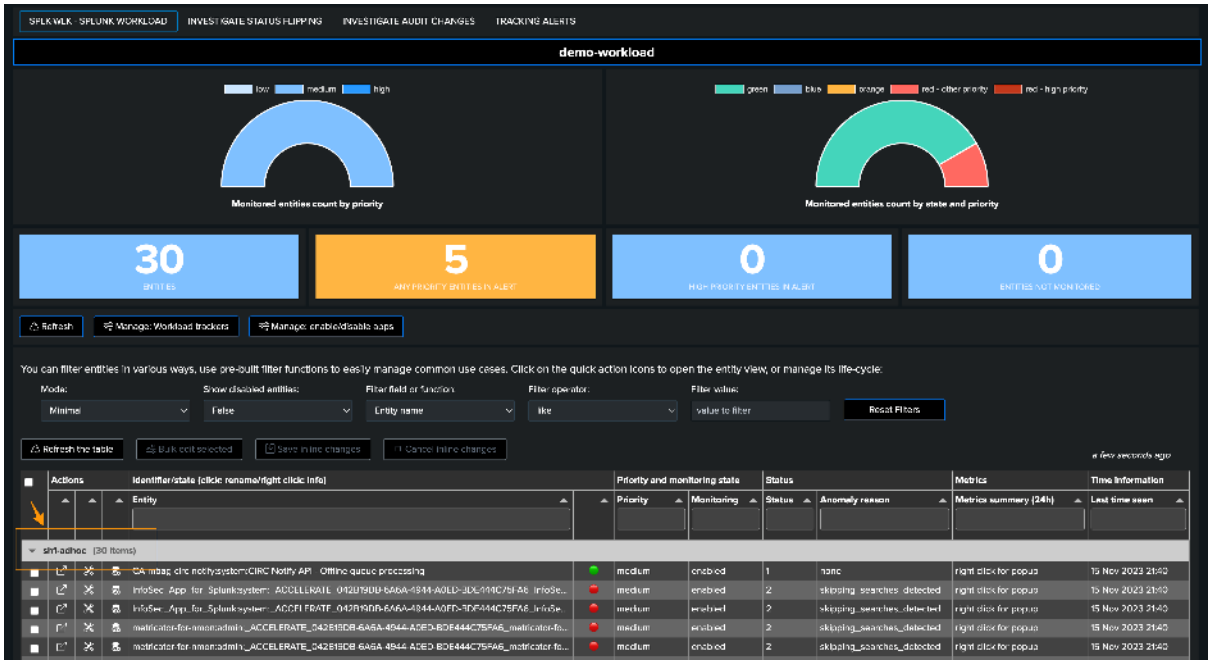
We start by creating a brand new Workload tenant, where we define the first Search Head tier constraint, target (account) and overgroup value:



Define everything as needed (account, constraints, etc) then enter a custom value for the overgroup:



Once created and after 5/10 minutes, entities will be visible under the overgroup:



Step 2: In the Workload tenant, create the additional trackers for the second Search Head tier

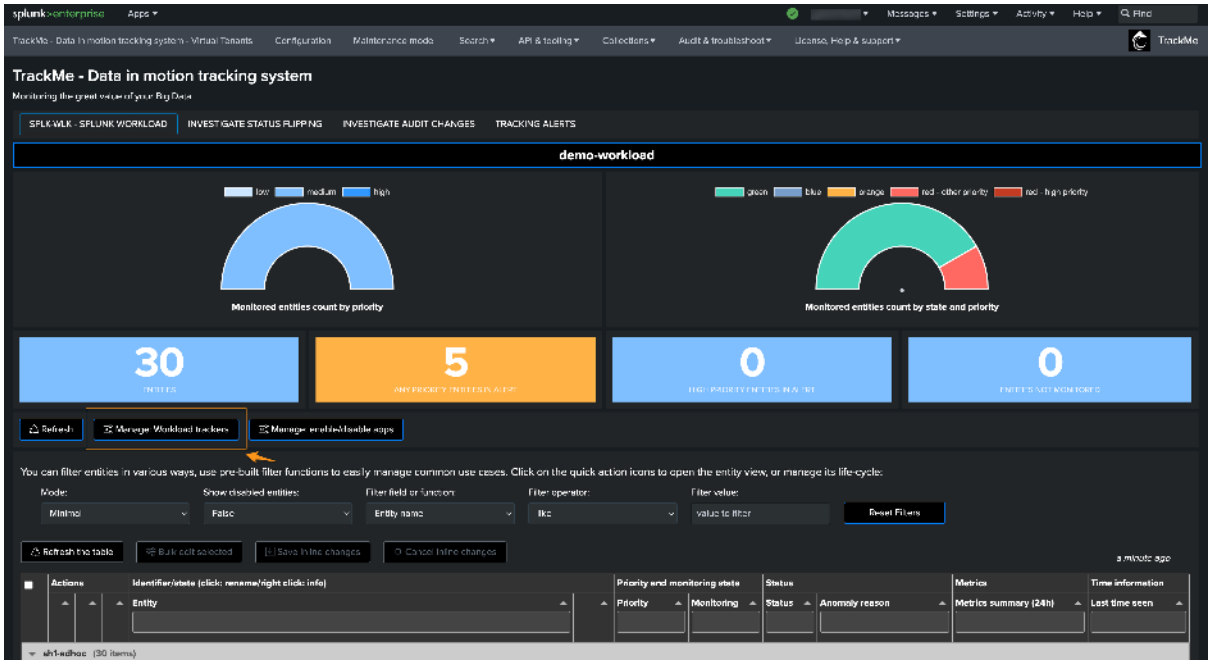
Now that the tenant is created, we can create the additional trackers for the second Search Head tier, the following types of trackers can be created:

- scheduler
- introspection
- Splunk Cloud SVC (optional, for Splunk Cloud only)
- Notable (optional, if you wish to track notable activity)

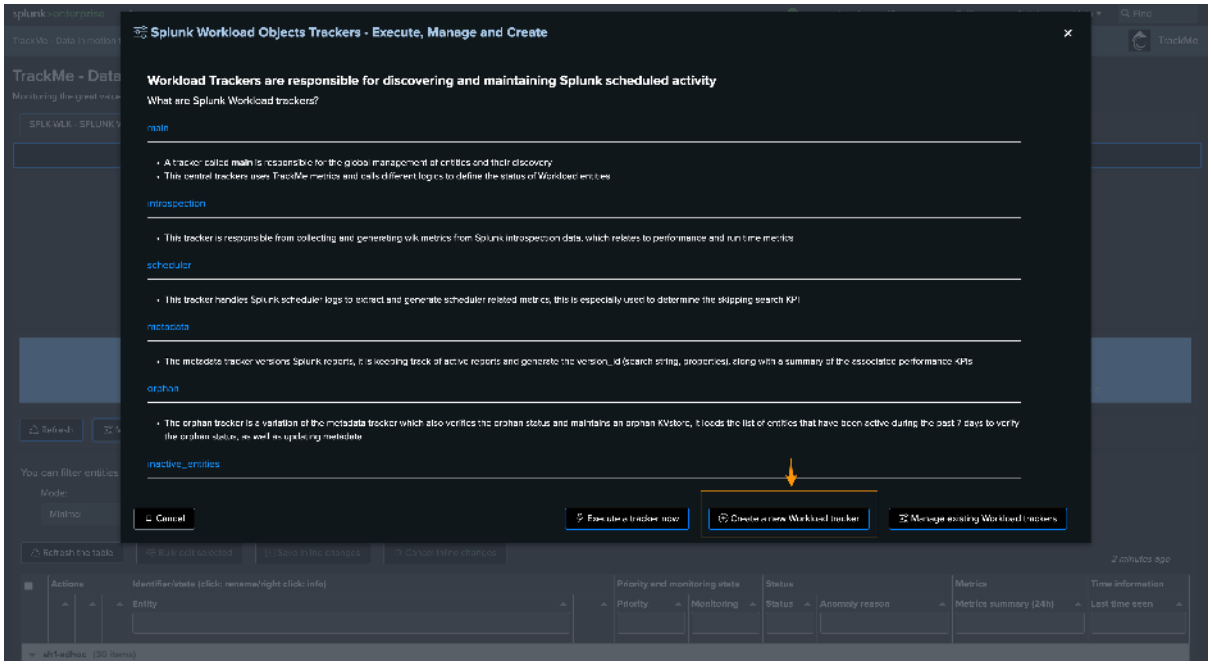
Note

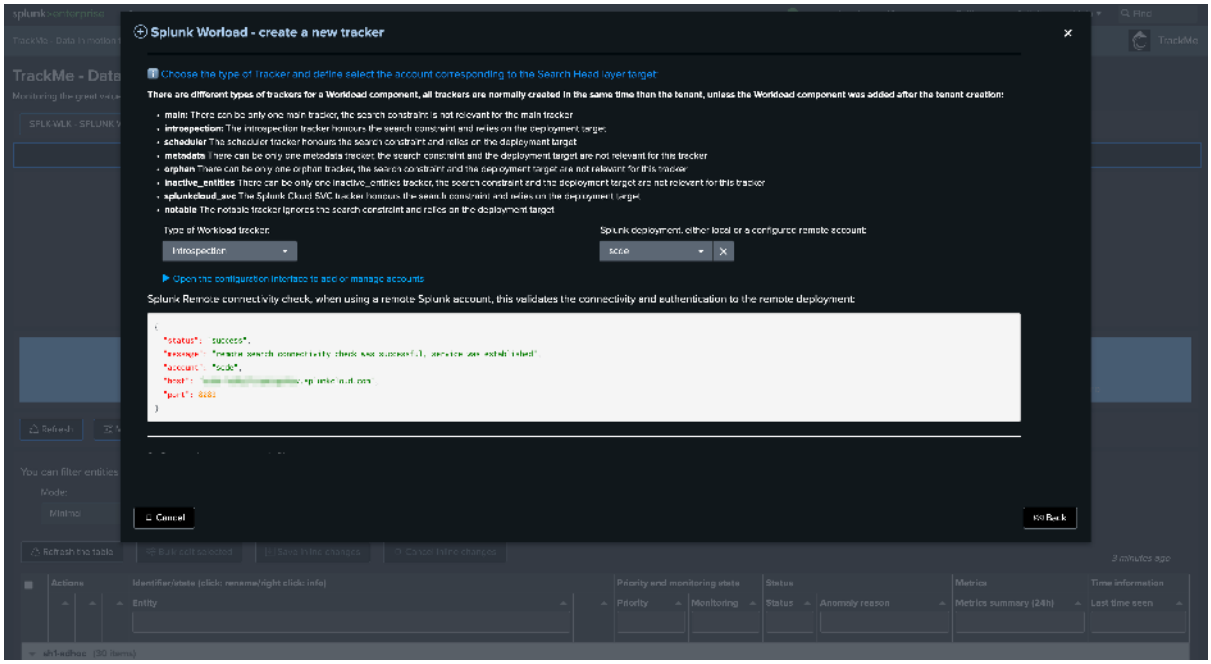
Common trackers:

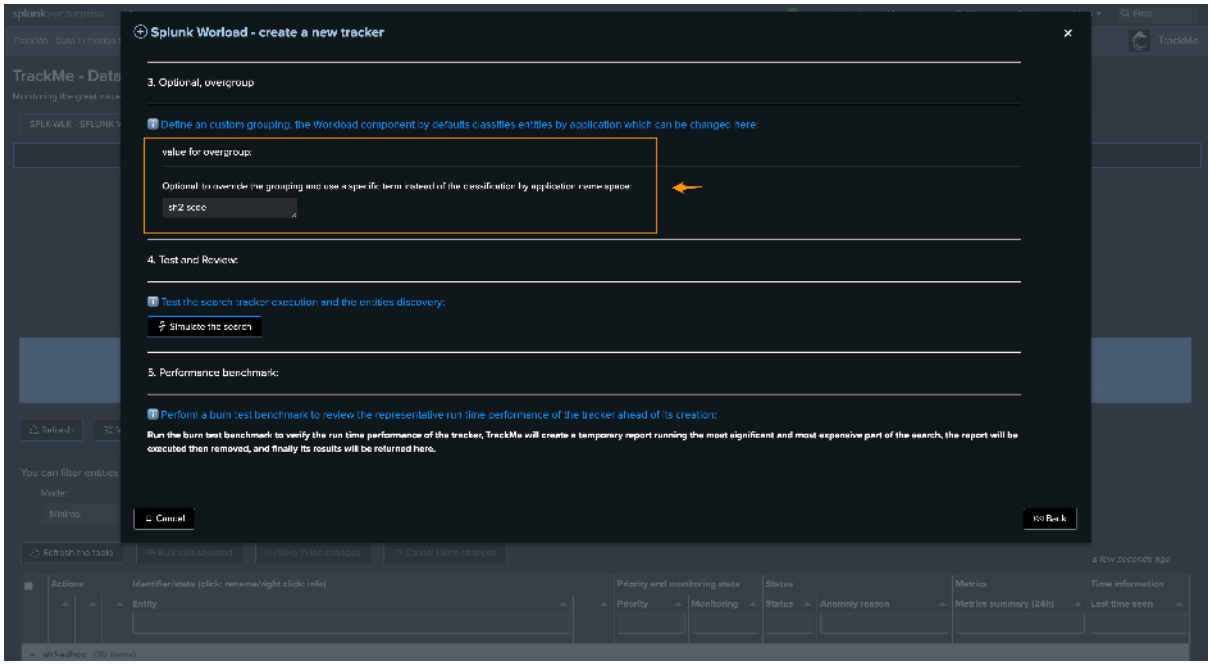
- You do not need to create additional trackers for main, metadata and inactive entities
- There can be only one copy of these trackers per tenant, and these trackers can manage entities accordingly as long as these entities refer to a different account than the one used when creating the tenant
- Therefore, we can manage multiple Search Head tiers in a same tenant as long as each Search Head tier corresponds to a different account (which in fact will be the case systematically in the Workload component)



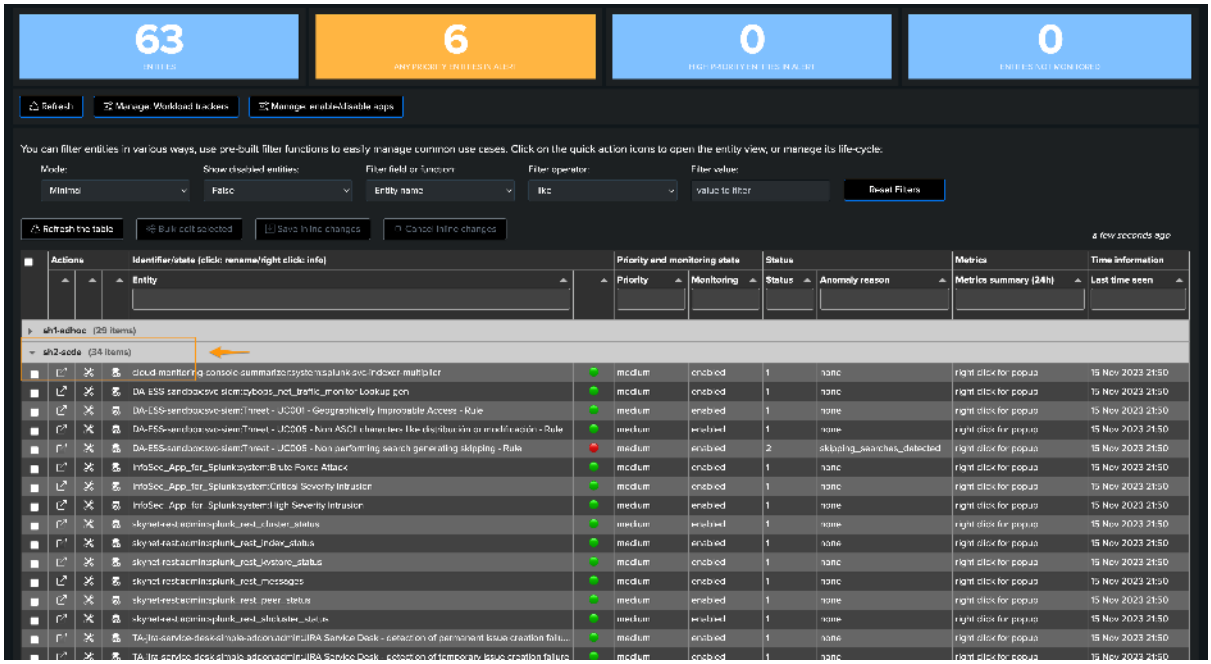
For instance, we will create trackers for a second Search Head tier targeting a remote account and will name the overgroup `sh2-scde`:



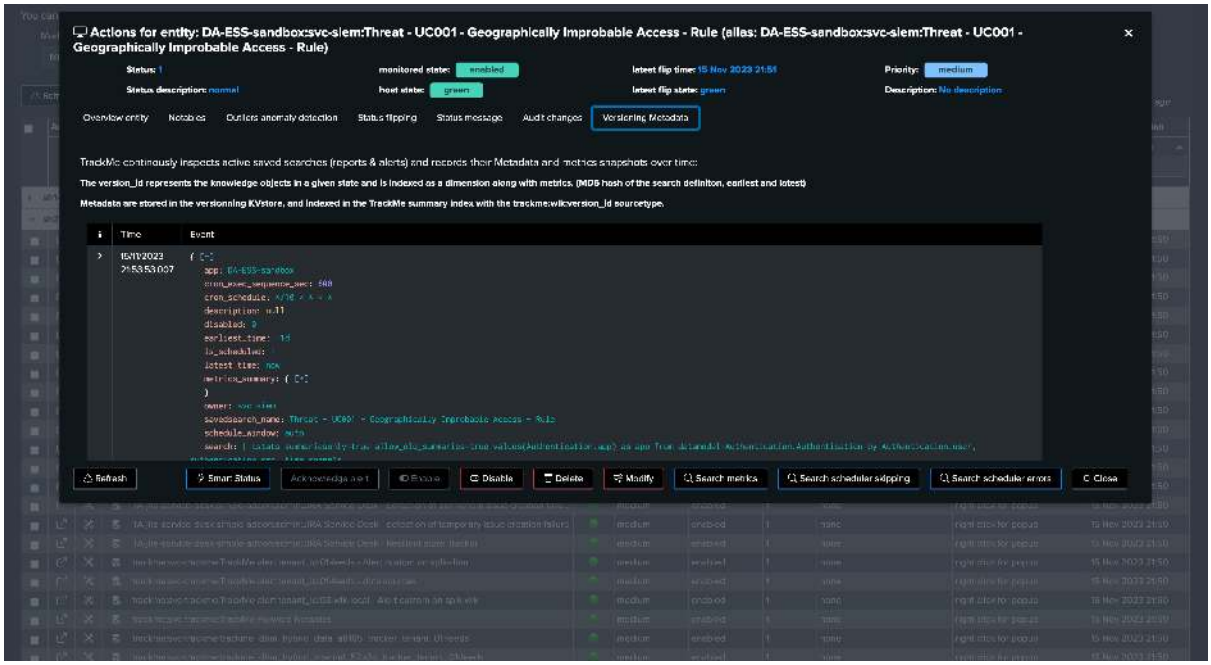




After 5/10 minutes, entities are now also created under the second overgroup as expected:



Metadata are managed transparently depending on their parent account, so TrackMe knows which Search Head tier to query for:



Workload monitoring — concepts & usage

The following material covers the Workload component from the user's perspective — what it discovers, how to read its anomaly reasons, metrics and status messages, and the investigation workflow.

Note

TrackMe Workload component

- This feature is part of TrackMe's restricted features and allows tracking the key value activity and KPIs of your Splunk scheduling, from alerts to scheduled reports and **Enterprise Security correlation searches**.
- We track and alert on sophisticated concepts such as the detection of **execution anomalies** or **delayed**

execution, **consumption behavior** changes using **Machine Learning** as well as **version control** and changes in the searches themselves.

- The **TrackMe Workload component** is extremely powerful and provides the missing deep visibility on your critical Splunk workflow, whether you are using Splunk for security or IT operations, or any other use case.

Hint

Evolutions in TrackMe 2.1.28

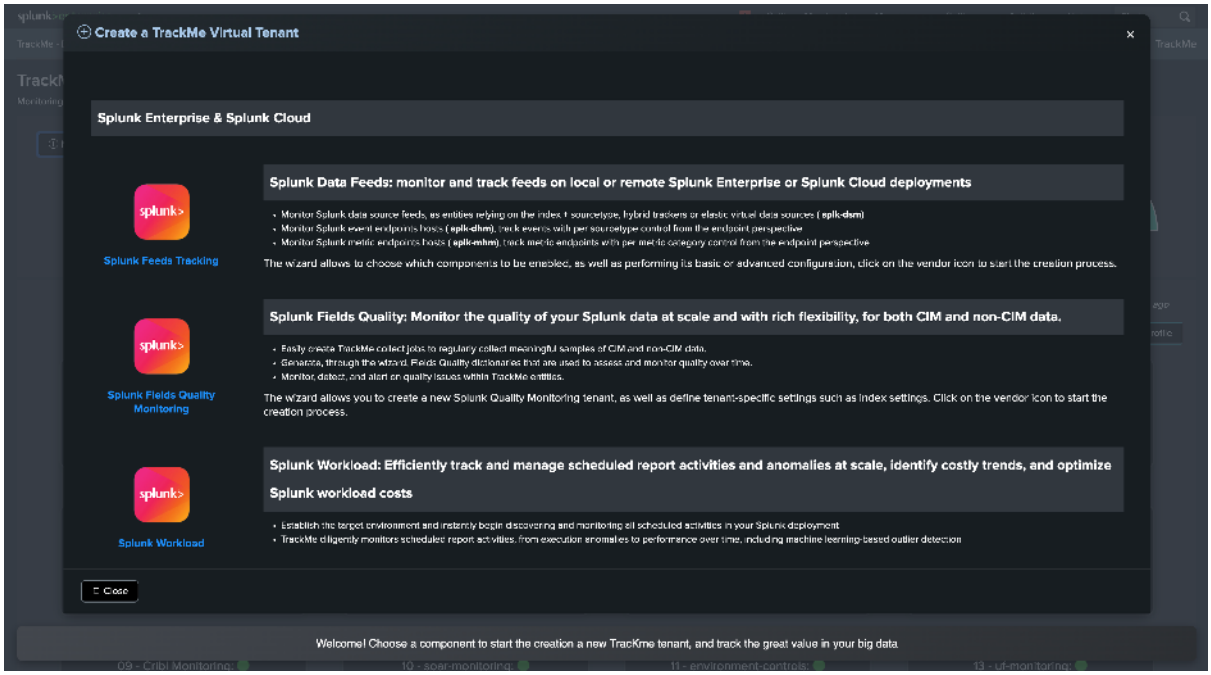
- Since TrackMe 2.1.28, you can now control the list of parameters that are taken into account to calculate the version_id hash.
- To do so, go in Configure / splk-general and update the `splk_general_workload_version_id_keys` parameter.
- The default is to take into account the following parameters: search,dispatch.earliest,dispatch.latest,description,cron_schedule

1. Introduction

The objective of the Splunk Workload component for TrackMe is to continuously track the scheduling activity of a Splunk deployment, and perform key activity and detection:

- Discover Splunk scheduled activity across the environment; an entity will be the association of the Splunk application namespace, the owner, and the search name
- Track the scheduled activity behavior, and detect issues that can affect the well-being of Splunk scheduled reports and alerts
- Track and identify the scheduled objects' Metadata, such as their definition, to investigate and detect changes impacting searches' behaviors over time
- Generate consistent and key value metrics from Splunk introspection, scheduler and SVC usage for Splunk Cloud customers
- Use Machine Learning Outliers detection to track for abnormal behaviors and changes, such as an abnormal increase in costs, run time or consumption
- Alert when scheduled reports and alerts are affected by issues, and get benefit from the full set of TrackMe's features and workflow to handle the lifecycle of Splunk scheduled activity

The TrackMe Workload component, associated with TrackMe's unique workflow, is a game-changing companion for Splunk, allowing it to quickly detect and alert on Splunk's most critical activity, as well as providing the keys to understand scheduled related costs like never before.



Create a TrackMe Virtual Tenant
Splunk Enterprise & Splunk Cloud
Splunk Data Feeds: monitor and track feeds on local or remote Splunk Enterprise or Splunk Cloud deployments
Splunk Feeds Tracking
Splunk Fields Quality: Monitor the quality of your Splunk data at scale and with rich flexibility, for both CIM and non-CIM data.
Splunk Fields Quality Monitoring
Splunk Workload: Efficiently track and manage scheduled report activities and anomalies at scale, identify costly trends, and optimize Splunk workload costs

Note

Grouping in the Workload component: group and overgroup

- By default, the Workload component groups entities by `app` which represents the Splunk application namespace hosting the scheduled report or alert.
- When creating the tenant and also later on when creating trackers manually, since TrackMe 2.0.70, you can optionnally override this behaviour by setting up an `overgroup` value.
- By doing so, the Workload will group entities based on a custom term instead of applications, this can be useful if for instance you want to have multiple Search Head tiers in the same tenant.
- Refer to the *Creating a Workload tenant to host multiple Search Head tiers with overgroup* section for more information.

2. Workload entities

Once a Workload TrackMe Virtual Tenant has been configured, TrackMe starts to track for any scheduled activity and will create and maintain associated entities:

An entity name is composed of:

- `app` + ":" + `owner` + ":" + savedsearch name

Should any of this information change, TrackMe will consider this as a new entity to be created and maintained, for instead of a search reassignment, if the search is moved between different application name spaces, or if the search knowledge object identifier is changed.

3. Anomaly reason

3.1 Anomaly reason definition

TrackMe considers each entity individually, and will trigger a status change based on the following criteria:

Anomaly Reason	Conditions
none	The entity is green and is healthy, there are no issues detected currently
skipping_searches_de	TrackMe detected skipping executions for that scheduled, by default orange<5% and red>5%
orphan_search_det	A previously active scheduled search is now orphaned, which means the owner is not valid any longer and the search cannot be executed
execution_errors_detec	Execution errors are detected and the scheduled report/alert is not working properly
anomaly_outliers	The Machine Learning outliers engine detected issues in one or more active ML models, this can be for instance an abnormal increase in the schedule runtime
execution_delayed	TrackMe uses the Metadata and the cron schedule translation to monitor if the search is delayed compared to its expected schedule (with 5 min of grace time by default)
status_not_met	The status of the entity is red, for unclassified reason
out_of_monitorir	The status of the entity is not healthy, however the current period is out of the monitoring window set for this entity

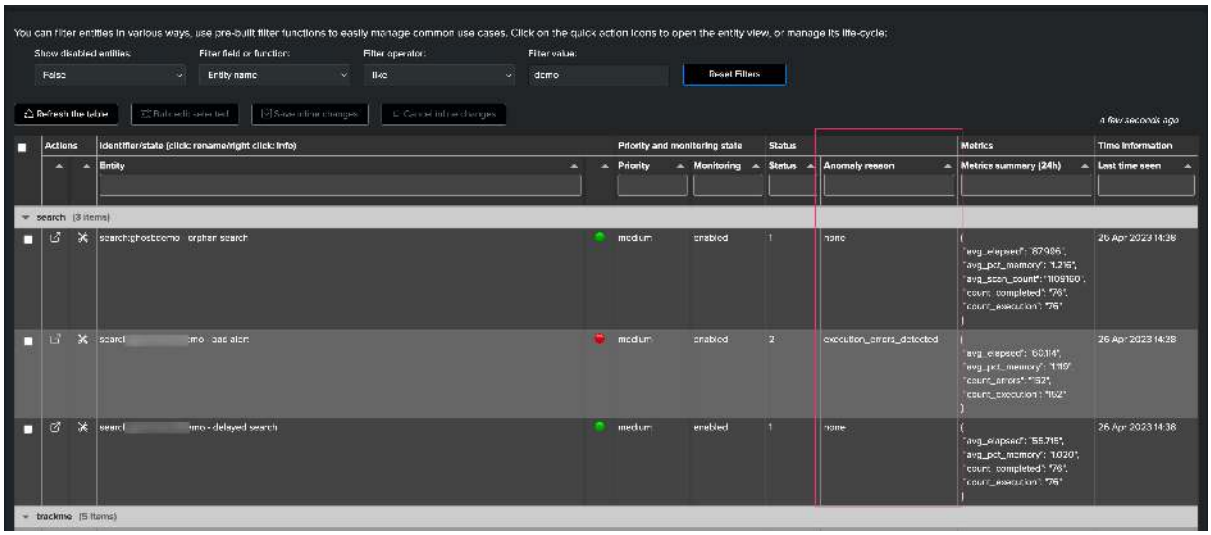
3.2 Checking the Anomaly Reason

You can observe the current anomaly reason in different locations:

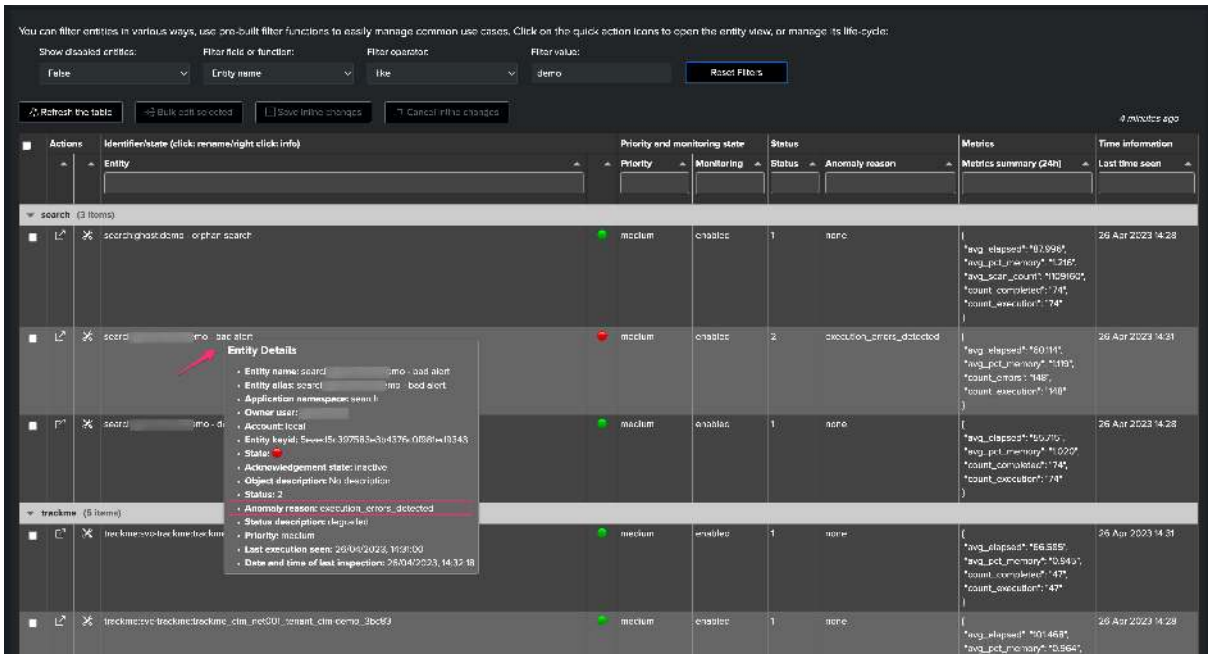
- In the table column called "Anomaly Reason"
- By right clicking on the entity, in the contextual menu
- When the alert is sent over, as part of the fields resulting from the alert

- When the alert fires, as part of the TrackMe notable event

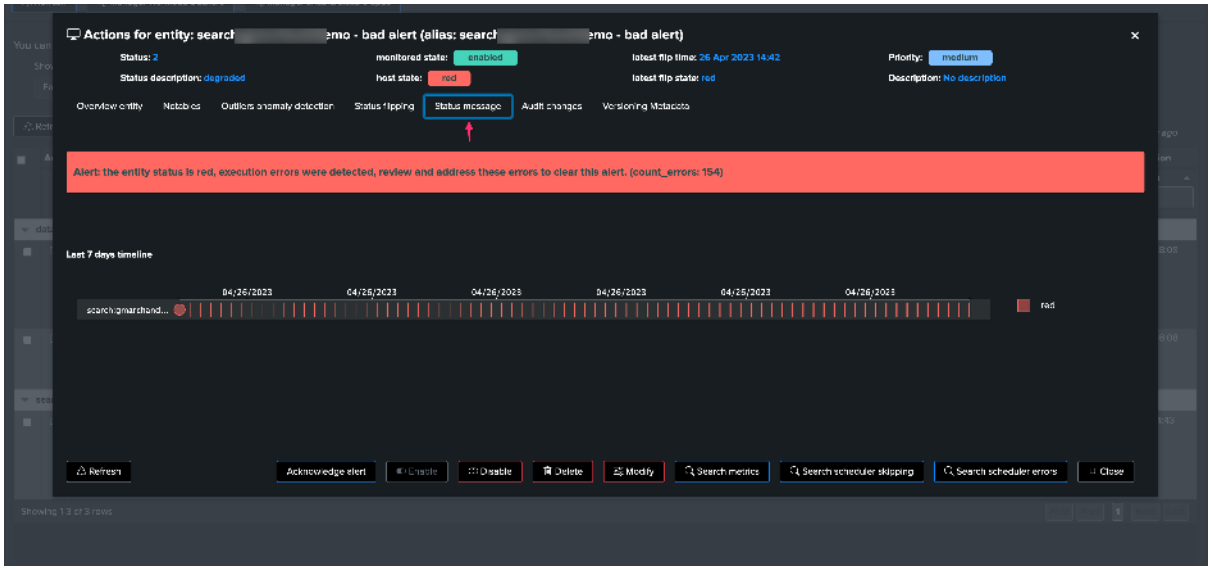
table anomaly reason column:



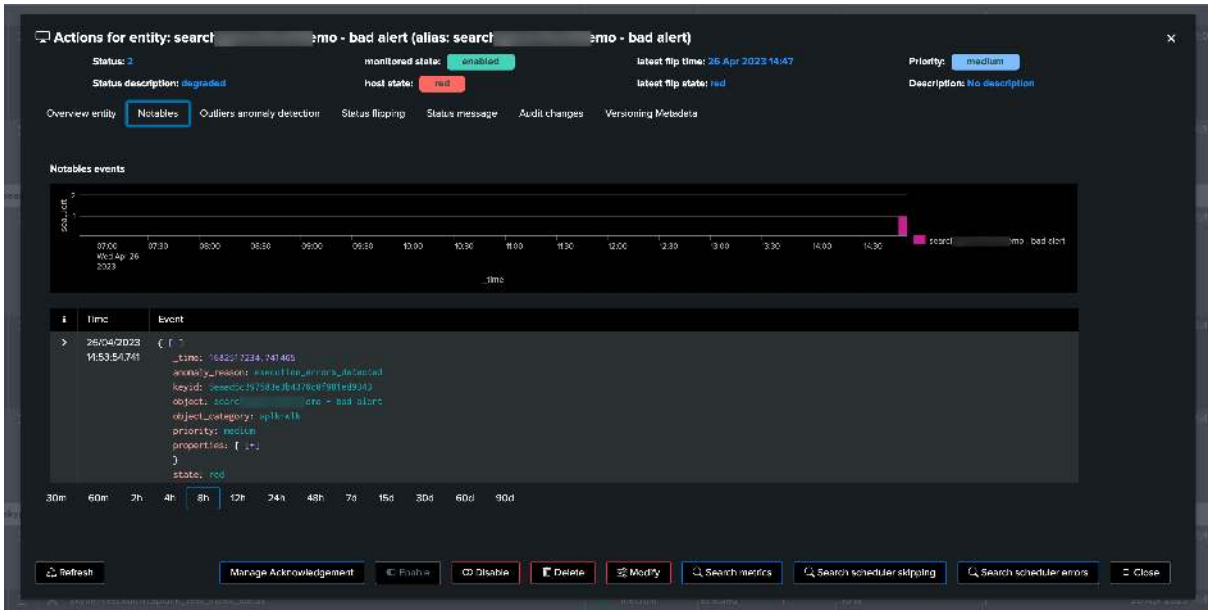
right click contextual menu on the entity name:



The status message is conditioned by the anomaly reason value and translated into a detailed message:

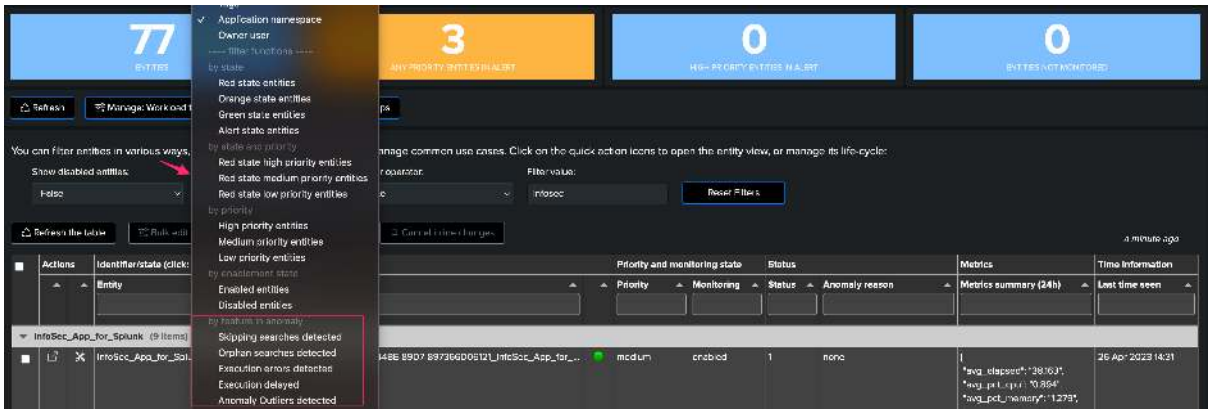


The anomaly reason is part of a notable event when an alert triggered:



3.3 Filtering on Anomaly Reasons

You can use the filter functions to check all entities with a given anomaly reason:



4. Workload metrics

Once a scheduled entity was discovered, TrackMe tracks its activity and generates various key metrics:

Metric name	Description
count_executior	Scheduler metric: the number of requested executions for this schedule
count_complete	Scheduler metric: the number of successfully completed executions for this schedule
count_skipped	Scheduler metric: the number of skipped executions for this schedule
count_errors	Scheduler metric: the number of executions errors detected for this schedule
elapsed	Introspection metric: the run time of the search, in seconds
pct_cpu	Introspection metric: the aggregated percentage of CPU used for this schedule (which can be more than 100%)
pct_memory	Introspection metric: the aggregated percentage of Memory used for this schedule (which can be more than 100%)
scan_count	Introspection metric: the number of events scanned for this schedule
svc_usage	Splunk Cloud metric: the SVC usage for this consumer

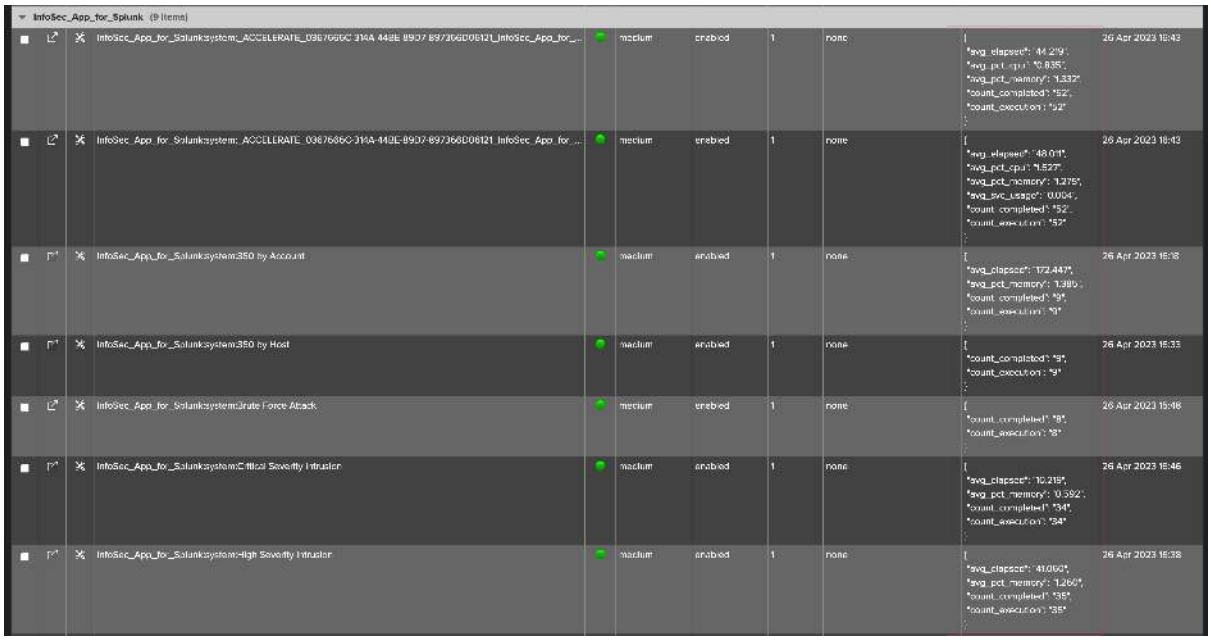
The Workload metrics are then used to condition the status of the entity, and feed the Machine Learning Outliers engine.

4.1 Accessing metrics

4.1.1 Metrics summary table

Metrics summary in the table:

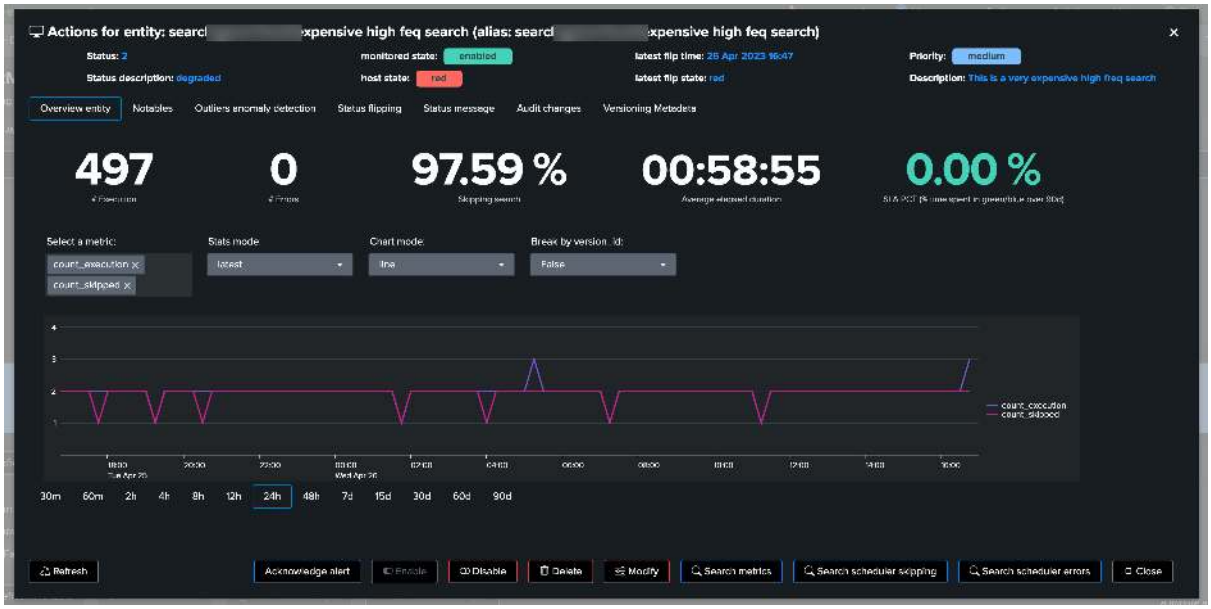
TrackMe shows a summary of the metrics of the last known 24 hours per entity:



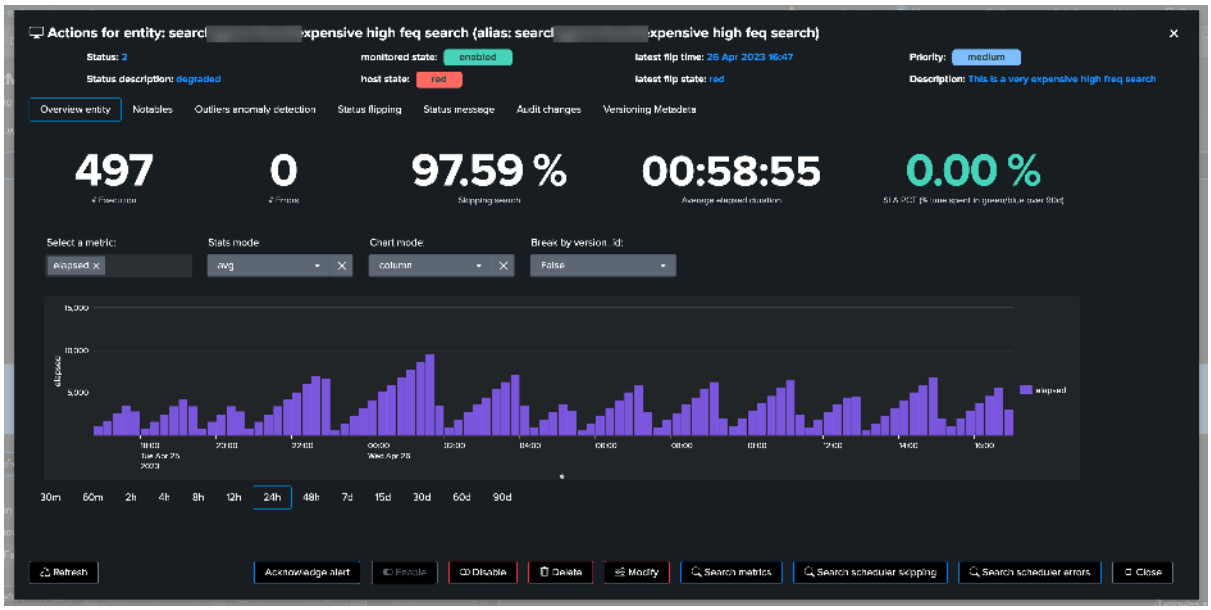
Note that metrics shown in the summary JSON vary depending on the metrics available, for instance an entity which has not been experiencing skipping searches will not show the metric as it is null.

4.2.2 Metrics chart over time

You access to the metric chart selector by opening an entity overview:



Use the metric selector, and optionally other settings according to your needs, in the following examples, we are looking at the average elapsed for that entity:



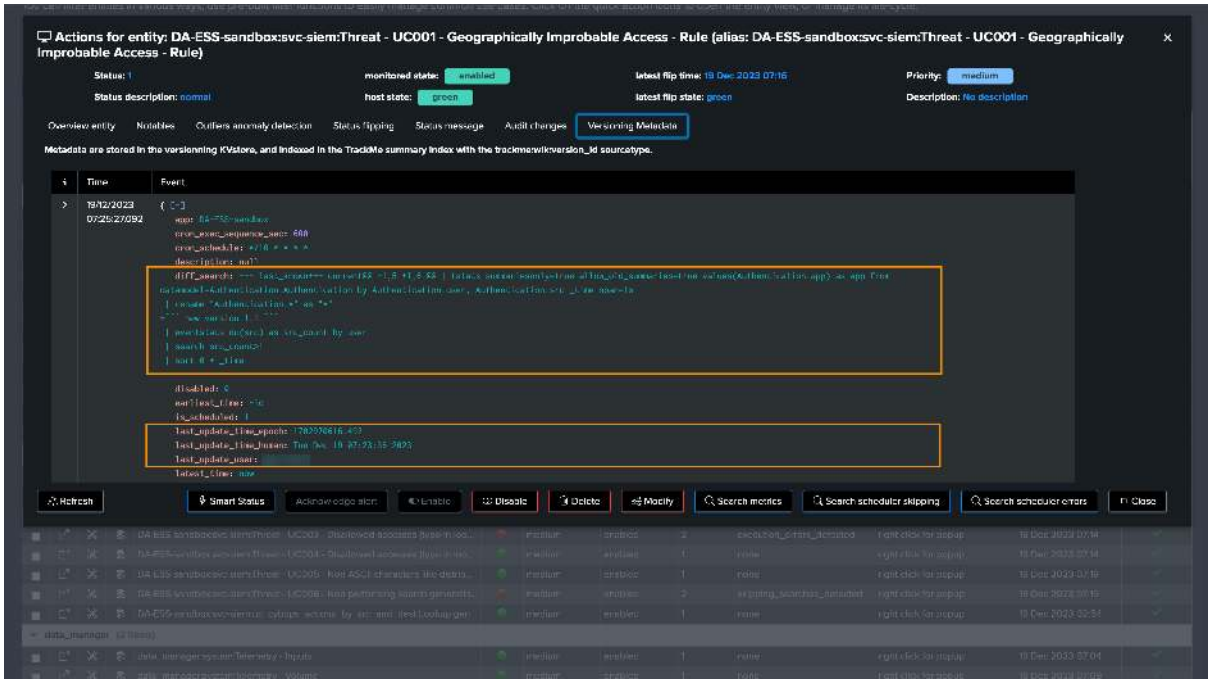
5. Metadata Versioning

TrackMe monitors the versioning of scheduled entities, to detect changes and allow linking a knowledge object state with its performance metrics.

Hint

Diff search/earliest/latest (new in TrackMe 2.0.72)

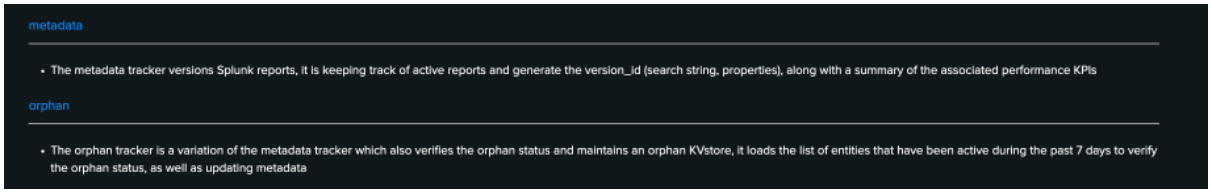
- Since TrackMe 2.0.72, the diff of the search and/or earliest/latest quantifiers is performed and stored as part of the versioning events and records
- This means that TrackMe automatically identifies the difference of the search when a change is detected against the previously known version, stored as part of the `diff_<context>` fields
- It will also attempt to identify the user that performed the change and when this change occurred (if the change occurred via Splunk Web/Splunk API, not application configuration push)



5.1 How the Metadata Versioning works under the cover

This activity is performed by two associated scheduled TrackMe trackers:

- metadata
- orphan

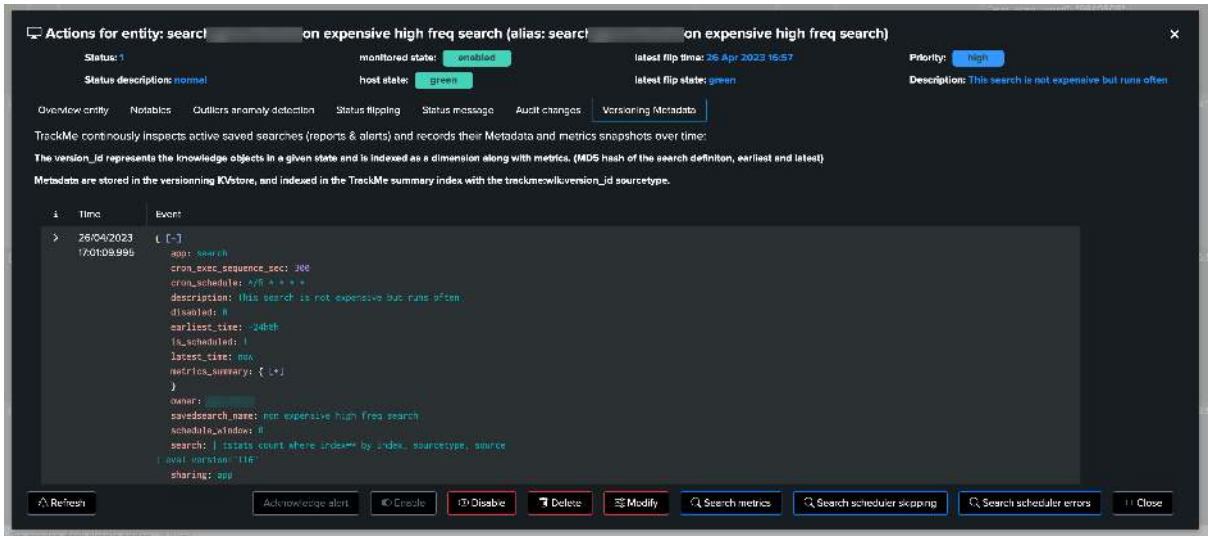


Via a Python based integration, TrackMe maintains the knowledge of scheduled entities, and identity a certain state as an MD5 hash which is composed by:

- The search code definition, basically the whole SPL statement whatever its complexity is
- The earliest time quantifier
- The latest time quantifier

5.2 Accessing Metadata information via the UI

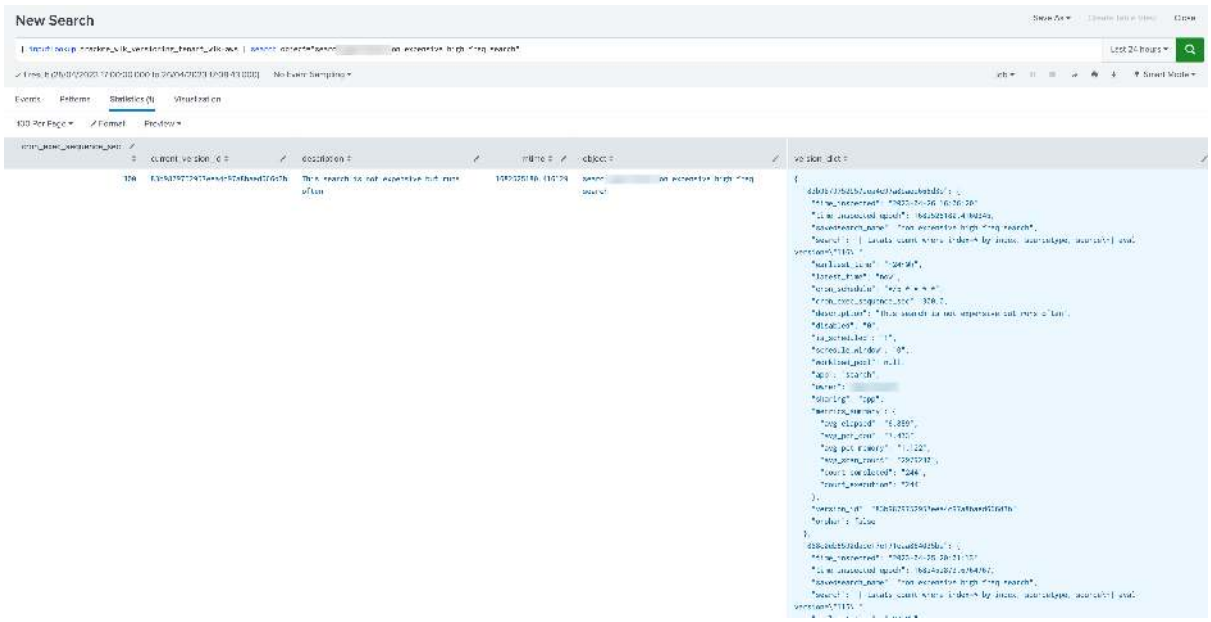
Regularly, active entities are inspected, if a change is detected, a new version_id is defined, a new set of Metadata are extracted and stored in a KVstore collection:



5.3 Accessing Metadata information via the KVstore

The Metadata version is stored in a JSON structure within the KVstore record associated with a given entity, in a persistent fashion:

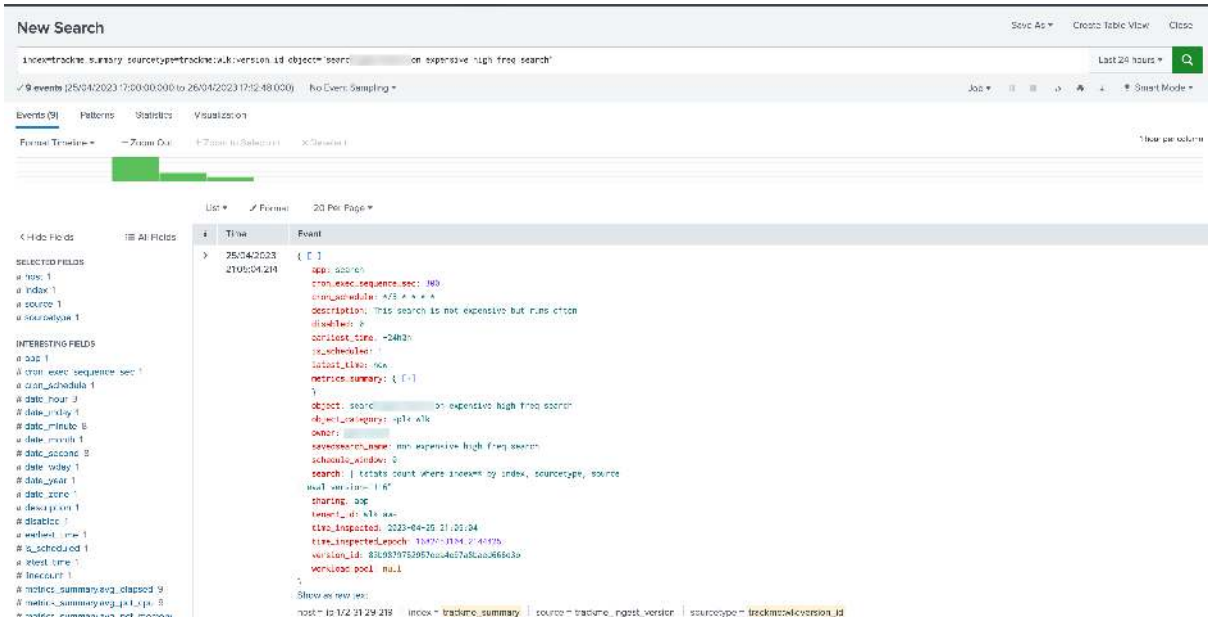
```
| inputlookup trackme_wlk_versioning_tenant_<replace with tenant_id> | search␣
↪object="<replace with object name>"
```



5.4 Accessing Metadata information via TrackMe indexed events

When TrackMe detects a new version of a monitored scheduled entity, it will as well generate an event in the trackme_summary index of the tenant, with the sourcetype:

```
index=trackme_summary sourcetype=trackme:wlk:version_id tenant_id="<replace with␣
↪tenant_id> object="<replace with object name>"
```

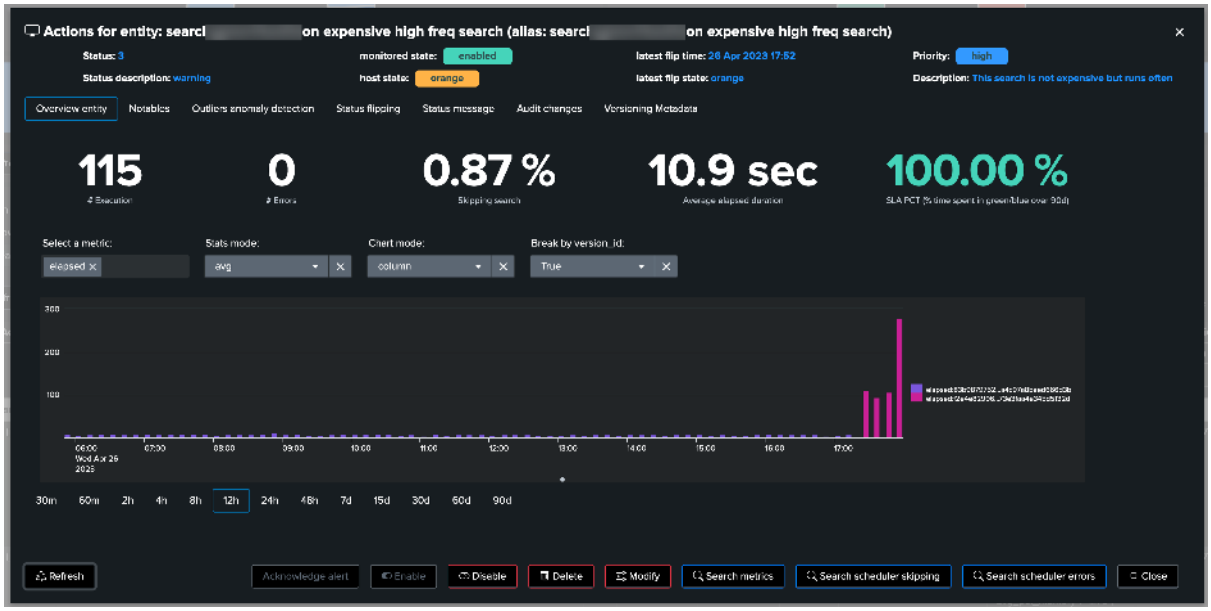


5.5 Use cases for versioning

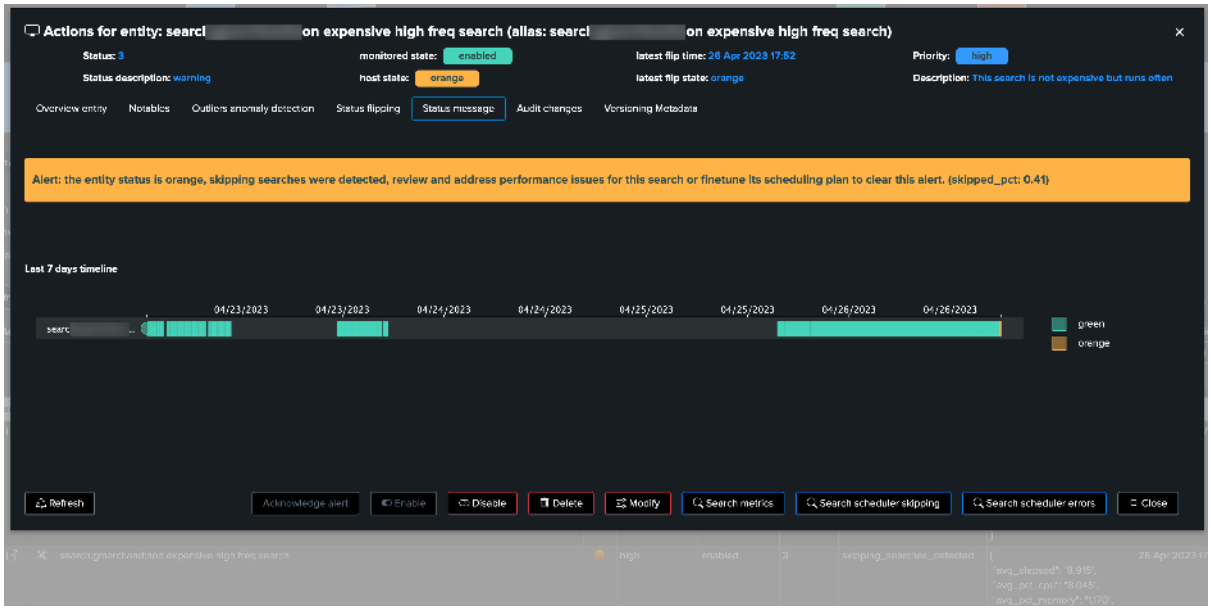
So, what are the use cases for the versioning TrackMe feature, associated with TrackMe's workflow, incident management, metrics generation and so forth? There are many valuable use cases of course.

For instance, it becomes fairly easy to link a change in the search logic to a massive increase of its run time or computing costs, potentially suddenly leading to alerts in TrackMe caused by skipping searches.

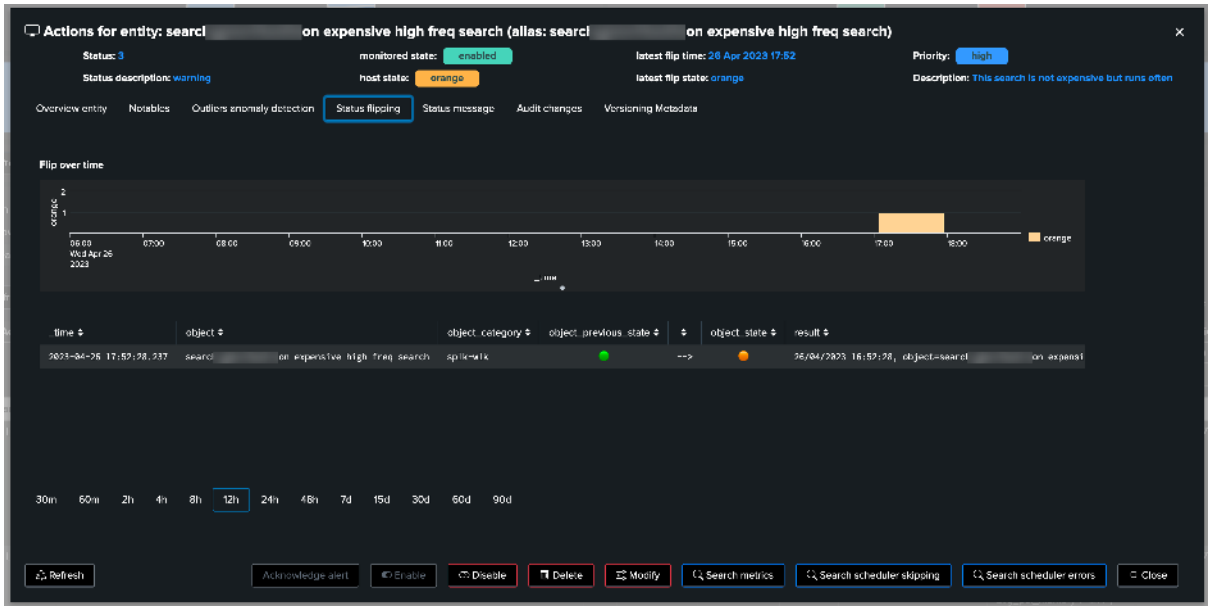
When accessing the metrics overview, use the break down selector to add the version_id as part of the break by statement:



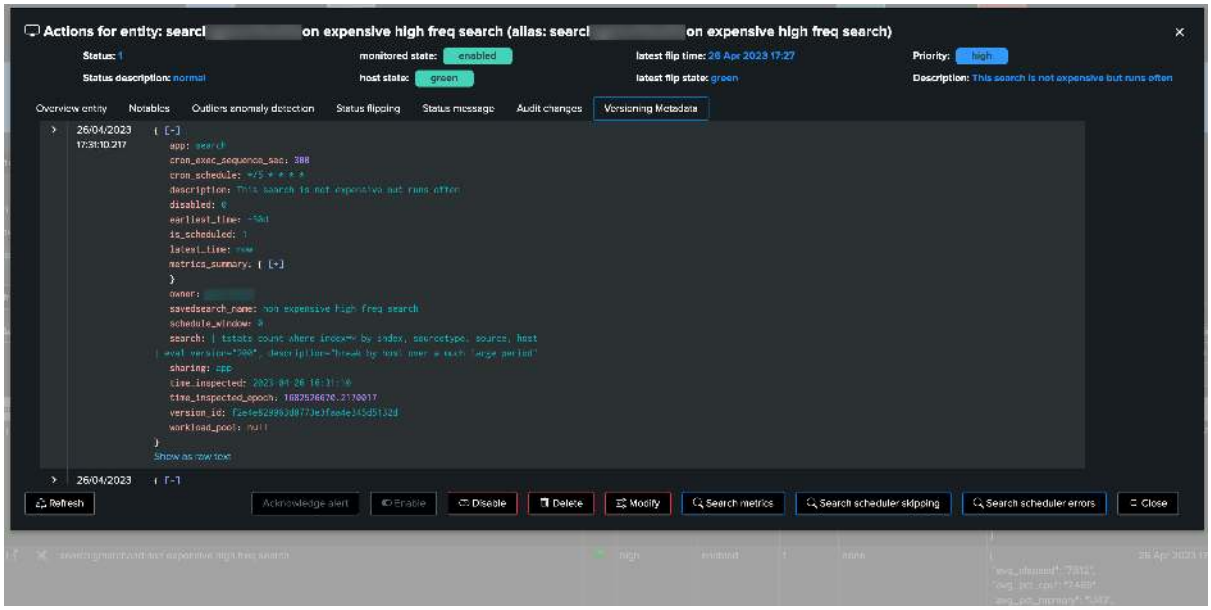
Perhaps TrackMe started to detect bad behaviour of the scheduled object, for instance starting to generate a certain level of skipping searches:



Wait what, don't we have information about flipping statuses? We also know the "when":



As we can see in the chart, a clear increase in in the elapsed (run time in seconds) became suddenly visible, which we have been able to easily associate with a change of the Splunk knowledge object itself:



A search which was very efficient suddenly starts consuming a huge amount of resources, potentially impacting the functional use case itself, perhaps even the platform and starting to cost real money to the company, with the need for additional resources and so forth!

Use cases for the Workload features and the versioning are legions, its value grows exponentially along with your deployment size, scale and maturity.

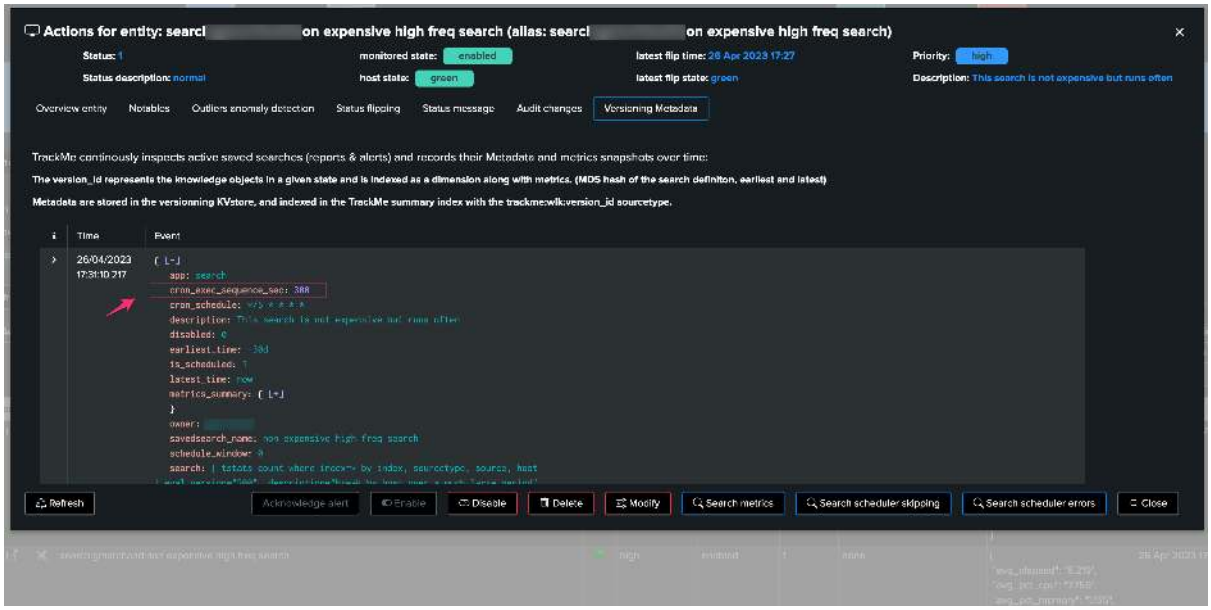
6. Delayed searches execution detection

As part of the Workload component, TrackMe verifies that scheduled entities have been executing properly according to their requested schedule.

A delayed search execution can have severe implications, from a functional perspective this can mean security events which are not considered properly for instance, with all the range of potential consequences.

This verification is called "execution_delayed" anomaly reason status, and works the following way:

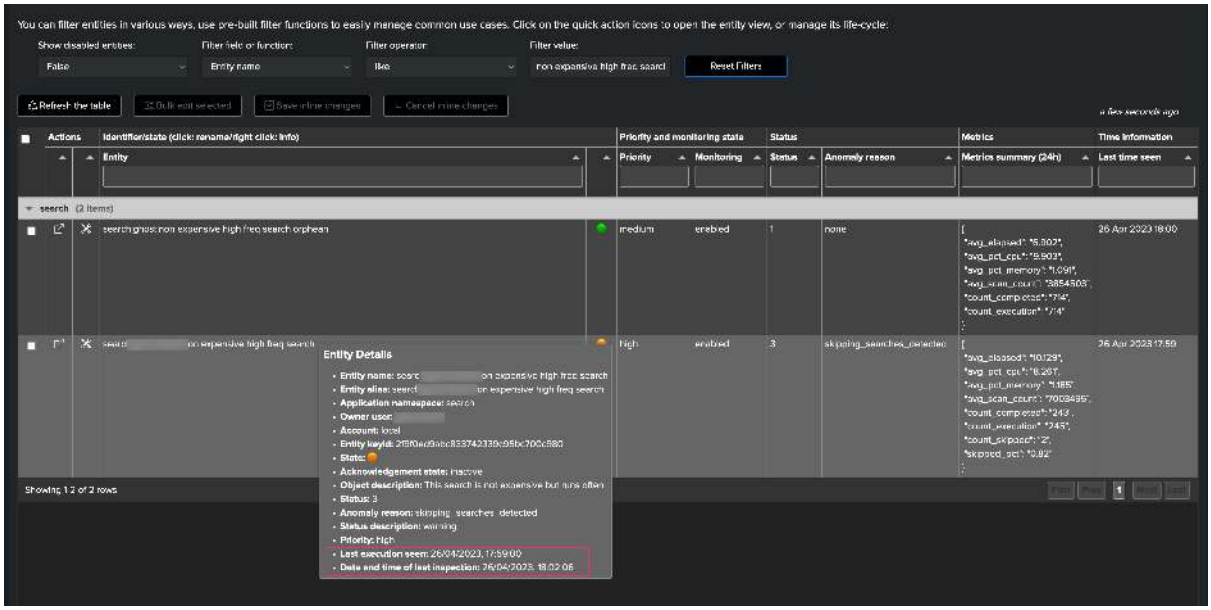
- When the versioning components inspect the Metadata of an entity, it retrieves the cron schedule expression too, which defines how often a scheduled is going to be scheduled
- This cron schedule is transformed into a per seconds value defining how often the search should have been executing (using the croniter Python library), and stored in the field `cron_exec_sequence_sec` along with the metadata record of the entity



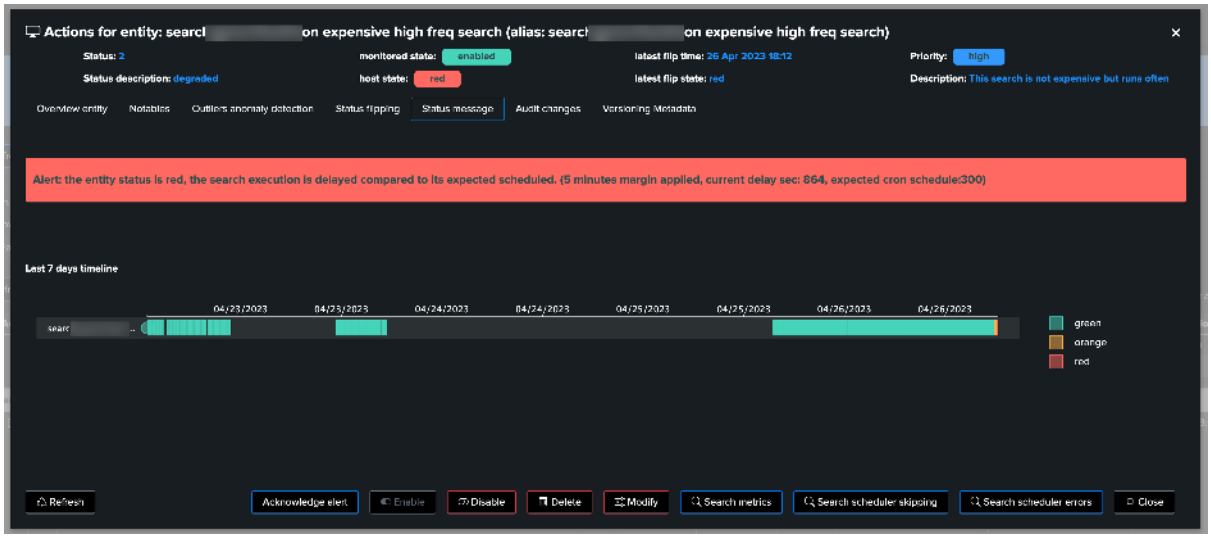
Finally, TrackMe verifies and stores the scheduled successful execution traces, if a search which should have executed at least once in the past 5 minutes has not been since active since more than 5 minutes, plus the grace period, then TrackMe can consider this entity as unhealthy and trigger and alert accordingly,

For instance, let's disable the scheduling of an active schedule (a mistake? bad behaviour?), after a short period of time, TrackMe detects the conditions which immediately impacts the entity, generates an alert and TrackMe notable!

we can observe the dates of latest inspection and latest execution in the contextual menu:



After some minutes, TrackMe detected that the scheduled search is delayed:

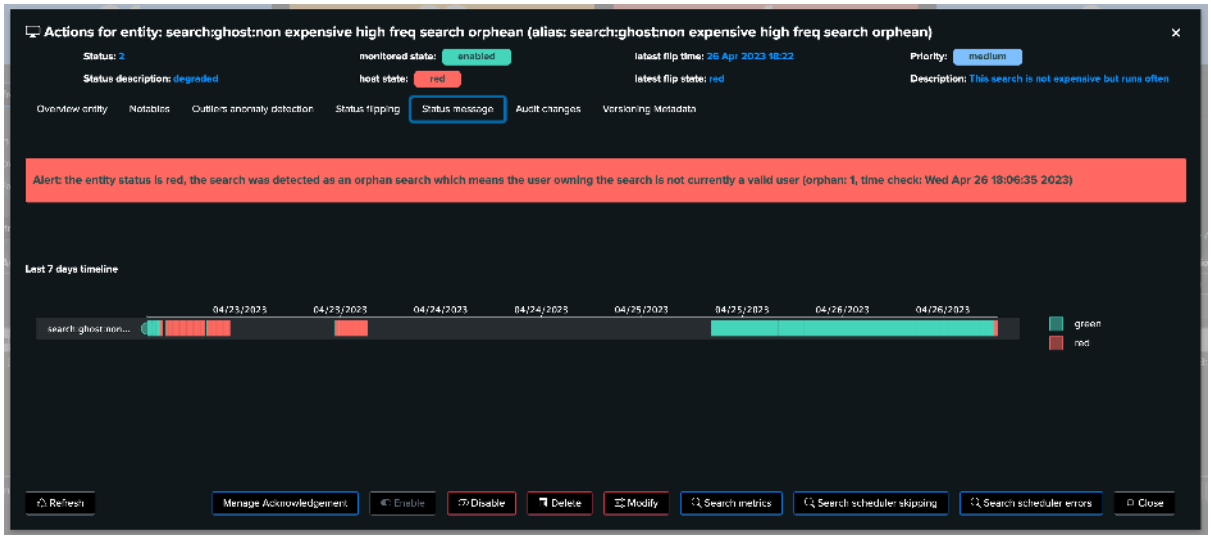


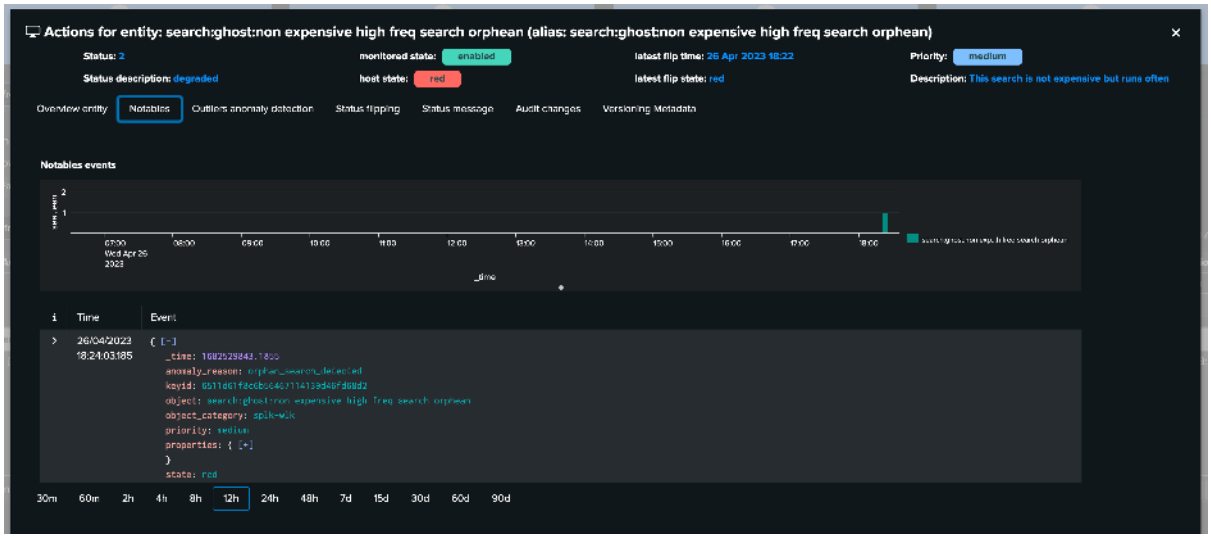
From this stage, we automatically detect an abnormal condition for our critical scheduled activity, and we can start acting accordingly before it starts having any severe consequences!

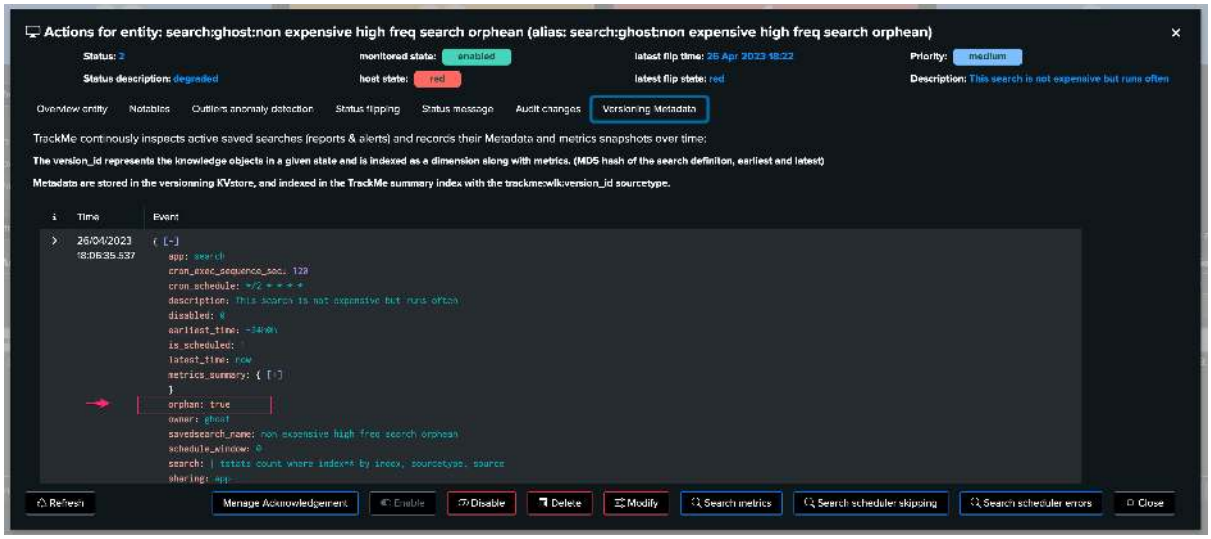
7. Orphan searches detection

Orphan search condition is also detected by TrackMe, for any search that has been actively discovered, in short:

- Once per hour, TrackMe verifies via the orphan tracker the current status of all active scheduled objects for the past 7 days
- It updates the Metadata information with the `orphan` boolean
- In return, TrackMe as part of its condition verifies that the search has not been detected as an orphan search, which otherwise will be considered as a critical condition for this entity



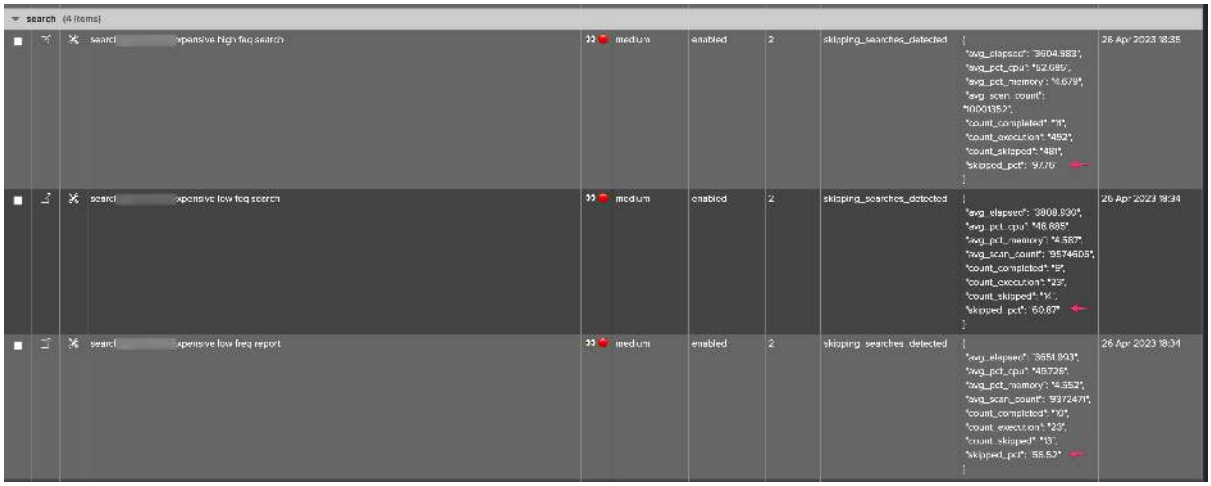


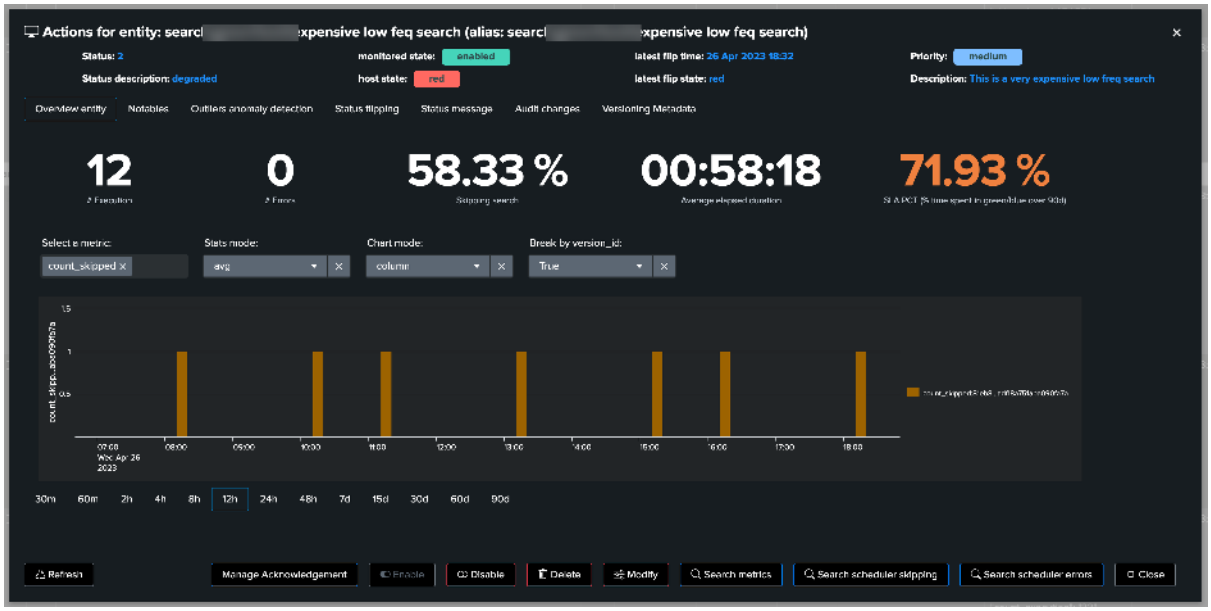


8. Skipping searches detection

Skipping search condition is achieved by comparing the collected count_execution and count_completed collected metrics, which gives the skipping search percentage:

- If the skipping search percentage is somewhere between 0 to less than 5%, the entity status will be **orange**
- Over 5% of skipping search percentage, the entity will turn **red**
- The skipping percentage can be seen in the summary metrics JSON in the table, or via the metric over time inspector

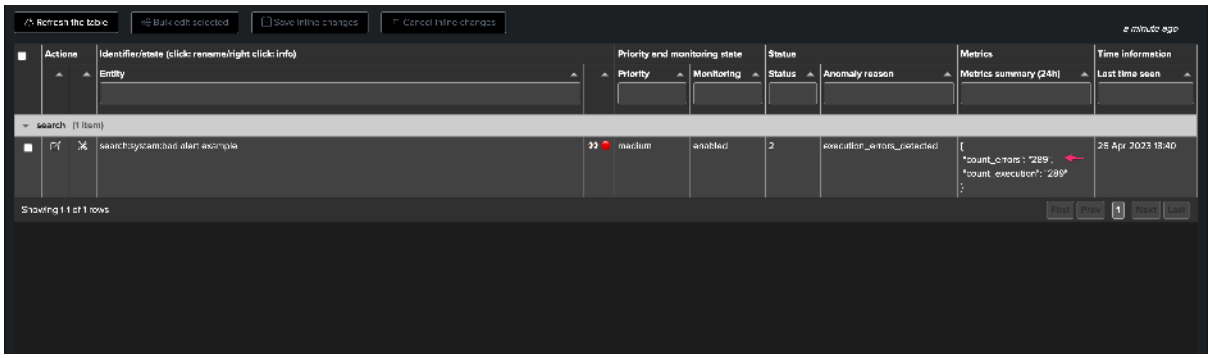


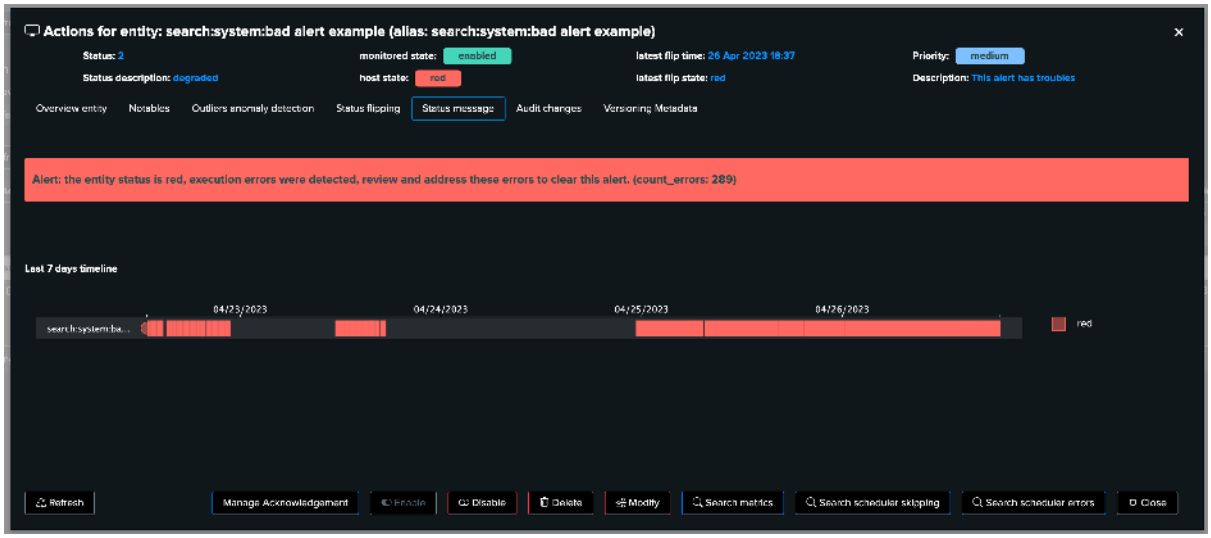


9. Error executions detection

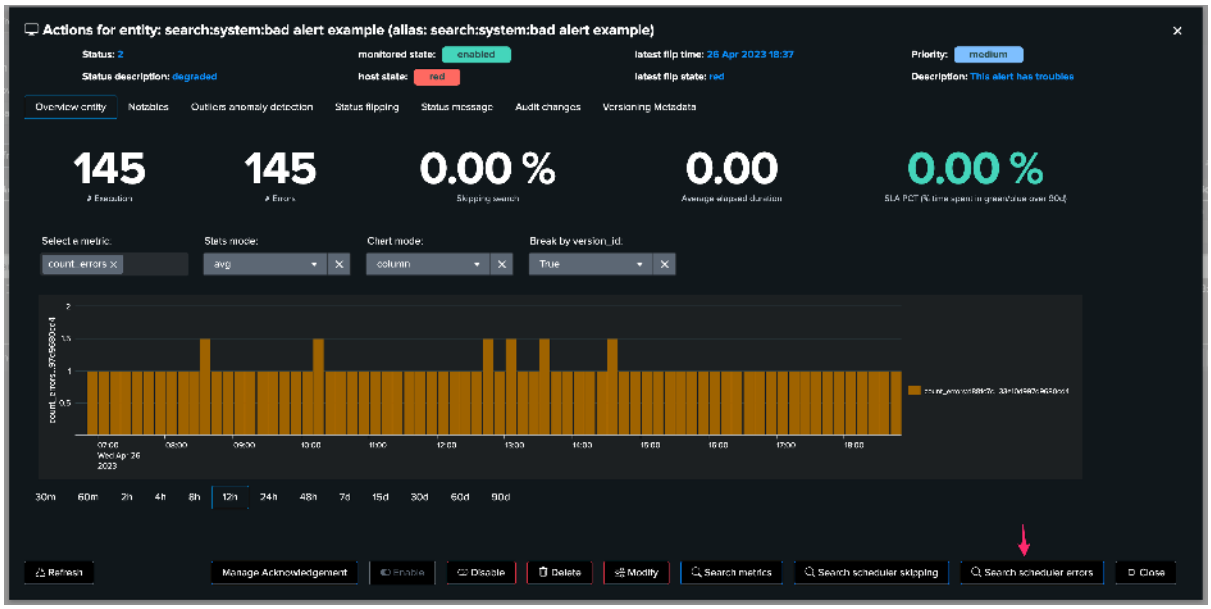
Detecting at scale and automatically execution errors is another challenge TrackMe tackles in the Workload component:

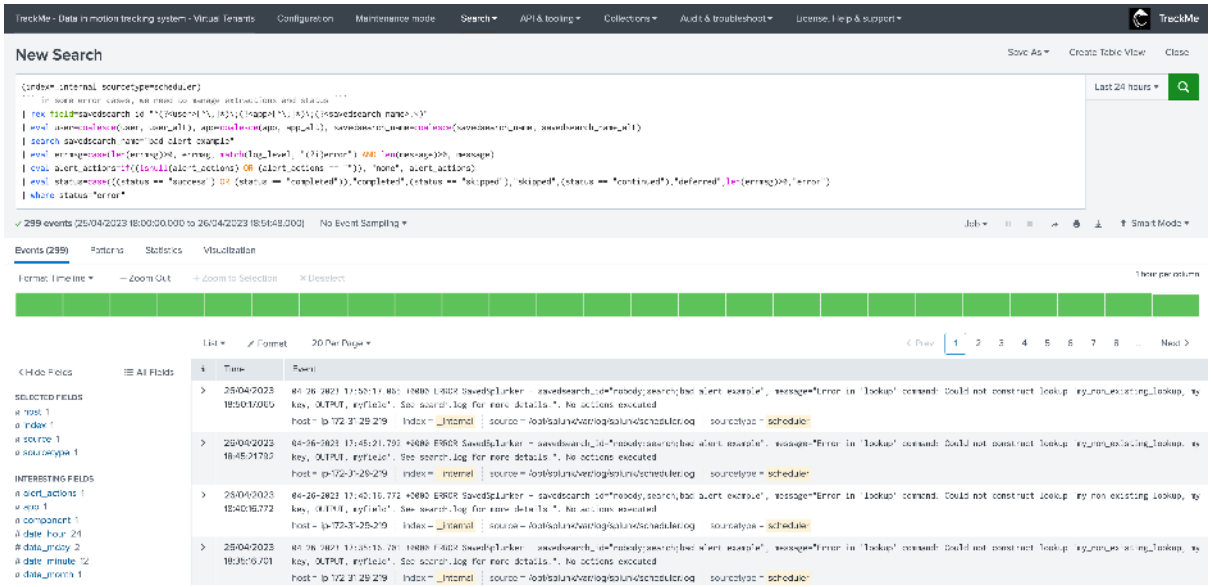
- Execution errors can happen for all sorts of reasons, for instance a related knowledge object (macro, lookup etc.) which is not available to the search logic
- Errors in the application development, lack of qualification, unexpected deployment side effect, etc. many combinations can lead to a scheduled search to be failing pretty much silently
- TrackMe handles the challenge by continuously looking at the scheduler activity, and extracting the executions errors turning these into a metric which we can take into account





From the overview (currently looking at the metrics), you can as well directly access to the scheduler errors:

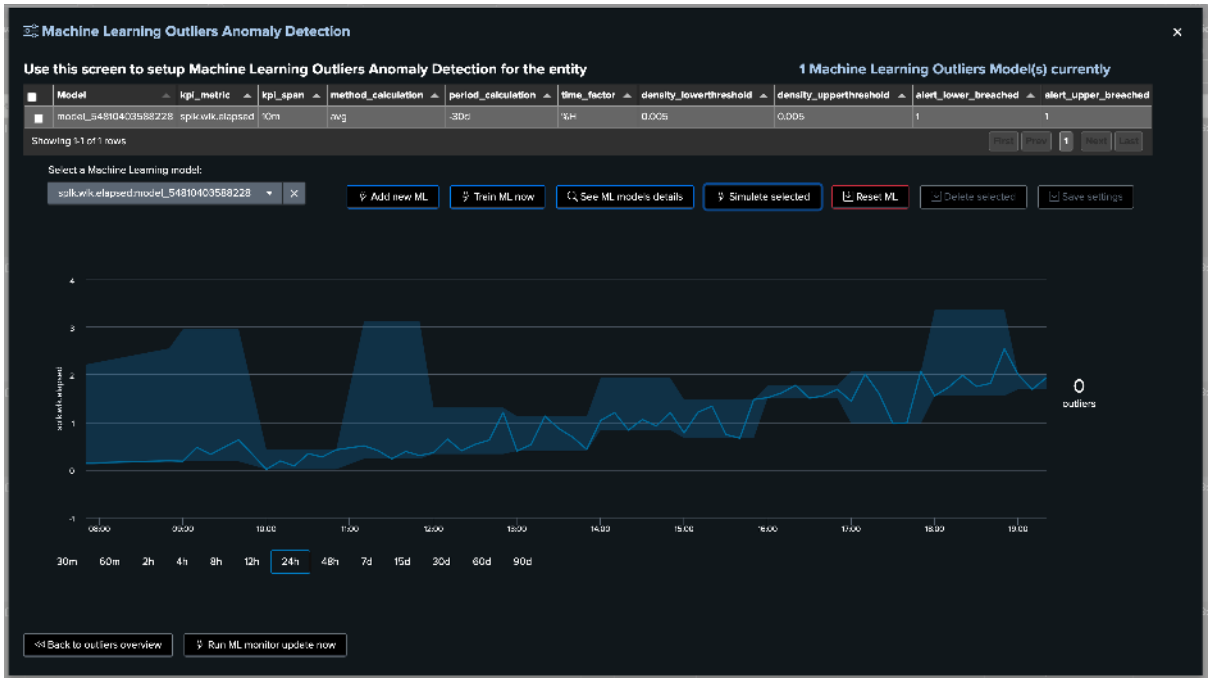




10. Machine Learning Outliers detection

Machine Learning Outliers detection can be used to detect abnormal trends for the scheduled entities, based on any of the available KPIs:

Machine Learning models created and trained by default depend on the Virtual Tenant configuration, additional ML models can be created on demand:

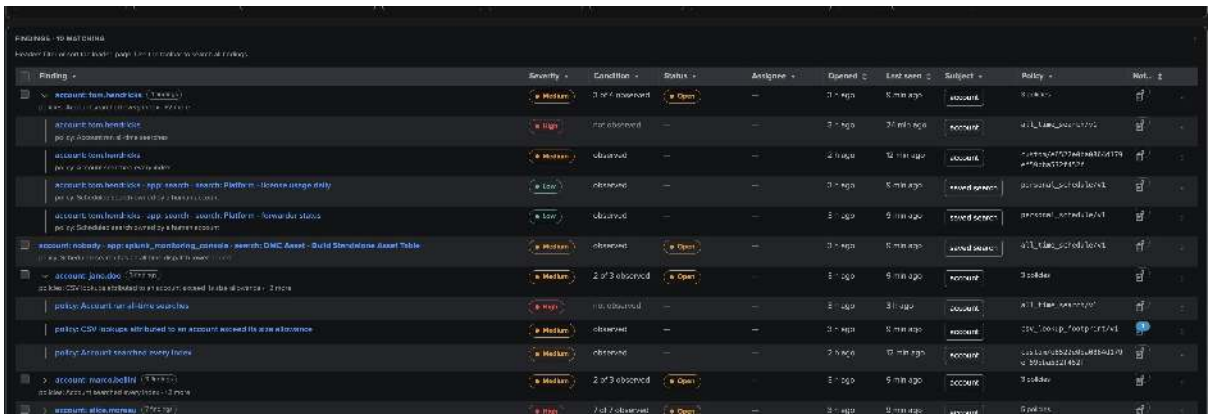


8.3.14 User Activity Monitoring

TrackMe has always watched the data. **User Activity Monitoring** watches the other half of a Splunk platform: the people and the automation that use it. It answers a question none of the entity components asks — **who is doing what on my Splunk?** Which accounts run searches, how often and at what cost; which scheduled searches are owned by a person who may leave tomorrow; which account started to run all-time searches; who consumes the search capacity of the platform; whose CSV lookups keep growing; which indexes are read, by whom, and which receive data no one reads.

A User Activity Monitoring tenant (UAM) reads what Splunk already keeps — the audit trail, the search resource

records and the knowledge objects of every search head — and turns it into **findings**: one finding per policy and subject, with its evidence, a severity, an investigation status, an assignee, notes and a history. You investigate, decide, notify the people concerned and move on.



UAM is a **dedicated tenant type**, not an eighth entity component: a tenant is either an entity tenant (DSM, DHM, MHM, FLX, FQM, WLK, VOL) or a UAM tenant, never both. There is no decision maker, no impact score and no state colour behind it: what you work with are findings. UAM shares its findings model — Finding groups, triage, assignment, notifications, findings actions, the AI Agent — with Cribl Stream and Cribl Edge; those concepts are explained once in *Findings, Finding groups and findings actions*, and this page documents how they work in UAM.

Tip

This page is the task-oriented guide: set the tenant up, find your way in the workspace, triage, communicate and tune. Every setting with its default and bounds, the schedules, the indexed evidence, the REST API and the troubleshooting table are in *User Activity Monitoring — reference*.

What UAM watches

One UAM tenant monitors **one indexing layer** seen through **one to ten search head tiers**: the local search head and / or remote Splunk deployments reached through TrackMe remote accounts, on Splunk Enterprise or Splunk Cloud.

What	What UAM knows about it
Accounts	Every account seen in the users inventory or in the search activity — people, service accounts and Splunk's own system identities — with its **class** (human, service or system), its roles, the tiers it exists on and its email address when Splunk has one.
Search activity	One compact audit record per search and collection window, read from `_audit`: the account Splunk reports, the app, the search type, the outcome, the run time, and whether the search covered all time. Executions are correlated per search.
Resource usage	The CPU time and peak memory of every search, on the search heads and on the indexers, and each account's share of the environment's search capacity. CPU follows Splunk's own accounting where it exists.
Saved searches	The saved-search inventory of every tier: owner, app, schedule, dispatch time range, enablement, and every change (added, changed, removed).
Other knowledge objects	Dashboards, macros, event types, field extractions and transforms, field aliases and calculated fields, lookup definitions, automatic lookups, CSV lookup files (size, owner, modification time — never their contents) and tags, read from the Splunk REST API of each tier.
Data usage	The indexes every search names, by account, app and path (literal term, macro, event type, saved search, data model or wildcard), the knowledge objects that declare each index, and — through linked VOL and DSM tenants — what each index ingests and costs. See *Data usage*.
Findings	What the **policies** raise: sixteen built-in policies and the custom policies you write in SPL.

Note

What UAM claims, and what it does not.

- An account in UAM is the account **reported by Splunk**: it is not a verified person. Shared credentials or an integration running as a person's account look like that person.
- Collection is bounded by time only, and nothing is dropped to fit a row count: what a run cannot finish in its time continues at the next run. Coverage still depends on what the Splunk sources retain and what the collection accounts can see; gaps and partial coverage are recorded and shown in **Collection health**, never hidden.
- There is no machine learning in UAM: thresholds are explicit, and the daily CPU baseline is a percentile over the account's recent days.
- UAM never changes, dispatches or deletes anything it observes. A decision on a finding stays in TrackMe.

Before you start

A licence beyond Foundation. UAM is available with the **Enterprise** and **Unlimited** editions, the Unlimited trial and the Developer licence. It is not available on the Foundation edition or the Foundation trial. When a licence expires, the workspace stays readable while changes are refused, and scheduled collection continues until the licence enforcement ladder stops the tenants.

The Splunk sources. UAM reads `_audit` (search activity), `_introspection` (search resource records and capacity) and the indexers' search completion records (CPU accounting), through one search head tier called the **route account**. Splunk Enterprise 9.4, 10.4 and 10.6 and Splunk Cloud 10.5 are qualified; other versions run as well and only add a soft diagnostic in Collection health. Three things to know:

- The automatic detection of **service accounts** relies on the classic `key=value` format of the `_audit` lines. A deployment whose `_audit` only contains the JSON format gets no automatic service detection (human detection and your own rules still work).
- What UAM can look back on is bounded by the retention of these indexes. `_introspection` is often kept for a shorter time than `_audit`, so resource history may end earlier than audit history.
- Before Splunk 10.4, the lookup file listing gives no file size: UAM reads the sizes of the CSV lookup files through Splunk's file explorer endpoint (`admin/file-explorer`), so the collection account of each tier must be allowed to read it. By default only the `admin` and `splunk-system-role` roles can, so a least-privilege account cannot retrieve CSV lookup sizes before Splunk 10.4. When the read is refused, Collection health reports *Lookup sizes refused* and the CSV lookup footprint policy cannot judge that tier. From Splunk 10.4, the listing reports the size and no extra access is needed.

Remote tiers. Each additional search head tier is a TrackMe remote account (*Configuration → Remote accounts*, see *Remote Splunk deployments*). The wizard tests each one. Live reads you make from the workspace as yourself — **Fetch SPL**, **Fetch definition** — also need your roles to be allowed on that remote account.

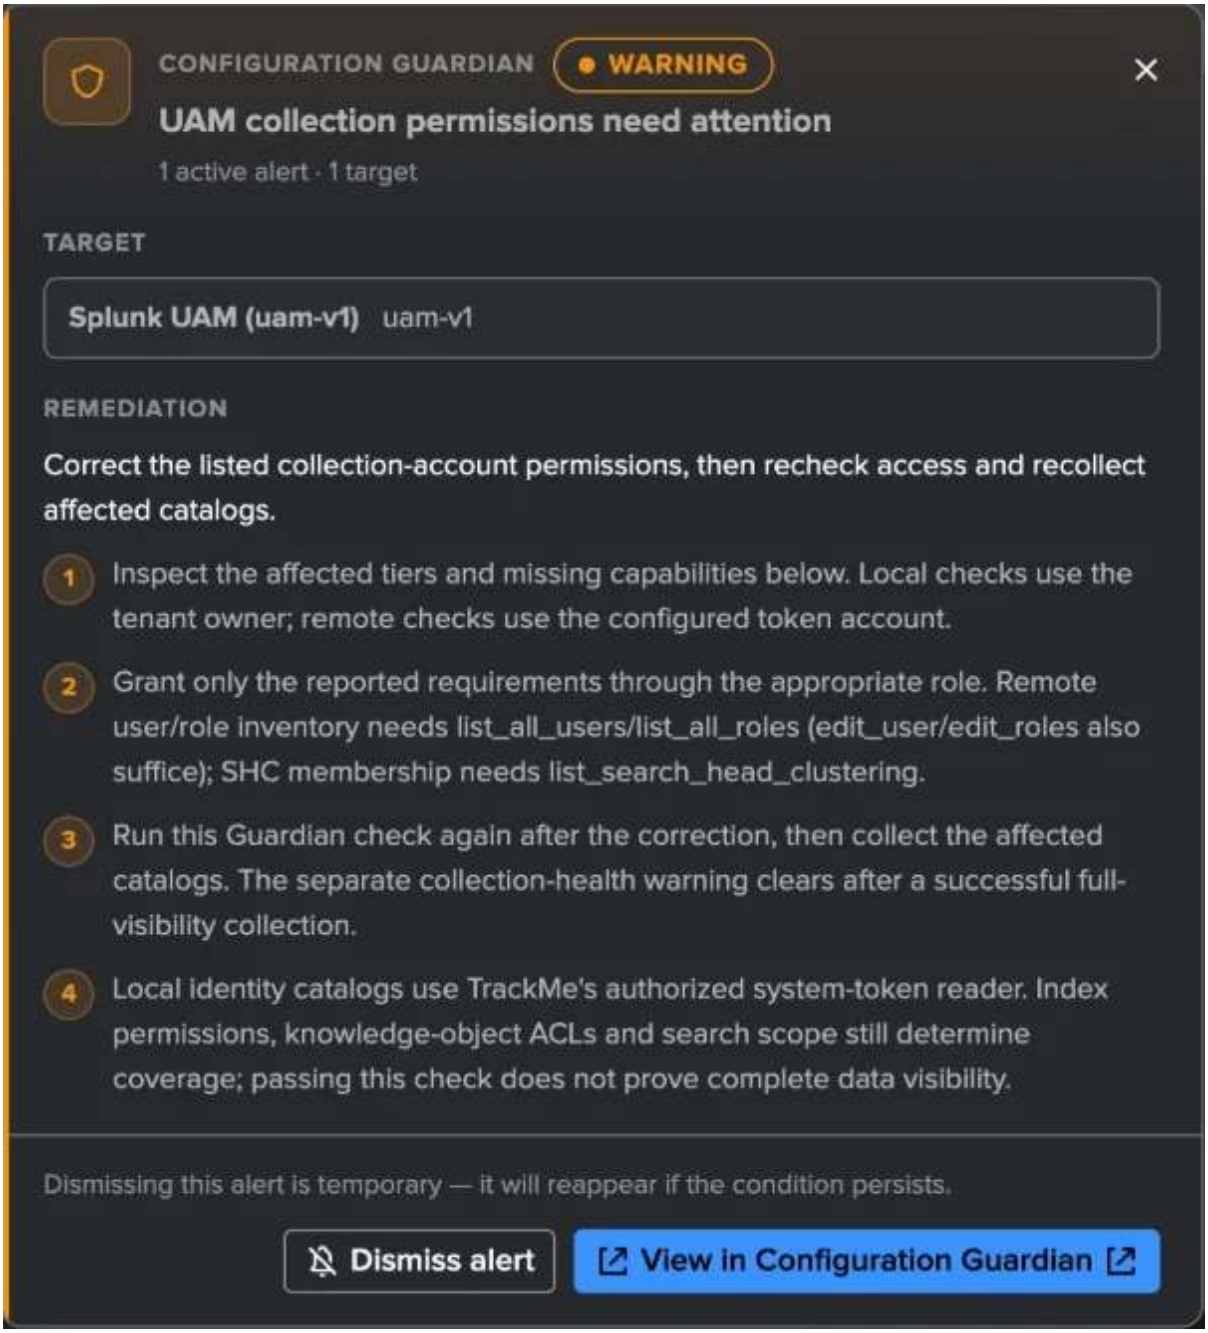
A tenant owner. Scheduled collection runs as the tenant owner. Prefer a dedicated service account (`svc-a` in the examples of this page) over `nobody`: the scheduled UAM AI Agent cannot run as `nobody` or `splunk-system-user`.

The collection accounts and their capabilities. Each search head tier is collected as one account: the **tenant owner** on the local search head, the **token account** of its remote account on a remote tier. UAM needs no `list_settings` and no `list_storage_passwords`. TrackMe checks these accounts when the tenant is created and on every health cycle. A gap raises the Configuration Guardian alert *UAM collection permissions need attention*, which names the tier and what is missing (*Configuration Guardian*).

Capability	Local tier (tenant owner)	Remote tier (token account)	What it is for
`search`	Required	Required	Run the collection searches.
`trackmeadminoperations` (or `admin_all_objects`)	Required, with one of the tenant's **admin roles**	Required	The UAM administrative boundary. On the local tier, users and roles are read through TrackMe's identity reader, which serves the tenant's administrators only. The capability is defined by the TrackMe app: on a remote deployment where TrackMe is not installed, only `admin_all_objects` satisfies it.
`list_all_users` and `list_all_roles` (`edit_user` and `edit_roles` also suffice)	Not required	Required	List every account and role of the tier. Without them, Splunk lists only the token account and its own roles, and the tier's users and roles catalogs hold one account. On the local tier, TrackMe reads them with its system token for the tenant owner.
`list_search_head_cluste`	On a search head cluster	On a search head cluster	Read the cluster members, to attribute activity to the tier.

Beyond capabilities:

- The **route account** must be allowed to search `_audit`, `_introspection` and `_internal` (the indexers' search completion records, and the searches they received, which Data usage reads).
- Before Splunk 10.4, the collection account of each tier reads `admin/file-explorer` for the lookup sizes (see above).
- Index permissions, knowledge-object permissions and the search scope of each account still decide what UAM sees. The check confirms the capabilities, not complete visibility: Collection health reports *Users or roles listed as one account sees them* (`identity_visibility_limited`) when a tier's listing still holds only the reading account.



Who can use it. UAM evidence is audit data, so the workspace is for the **TrackMe administrators of the tenant** — accounts holding the TrackMe administrator capability and one of the tenant's admin roles; Splunk administrators can do everything on every tenant. Power users of the tenant have read access through the REST API (and can send user communications and run findings actions through it); read-only users have no UAM access. The workspace's own searches (the Data usage views, the Privileged users activity, Fetch SPL) run as you, so your roles also need the tenant's TrackMe indexes, and the search text index when it is a restricted one.

Email delivery (optional). Notifications and communications are sent through a TrackMe email delivery account (*Configuration → Emails*), or the local mail transfer agent when none is selected. The account's allowed-domain rules apply.

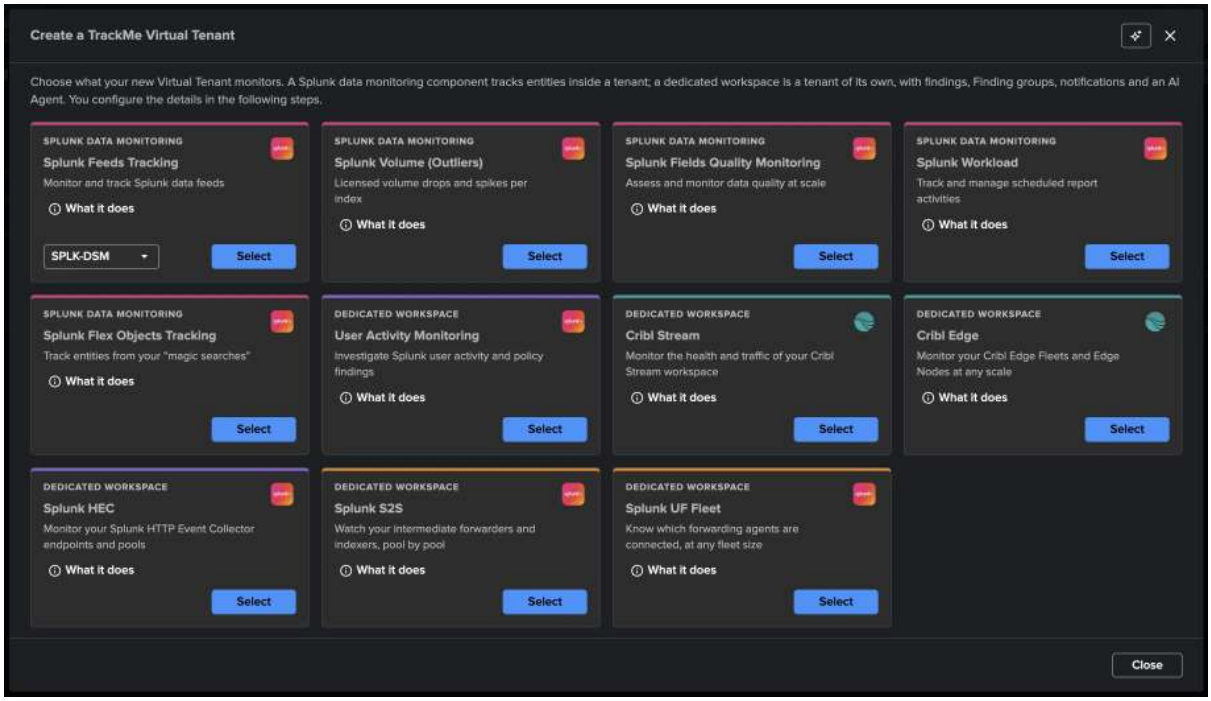
Note

UAM indexes its evidence in the tenant's summary index and its finding events in the tenant's notable index, as `trackme:uam:*` events. This evidence counts against your Splunk licence like any TrackMe summary data; it is compact by design (one record per search and window). Some indexed fields of these events take effect after

the splunkd restart that follows the app installation or upgrade; until then, reads fall back to slower searches.

Create the tenant

From the *Virtual Tenants* page, open **Actions → Create a tracking tenant** and choose the **User Activity Monitoring** card (*Investigate Splunk user activity and policy findings*). The wizard has four steps.



Step 1 — Basics

The **tenant identifier** (lowercase letters, digits and hyphens, up to 20 characters; it cannot change later), an optional **alias** shown on the tenant card and an optional description.

Step 2 — Configure UAM

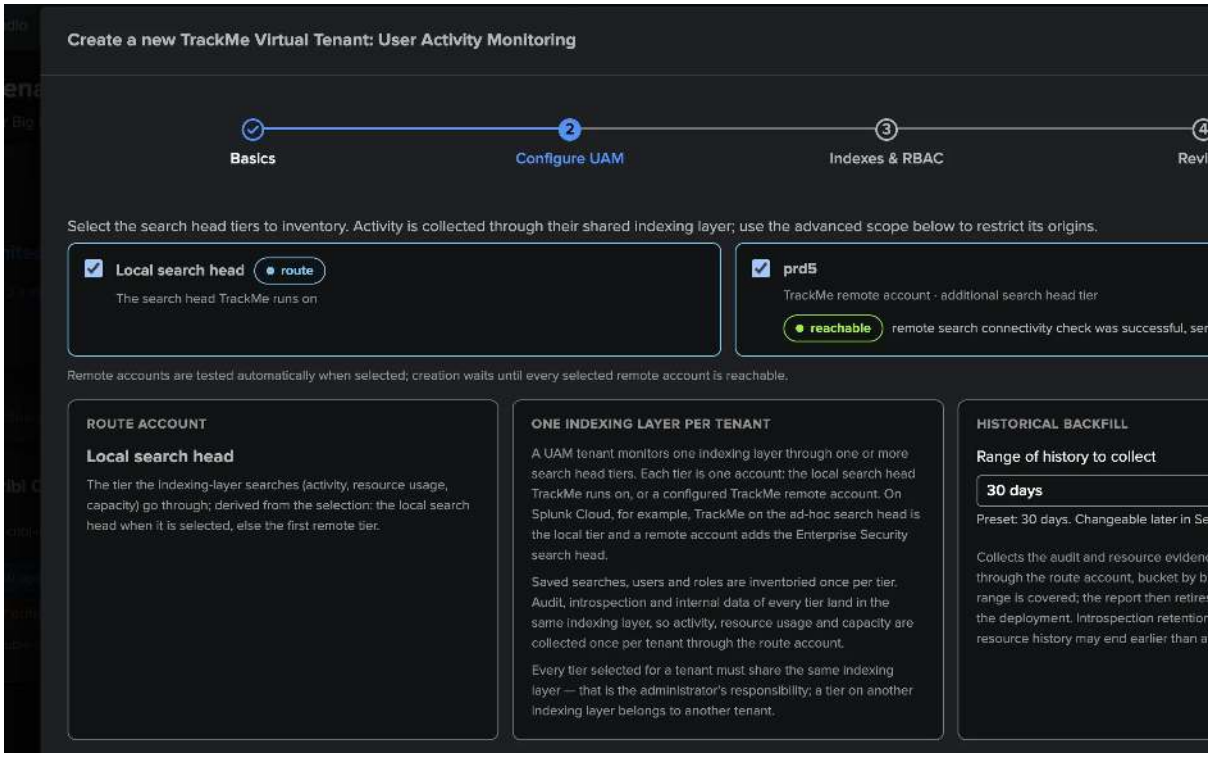
Search head tiers. *Local search head* is selected by default; each TrackMe remote account can be added as another tier, up to ten. Select every search head tier that shares the indexing layer you want to monitor — for example an ad hoc search head cluster and an Enterprise Security cluster on the same indexers. Remote accounts are tested as soon as you select them, and creation waits until every selected one is reachable (**Retry connection test** if one fails).

Route account. Derived from your selection: the local search head when it is selected, otherwise the first remote tier. The indexing-layer searches — audit activity, resource usage, capacity, logins and automation — go through it, once for the whole layer, while the knowledge objects are read on every tier.

One indexing layer per tenant. All the tiers of a tenant must search the same indexers. Monitoring two independent deployments takes two tenants.

Historical backfill. How far back UAM collects the audit and resource evidence that existed before the tenant: **No backfill** (the default), 7, 14, 30, 60 or 90 days. The backfill runs hourly in 5-minute buckets, newest history first, and retires itself once the range is covered or the retention of the sources is reached. It makes the account classification and the activity history useful from the first day, at the cost of reading that history from the indexers: on a busy deployment, start without it, or with a short range, and extend it later in *Settings → Collection limits*.

Activity scope (advanced). Optional hostname patterns (`*` and `?`, up to 20 include and 20 exclude patterns) that restrict which search heads' activity is collected, for example to leave out a test search head that shares the indexers. Exclusions win. The scope is part of the base searches, so the indexers only return the events of the search heads in scope: on a large indexing layer shared by several search head clusters, it is also the first way to make collection lighter.



Step 3 — Indexes & RBAC

The TrackMe indexes of the tenant (summary, audit, metric and notable), the **tenant owner** and the admin, power and user roles. The summary index receives the evidence and the notable index the finding events; each family can be pointed at another index later in *Settings → Indexes*.

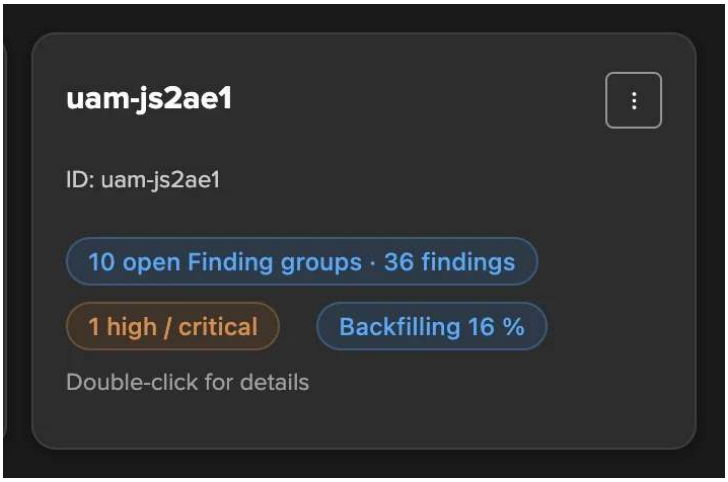
Step 4 — Review

Check the summary — the tiers with the route, the owner, the activity scope, the backfill — and create. Everything is provisioned and scheduled at once: the inventory, audit activity and resource usage reports start within minutes, the account signals and the policies follow, and each tier's first full saved-search listing runs within the hour. If the creation result is incomplete, the wizard says so and the workspace offers **Repair UAM workspace**.

The step-by-step creation is also described in *Creating a splk-uam tenant*.

After creation

The tenant appears on the *Virtual Tenants* page with its open Finding groups and findings, the high or critical ones, and its collection status — here the historical backfill in progress. Selecting it opens the workspace; double-clicking it opens a read-only overview.



Your first hour with a new tenant:

1. Open **Collection health**: the **Status** view says whether anything needs attention, and **Trackers** shows the first inventory, audit activity, resource usage, account signals and policies runs of every tier.
2. **Classify the monitoring accounts** as system — the tenant owner, your administrator accounts — so that they never appear in findings (see *Accounts and classification*).
3. Review the **Policies** tab: the enabled policies, their severities and exclusions.
4. Come back to **Findings** after the next policies run (every 15 minutes).

The workspace

The workspace opens on the **Findings** tab. At the top, the **status strip** tells you that the tenant is working: the search head tiers (the route account marked · *route*), the age of the last **Inventory**, **Audit activity**, **Resource usage**, **Account signals**, **Data usage** and **Policies** runs, the activity checkpoint lag and coverage, the backfill progress, a **Configuration changed since last run** warning after a settings change, **Refresh**, and **Collect now** — which runs every tier's inventory, then the audit activity, the data usage, the resource usage and the account signals, then the policies, with the current configuration, and every tier's full saved-search listing alongside.

Eleven tabs follow: **Findings**, **Users**, **Privileged users**, **Data usage**, **Activity**, **Scheduled searches**, **Policies**, **Audit changes**, **Collection health**, **AI Agent** and **Settings**.

A few conventions apply everywhere, shared with the Cribl workspaces (*The shared workspace conventions*):

- Column headers filter and sort the loaded page; the toolbar filters search everything.
- Every panel has a ⍰ menu with *Open in Search* (the search behind the figure, ready to edit) and *Refresh*.
- Three personal display preferences per tenant live in the Tenant Home settings panel, under *Personal preferences for this tenant*: **Collection monitors** (the status strip), **Single stats** and **Charts**. They change your view only.
- **Exclude TrackMe activity** (Users, Activity and the account view) leaves out the searches run in the `trackme` app — TrackMe's own scheduled trackers (recognised by their search id) and your own use of TrackMe. An ad-hoc search that reports another app or none, such as the tracker searches TrackMe dispatches over REST, cannot be attributed and stays in. Findings are not affected. It is remembered per viewer.
- Notification emails link straight to a finding or a Finding group, opened in its investigation.

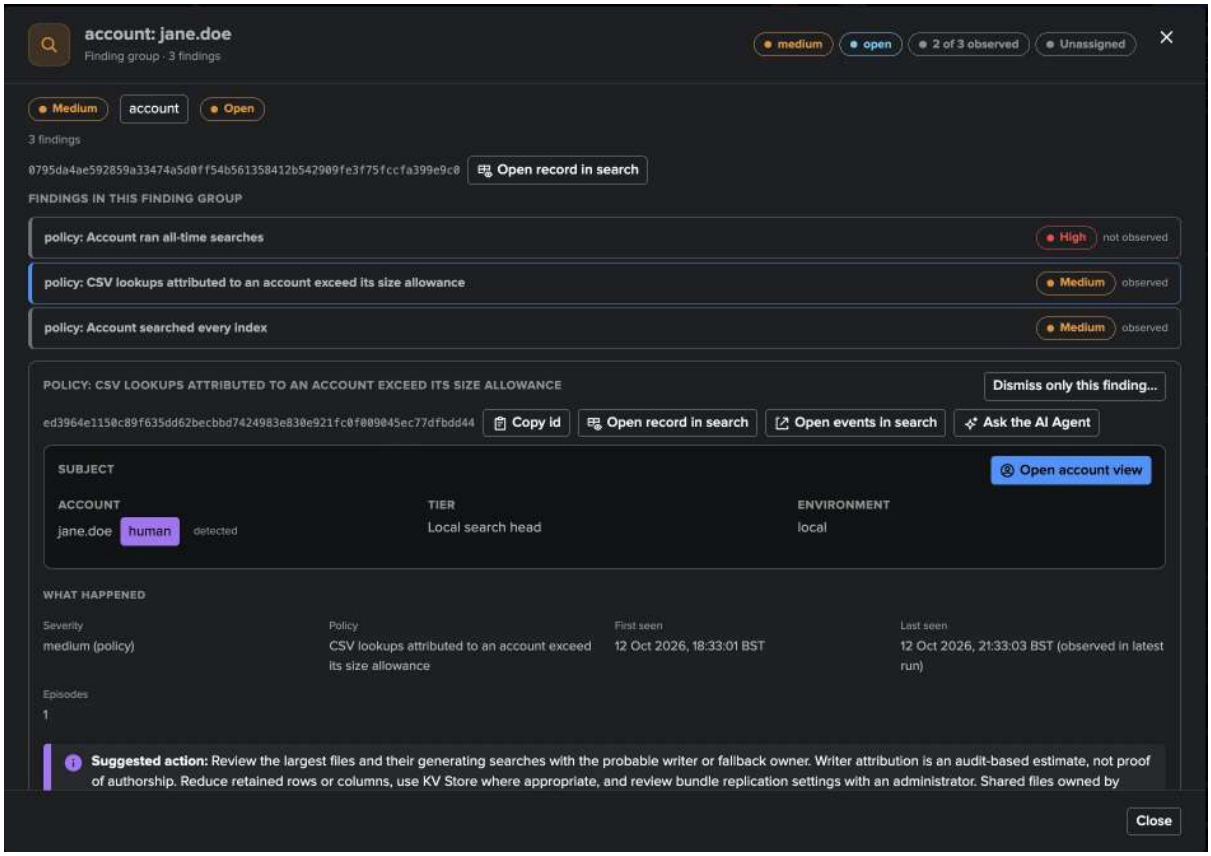
Findings

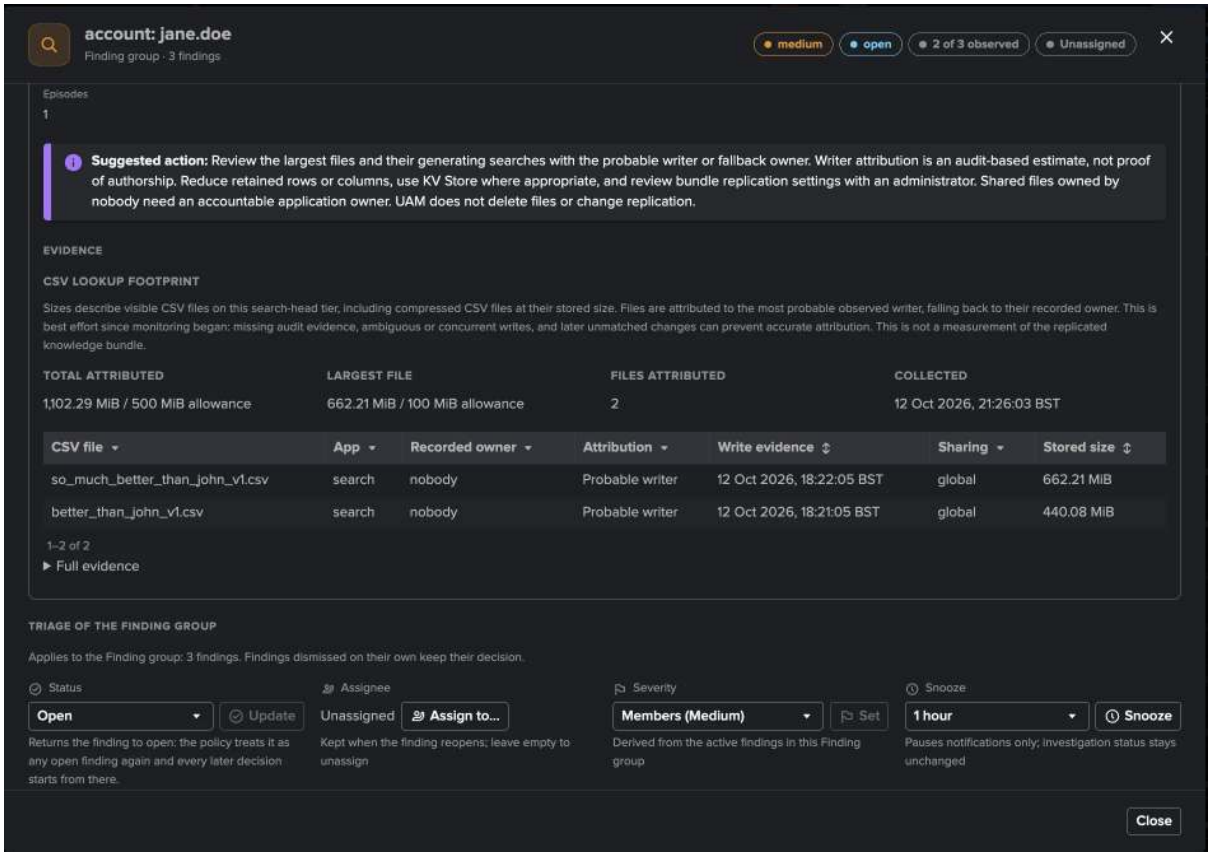
Your investigation backlog. Tiles count **Open groups**, **High / critical groups**, **Groups assigned to me**, **Resolved groups** and **Dismissed groups** — Finding groups — plus **New findings in range** (findings first seen in the time range), and drive the filters; charts show the finding transitions over the time range (24 hours by default) and the open

findings by severity and by policy. Filters cover the status, severity, policy, subject (accounts, saved searches or roles), first seen, assignment (including assignment groups) and free text (owner, app, search name).

The table lists **one row per Finding group**: an account and the saved searches it owns. A group of several findings has an expander showing each member with its own policy, severity and whether the latest policies run still **observed** it. Selecting rows offers **Merge into one Finding group**, **Add to the Finding group** (a manual group), **Run action**, **Assign to…** and **Bulk edit**; **AI Agent review** asks the AI Agent to review the open and investigating findings.

Selecting a row opens the **Investigate** view: the subject, the findings of the Finding group, *What happened* in plain words, the suggested remediation, the evidence of the selected finding, **Triage** of the Finding group (status, dismissal, assignee, notification snooze, severity, investigation note), the notes and both histories — the finding's and the group's. From there, open the account view or the saved search view, or the record and its events in Search.

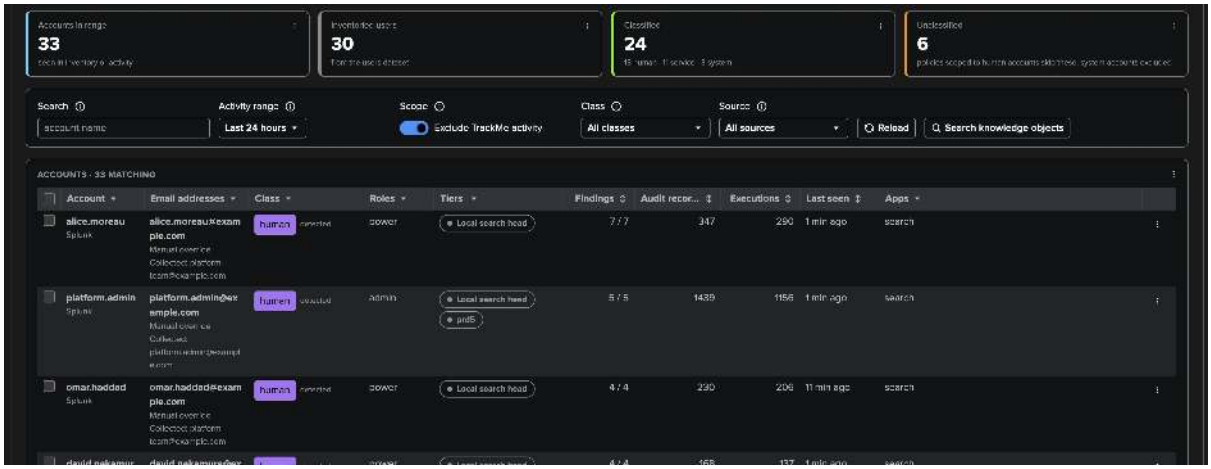




Each finding explains its own evidence. A CSV lookup footprint finding, for instance, lists the files attributed to the account, their size and how each was attributed: to its **probable writer** — the account whose searches wrote the file — or, when no writer could be identified, to its **recorded owner**.

Users and the account view

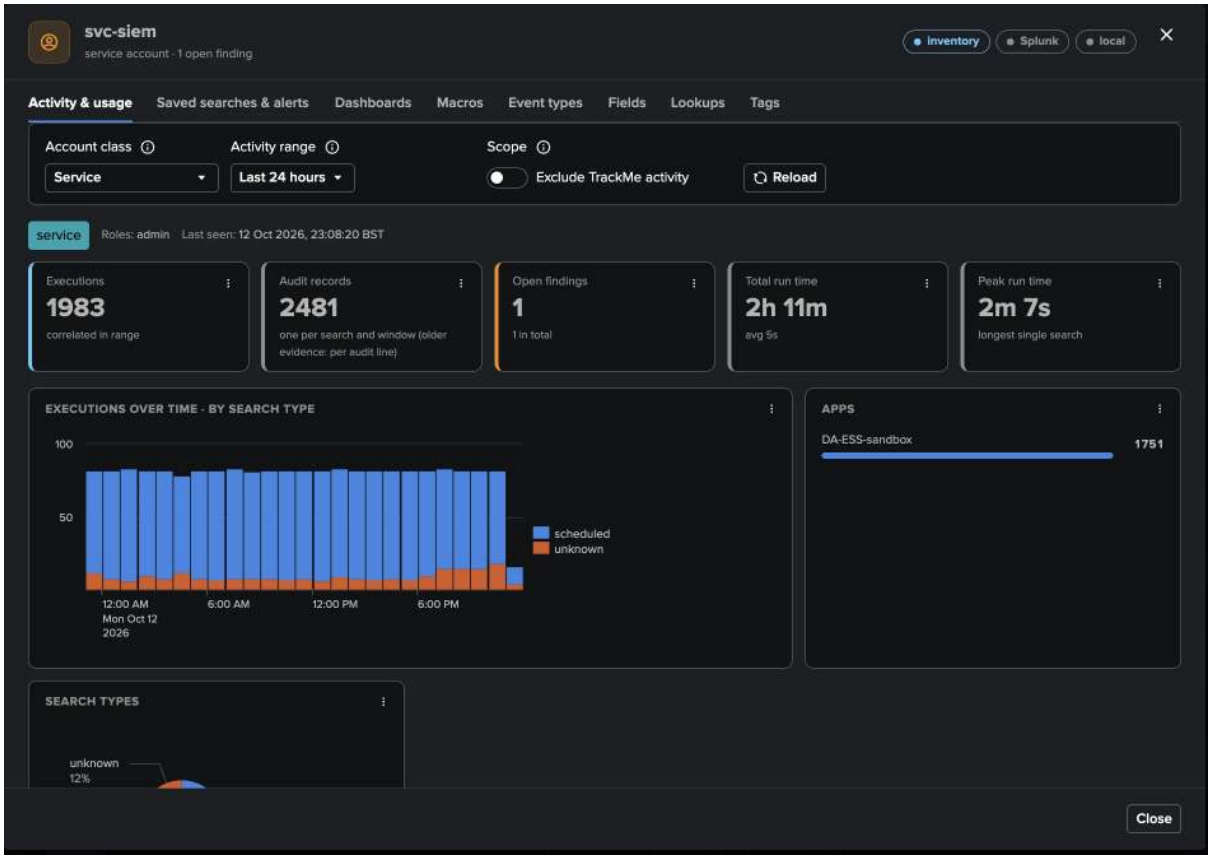
Every account across the tiers: tiles for the accounts in range, inventoried, classified and unclassified; filters by class, source and activity range; columns for email addresses, class (with a *detected* marker when a detection set it), roles, tiers, findings, audit records, executions, last seen and apps. The row menu sets the class or overrides the email address used for user notifications (**Override email address…**); a selection can be classified at once, or decided on as a whole (resolve, dismiss or mark investigating its open findings).

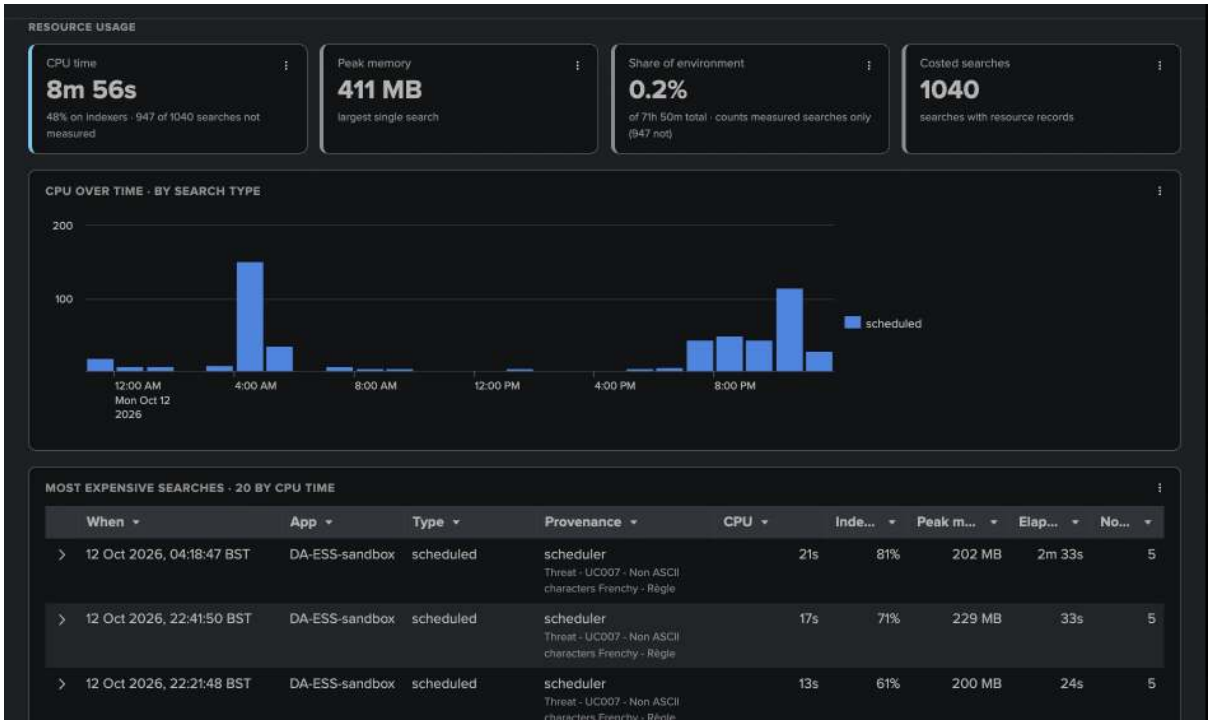


Selecting an account opens the **account view**:

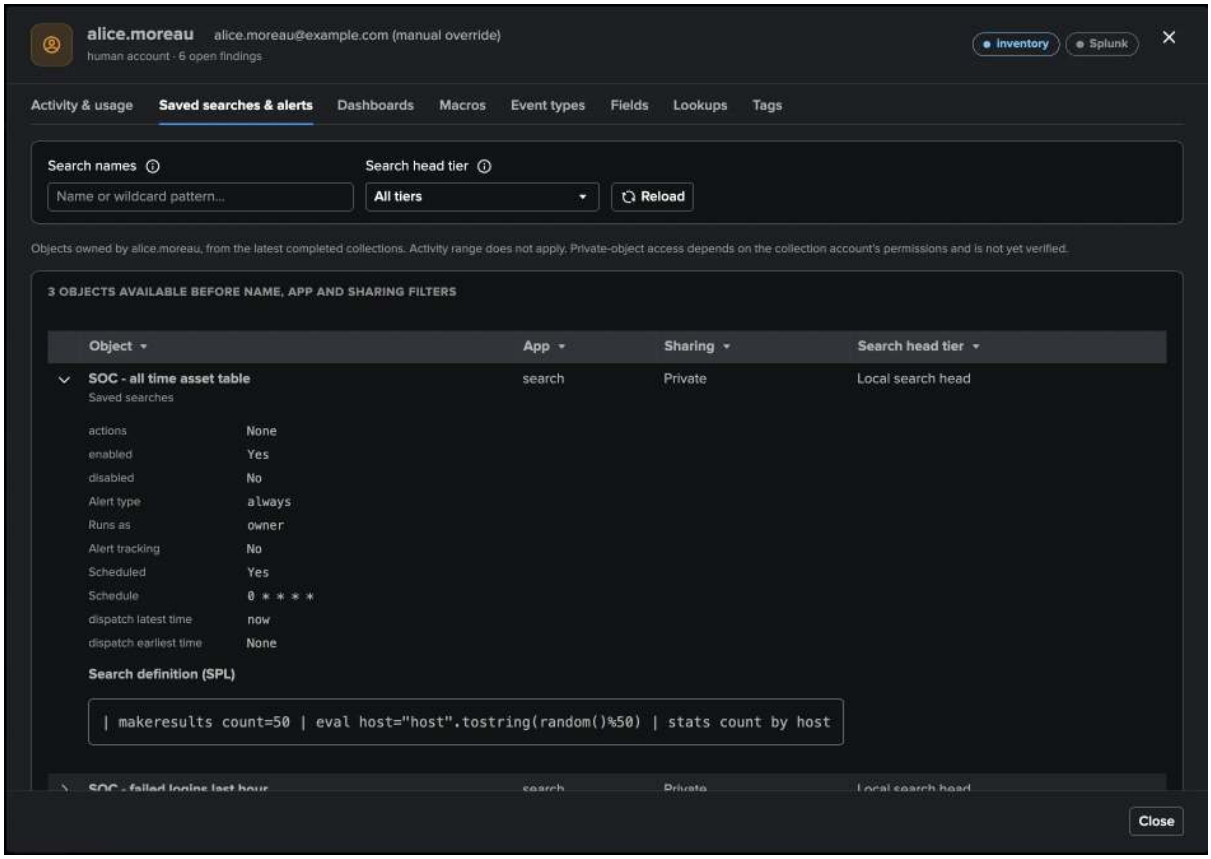
- **Activity & usage** — executions and run time over time by search type, CPU over time, the daily CPU baseline, the resource usage (CPU time, peak memory, share of the environment), the most expensive and the most recent searches with **Fetch SPL**, the account's findings and the scheduled searches it owns.

- **Data accesses** — which indexes the account read, over time: a chart of its named reads per index and one lane per index with a marker for each observation (see *Data usage*).
- The account's **catalogs**, one tab per family: *Saved searches & alerts*, *Dashboards*, *Macros*, *Event types*, *Data models*, *Indexes*, *Fields*, *Lookups* and *Tags* — what this account owns on each tier.



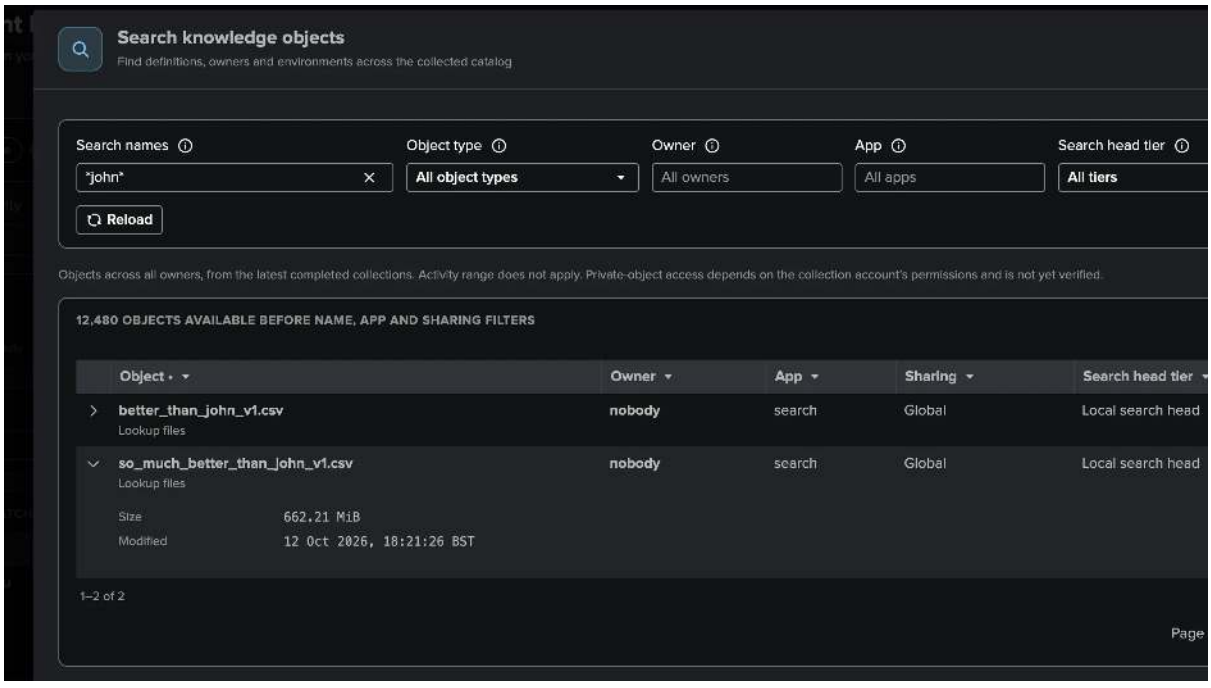


The resource usage tells what an account costs: here a service account whose scheduled detection searches use 0.2% of the environment's search CPU over the day, with the most expensive runs listed first. Searches the resource records could not measure are counted and shown as such, never estimated.



Fetch SPL shows the text of a search. By default UAM does not store search text: it reads it live from `_audit`, as you, and stores nothing. If you switch on *Store SPL search* (*Settings → Collection*, off by default), the text is indexed in its own record in the search-text index — point that index at a restricted index first, since search text can contain literals and secrets. When a text cannot be shown, the reason is given.

Search knowledge objects (on the Users tab) searches the collected catalogs across every owner: a name or a wildcard pattern, filtered by object type, tier, app, owner and sharing. Use it to answer "who owns the macro `app_a_base`?" or "which dashboards use this name on which tier?".



Note

The catalogs reflect what the collection account can see on each tier: the coverage of private objects depends on its permissions. They are collected on a cadence (daily in the off-peak window by default for most families, every 15 minutes for CSV lookup files, hourly for users and roles), not as atomic snapshots. A listing too long for one run continues at the next one, and the previous catalog stays in use until the new one is complete.

Privileged users

Which accounts hold high privileges on the monitored search head tiers, and why. An account is **privileged** when one of its roles — or a role that role imports, however indirectly — is a **privileged role** or grants a **privileged capability**:

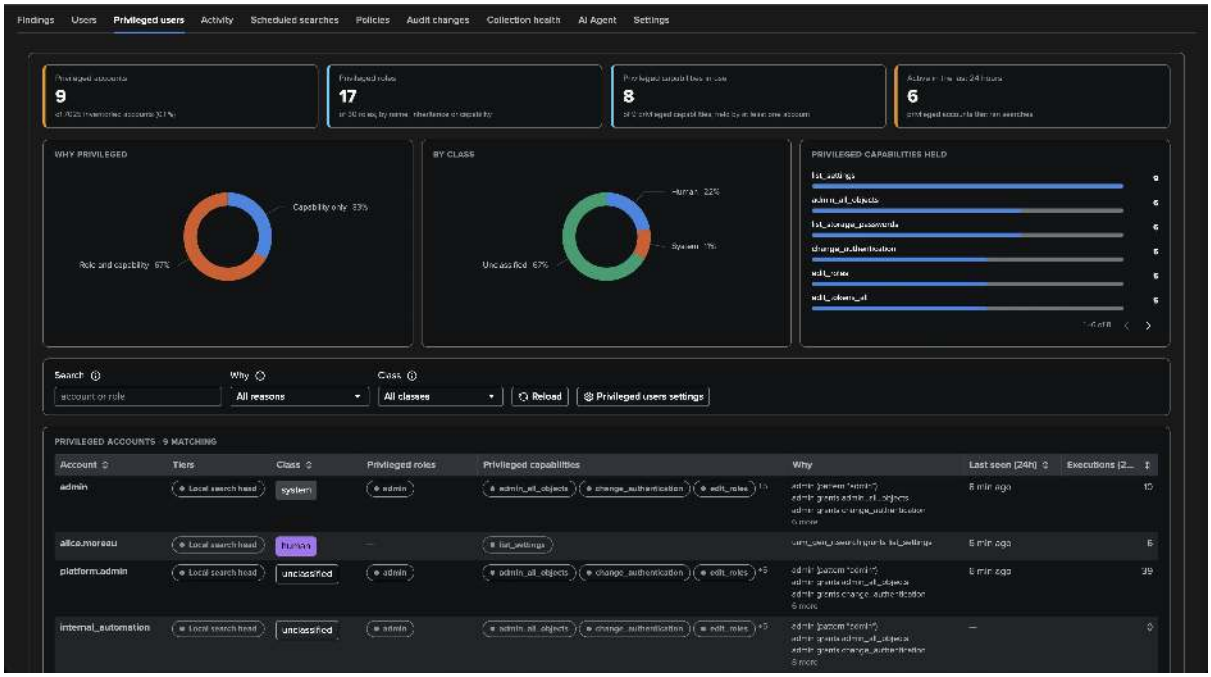
- **Privileged roles**: every role whose name matches a pattern (`*admin*` by default, case-insensitive, `*` and `?`), plus the roles you add by name, minus the roles you exclude. The patterns are live: a role created later is privileged as soon as its name matches. `trackme_admin` is excluded by default: TrackMe's own administrator role holds TrackMe capabilities, not Splunk-level ones.
- **Privileged capabilities**: `admin_all_objects`, `change_authentication`, `delete_by_keyword`, `edit_roles`, `edit_tokens_all`, `edit_user`, `list_settings`, `list_storage_passwords` and `rest_apps_management` by default, granted directly or through an imported role.
- An exclusion only removes a role's **name** rule: an excluded role that grants a privileged capability still makes its users privileged, through the capability.

The tab shows the privileged accounts and their share of all accounts, the privileged roles, the privileged capabilities in use and the privileged accounts active in the last 24 hours; charts of why accounts are privileged (role, capability or both), of their classes and of the accounts holding each privileged capability; the **privileged accounts** with their reasons in words (`team_lead imports admin (pattern *admin*)`, `secops grants list_storage_passwords`), last seen and executions; and the **roles** of every tier, the privileged ones by default. An account present on several tiers is one account, each reason naming the tier that grants it.

Everything is read from the users and roles catalogs UAM already collects: the view follows their cadence (hourly by default) and makes no call to Splunk. The rules are set in *Settings → Privileged users*: the patterns, and two dual lists — the roles and the capabilities the tiers hold — where moving a role a pattern matches out of the privileged list excludes it, and moving any other role in adds it by name.

Splunk grants roles and capabilities through direct membership and through inheritance, and a role inherits from roles that inherit further: every reason keeps its chain — *team_lead imports admin*, *team_lead inherits admin through ops*, *leaf inherits list_settings from base through mid*. The full rules are in *Privileged users*.

Four **privileged** policies build on this assessment, all off by default: an account that became privileged, a role that gained a privileged capability, a dormant privileged account, and privileged accounts that differ from a reference you maintain. See *Privileged policies*.



Data usage

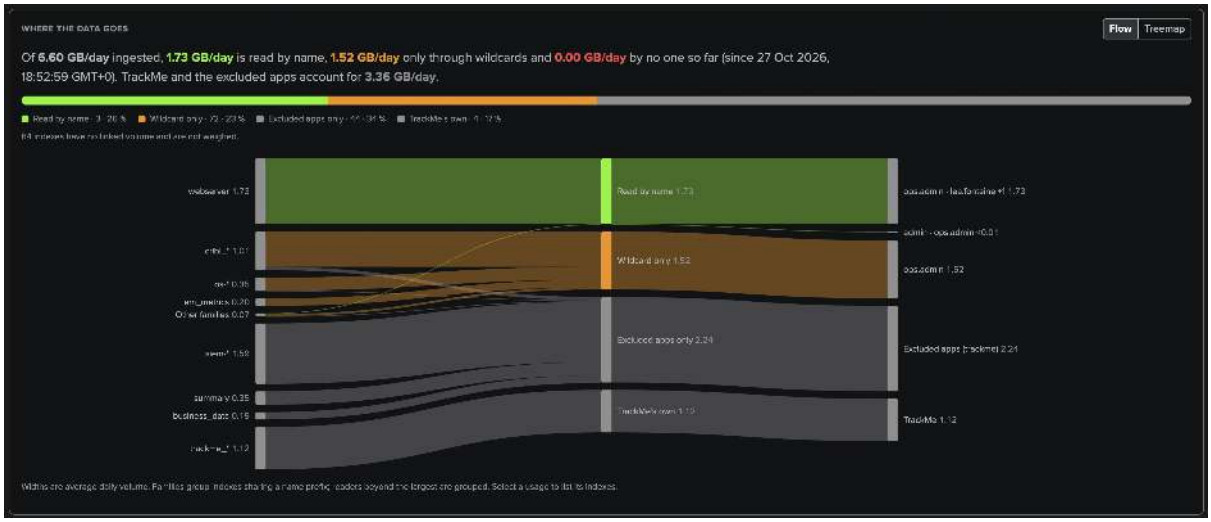
Which indexes are read, by whom, and which receive data no one reads? UAM already reads every search from the audit trail. The **Data usage** tab turns those searches into a map of your data: for every index, the searches that named it, the accounts and apps behind them, the path they took (a literal `index=` term, a macro, an event type, a saved search, a data model or a wildcard), the knowledge objects that declare it, and — when the tenant is linked to a VOL or DSM tenant — what the index ingests per day and what it costs.

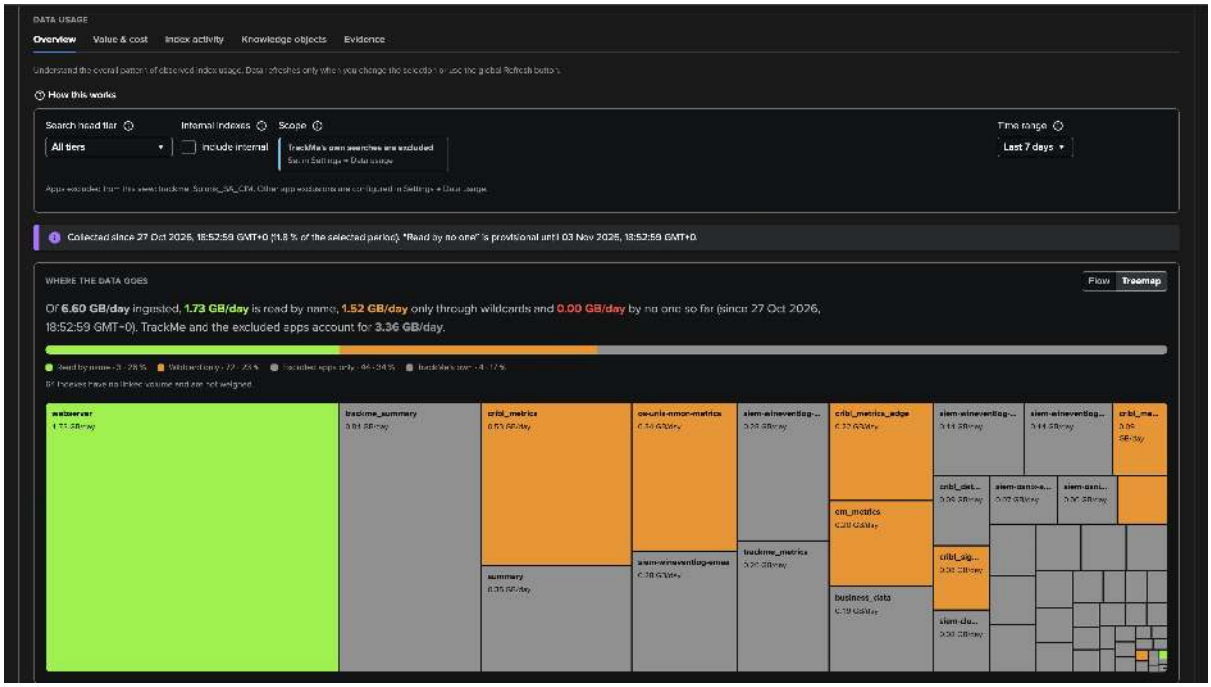
It rests on one rule: **an absence of reads is a claim, made only when the evidence supports it.** An index is never called unread from a few hours of collection, an incomplete read or a wildcard that may reach it. Every view says what it covers, in one **coverage card** under its controls: when the collection started and what that means for the view ("Collected since 27 Oct 2026 (11.8 % of the selected period). "Read by no one" is provisional until 3 Nov 2026."), a fault with its cause, or *Coverage complete*.

Five views share the same controls: the **search head tier**, **internal indexes** (left out by default), the **scope** (TrackMe's own searches and the excluded apps, set in *Settings → Data usage*) and the **time range** (the last 7 days by default).

Every tile, chart and table of the Overview, Value & cost, Knowledge objects and Evidence views has a three-dots menu with **Open in Search**. It opens the search over the recorded facts behind that view, with a note on what only the map adds when you read the view: the catalog expansion of wildcards, the role scopes and the VOL volumes. How each kind of claim is recorded is described in *Data usage reference: how each claim is processed*.

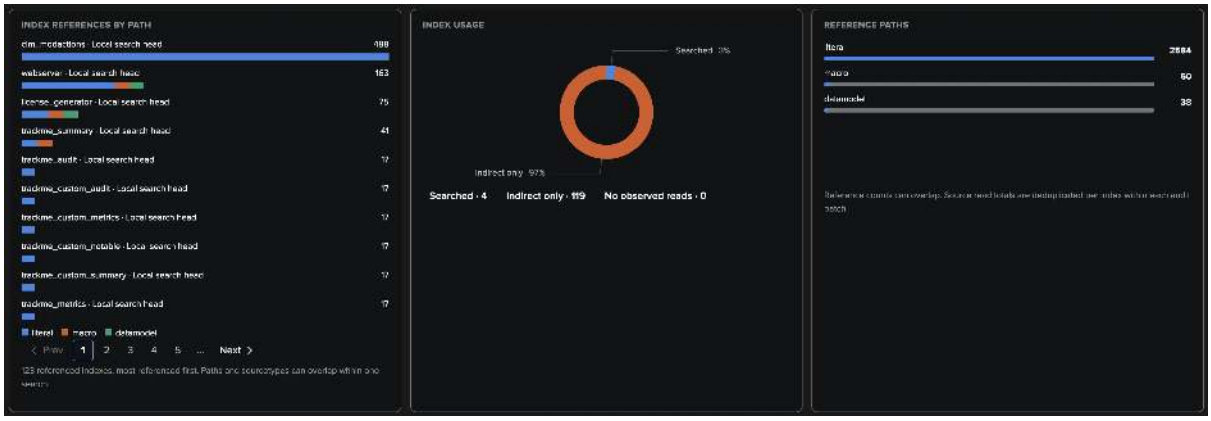
Overview — where the data goes. One sentence answers the question: *Of 6.60 GB/day ingested, 1.73 GB/day is read by name, 1.52 GB/day only through wildcards and 0.00 GB/day by no one so far.* A bar splits the volume by usage, and the hero shows it either as a **flow** — from data families (indexes sharing a name prefix) to their usage, then to the accounts that read them — or as a **treemap** of ingestion, one tile per index sized by its daily volume and coloured by its usage.



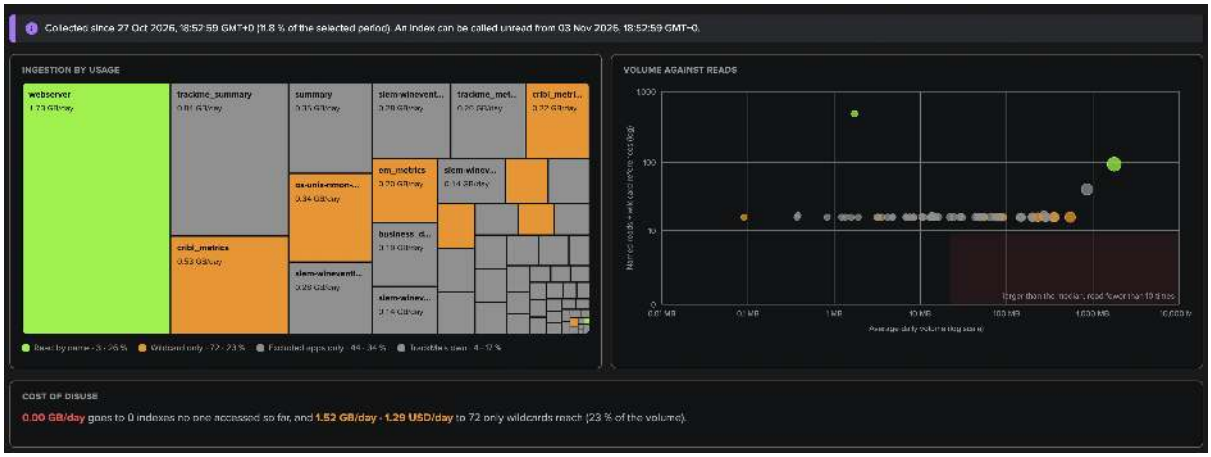


The usage classes are decided across the whole indexing layer, never per tier: **Read by name** (a search named the index), **Wildcard only** (only wildcards such as `index=cribl_*` reach it: they do not prove which index supplied the events), **No reader**, **Excluded apps only** (only the apps you exclude read it, for example `trackme`) and **TrackMe's own** (the indexes TrackMe writes to, never a review candidate). An index without a linked volume is counted but not weighed.

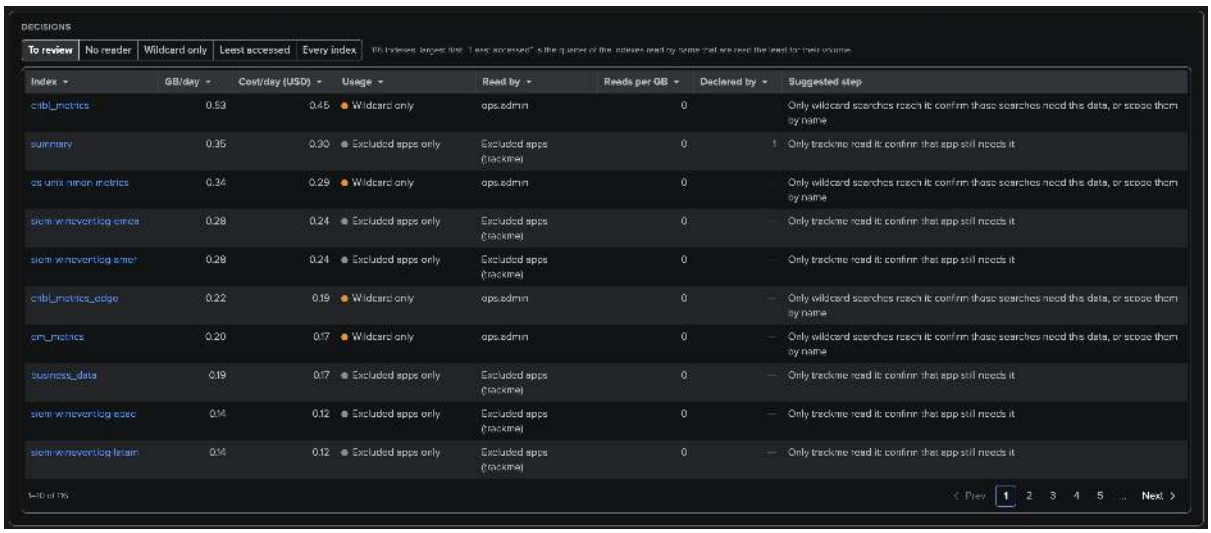
Under the hero, three panels list the **index references by path**, the **index usage** verdicts and the **reference paths** (literal, macro, event type, saved search, data model).



Value & cost — weigh what an index costs against how it is read. The treemap of ingestion by usage sits beside **Volume against reads** (log scales, one dot per index: the shaded corner holds the indexes larger than the median and read fewer than ten times), and **Cost of disuse** states what the indexes no one accessed, and those only wildcards reach, cost per day.

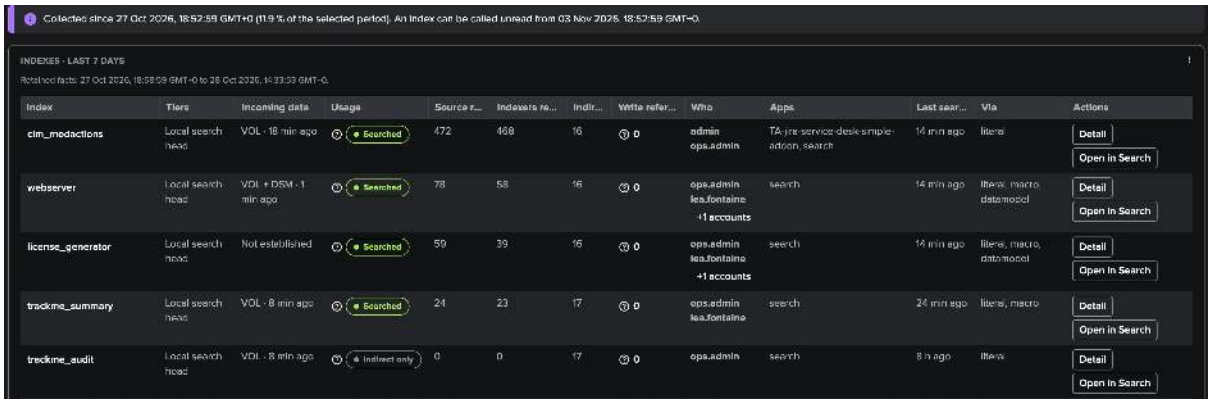


The **Decisions** list turns it into work: one row per index, largest first, with its daily volume and cost, its usage, who read it, its reads per GB, the knowledge objects that declare it and a **suggested step** ("Only wildcard searches reach it: confirm those searches need this data, or scope them by name"). Five views filter it: **To review** (no reader, wildcard only, excluded apps only and the least accessed), **No reader**, **Wildcard only**, **Least accessed** (the quarter of the indexes read by name that are read the least for their volume; the ranking needs at least four such indexes with a daily volume) and **Every index**. An empty list says why — for example, while the collection is younger than the period, nothing is called unread. The list pages 10, 25, 50 or 100 rows.

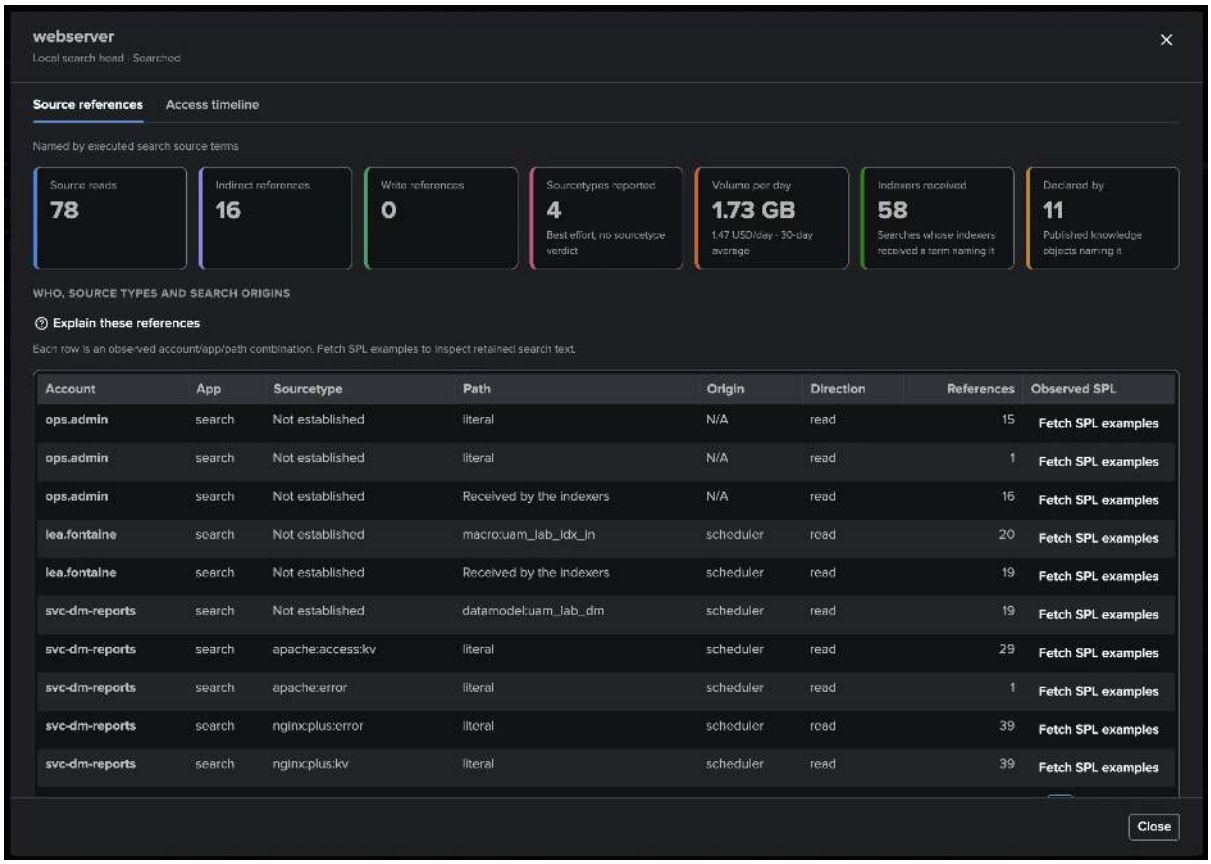


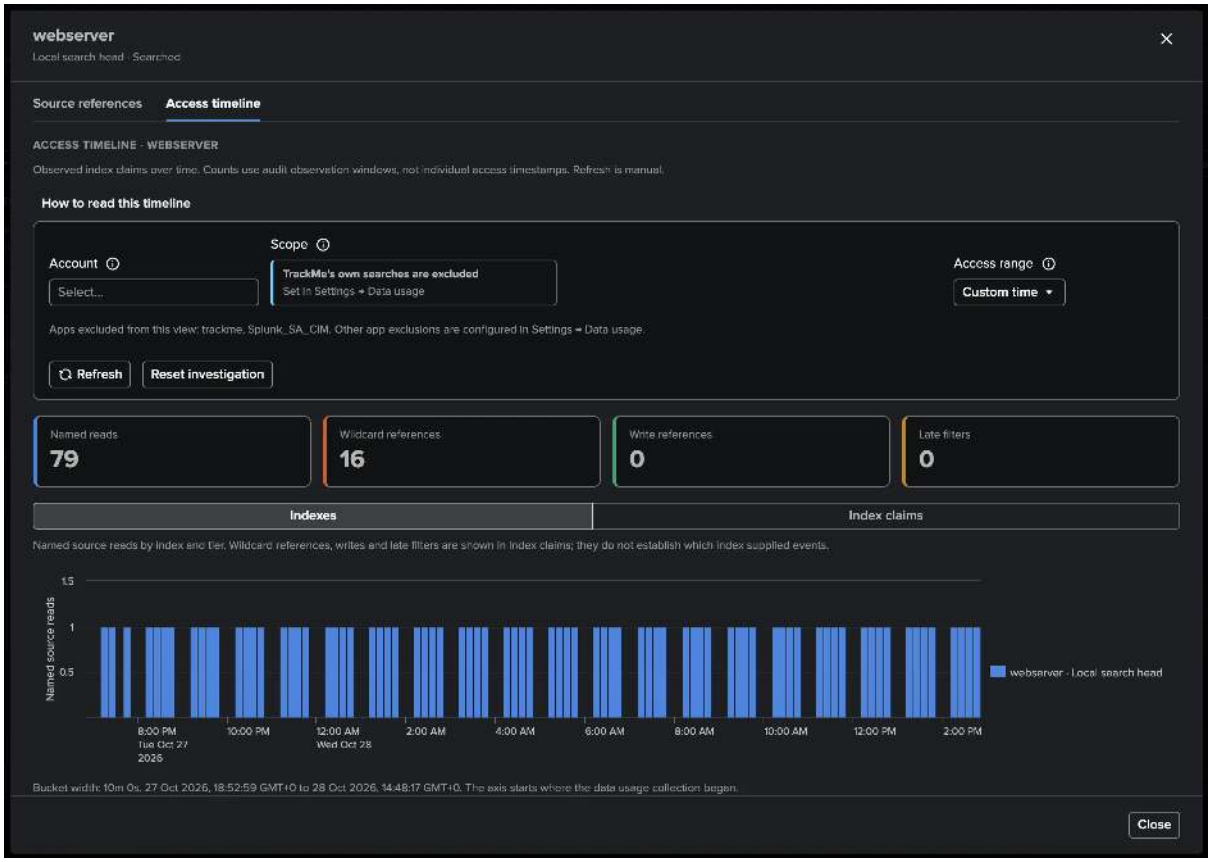
Index activity — investigate an index. One row per index and tier: the incoming data (from the linked VOL or

DSM tenant), the usage verdict, the source reads, the reads the **indexers received** (on distributed deployments, the indexers' own record of the searches they ran, shown beside the search head's figures, never added to them), the wildcard references, the write references (`collect` destinations, and the target index of a saved search's summary indexing or Log event alert action), who read it, from which apps, when, and through which paths. Filters cover the usage, the path (its **wildcard** choice selects the wildcard references), the account class, the index name, the account and the app.



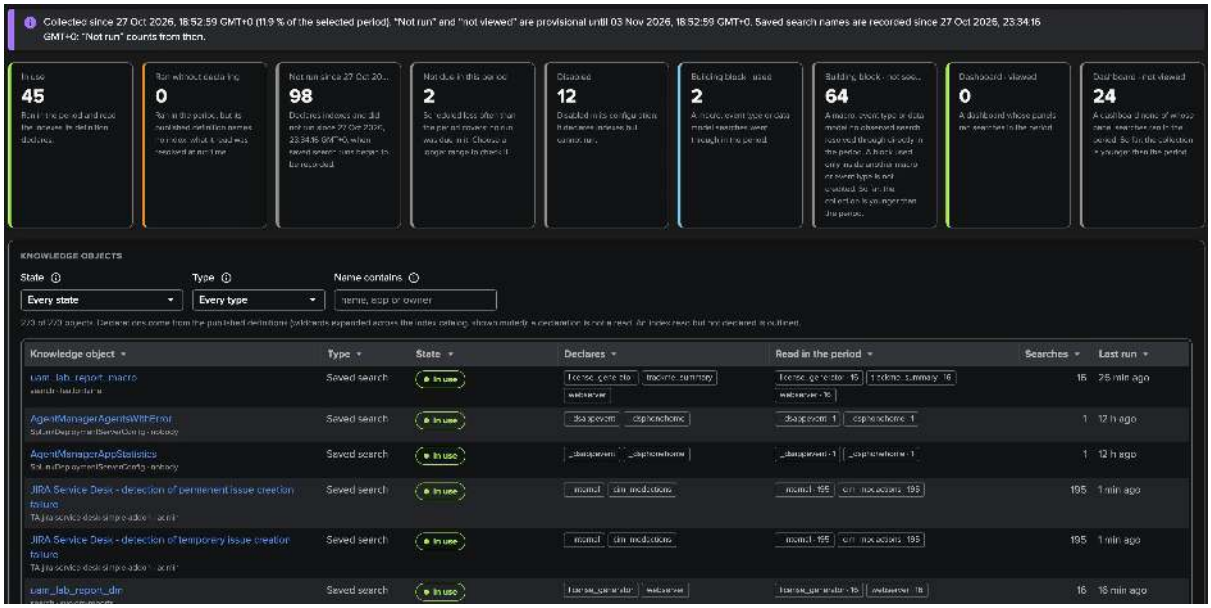
Detail opens the index. **Source references** gives the tiles — source reads, indirect and write references, the source-types reported (best effort: a sourcetype never gets a verdict of its own), the volume per day and its cost, the reads the indexers received and the knowledge objects that declare it — and one row per account, app, sourcetype and path, with **Fetch SPL examples** to read the retained searches. **Access timeline** charts the named reads of the index over the period, clock-aligned, from the start of the collection.



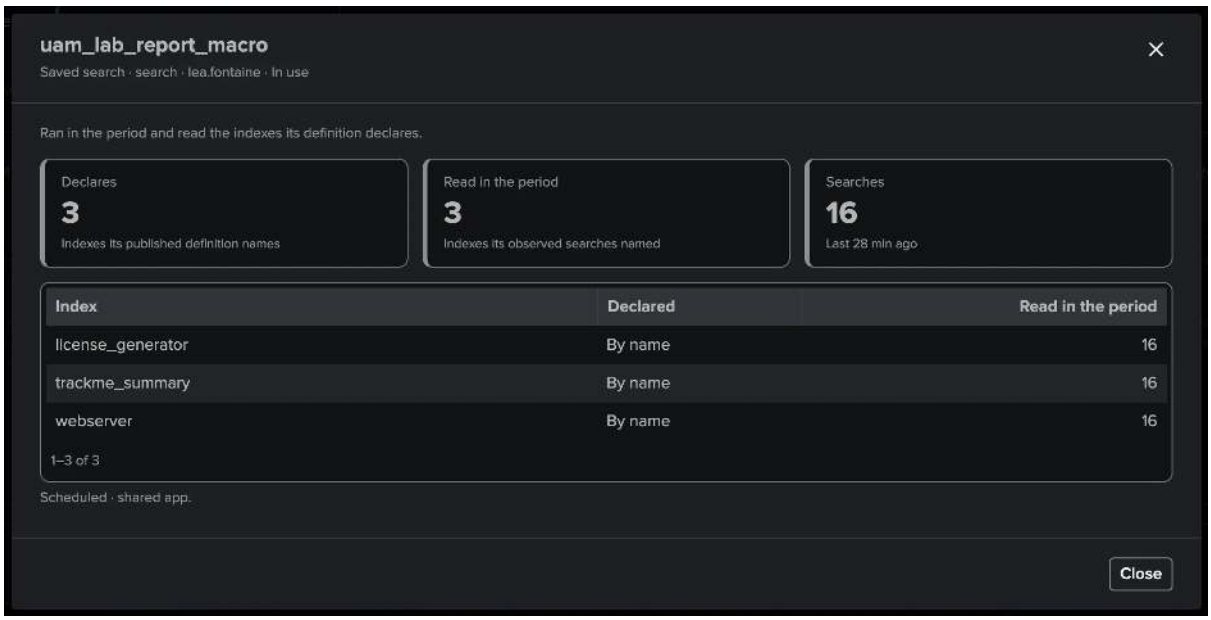


Knowledge objects — declared against observed. Each published saved search, macro, event type, dashboard and data model, with the indexes its definition **declares** (wildcards expanded across the index catalog, shown muted) against the indexes its searches **read** in the period (an index read but not declared is outlined). Tiles count the states and filter the list:

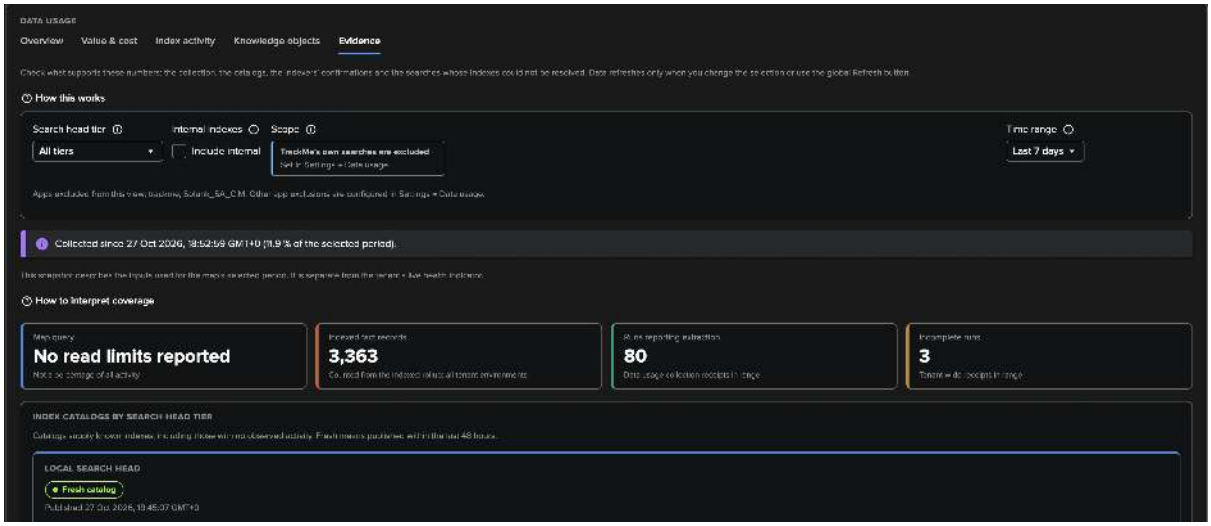
- **In use** — ran in the period and read the indexes its definition declares.
- **Ran without declaring** — ran, but its definition names no index: what it read was resolved at run time.
- **Not run** — declares indexes and did not run in the period, dated from when saved search runs began to be recorded.
- **Not due in this period** — a scheduled search whose schedule leaves a longer gap than the period covers: it was not due, so it is not called *Not run*.
- **Disabled** — disabled in its configuration.
- **Building block · used / not seen** — a macro, event type or data model that searches went through, or that no observed search resolved directly.
- **Dashboard · viewed / not viewed** — a dashboard whose panels ran searches in the period, or not.



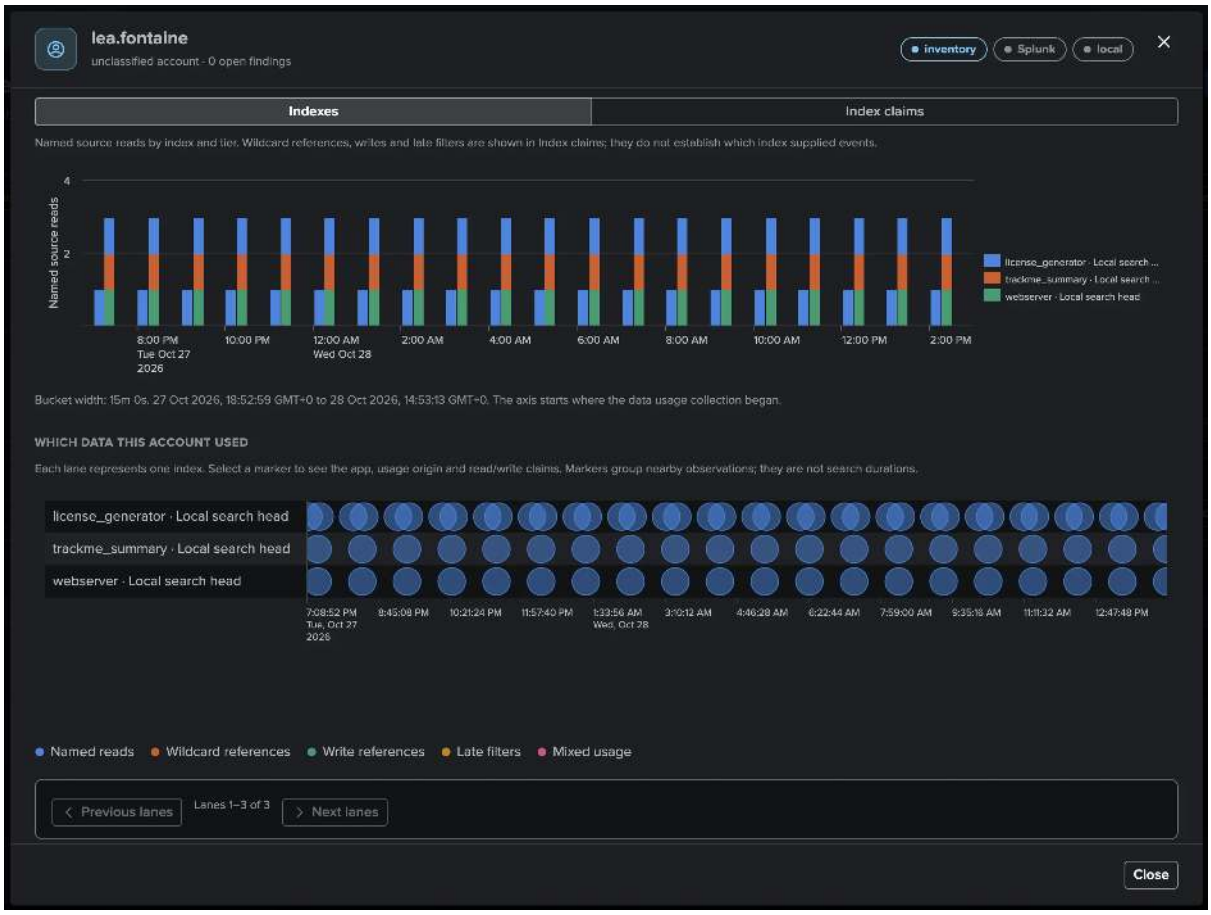
An object opens its detail: what it declares, what it read, how many searches ran and when.



Evidence — what supports these numbers. The collection behind the figures: the fact records read, the collection runs and their outcome, the index catalog of each tier, the indexers' confirmations, and the searches whose indexes could not be resolved, with the reason for each (a macro or saved search that cannot be found, a dynamic term, a wildcard role default) and the steps to resolve it.



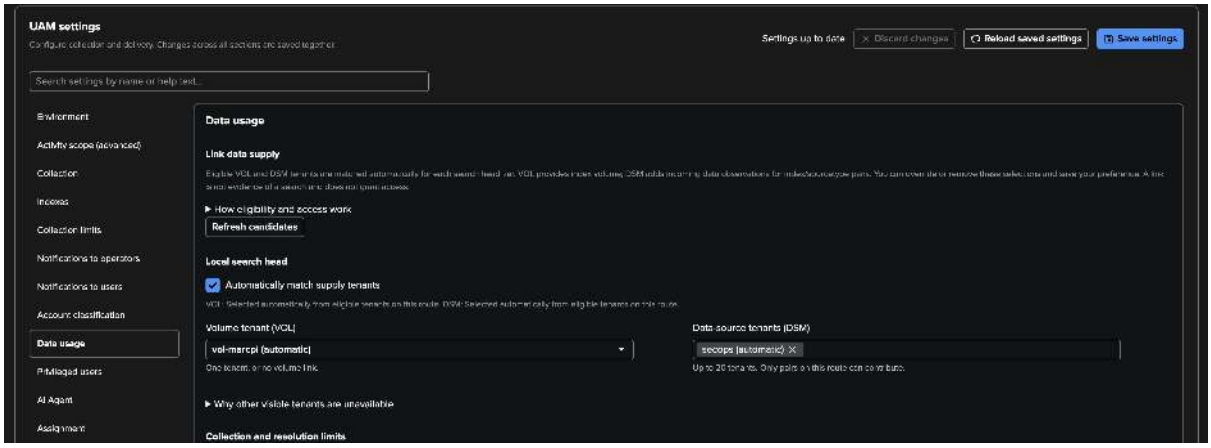
An account's data accesses. The account view has a **Data accesses** tab: the named reads of the account per index over the period, and **Which data this account used**, one lane per index with a marker for each group of nearby observations. Select a marker for the app, the usage origin and the claims behind it. An index view of the same timeline shows **who used this index**.



Searches run as long as they need. Every view reads the evidence through your own Splunk search jobs, started when the view opens and followed by the UI: the loader names what is still being read (*Still reading Collection runs…*), and the searches are cancelled when you change the selection or close the view. Nothing is cut after a fixed time: a long period or a large tenant takes longer, and is complete when it is shown. Only a safety timeout of 10 minutes applies.

Settings → Data usage. Each search head tier is linked to the VOL tenant that gives its index volumes and to the DSM tenants that give its incoming data. Matching is **automatic** by default — the first VOL tenant and every DSM

tenant you can see that is enabled and has the component, whatever account it collects through (2.4.23) — and you can override or remove a link. Indexes are matched by name: unselect a tenant that measures other indexers. A link grants no access: every read repeats the visibility check of the caller. The same section sets the apps whose reads are left out (`trackme` and `Splunk_SA_CIM` by default), whether internal indexes are shown, and the collection's own limits.



Note

What Data usage claims, and what it does not.

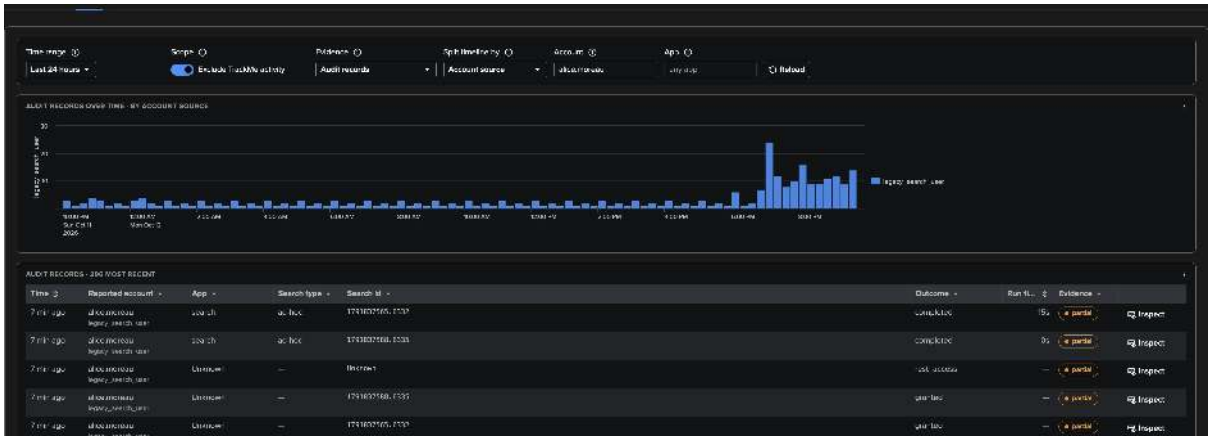
- A read is a search that **named** an index — directly or through a macro, event type, saved search or data model that resolves to it. A wildcard is a reference, not a read: `index=cribl_*` does not prove which index supplied the events.
- Each search is counted once. A search Splunk refused at its quota is not a read; a canceled or failed search that started is.
- A sourcetype is reported on a best-effort basis and never gets a verdict.
- The map covers what the audit trail of the indexing layer records and what the collection has seen so far. Until the collection covers the period, or seven days of it, nothing is called unread.
- A declaration in a knowledge object is not a read, and a link to a VOL or DSM tenant is not evidence of a search.

The collection behind the tab — the Data usage report, its facts, the resolution limits and the REST operations — is described in *Data usage*.

How each kind of claim is processed (named reads, wildcards and their narrowing to the reader's roles, searches the roles deny, definitions, index-less searches, late filters, writes, indexer confirmations, declarations, incoming data, verdicts and coverage), with diagrams, worked examples and limits, is the *Data usage reference: how each claim is processed*. The same reference opens in the product from every **How this works** link of the tab.

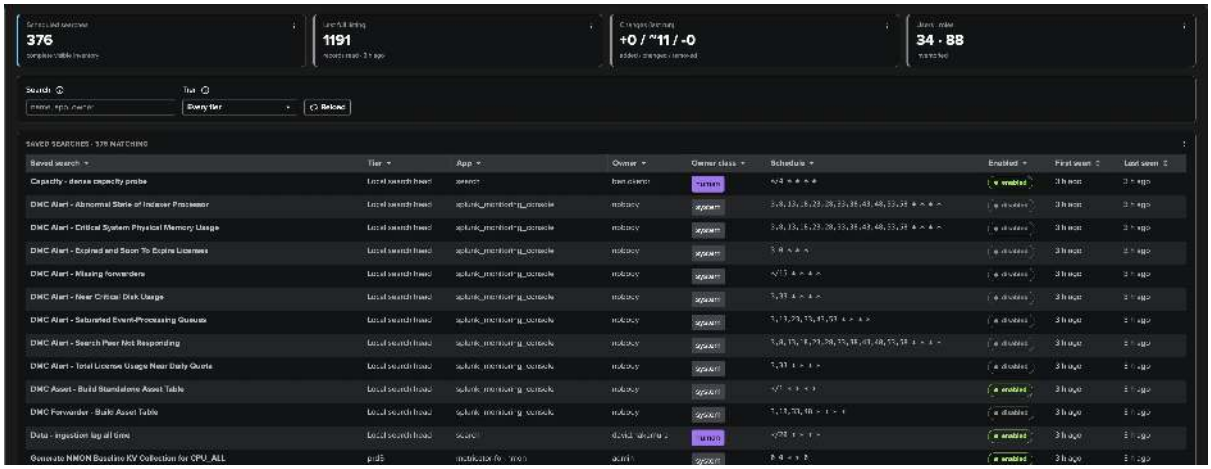
Activity

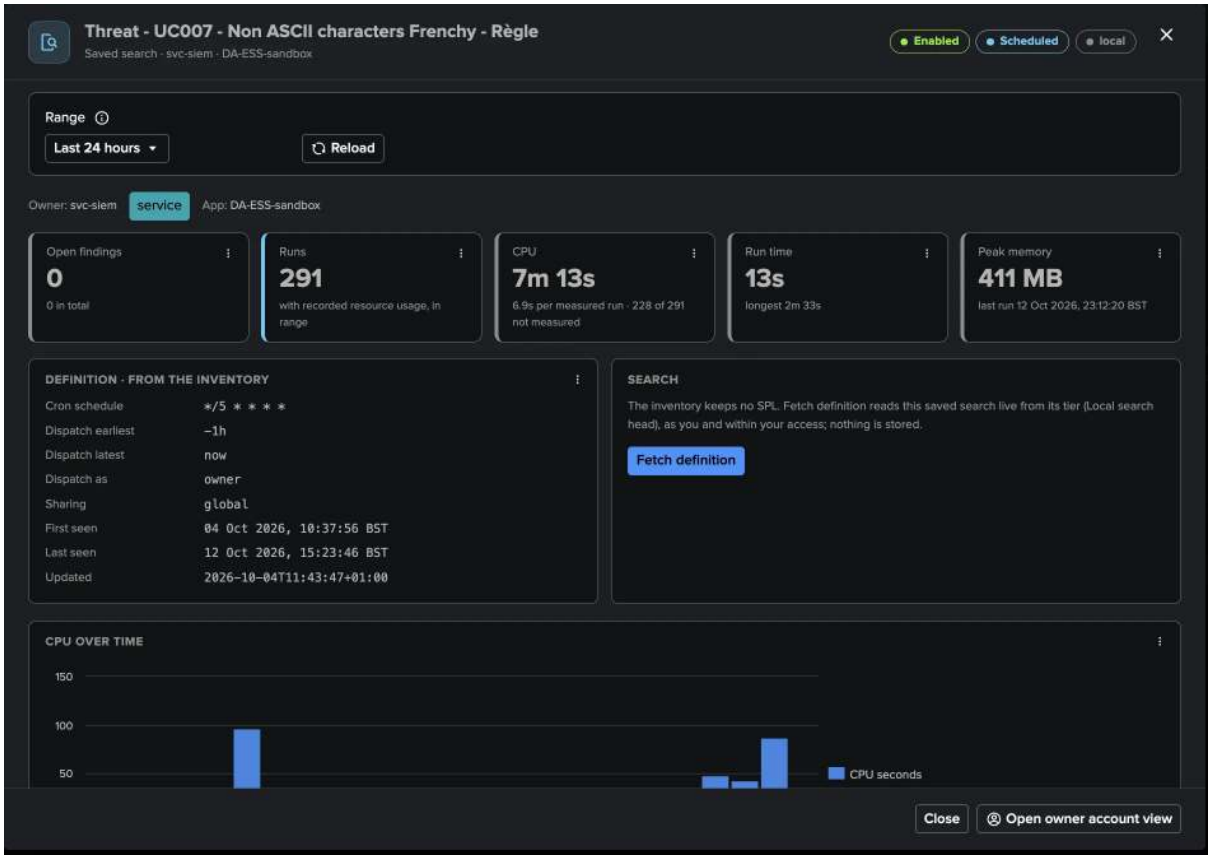
The raw evidence: **Audit records** or **Correlated executions** over a time range, a timeline split by account source, evidence status or account, account and app filters, and the 500 most recent records with an evidence inspector (**Inspect**). Executions are correlated from the audit records when you read them — the start and the completion of each search, the accounts and apps reported — and a notice says when an answer covers part of the range only.



Scheduled searches and the saved search view

The saved-search inventory per tier: tiles for the scheduled searches, the last full listing, the changes of the last run and the users and roles counts; the table with owner, owner class, schedule, enablement and first and last seen. Selecting a name opens the **saved search view**: its definition from the inventory, **Fetch definition** for the live definition, its runs with run time, CPU and peak memory, its findings and its change history, and a way to the owner's account view.

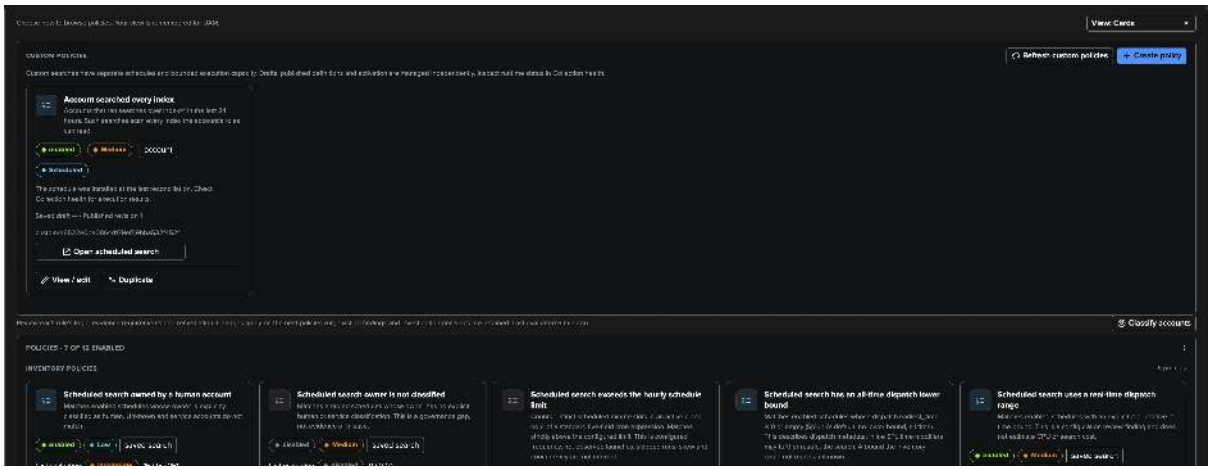




Peak memory can read *not measured* for short searches that Splunk's resource records never sampled. A saved search with the same name, app and owner on two tiers shares one set of run figures.

Policies

The built-in catalogue grouped by family (inventory, activity, resource, privileged) and your **custom policies**, shown as **Cards**, **Compact cards** or a **List** (remembered per user). Each policy shows its status, severity, account scope, thresholds (the effective values when they are derived from the capacity), exclusions, what it does on bank holidays and its **last evaluation**. Selecting the last evaluation opens the **policy insight**; **Edit** opens the policy editor. See *Tuning the policies*.



Audit changes

TrackMe's own audit of this tenant: every configuration change, decision and collection request, with who did what and when — the same view every tenant type offers.

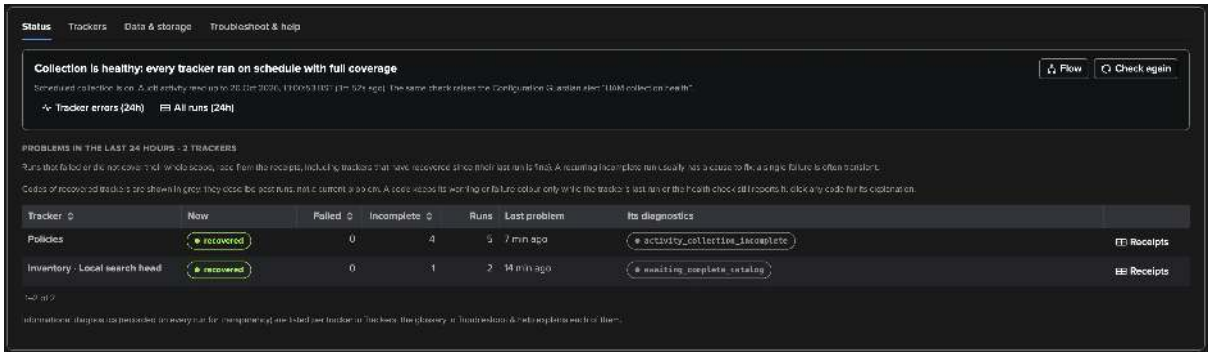
Collection health

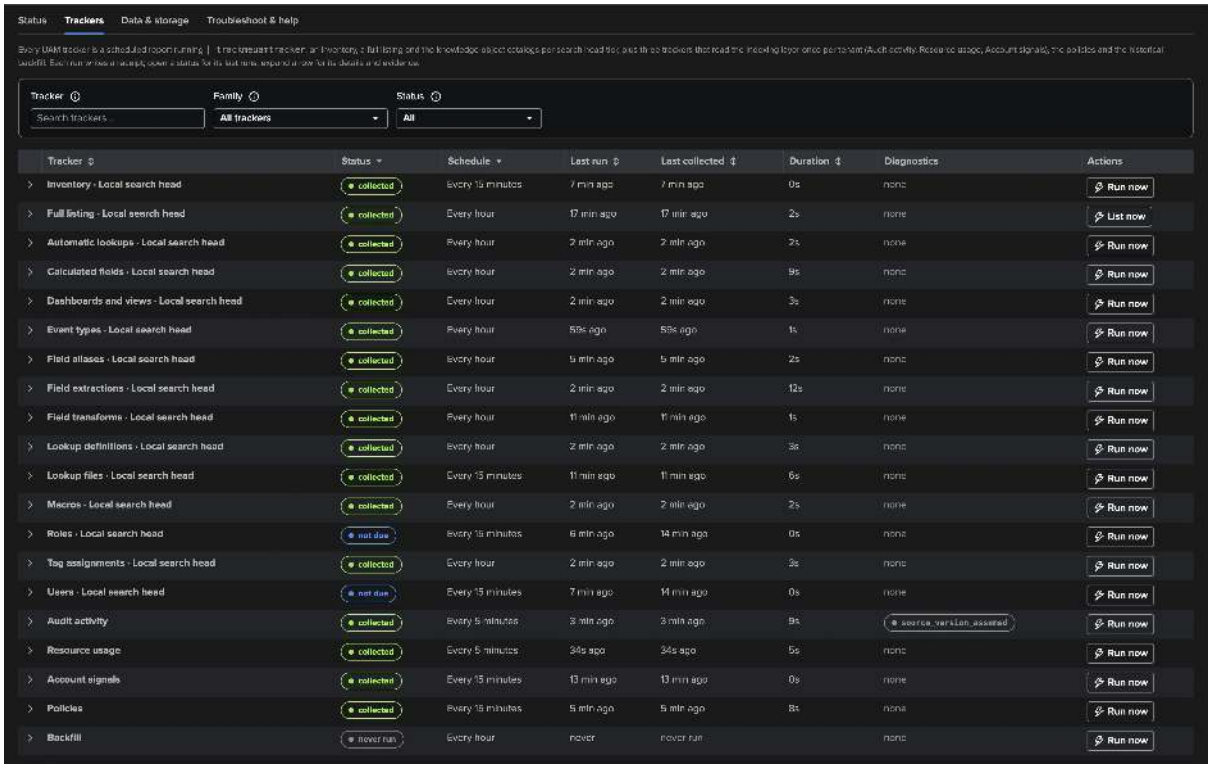
Is UAM collecting what it should, and if not, why and what to do? Everything that says something is wrong comes with its explanation, its evidence and its action. Four views:

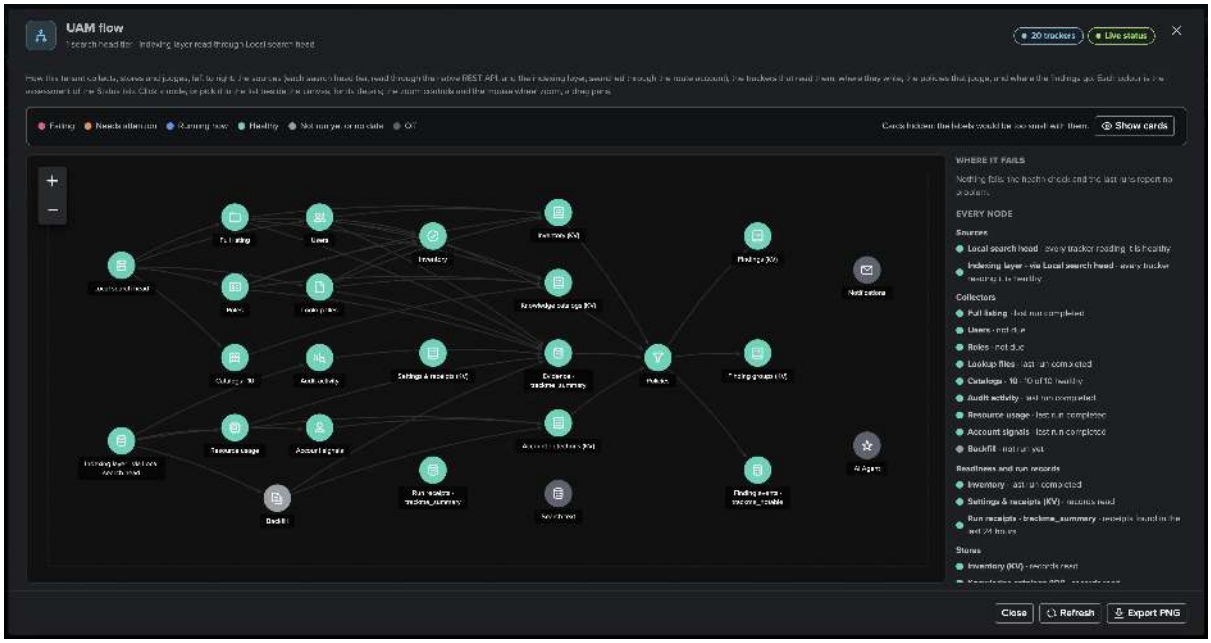
- **Status** — one row per tracker that needs attention, from the same assessment the Configuration Guardian raises, so the page and the alert never disagree. A row expands to every reason with its meaning and where it was reported, **What to do**, the facts of the last run (status, finish, consecutive failures, search job, report and its live schedule, lock), the policies a run could not complete (with **Show why**), shortcuts to the evidence (**Receipts**, **Tracker log**, **Search job**, **Report**, **Scheduler log**) and **Run now / Recover**. Below, **Problems in the last 24 hours** lists the failed and incomplete runs of each tracker, recovered or not. **Flow** draws UAM's own collection pipeline — the search head tiers and the indexing layer, the trackers, what they store and the policies — coloured by health.

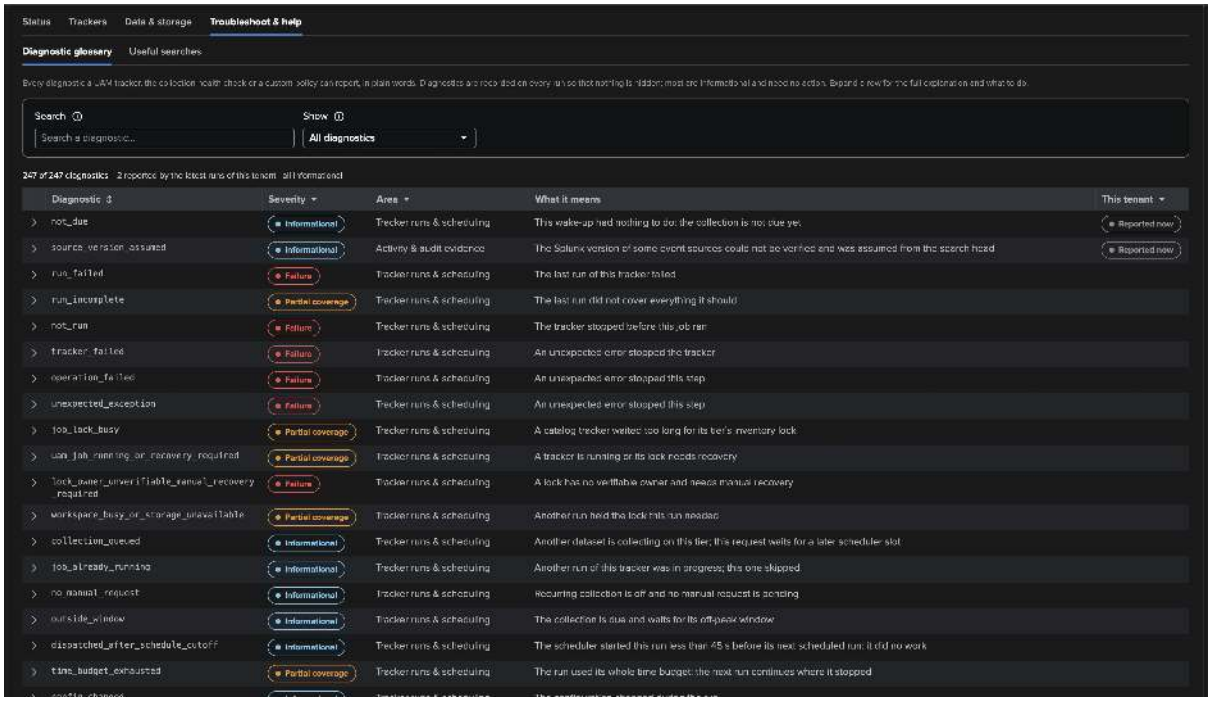
- **Trackers —** every tracker in one table: status, live schedule (read from Splunk), last run, **last collected**, duration, diagnostics, **Run now** (**List now** for a full listing) and **Recover**, filtered by name, family, status or tier. A row expands to its details: the activity checkpoint and the windows of the last run for Audit activity, the facts written, the claims and the unresolved searches for Data usage, the resource windows and the capacity for Resource usage, the login and automation scans for Account signals, the datasets of a catalog, the backfill progress and its controls (**Pause**, **Resume**, **Cancel backfill**, **Plan again**). For Audit activity, Data usage, Resource usage, Account signals and Policies, **Searches of the last run** lists each search the run sent, exactly as sent, with its time range, **Copy** and **Open in Search**. Custom policies have their execution health in their own family.
- **Data & storage —** what UAM writes for the tenant and how to read it: the events per index and sourcetype (volume over a range, latest event), the KV collections (records, size, lookup, and a record viewer), the logs and every scheduled report with its live state, each with a shortcut.
- **Troubleshoot & help —** the **diagnostic glossary** (every code UAM can report: what it means, where it comes from, possible causes and what to do; the codes this tenant reports now come first) and ready-made searches (tracker errors, failed or incomplete runs, skipped scheduled reports, REST calls, who changed UAM).

Every diagnostic code, wherever it appears, opens its explanation. A code is coloured as a warning or a failure only while its condition is current; a code that only describes a past, recovered run stays neutral. Only one run of a report happens at a time; a run whose search provably stopped is recovered automatically after five minutes, otherwise **Recover stopped run** releases it. A lock is never taken over on age alone.





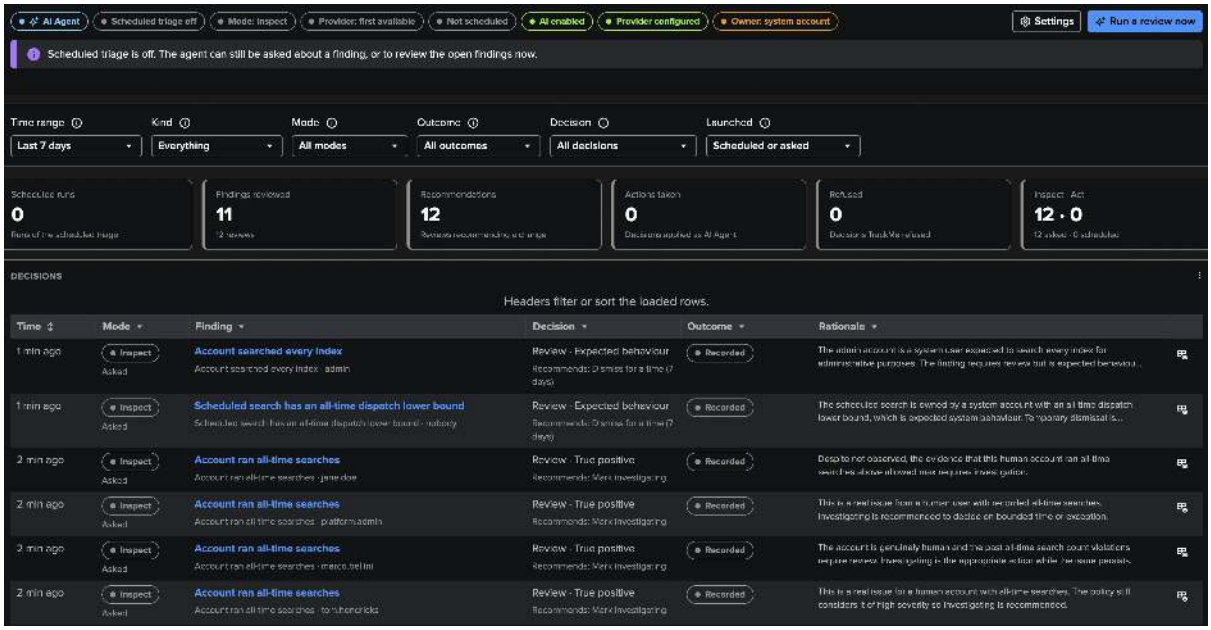




The Configuration Guardian check `uam_collection_health` warns when collection is not running as configured — a missing or unscheduled report, missed schedules, repeated failures, a checkpoint that does not move, a range held for 15 minutes, windows or recounts waiting more than a day, an overdue listing, failing notification delivery, a custom policy that drifts from its schedule. See *Configuration Guardian*.

AI Agent

The **UAM AI Agent**: whether scheduled triage is on, its totals over 24 hours to 90 days, **Run a review now**, and the decision log with its filters (decision, mode, outcome, scheduled or asked). See *The UAM AI Agent and the AI Assistant*.



Settings

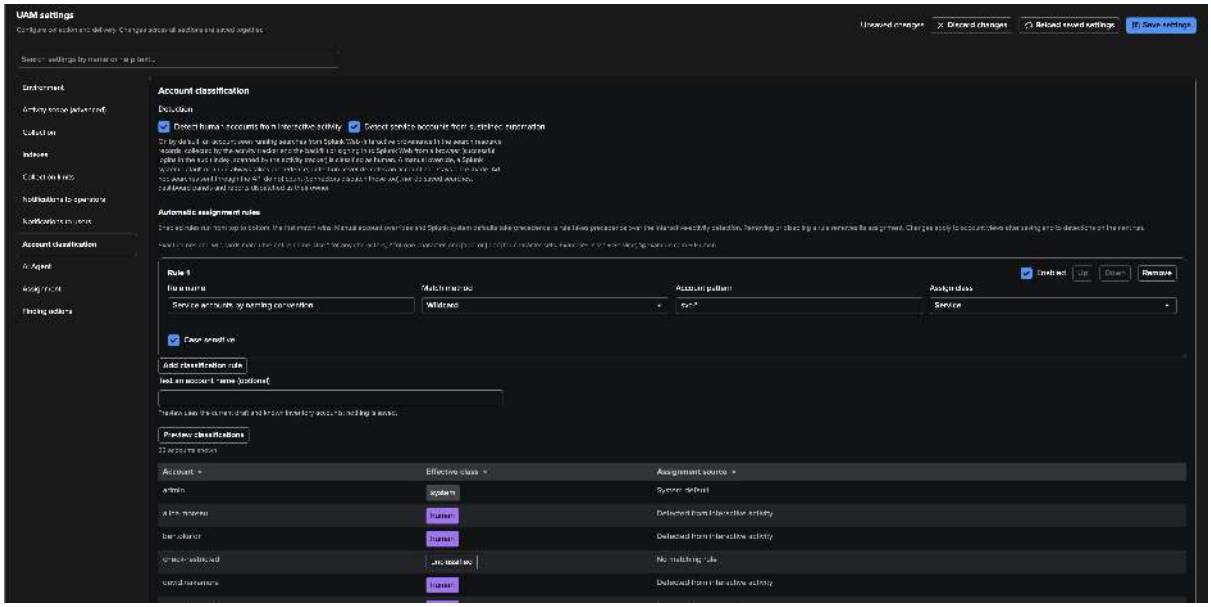
Every tenant setting in one page with one **Save settings**: **Environment** (the tiers and the route account), **Activity scope (advanced)**, **Collection** (scheduled trackers, *Store SPL search*, resource collection), **Indexes**, **Collection limits** (time budgets, windows and cadences: there is no row limit), **Notifications to operators**, **Notifications to users**, **Account classification**, **Data usage** (the VOL and DSM links, the excluded apps and the resolution limits), **Privileged users**, **AI Agent**, **Assignment** and **Finding actions**. Changes apply from the next runs; **Collect now** applies them immediately. If someone else saved in the meantime, your save is refused and you are asked to reload. Every setting is described in *Settings reference*.

Accounts and classification

A finding about an account only makes sense once you know what the account **is**. UAM keeps three classes, and the class decides which policies apply:

- **human —** a person. Detected automatically from **interactive activity**: a search run from Splunk Web (the Search app, a dashboard, a report opened by a person) or a browser login to Splunk Web. One is enough, and the class stays.
- **service —** automation. Detected after **seven distinct days** of automation-only activity (API jobs, the scheduler, acceleration) and nothing a person does; withdrawn as soon as the account does what a person does. This detection needs the classic `key=value` `_audit` format, and the seven days must be inside the audit retention.
- **system —** Splunk's context identities (`nobody`, `splunk-system-user`) and the built-in `admin`, preset. System accounts are never evaluated by the account policies and never receive email.

On top of the detection, set **manual classes** per account (Users tab or *Settings → Account classification*) and ordered **classification rules** (exact names or wildcard patterns such as `svc-*`), with a preview of the effective class before saving. Precedence is always: manual class, system defaults, the first matching rule, human detection, service detection. An account nothing classifies stays **unclassified** and is left out of the policies scoped to human accounts.



Tip

Classify the monitoring itself first. Classify the tenant owner (`svc-a`), your administrator accounts and other platform automation as **system** or **service**: they run TrackMe's collection and the platform's housekeeping and should not fill the findings. The `trackme` and `Splunk_SA_CIM` apps are excluded from the policies by default for the same reason.

Triage findings

Observed, not observed, and the status

A finding has two independent axes:

- **Whether the policy still sees the condition.** While it does, the finding is **observed**. After a complete policies run that no longer sees it, the finding reads **not observed** — UAM never resolves it for you: a configuration or a behaviour that disappears from one evaluation still deserves a human decision. A run that could not cover everything (an incomplete inventory, an activity gap) may add findings, never clear them.
- **Your decision**, the status: **Open**, **Investigating**, **Resolved** or **Dismissed**.

A resolved finding that is observed again is **reopened**. A dismissed finding stays dismissed until its dismissal ends — then it returns to open, so you get another look. The lifecycle shared with the other findings tenants is described in *A finding and its lifecycle*.

Finding groups

All the findings about **one account and the saved searches it owns** form one **Finding group**: the all-time searches and resource consumption of `analyst-a` together with the personal-schedule and real-time-schedule findings of the searches `analyst-a` owns. A saved search without an owner keeps a group of its own. You decide once, for the group: status, dismissal, assignee, notification snooze and severity apply to every member, and a finding that joins the group later takes its state.

Two UAM specifics:

- **Dismiss only this finding** (member menu) sets one finding aside — for example a personal schedule you accept inside a group that also holds a real problem. It stays dismissed on its own while the rest of the group is decided on; **Reopen this finding** brings it back into the group's state.
- A new kind of finding on a dismissed group returns the group to open with the new finding, while the findings the dismissal covered stay dismissed: a dismissal never silences a new problem.

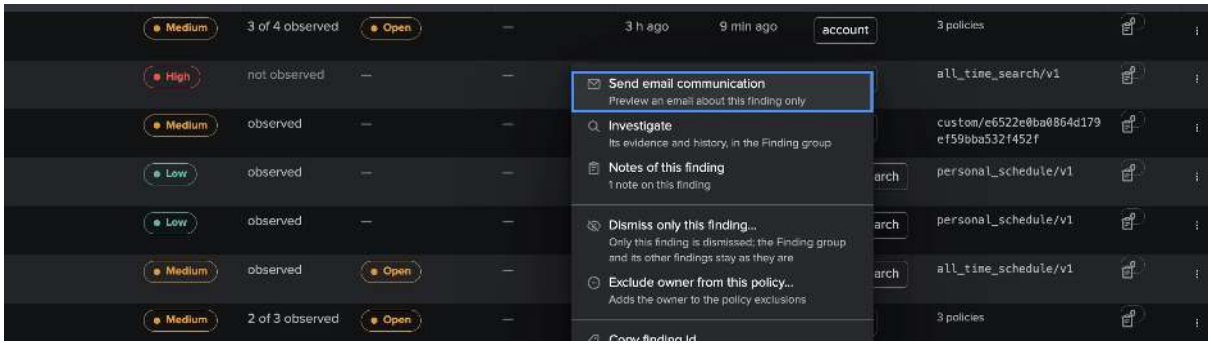
You can also group by hand — **Merge into one Finding group** (2 to 25 groups), **Add to the Finding group** (an existing manual group), **Remove from the Finding group**, **Ungroup** — for example to handle the accounts of one project together. The findings of one account always move together. See *Finding groups*.

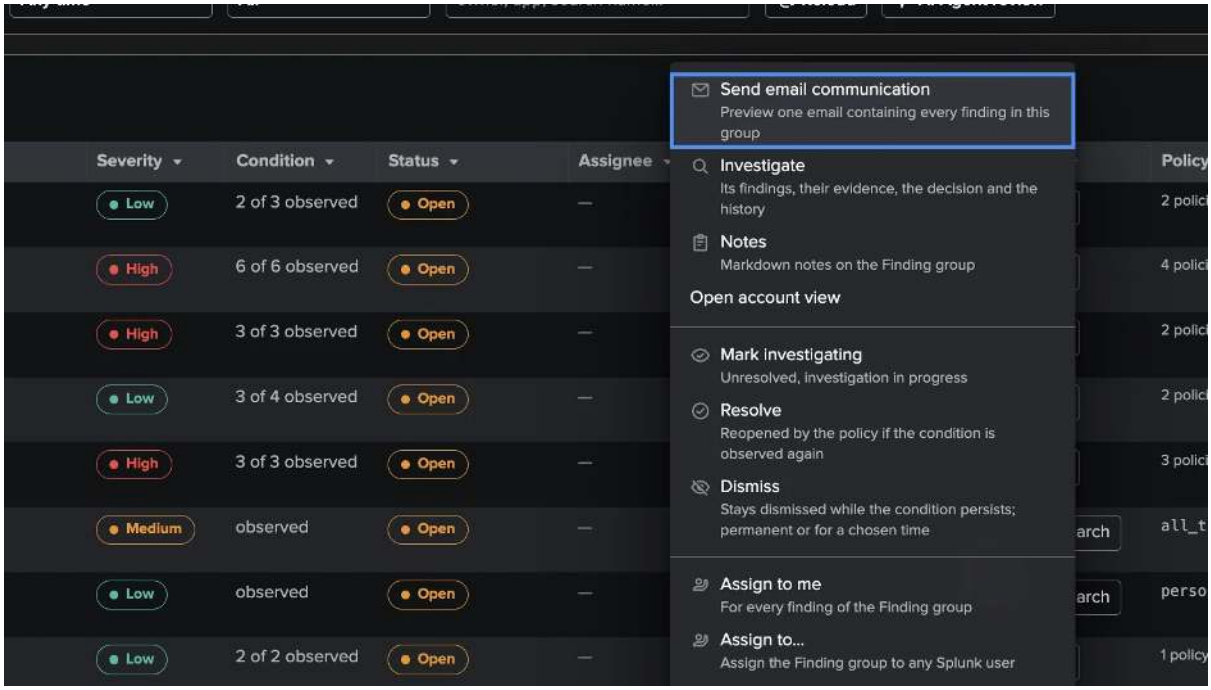
Decisions

From the row, group and member menus, the selection toolbar (**Bulk edit**) and the Triage panel of the Investigate view:

Decision	What it does
Mark investigating	Someone is on it.
Resolve	The investigation concluded. The policy reopens the finding if it observes the condition again. Nothing is changed on the saved search or the account.
Dismiss	No action needed: for 1, 7, 30 or 90 days, or **until reopened by hand** (permanent). A dismissed finding stays listed under the *Dismissed* tile.
Reopen	Back to open; on a dismissed finding, ends the dismissal now.
Assign to me, **Assign to…**, **Unassign**	To a Splunk user or an assignment group. The assignee is kept when the finding reopens.
Snooze notifications	Holds the operator emails (from 1 hour to 30 days) without changing the status; **Clear notification snooze** resumes them. It does not hold the notifications to users.
Set severity	Overrides the policy severity (Low, Medium, High, Critical); the override survives later runs. Choosing the derived severity again (**Members** on a Finding group, **Use policy severity** on a single finding) restores it.
Notes	Markdown notes on a finding or a Finding group, permanent or expiring, plus a short investigation note recorded with each decision.
Exclude owner from this policy	Adds the finding's owner to the exclusions of its built-in policy (custom policies write their exclusions in their SPL).

The row menu also has **Send email communication**, **Send webhook…** and your own actions under **Custom actions**, **Ask the AI Agent…**, the account view and saved search view, **Copy finding ID** and *Open record / events in search*.





Every decision is recorded in the history of the finding and of its Finding group, with the actor, the time and the note. Decisions are protected against concurrent changes: if the Finding group changed since you opened it, your decision is refused and the table reloads.

Assignment and findings actions

Assignment groups — "Platform team", "Security operations" — and ordered **routing rules** (by policy, severity, subject type, owner or account, app, environment) are set in *Settings → Assignment*; routing assigns new Finding groups automatically, never overriding an existing owner, and can email the assigned team. See *Assignment and automatic routing*.

Findings actions (*Settings → Finding actions*) add **drilldown searches**, **links**, **webhooks** through system-wide Webhook accounts, and the **email** action to the finding menus, by hand or through per-policy **automation rules** (policy editor → *Automations*). UAM presets include *Audit activity of this account*, *Scheduler runs of this saved search* and *Finding transitions*. Tokens such as `$subject.account$`, `$subject.owner$`, `$subject.app$` and `$subject.name$` carry the finding's values. See *Findings actions* and *Webhook accounts*.

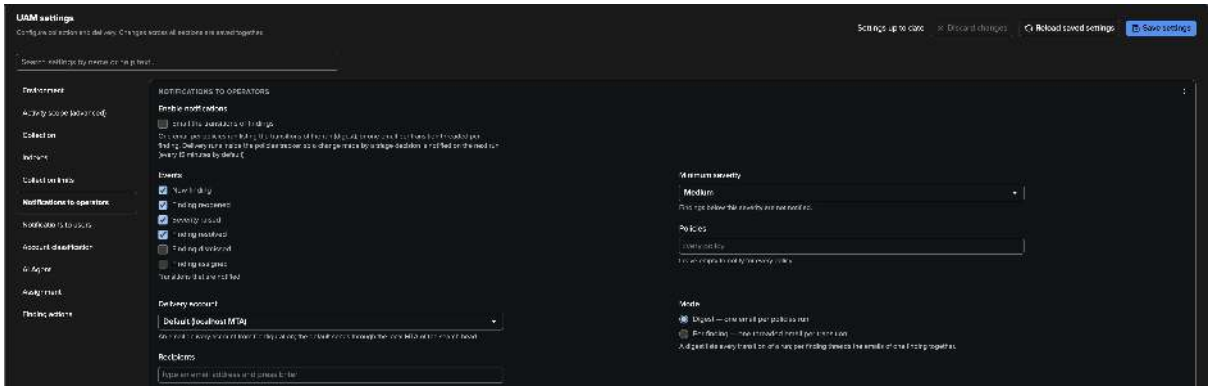
Every finding transition is also indexed in the tenant's notable index as `sourcetype=trackme:uam:finding`, ready for your own Splunk alerts, Enterprise Security correlations or SOAR playbooks.

Communicating with users

UAM can talk to two audiences: the **operators** who triage, and the **accounts** the findings are about. The two are independent.

Notifications to operators

Settings → Notifications to operators (off by default): the events that send an email (**New finding**, **Finding reopened**, **Severity raised**, **Finding resolved**, and optionally **Finding dismissed** and **Finding assigned**), the minimum severity (Medium), the policies (all), the email delivery account, up to 50 recipients, and the mode: a **Digest** (one email per policies run) or **Per finding** (one thread per finding). Emails are sent at the end of the next policies run, within about 15 minutes, and link to the finding. **Send test email** uses the saved settings, even while notifications are off.

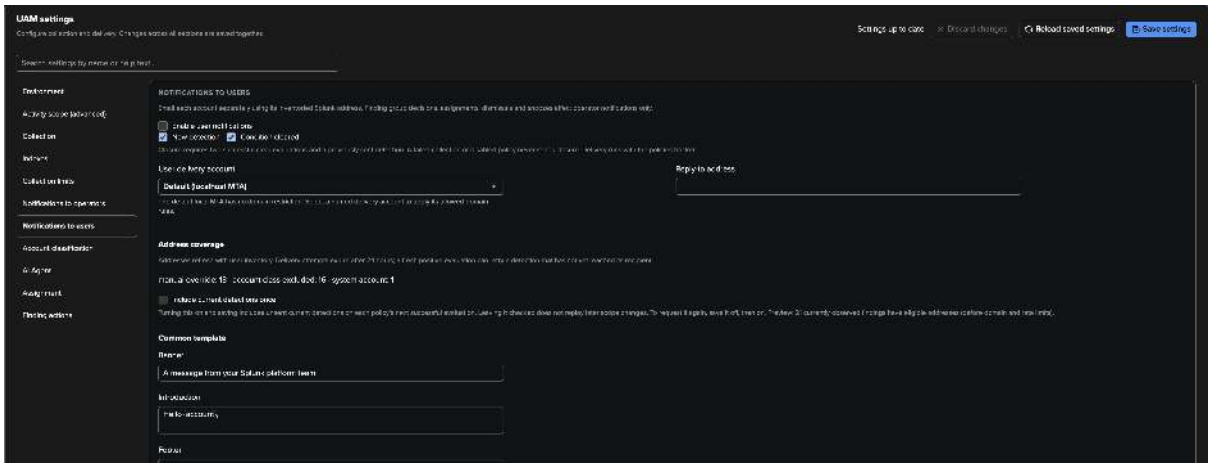


Notifications to users

Settings → Notifications to users (off by default) emails **the account a finding is about**, so that people fix their own searches:

- on a **New detection**, and when the **Condition cleared** (after two consecutive complete evaluations without it);
- addresses come from Splunk's user records on each tier, or from an administrator's **Override email address**; system accounts never receive mail, human accounts do by default, service and unclassified accounts only if you opt in;
- a common banner, introduction, footer, reply-to address and HTTPS support link, combined with each policy's own subject and body (*Policies → Edit → Email template*);
- limits: 50 emails per run, 3 per address per hour, 24 hours between repeat detections.

When you turn it on, UAM records the current findings as a baseline and only emails what is detected from then on, unless you choose **Include current detections once**. User emails follow the policy's detection, not your triage: resolving, dismissing or snoozing a finding does not stop them.



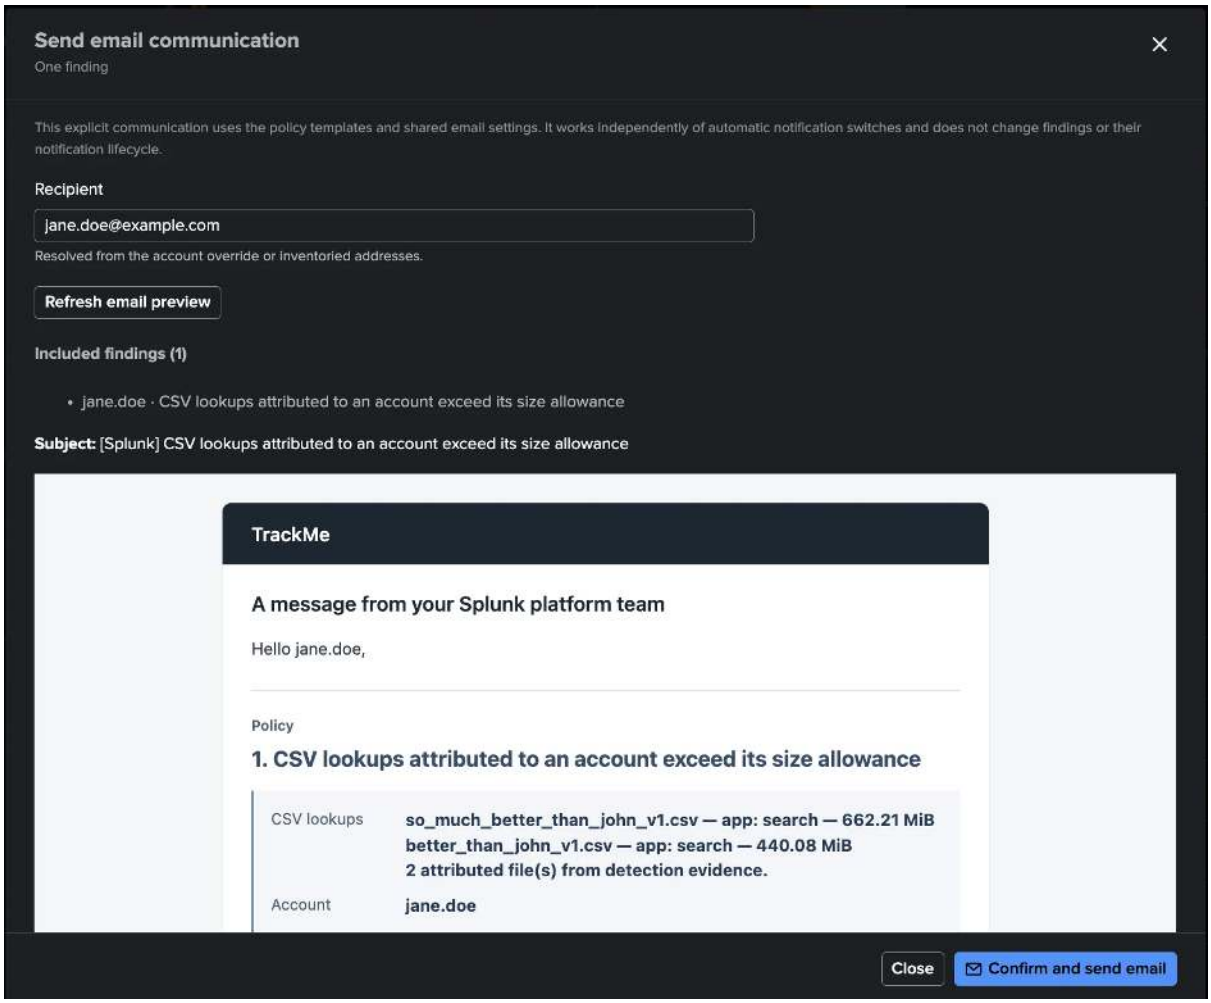
Important

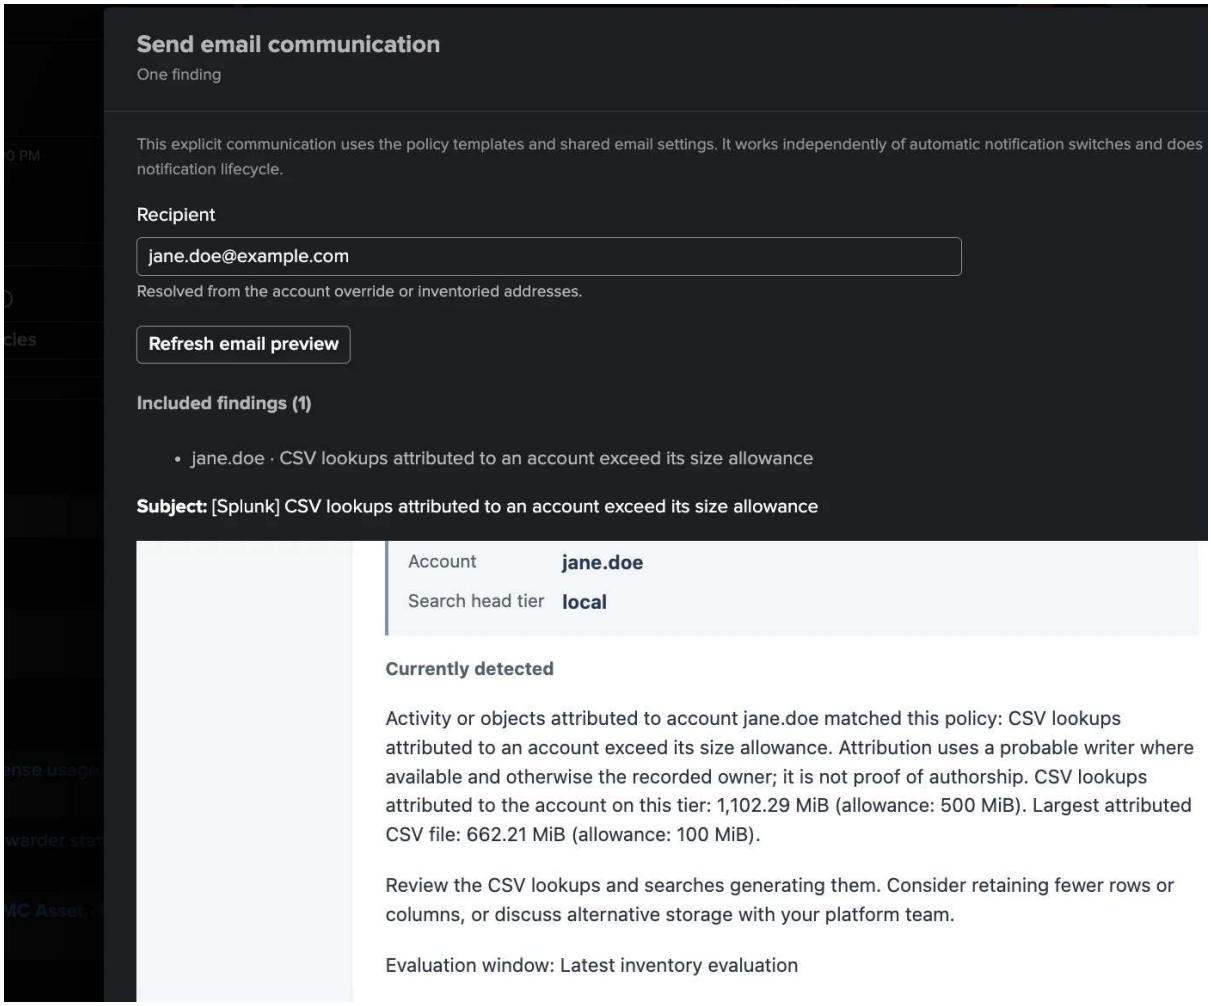
Before turning on notifications to users, check the **address coverage** shown in the section, set the reply-to address and the support link to your team, and preview the email template of each enabled policy. The people who receive these emails did not ask for them: make the first one clear and useful.

Send email communication

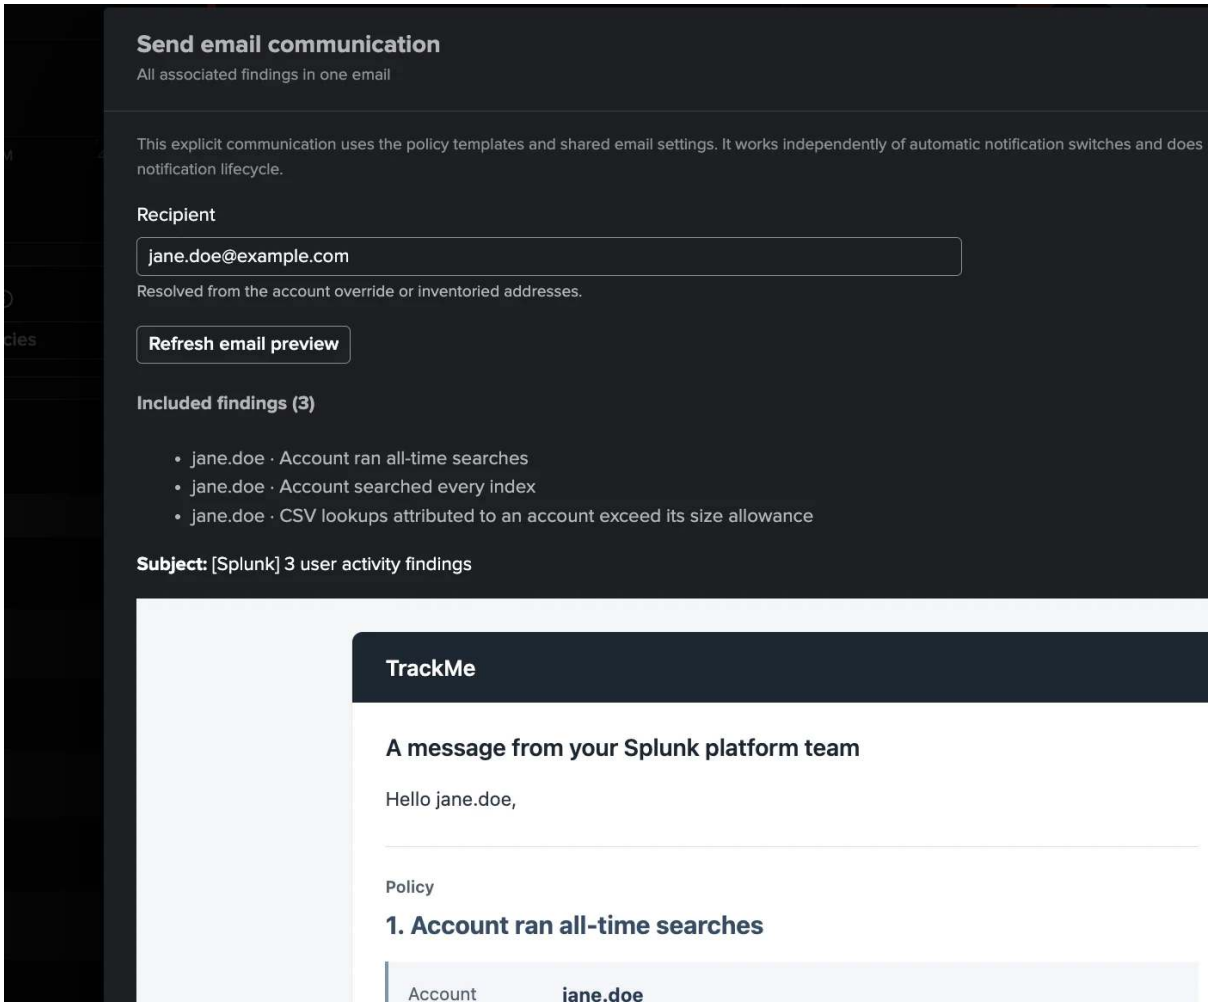
For a one-off message, **Send email communication** in a finding, member or Finding group menu prepares an email to the account concerned — one finding, or a whole group (up to 200 findings) in one email. You review the preview,

can change the recipient once, and confirm explicitly. The email is sent by a TrackMe search job, never by the browser, and a delivery that could not be confirmed is reported, never resent blindly.





From a Finding group menu, the same dialog prepares one email for every finding of the group: here the three findings of `jane.doe` — a built-in activity policy, a custom policy and the CSV lookup footprint — under the subject *3 user activity findings*.



The UAM AI Agent and the AI Assistant

The **UAM AI Agent** reviews findings the way an operator would: it reads the evidence TrackMe holds and writes its assessment as one current `[AI Agent]` note per finding.

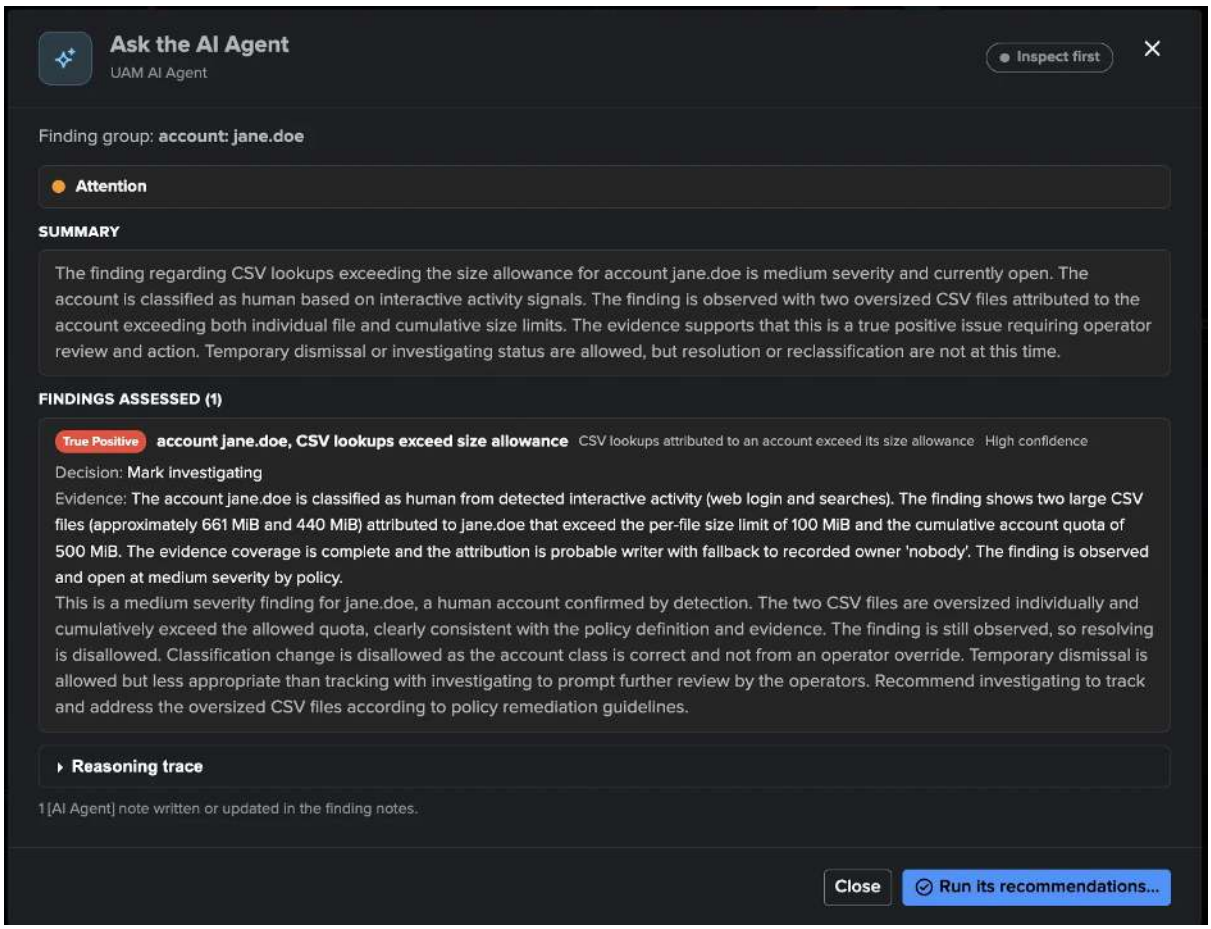
- **Inspect** changes nothing: assessment, confidence and recommendation.
- **Act** also applies the decisions the tenant allows: *mark investigating* and *dismiss for a time* (on by default, never for a critical or high finding still observed), *resolve* a finding its policy no longer observes and *classify* an unclassified account (off by default). It never dismisses permanently, assigns, or changes a severity, a policy or a setting.

Ask the AI Agent… in a finding or group menu inspects one Finding group on demand; you can then let it act on that inspection. **Scheduled triage** (*Settings → AI Agent*, off by default) reviews up to 10 findings every hour — by default only **critical and high** ones, one per Finding group — and never overrides a decision or an assignment made by a person. Every decision appears under the actor **AI Agent** in the history and in the **AI Agent** tab. The AI Agent needs the AI Assistant to be enabled with at least one AI provider; the scheduled triage also needs a tenant owner other than `nobody` or `splunk-system-user`. The UAM AI Agent replaces the UAM Findings Advisor of earlier releases. See *Findings AI Agents* and *AI Agents for findings*.

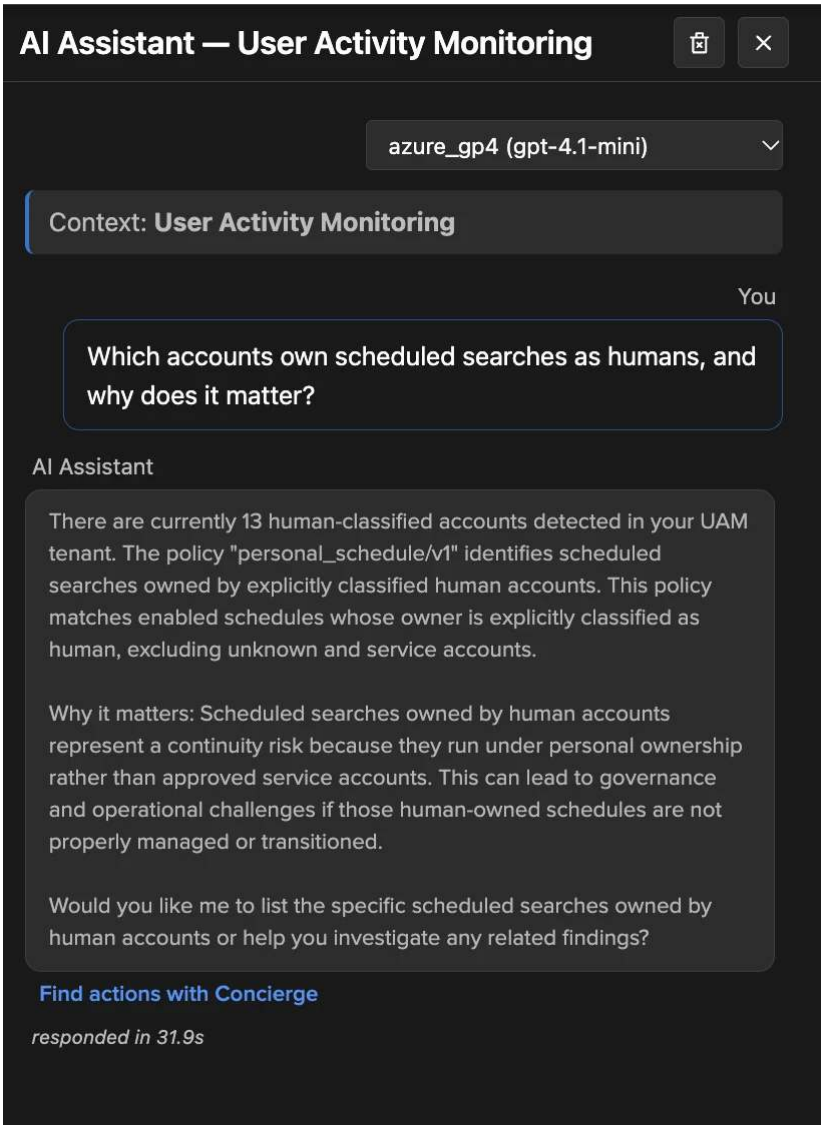
Custom instructions. The tenant administrators can give the agent instructions in plain English (*Settings → AI Agent → Custom instructions*, also in *Manage AI Agents automation* and in the *Configure tenant* dialog): at most 4,000 characters, line breaks kept. Every run of the agent follows them, asked or scheduled — for example, "The accounts named `svc_*` are service accounts." They never widen what the agent may do: the allowed decisions and TrackMe's checks before every decision still decide. The tenant's shared **Custom Instructions** of *Manage AI Agents automation* are different: they apply to scheduled runs only.

Evaluate… tries the unsaved draft before you save it: the agent runs in inspect mode on one open finding, or on

a review of the open findings (at most 10, the most severe first), optionally side by side with a run without custom instructions. An evaluation writes nothing — no note, no decision, no review record — and is recorded with the status `evaluation`. See *AI Agents for findings*.



The **AI Assistant** of a UAM tenant knows the workspace, the policies and the open findings: ask it to explain a finding, compare accounts or suggest what to tune, and it can propose an AI Agent review or a triage action for you to confirm. See *AI Assistant & Concierge*.



Tuning the policies

The built-in catalogue

Sixteen policies in four families. Seven are enabled on a new tenant; the four privileged policies are off until you turn them on.

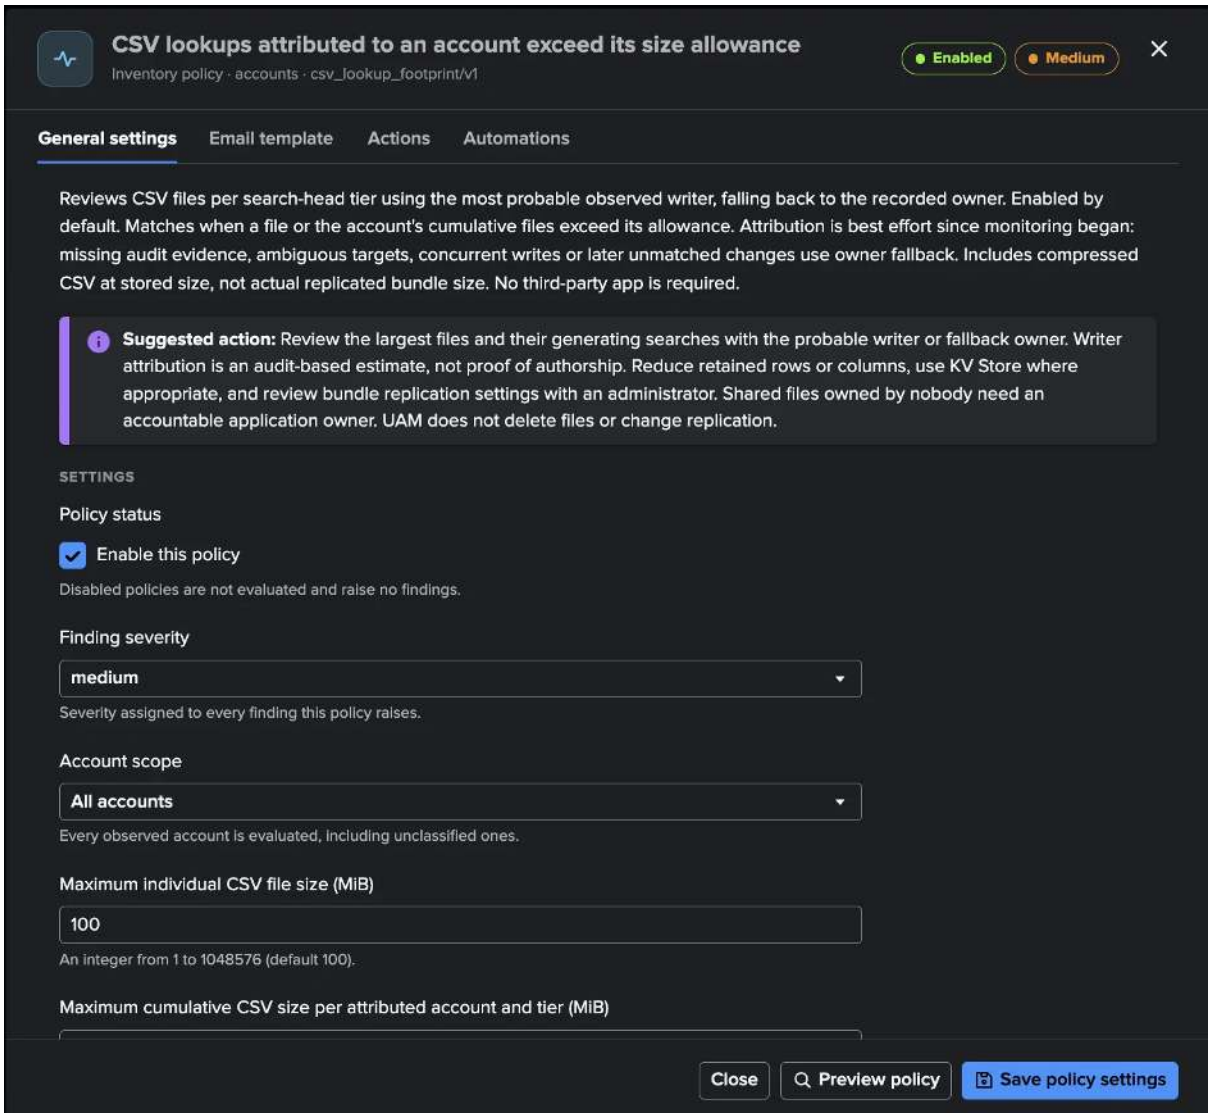
Policy	Family	Default	What it detects
Scheduled search owned by a human account (`personal_schedule/v1`)	inventory	on, Low	An enabled schedule owned by a person: it stops when that account goes.
Scheduled search owner is not classified (`unclassified_schedule/v1`)	inventory	off, Medium	An enabled schedule whose owner is neither human nor service.
Scheduled search exceeds the hourly schedule limit (`dense_schedule/v1`)	inventory	off, Medium	A cron with more minute slots per active hour than the limit (12).
Scheduled search has an all-time dispatch lower bound (`all_time_schedule/v1`)	inventory	on, Medium	A schedule whose earliest time is `0` or empty.
Scheduled search uses a real-time dispatch range (`realtime_schedule/v1`)	inventory	on, Medium	A real-time scheduled search.
CSV lookups attributed to an account exceed its size allowance (`csv_lookup_footprint/v1`)	inventory	on, Medium	Per tier, one CSV lookup over the file limit (100 MiB) or an account's CSV lookups over its total (500 MiB), attributed to the probable writer, else the recorded owner.
Account launched an unusual number of searches (`launch_burst/v1`)	activity	off, Medium	More distinct searches in the policy window than the limit (200).
Account ran repeated long searches (`costly_search/v1`)	activity	off, Medium	More than 3 searches of at least 300 seconds.
Account ran all-time searches (`all_time_search/v1`)	activity	on, **High**	Any all-time search (the maximum is 0).
Account's search resource consumption exceeded its allowance (`resource_consumption/v1`)	resource	on, Medium	CPU over the allowance in the window (10 % of the search capacity by default); the severity is raised one level when the account dominates the environment (40 %).
Account ran repeated resource-intensive searches (`resource_intensity/v1`)	resource	on, Medium	More than 3 searches heavy in CPU or memory.
Account's CPU consumption is unusual for its daily baseline (`resource_deviation/v1`)	resource	off, Medium	Today's CPU above a multiple (3) of the account's daily 95th percentile over 14 days. Ships in **Preview mode**: it shows what it would match, without raising findings or sending notifications, until you turn the mode off.
Account became privileged (`privileged_account_new/v1`)	privileged	off, **High**	An account that became privileged: created privileged, given a privileged role, or a role it holds now imports one. Reported once per change, with who made it when Splunk audited it.
Role gained a privileged capability (`privileged_role_capabil:v1`)	privileged	off, **High**	A role whose own capabilities or imported roles changed so that it grants more privileges, or a new role created privileged. One finding about the **role**, listing the roles that inherit it and the accounts newly privileged through them.
Privileged account is dormant (`privileged_account_dorma v1`)	privileged	off, Medium	A privileged account with no search, no Splunk Web login and no successful login reported by Splunk for 30 days.
Privileged accounts differ from the reference (`privileged_reference/v1`)	privileged	off, **High**	A privileged account your reference (typed names and lookup tables) does not declare; optionally a declared account that holds no privilege or no longer exists (Low).

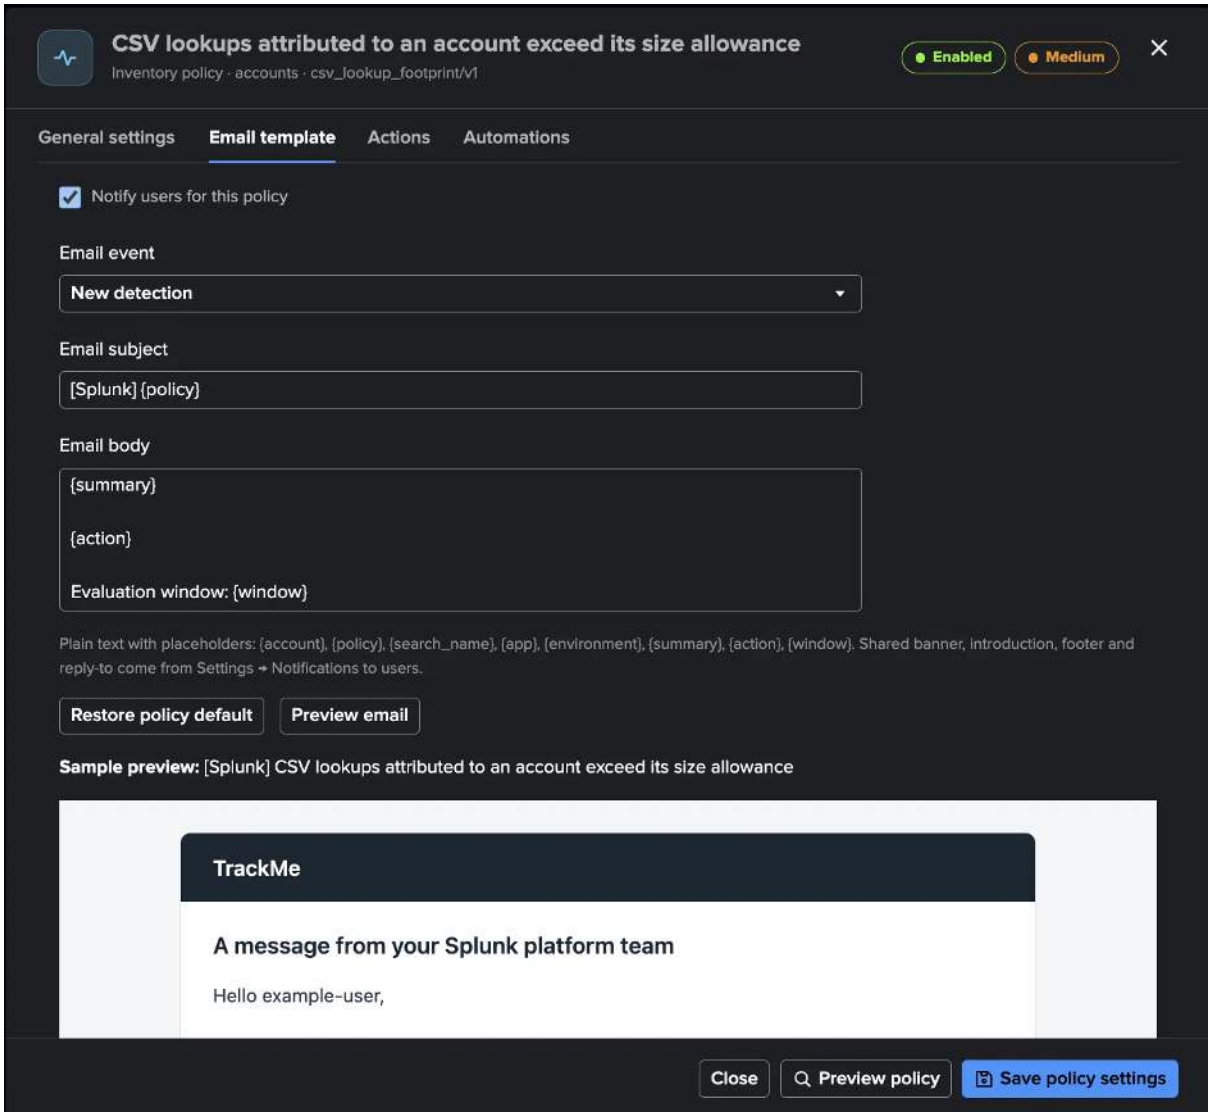
The activity and resource policies judge 15-minute windows of collected evidence by default. A window ends where the collected evidence ends, never at the current time, and consecutive windows always touch: no minute is skipped, and activity collected late is evaluated once it is collected. The inventory policies follow the catalog cadence (the full saved-search listing is daily by default). The resource policies stay **learning** — no finding, nothing cleared — until the tenant holds 24 hours of resource history and a measured capacity. The full catalogue, with every threshold and its bounds, is in *The built-in policy catalogue*.

Editing a policy

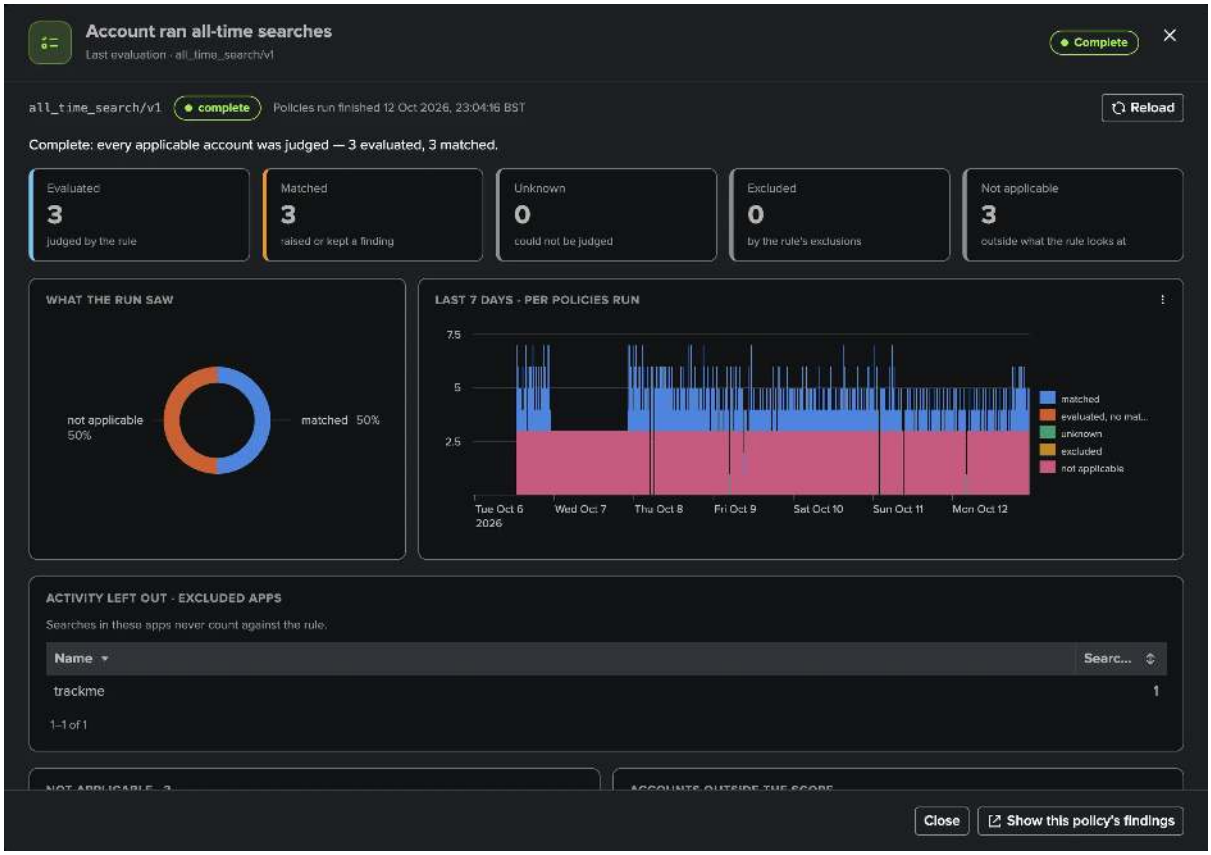
Edit opens the policy editor:

- **General settings** — status, **During bank holidays** (see *Bank holidays*), severity, account scope (human accounts only, classified accounts, all accounts), thresholds (the resource policies can derive them from the measured capacity, **auto thresholds**), excluded owners and excluded apps (exact names, up to 500), and **Preview policy** to see what the draft would raise against the current data before you save.
- **How it is evaluated** — the rule in plain words, then the exact searches it runs (built from the saved settings, with their time range, **Copy** and **Open in Search**), or, for an inventory policy, the records it judges.
- **Email template** — the subject and body of the user emails for this policy, for a new detection and for a cleared condition, with a preview and a test delivery; **Restore policy default** brings back the shipped text.
- **Actions** and **Automations** — the findings actions offered on this policy's findings, and the automation rules that run a webhook when they change.





The **policy insight** (from the last evaluation of a policy) explains a run: the verdict, what the run saw, what was matched, excluded, not applicable or could not be judged and why, the owners behind the unknowns (classifiable in place), the exclusions and a seven-day history, with the runs of those seven days that could not judge everything and their reasons (kept after the problem recovered). It is the first place to look when a policy raises nothing, or too much.



Privileged policies

Four policies watch who holds high privileges, from the assessment of the **Privileged users** tab (its rules: *Settings → Privileged users*). They are off by default: turn on the ones you need in *Policies*.

- **Account became privileged** reports, once, an account that became privileged on a tier: a new account created privileged, a privileged role assigned to it, or a role it holds that now imports a privileged role. When Splunk audited the change, the finding names who made it and when; a role mapped by a SAML or LDAP provider has no such record.
- **Role gained a privileged capability** reports, once, a role whose **own** definition changed so that it grants more: its own capabilities, the roles it imports, or a new role created privileged. Inheritance is transitive, so one change reaches every role that inherits it, directly or through other roles: the finding is about the role whose definition changed, and lists the roles that inherit it and the accounts newly privileged through them — one change, one finding.
- **Privileged account is dormant** reports a privileged account with no activity for 30 days (configurable): no search, no Splunk Web login, no successful login that Splunk reports on any tier. It judges an account only once it has been in the inventory and the tenant's evidence covers the whole period.
- **Privileged accounts differ from the reference** compares the privileged accounts with a reference you maintain — the accounts declared privileged, optionally per search head tier. It reports a privileged account the reference does not declare (High) and, if you keep *Report stale references* on, a declared account that holds no privilege or no longer exists (Low).

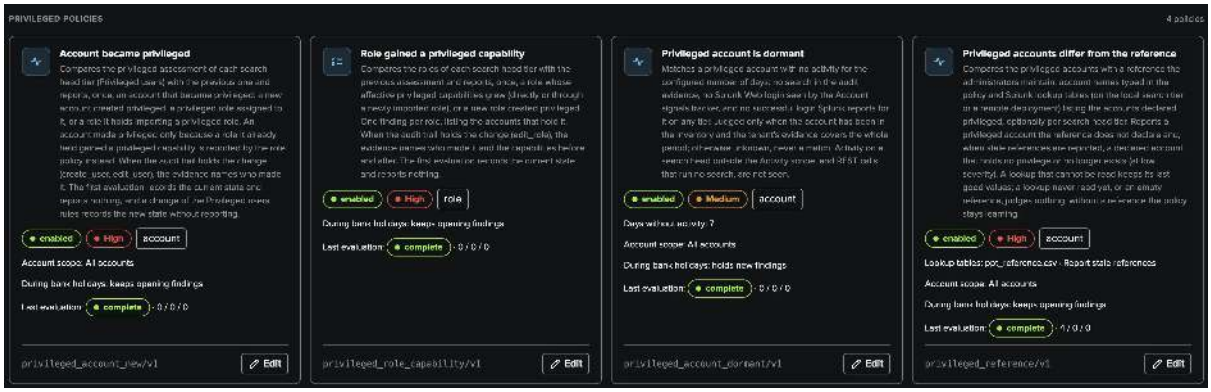
The reference is set in the policy editor, from two sources that add up, case-insensitive:

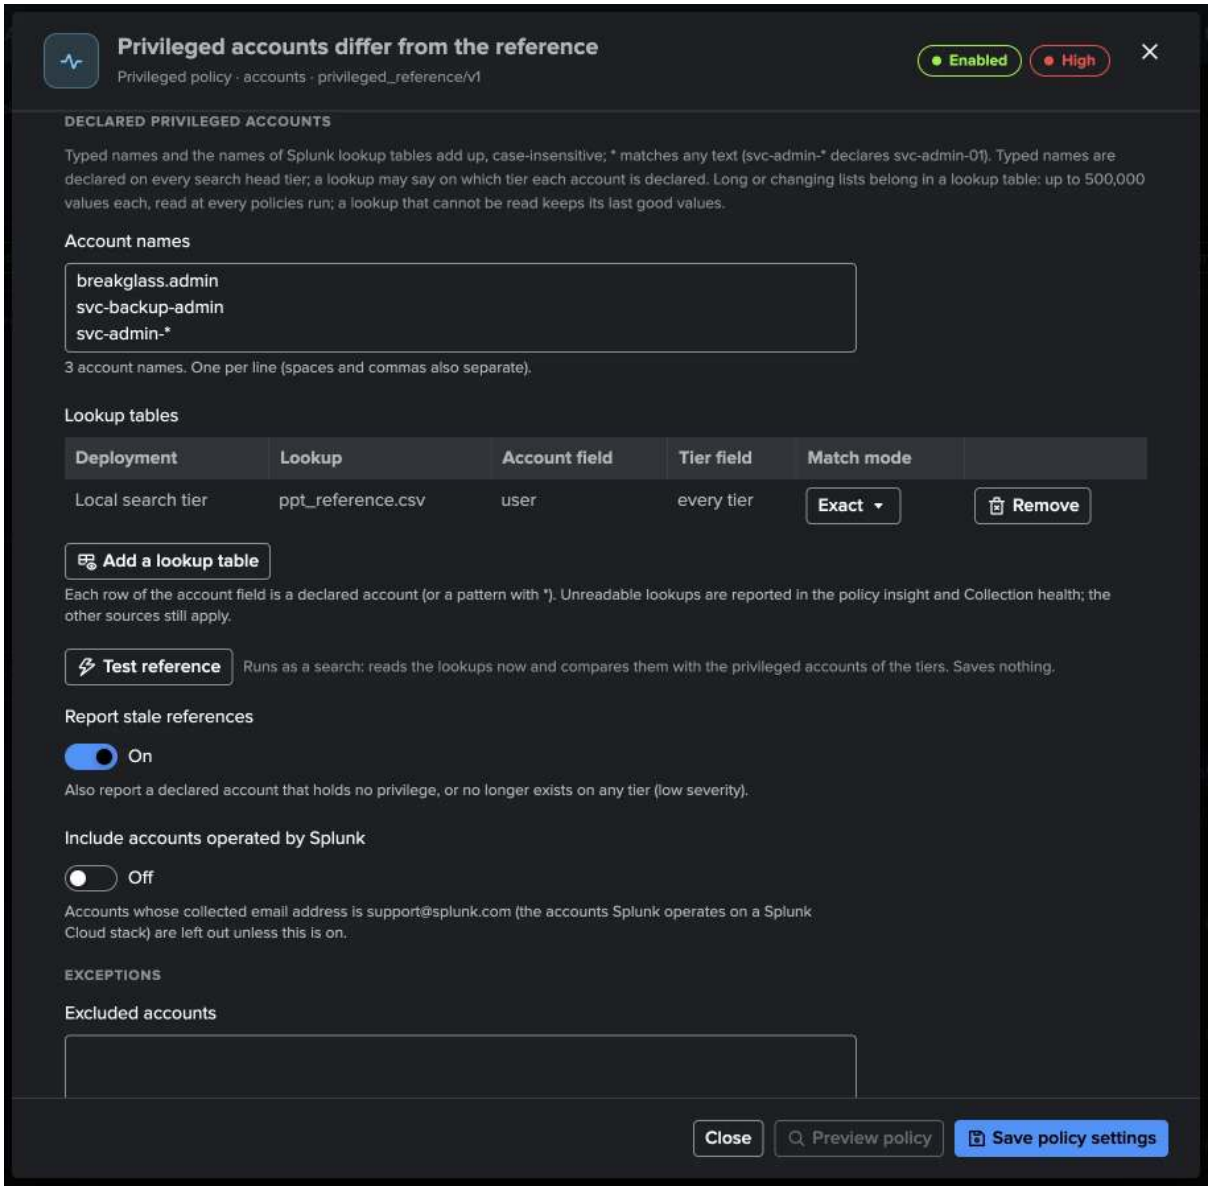
- **Account names** typed in the policy (up to 1,000), declared on every search head tier; `*` matches any text (`svc-admin-*`).
- **Lookup tables** (up to 20): **Add a lookup table** picks the Splunk deployment (the local search tier, or a remote deployment through a TrackMe remote account), the lookup (a CSV or KV store lookup shared with the TrackMe app, with a preview of its first rows), the **account field**, an optional **tier field** (the search head tier a row declares the account for: `local` or a remote account name; not set: every tier) and the match mode

— **Exact** (a value holding `*` is ignored) or **Wildcard**. Each lookup holds up to 500,000 values and is read at every policies run; a lookup that cannot be read, or reads empty, keeps its last good values, and one never read yet makes the policy judge nothing until it can be read. TrackMe's own lookups are not offered.

Test reference reads every lookup now, as a search, and shows what each source declares, the privileged accounts the policy would report as undeclared, the stale references and the patterns that declare nothing. It saves nothing.

The first evaluation of a change policy records the current state and reports nothing, and a change of the Privileged users rules records the new state without reporting. The accounts Splunk operates on a Splunk Cloud stack (their email address is `support@splunk.com`) are left out unless you include them. These policies never email the account a finding is about; notifications to operators work as for every policy. A role finding has no account to write to: *Send email communication* is not offered on it.





Privileged accounts differ from the reference
Privileged policy · accounts · privileged_reference/v1
Enabled
High
DECLARED PRIVILEGED ACCOUNTS
Typed names and the names of Splunk lookup tables add up, case-insensitive; * matches any text (svc-admin-* declares svc-admin-01). Typed names are declared on every search head tier; a lookup may say on which tier each account is declared. Long or changing lists belong in a lookup table: up to 500,000 values each, read at every policies run; a lookup that cannot be read keeps its last good values.
Account names
breakglass.admin
svc-backup-admin
svc-admin-*
3 account names. One per line (spaces and commas also separate).
Lookup tables

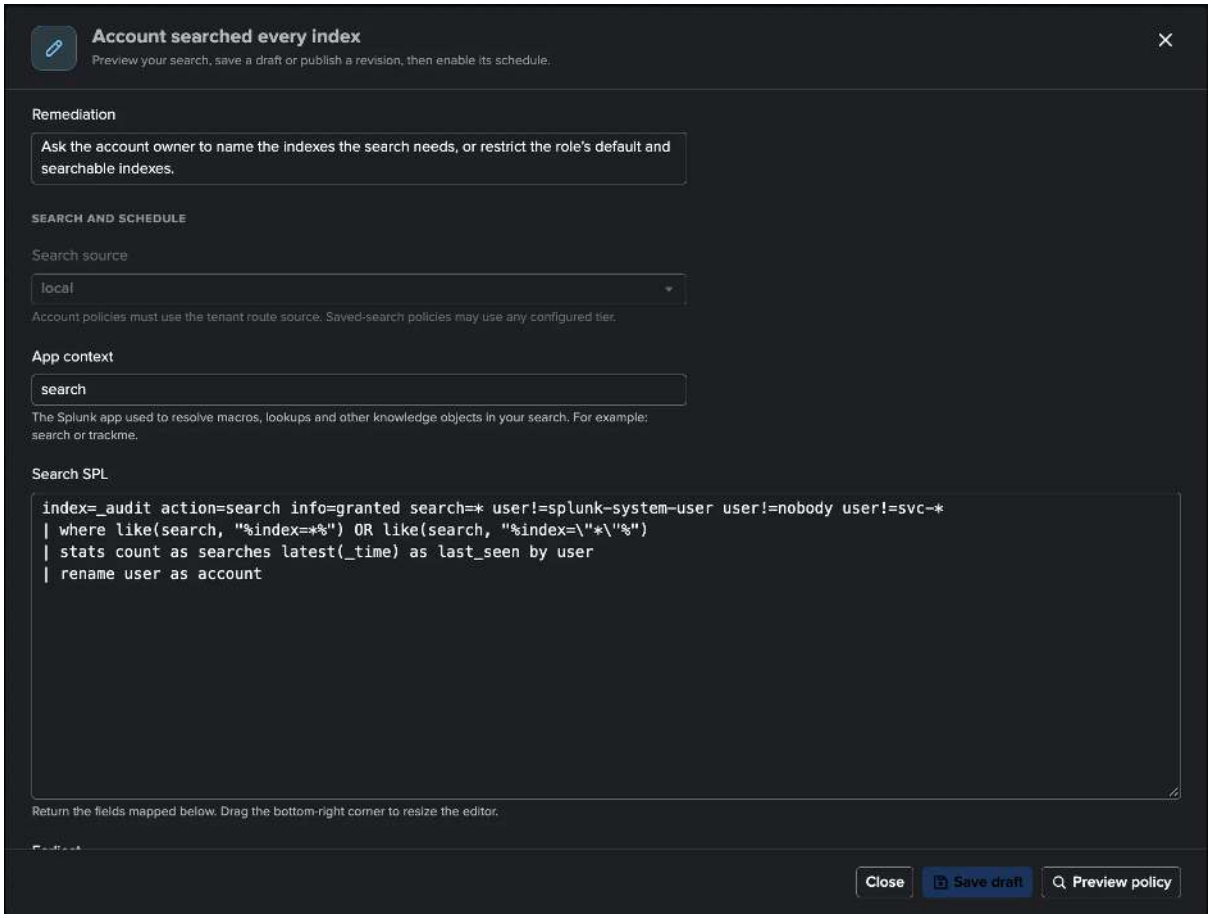
Custom policies

When the catalogue does not cover a rule of your own, write it in SPL: **Policies → Create policy** (TrackMe administrators of the tenant).

1. **Definition** — title, description, default severity and remediation.
2. **Search and schedule** — the search source (an account policy reads through the route account), the app context, the SPL (up to 64 KiB), a relative window ending now (at most 31 days) and a five-field cron.
3. **Map search results to findings** — the subject type, **Account** or **Saved search** (owner, app, name), and which result fields carry the identity, dimensions, evidence, count and time.
4. **Preview policy** — runs the draft as you and shows up to 20 candidate findings. A preview with no results cannot verify the mapping.
5. **Save draft**, **Publish** (an immutable revision), **Enable** (a scheduled search for the published revision). Version history lets you load, compare, restore or delete versions; **Disable**, **Archive** and **Delete permanently** end a policy (its findings, evidence and notes remain).



Account searched every index
Preview your search, save a draft or publish a revision, then enable its schedule.
Remediation
Ask the account owner to name the indexes the search needs, or restrict the role's default and searchable indexes.
SEARCH AND SCHEDULE
Search source
local
Account policies must use the tenant route source. Saved-search policies may use any configured tier.
App context
search
The Splunk app used to resolve macros, lookups and other knowledge objects in your search. For example: search or trackme.

The definition also has a **Bank holidays** section (see *Bank holidays*). Custom findings appear with the built-in ones, join the Finding groups and are triaged the same way. In this release, operator and user notifications cover the built-in policies only, and a custom policy writes its exclusions in its SPL. A tenant holds up to 100 custom policies, 25 of them enabled; their execution health is in *Collection health → Trackers*, family *Custom policies*.

Bank holidays

A UAM tenant uses the *bank holiday calendars* like every tenant: the system default calendars, unless it selects its own or none (*Manage Bank Holidays → Tenants & settings*, or *Configure tenant → Bank Holidays*). One effect applies to it, **Suppress new alerts**, shown as **Hold new findings** and on by default: while a holiday of the tenant's calendars is active, the **policies set to hold** open no new finding. SLA, monitoring windows and ML training do not apply to a UAM tenant.

Each policy chooses in its editor, under **During bank holidays**: **Hold new findings** or **Keep opening findings**. The defaults:

Holds new findings	Keeps opening findings
Scheduled search owned by a human account, **Scheduled search owner is not classified**, **Scheduled search exceeds the hourly schedule limit**, **Scheduled search has an all-time dispatch lower bound**, **Scheduled search uses a real-time dispatch range**, **CSV lookups attributed to an account exceed its size allowance**, **Privileged account is dormant**	**Account launched an unusual number of searches**, **Account ran repeated long searches**, **Account ran all-time searches**, **Account's search resource consumption exceeded its allowance**, **Account ran repeated resource-intensive searches**, **Account's CPU consumption is unusual for its daily baseline**, **Account became privileged**, **Role gained a privileged capability**, **Privileged accounts differ from the reference**

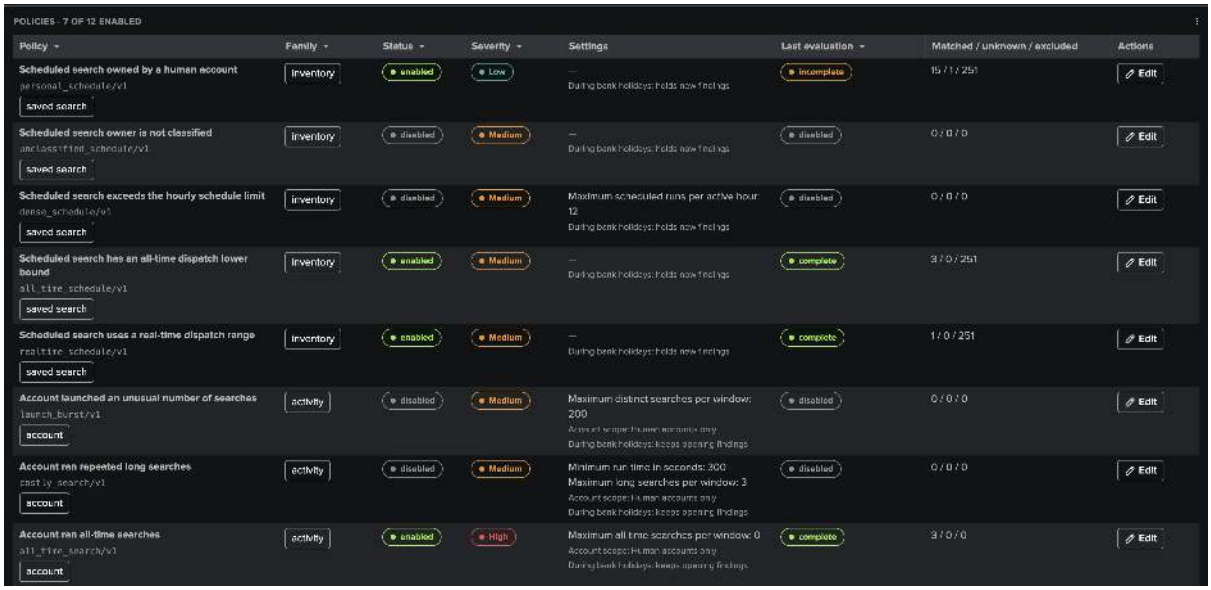
The inventory policies and the dormancy policy are reviews: nobody reviews them on a day off, and they are still there the next working day. A privilege granted on a day off is more telling, not less. The activity and resource policies keep opening findings, because unusual activity on a day off is more telling, not less. A configuration saved before TrackMe 2.4.19 reads each policy's default.

When a policy holds:

- An inventory policy holds while a holiday is active at the time of the run; an activity or resource policy holds when a holiday overlaps its activity window, so a burst on the last evening of a holiday is still a holiday burst.
- A held match writes nothing: no finding, no Finding group, no notification to operators or users, no findings action, and it uses none of the findings capacity. The first policies run after the holiday opens the finding if the condition is still there.
- A finding already observed is evaluated as on any other day: updated, escalated, or no longer observed. A held match does not reopen a resolved or dismissed finding.
- If the calendars cannot be read, nothing is held.

A **custom policy** keeps opening findings unless its definition turns the setting on (*Bank holidays* section of the custom policy editor; it takes effect when published). It holds while a holiday is active at the end of its search window.

Where to see it. Each policy on the Policies tab says *During bank holidays: holds new findings* or *keeps opening findings*. A policy that held matches shows *held N (bank holiday)* under its last evaluation, and its policy insight says *Held N (bank holiday: <names>)* with a **Bank holidays** line for the run. The policies run receipt records the state (holding, off or unavailable), the holiday names, the matches held and the enabled policies set to hold; a custom policy run records what it held the same way.



Upgrading to TrackMe 2.4.21

- **Three trackers for the indexing layer.** What the activity tracker did in one run is now **Audit activity**, **Resource usage** and **Account signals**, each with its own schedule, time budget, lock and health. The two new reports are created automatically within five minutes of the upgrade, with the tenant's owner; they continue where the earlier tracker stopped, and nothing is collected twice.
- **No row limits any more.** The seven record-count settings of *Collection limits* are removed: what a run cannot finish in its time continues at the next run. Stored values are ignored and disappear at the next save; an API client that still sends them keeps working.
- **New time budgets.** Every run budget defaults to its tracker's interval less 30 seconds. A budget still at its earlier default moves to the new one; a value you chose is kept. A scheduled run dispatched late ends 30 seconds before the next scheduled run, so the scheduler never skips one.
- **Correlated executions are no longer indexed.** They are correlated from the audit records when they are read. Your own searches, dashboards, alerts or custom policies on `sourcetype=trackme:uam:execution` return nothing for activity after the upgrade: move them to `sourcetype=trackme:uam:observation`. The UAM events also carry fewer fields (see *The evidence*).
- **Backfill.** A new tenant starts without backfill unless you choose a range, in 5-minute buckets. An existing tenant keeps its bucket size; set *Backfill bucket (s)* to 300 to move it to 5-minute buckets (the coverage already collected is kept).
- **Splunk restart.** Some index-time settings of the UAM events take effect after the splunkd restart of the upgrade, on the instances that parse the UAM log.
- **Privileged users and privileged policies.** The Privileged users tab and its settings appear with the release defaults (`*admin*`, `trackme_admin` excluded). The four privileged policies are off; when you turn on a change policy, its first evaluation records the current state and reports nothing. The users catalog now also collects the last successful login Splunk reports (never an inventory change).

Upgrading from TrackMe 2.4.18

- The first policies runs gather the existing findings into Finding groups; decisions, notes and history are kept.
- The inventory moves to the REST API catalogs: each tier gets its new knowledge-object reports, and its first full listing runs within the hour. The users and roles reports move from a 5-minute to a 15-minute schedule.
- The UAM Findings Advisor is replaced by the UAM AI Agent; an enabled advisor's settings are carried over once.

Where to go next

8.3.15 User Activity Monitoring — reference

This page is the reference companion of *User Activity Monitoring*: the tenant model and the search head tiers, every report and its schedule, the knowledge-object catalogs, the historical backfill, the indexed evidence, identity and classification, privileged users, the catalogue of built-in policies, custom policies, the findings lifecycle and Finding groups, notifications and communications, the UAM AI Agent, Collection health and the Configuration Guardian check, every setting, the roles and licence, the REST endpoints, the upgrades and the troubleshooting table.

For the task-oriented guide (creating a tenant, reading the workspace tab by tab, triaging a finding), read *User Activity Monitoring*. The concepts User Activity Monitoring shares with the other findings tenants — Finding groups, triage, assignment, notifications, findings actions, Webhook accounts and the AI Agents — are explained once in *Findings, Finding groups and findings actions*. For a narrated end-to-end walkthrough, read the *User Activity Monitoring white paper*.

The tenant model

User Activity Monitoring (UAM) is a **dedicated tenant type**, created from the *User Activity Monitoring* card of the tenant creation wizard:

- A tenant is either an entity tenant (DSM, DHM, MHM, FLX, FQM, WLK, VOL) or a UAM tenant, never both. Creation refuses a mix (`uam_tenant_must_be_dedicated`), the *Manage components* menu is disabled on a UAM card, replica trackers are refused and the add / remove component endpoints answer `uam_tenant_is_dedicated`.
- There are **no entities**: no decision maker, no impact score, no green / orange / red state, no stateful alerting, no priority / SLA / logical group. The unit of work is the **finding**, triaged as a **Finding group**.
- A UAM tenant watches **one indexing layer seen through one to ten search head tiers**: the accounts (human, service or system) and their search activity, their resource cost (CPU, peak memory, share of the environment) and their knowledge objects; the saved searches and the other knowledge objects of each tier; and the policies — sixteen built in, plus the custom policies you write — that raise findings about them.
- **Evidence lives in indexes, state in the KV store.** Collection runs in scheduled searches, never in a REST handler.
- The tenant identifier of a UAM tenant is short — lowercase letters, digits and hyphens, up to 20 characters — because it keys the per-tenant collections and reports.
- The Virtual Tenants card shows the open and high / critical findings and the collection problems; a double-click opens a read-only overview. Tenant Home opens the UAM workspace (tabs Findings, Users, Privileged users, Activity, Scheduled searches, Policies, Audit changes, Collection health, AI Agent and Settings, described in *User Activity Monitoring*).

Note

What UAM claims, and what it does not. An account is the principal **reported by Splunk** in the audit records — not a verified person. Distinct search ids are a launch-count proxy. Collection is bounded by time only and resumable: nothing is dropped to fit a row count, and what a run cannot finish continues at the next run. Coverage still depends on what the sources retain and what the collection accounts can see: gaps and partial coverage are recorded and shown (receipts, *Collection health*), never hidden. There is no machine learning: the daily CPU deviation rule compares against a percentile baseline.

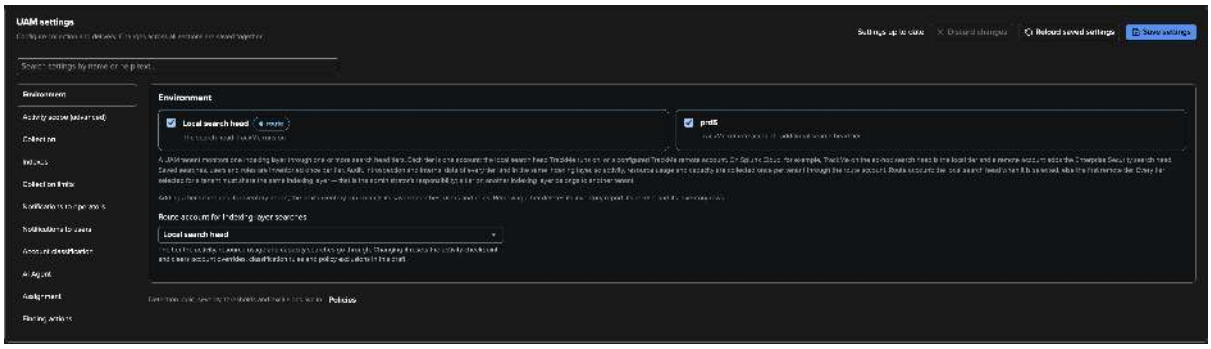
Per-tenant storage

KV collection	Content
`kv_trackme_uam_settings_tenant_<t`	The configuration, the checkpoints, the latest receipt and the lock of every job, the capacity, the detection records, the notification outbox, the user notification state and the private contact store.
`kv_trackme_uam_inventory_tenant_<`	The policy inventory: one row per saved search, user, role and CSV lookup file, per tier, with `present`, first / last seen and the owner's class.
`kv_trackme_uam_knowledge_tenant_<`	The published knowledge-object catalogs and their definitions (administrator access only, no lookup).
`kv_trackme_uam_findings_tenant_<t`	One row per finding, with its investigation state and its Finding group.
`kv_trackme_uam_finding_groups_ter`	One row per Finding group (automatic or manual).
`kv_trackme_uam_custom_policies_te` / `kv_trackme_uam_custom_policy_sta`	Custom policy definitions (drafts, published revisions) and their execution state.
`kv_trackme_uam_actions_tenant_<t:`	Findings actions definitions and automation rules.

The settings, inventory and findings collections each have an administrative lookup `trackme_uam_<kind>_tenant_<tid>`. Two global collections serve every UAM tenant: `kv_trackme_uam_agent_decisions` (the UAM AI Agent decision log, 90-day retention) and `kv_trackme_uam_custom_execution` (custom policy execution slots).

Search head tiers and the route account

One indexing layer, one to ten search head tiers:



Data	Lives on	Collected
Saved searches, users, roles, lookup files and the other knowledge objects	each search head tier	**once per tier**, from the Splunk REST API
`_audit` activity, `_introspection` resource usage, search completion lines	the indexing layer (every tier forwards its internal indexes there)	**once per tenant**, through the route account

- **Search head tiers** (`tiers`) — 1 to 10 unique names: `local` (the search head TrackMe runs on) and / or TrackMe remote accounts (see *Remote Splunk deployments*), one account per tier. Every selected tier must feed the **same indexing layer**; that invariant is the administrator's responsibility. The wizard tests every remote tier and waits until each is reachable.
- **Route account for indexing-layer searches** (`account`) — the tier through which activity, resources, capacity and the audit lookups are read: `local` when selected, else the first tier. It must be one of the tiers.
- A user present on several tiers is **one account** (roles united, tiers listed); a saved search belongs to its tier. Each tier has its own reports, locks and receipts, so a slow tier never starves another and a skipped tier is visible on its own.
- Typical shapes: on Splunk Cloud, TrackMe on the ad hoc search head (`local`) plus a remote account for a premium-app search head; on Splunk Enterprise, any number of remote accounts over the same indexers; for central monitoring, remote accounts only.
- A search head that keeps its internal indexes local (no forwarding of `_audit` / `_introspection`) hides its searches, logins and resource usage from the tenant — the forwarding prerequisite applies to every signal alike.

Activity scope (advanced)

The tiers select **REST connections** for the inventory; they do not restrict which events are read in a shared indexing layer, so a search head that is not a tier still contributes activity, classification evidence and resource cost. **Activity scope** (`search_head_scope`, wizard and *Settings*) restricts the activity to search head hostnames:

- `include` and `exclude` — up to 20 hostname patterns each (1 to 253 characters), matched case-insensitively on the whole hostname; `*` matches any characters, `?` one character, everything else is literal. No SPL, no regular expression.
- Both empty (the default): every origin. An empty include list means every origin except the exclusions. **Exclusions win.**
- Include every member of a cluster. Excluding only the cluster members does not exclude a management node that also runs searches; to isolate one search head tier completely, include its hostnames.
- The scope applies to the live collection and to the backfill: audit records, logins, automation evidence, resource records (indexer samples are mapped back to the search head of their search; an ambiguous mapping is excluded and reported as incomplete coverage), completion CPU and the capacity's search head part. A change starts a new scope.
- The scope is written into the **base searches**, so the indexers return only what can be in scope instead of every search head's events. The audit, login and automation reads filter on `host` (indexed metadata, matched case-insensitively); the resource and capacity reads keep the in-scope search heads' samples and the indexer processes of their searches (`remote_<search head>` origins), so the capacity lists the indexers that serve the scope. The base-search terms always select at least what the exact rule keeps. An exact name or a name ending in `*` is the filter itself. An include holding `?` or an inner `*` is written on its literal prefix (`team-*.example.net` → `team-*`; an include without one, such as `*.example.net`, leaves the includes out of the base search), an exclude of that kind is not written in the base search, and the exact rule is applied after the base search, so nothing in scope is ever skipped. Patterns written as exact names or with a trailing `*` filter the most at the source. A tenant without a scope runs the same searches as before.
- It is a monitoring rule, not an access-control boundary: nothing is deleted from the source indexes.

Reports and schedules

Provisioning creates every report of the tenant and schedules them at once. Each report runs `| trackmeuam-tracker tenant_id=<tid> job=<job>` (or its own command) as the **tenant owner**, with its own **lock**, its **receipt** (the outcome of the latest run, kept in KV and indexed as `trackme:uam:receipt`) and its entry in the tenant's operational status.

Report	Schedule	Does
`trackme_uam_activity_tracker_te` (**Audit activity**)	`*/5 * * * *`	The audit trail from a durable ingestion checkpoint through the route account, the delayed recounts and re-reads of its ranges; CSV writer hints.
`trackme_uam_resources_tracker_t` (**Resource usage**)	`2-59/5 * * * *`	The CPU and memory of every search, window by window from its own checkpoint, their re-reads, and the hourly search capacity. Unscheduled while resource collection is off.
`trackme_uam_signals_tracker_ten` (**Account signals**)	`9-59/15 * * * *`	The Splunk Web logins and the automated searches of the audit trail, up to where the audit activity has read, for the human and service account detection.
`trackme_uam_data_usage_tracker_` (**Data usage**)	`4-59/15 * * * *`	The indexes each audited search names, from its own checkpoint in the audit trail, resolved through the published catalogs of the search's tier; the indexers' confirmations on distributed deployments. See *Data usage*.
`trackme_uam_policies_tracker_te`	`3-59/15 * * * *`	Evaluates the built-in policies, writes findings and Finding groups, expires temporary dismissals, delivers operator and user notifications, runs the automation rules.
`trackme_uam_inventory_tracker_t`	`*/15 * * * *`	Summarises the published catalogs of the tier for the policies run (reads no source).
`trackme_uam_listing_tracker_ten`	hourly wake (`37 * * * *`)	Lists every saved search of the tier when due: every *Catalog collection every* hours (24) inside the off-peak window (01:00 for 5 hours, search head local time). A tier's first listing runs at the next hourly wake, whatever the window. A listing longer than its budget continues at the next wake its window allows.
`trackme_uam_kos_users_tracker_…` / `…kos_roles…`	15-minute wake	Users (with the email address for user notifications) and roles, read every *Users and roles every* minutes (60).
`trackme_uam_kos_lookup_files_tr`	15-minute wake	CSV lookup file metadata (size, owner, modification time; never the contents), read every 15 minutes.
`trackme_uam_kos_<family>_tracke` × 10	hourly wake, each at its own minute	The ten other knowledge-object families, on the catalog cadence, in the off-peak window.
`trackme_uam_backfill_tracker_te`	`17 * * * *`	The history before the live start, bucket by bucket; retires itself when done.
`trackme_uam_custom_<id>_tenant_`	the policy's own cron	One per enabled, published custom policy.
`trackme_uam_agent_tracker_tenan`	hourly, at a minute derived from the tenant	The UAM AI Agent's scheduled triage; created unscheduled, scheduled only when AI is available and the tenant enables it.

The per-tier catalog reports are named `trackme_uam_kos_<dataset>_tracker_tenant_<tid>_tier_<tier>`. The tracker schedules are fixed; the cadences inside them (*Catalog collection every*, *Users and roles every*, the listing window) are settings.

Run budgets

Time is the only bound of a run: what a run cannot read in its time continues at the next run through its checkpoint, never cut to fit a row count. Every budget defaults to its tracker's interval less 30 seconds, the margin covering the run's own writes before the next scheduled run:

Tracker	Setting (key)	Default
Audit activity	*Audit activity max seconds per run* (`activity_max_seconds`)	270 s (30–900)
Resource usage	*Resource usage max seconds per run* (`resources_max_seconds`)	270 s (30–900)
Account signals	*Account signals max seconds per run* (`signals_max_seconds`)	870 s (30–900)
Data usage	*Run budget* in *Settings → Data usage* (`data_usage_max_seconds`)	870 s (30–14,000)
Saved-search listing and catalogs	*Full listing budget* (`inventory_listing_max_seconds`)	3,570 s (300–14,000)
Historical backfill	*Backfill max seconds per run* (`backfill_max_seconds`)	3,570 s (600–3,570)

No skipped runs. The scheduler may dispatch a run up to five minutes late, and it skips a run whose previous run is still going. A scheduled run's budget is therefore capped to end 30 seconds before the tracker's next scheduled run; a run dispatched so late that less than 15 seconds would remain records a skip (`dispatched_after_schedule_cutoff`) instead of starting. The receipt records the budget applied (`run_budget`: the seconds, whether they were capped and by how much the dispatch was late), and the tracker's Duration in Collection health explains a cap.

Each indexing-layer tracker keeps a share of its own budget for its re-reads, recounts or capacity refresh only when some are due; nothing is shared between trackers, so a slow resource read never takes time from the audit trail, and the other way round.

Collect now, Run now and manual collection

- **Collect now** (workspace status strip) runs every tier's inventory summary, then the audit activity, the resource usage and the account signals, then the policies, and every tier's full saved-search listing. The other catalog families record a request their reports pick up at their next wake.
- **Run now / List now** (*Collection health*) dispatches one tracker.
- With **Scheduled trackers** off, nothing runs on a schedule: collection only happens on request. Scheduled collection requires a tenant owner (`scheduled_collection_requires_tenant_owner`).
- A scheduled run never blocks the workspace. A *Collect now* refused because a run holds the lock (`uam_job_running_or_recovery_required`) is explained, not reported as an error.

Locks and recovery

One run per tracker at a time. Locks carry the local server GUID and the search id and are **never stolen by age alone**:

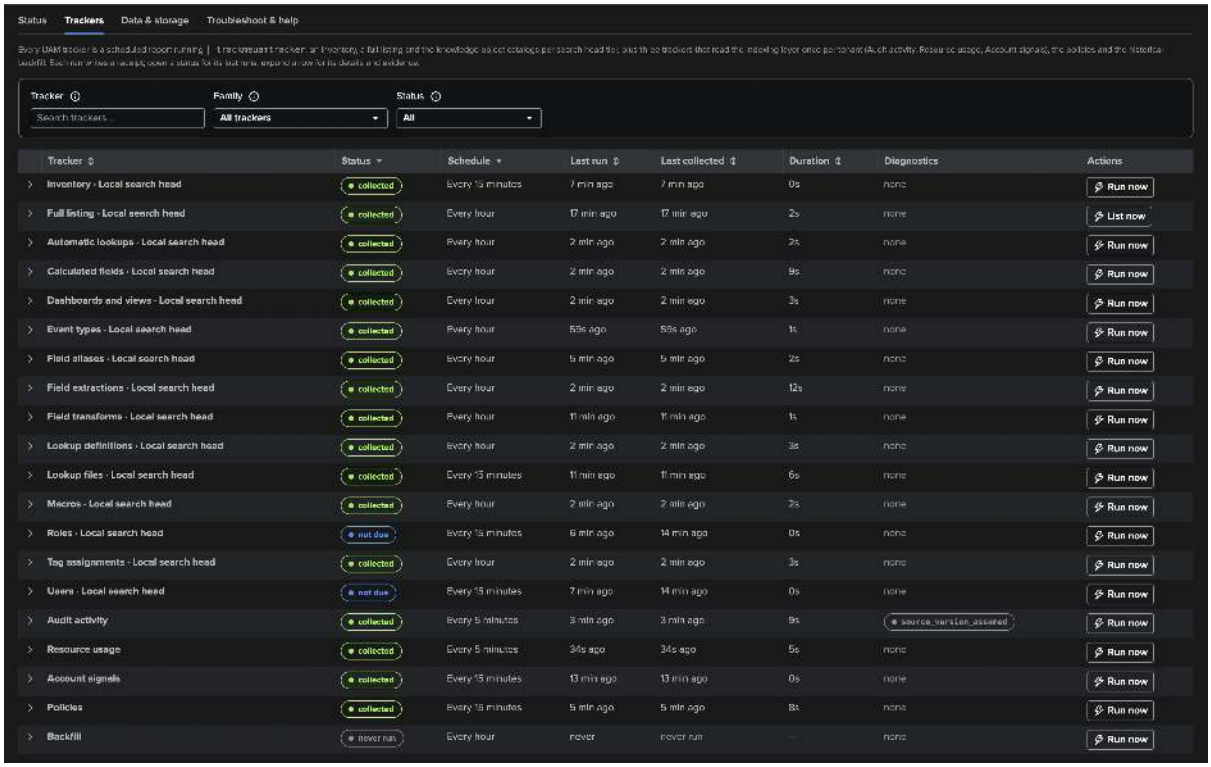
- A lock at least five minutes old whose search job has provably stopped **on the same search head** is recovered automatically at the next acquisition.
- **Recover stopped run** (*Collection health*, `POST recover`) does the same on demand.
- Locks held by another cluster member, locks without a search id and configuration locks without job ownership are never recovered automatically: verify the originating process on its search head.
- The tenant lifecycle (delete, enable, disable, RBAC) has its own guard bound to the process that holds it, so a request whose process died never blocks the tenant for good.

Knowledge-object catalogs

The inventory is read from the **Splunk REST API only** — no `_internal` or `_audit` search is used to discover objects or changes. Each dataset of each tier is its own scheduled traversal:

Family (account view tab)	Datasets	Cadence
Saved searches & alerts	Every saved search (reports and alerts), with owner, app, sharing, cron, dispatch bounds, enablement and the definition.	*Catalog collection every* (24 h), off-peak
Users and roles	Users (with their email address, kept in a private store) and roles.	*Users and roles every* (60 min)
Lookups	CSV lookup files (metadata only), lookup definitions, automatic lookups.	Files every 15 min; the others on the catalog cadence
Dashboards	Dashboards and views.	Catalog cadence
Macros	Macros.	Catalog cadence
Event types	Event types.	Catalog cadence
Fields	Field extractions, field transforms, field aliases, calculated fields.	Catalog cadence
Tags	Tag assignments.	Catalog cadence

- Every traversal is paged (*Inventory page size*) and bounded by time (*Full listing budget*), never by a record count, and **publishes a complete generation or nothing**. A traversal that does not finish within its budget continues at the next run of its tracker, from where it stopped, in a staging generation, and is published once complete; until then the previous catalog stays in use and keeps the policies complete. Collection health shows such a run as collected with *Listing continues next run*; *Listing made no progress*, *Listing restarted (access refused)* and *No page read in time* are the warnings, and a listing carried over for more than seven days starts over. A failed traversal keeps the last good catalog. Only one traversal runs at a time per tenant and tier; a busy report waits for its next wake.
- **Definitions** — saved search SPL, macro bodies, event type searches, dashboard source, field expressions, lookup configuration, tag assignments — are kept up to 256 KiB per object in the administrator-only knowledge collection, from an explicit attribute list (never credentials, never CSV contents). They are not executed, indexed or copied to the policy inventory. Older generations (other than the current and the previous one) are deleted after 30 minutes.
- **CSV lookup sizes before Splunk 10.4.** The lookup file listing gives no size before Splunk 10.4 (Splunk 10.4 and later report it, with no extra access); UAM then reads the size and modification time of each CSV lookup file listed without one through `admin/file-explorer`, one lookups directory at a time (the path only locates the file and is never stored). The tier's collection account must be allowed to read that endpoint, which by default only `admin` and `splunk-system-role` can: a least-privilege account cannot retrieve CSV lookup sizes before Splunk 10.4. A refusal is reported as `lookup_size_access_denied` (*Lookup sizes refused*), never as a partial listing.
- Each saved search, user, role and lookup file is diffed against its previous row: a new row is `added`, changed fields `changed` (with `changed_fields`), a classification change alone `reclassified`, a row seen again after removal `reappeared`; a row absent from a **complete** traversal is marked `present=false` — never deleted. A partial traversal marks nothing removed. Each change is indexed as `trackme:uam:inventory`.
- The catalogs reflect what the tier's account can see: coverage of private objects depends on its permissions. A traversal is not an atomic snapshot.
- Where they appear: the account view's owner catalogs (*Saved searches & alerts*, *Dashboards*, *Macros*, *Event types*, *Fields*, *Lookups*, *Tags*), **Search knowledge objects** on the Users tab (across every owner), the saved search view, and *Collection health → Trackers* (family *Knowledge object catalogs*). Tenant administrators only.



Activity

The **Audit activity** tracker reads the `_audit` trail from a **durable ingestion-time checkpoint**. Time is the only bound of a run: nothing is cut to fit a row count, and what a run cannot read in its time continues at the next run.

1. It loads the checkpoint, or initialises it at *now* − *window* on the first run or when the environment changed (`checkpoint_reset` on the receipt).
2. It reads ranges of up to *Activity window* (300 s) from the cursor, less the part of the *Activity overlap* still owed, until it catches up (*now* − *10 s*) or its budget (*Audit activity max seconds per run*, 270 s) is spent. Both audit formats are evidence: the legacy `Audit:[…]` key=value line and the structured JSON record. The rows are normalised and correlated by search id.
3. **A busy range is split, never cut.** A range holding more audit lines than one read returns, or that Splunk finalized, truncated or reported with dropped results, is halved, down to one second, and a one-second range is read whole, streamed in ingestion order.
4. **A range cut by the run's budget resumes** at the next run after the last line it wrote (`resume_next_run`); near the live edge it is read again from its first line instead, so a line indexed a moment late is not missed.
5. **A failing range is held and retried, never skipped** (`window_held`): it is retried at once within the run, then at the next runs, and halved after three failures to isolate the failing span. A range held for 15 minutes is a Collection health problem.
6. **Indexers that do not answer.** A range read while some search peers did not answer keeps what the others returned and is listed to be **read again** once every peer answers (`window_reread_pending`), with a back-off of 5 minutes up to an hour. The re-read writes only the lines missing the first time.
7. **Late lines are recounted.** About ten minutes after a range is closed, it is counted again with the same search; more lines than were written lists the range for a re-read (`window_recount_mismatch`).
8. The overlap and a ledger of what was written make sure **nothing is written twice**, resumed, retried and re-read ranges included. The checkpoint is persisted after **every** range.
9. Splunk's search messages are recorded, never interpreted: only a clear failure (a failed or cancelled job, a broken read) discards a search. Evidence-quality diagnostics (`normalization_gap`, `locator_conflict`, `invalid_event_envelope`, `unsupported_source_contract`) are recorded but never block.

The same run records the **CSV lookup writes** it saw (probable writer hints for the CSV policy). The resource usage, the capacity and the login and automation scans are trackers of their own (below).

Account signals

The **Account signals** tracker (every 15 minutes, *Account signals max seconds per run*, 870 s) scans the audit trail for **Splunk Web logins** and **automation** evidence (searches run by the scheduler, the REST API, acceleration), the signals behind the human and service detection (see *Data usage*). Each scan has its own cursor and trails the audit activity's cursor without ever holding it; the login scan takes up to half of the budget, the automation scan the rest. A scan range that cannot be read is listed to be read again, like an audit range. Before the first audit activity run, the tracker waits (`account_signals_wait_for_activity`).

Source contract. The audit source contract is the **format**, never the Splunk version: a line that parses as the legacy key=value grammar or the structured JSON is evidence. The qualified families are Splunk Enterprise 9.4, 10.4 and 10.6 and Splunk Cloud 10.5; any other version is read all the same and only adds the soft diagnostic `source_version_unqualified`. With *Source version assumption* on (the default), emitters whose version could not be verified are parsed under the connected head's version and labelled `assumed`.

Resource usage and CPU accounting

With *Collect search resource usage* on (the default), the **Resource usage** tracker (every 5 minutes, two minutes after the audit activity, *Resource usage max seconds per run*, 270 s) reads the resource records window by window from its own checkpoint and writes one `trackme:uam:resource` record per search and account: CPU seconds, the part spent on the indexers, peak memory, elapsed time, node count, and Splunk's own search type, provenance, mode and label. Its reads are paged and resumable like the audit's: every search of a window is kept, a window read while peers did not answer is collected again and replaces the earlier collection, and the policies never count a replaced collection. With resource collection off, the report is unscheduled and not assessed.

CPU follows Splunk's own accounting where it exists, decided per window and per tier (search head, indexers) from the data:

- Splunk Cloud 10.5 accounts CPU at search completion (the audit `cpu_time` on the search head, the indexers' completion lines). A tier with a completion figure counts its CPU once, at completion.
- A tier without one keeps the CPU integrated from the `_introspection` per-process samples (Splunk Enterprise 10.4).
- Every record carries `cpu_source` (`completion`, `head_completion`, `peer_completion` or `introspection`). Real-time searches always use sampled CPU.
- Peak memory reads **not measured** for a search no introspection sample caught (short searches in pooled processes on Splunk Cloud).

The **capacity** — the cores and memory of the *search hosts*, the nodes that ran a meaningful share of the search processes (a utility node running its own few searches is listed but kept out of the basis) — is refreshed at most hourly by the Resource usage tracker and drives the automatic budgets of the resource policies. With an activity scope, it counts the search heads in scope and the indexers that serve them. A failed refresh keeps the previous record.

Policies run

Every 15 minutes the policies job:

1. reads the present inventory rows of every tier under the inventory lock (a long inventory publication makes it wait up to 90 seconds, then fail with `inventory_publication_in_progress` and retry at its next schedule) and evaluates the **inventory** policies with the completeness of each tier's catalogs;
2. aggregates the indexed audit and resource records of the *Activity policy window* (15 minutes) and evaluates the **activity** and **resource** policies per account. The window ends where the collected evidence ends — the audit activity cursor, and the resource cursor when a resource policy is enabled — never at the current time, and never starts before the collected history. Consecutive windows always touch (with less than a whole window of new evidence, the window reaches back into what was already evaluated), so no minute is skipped; a run evaluates a further window only for a whole window of new evidence. Every aggregation is read whole; one Splunk reports as partial (missing peers, truncated output) is refused, and its window is evaluated again;

3. reconciles the findings and the Finding groups under the findings lock (see *Findings and Finding groups*), expires temporary dismissals, publishes the counts the card reads and writes one `trackme:uam:finding` event per transition;
4. delivers the operator notifications and the user notifications, and runs the automation rules (fail-open: a delivery failure never fails the run).

The receipt stores one **evaluation** per policy (enabled, state, evaluated / matched / excluded / unknown / not applicable counts, readiness, thresholds source) and its bounded **insight** (see *Policy insight and preview*). Completeness is per family: inventory findings are marked not observed only when every tier's catalogs are complete, audit findings when the activity window was complete, resource findings when the resource coverage is complete on top. A rule whose aggregation failed is `incomplete` and neither creates nor clears anything. There is no findings limit: every match opens a finding. A very large live investigation queue (more than 50,000 findings one run can change) raises the Collection health warning `findings_working_set_large`; nothing is refused.

Bank holidays. A UAM tenant takes one effect of the *bank holiday calendars*, **Suppress new alerts** (*Hold new findings*). While a holiday of the tenant's calendars applies and the effect is on, the policies set to hold (`policies.<policy id>.hold_on_bank_holidays`, defaults in *The built-in policy catalogue*) open no new finding:

- The run reads the holidays once, only when an enabled policy holds: the holidays that overlap the evaluated activity window, then the tenant's calendars and effect. The outcome is `holding`, `off` (a holiday applies but the tenant does not hold) or `unavailable` (the calendars could not be read: nothing is held, a warning is logged).
- An **inventory** policy holds while a holiday is active at the time of the run (it judges the configuration as it is now). An **activity** or **resource** policy holds when a holiday overlaps its activity window: a burst on the last evening of a holiday is a holiday burst, even when the run comes after midnight.
- A match of a held policy whose finding does not exist, or is not observed (resolved, dismissed, or not seen by the previous run), is skipped before the capacity check: no finding, no Finding group, no transition, no `trackme:uam:finding` event, no operator notification, no findings action, and no findings capacity used. The direct user notifications leave its state untouched: a held match is neither a detection nor a step towards a recovery.
- A finding already observed is evaluated as on any other day (updated, escalated, no longer observed); expiries and housekeeping are unchanged. A held match never makes the run incomplete, and the first run after the holiday opens what was held.

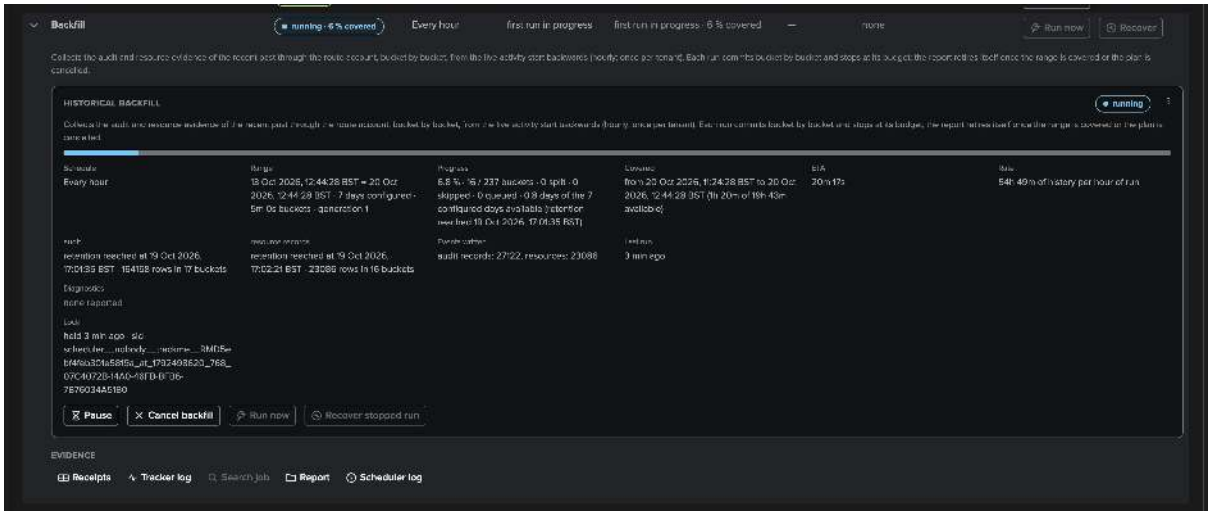
When the outcome is not "no holiday", the receipt carries `bank_holidays`: `state`, `names` (up to five holidays), `held` (the matches held) and `policies` (the enabled policies set to hold). Each evaluation that held carries its own `held` count, and the findings counters carry `held` while the run holds. The `policy_evaluation` endpoint returns the run's `bank_holidays`.

Historical backfill

The backfill report collects the audit and resource evidence of the configured range before the live activity start (*Backfill days*: none — the wizard's preset —, 7, 14, 30, 60 or 90 days in the wizard, 0–90 in *Settings*), through the route account. Evidence in an index cannot be taken back, so the backfill **never collects a span twice**, and nothing is skipped:

- The **plan** ends exactly where the live activity started and **waits** until the first audit activity and resource usage runs have set that point (`backfill_waits_for_first_activity_run`, `backfill_waits_for_first_resources_run`, normal receipts).
- **Fixed buckets** (*Backfill bucket*, 5 minutes by default) are walked **backwards**, newest history first, one audit read and one resource read each, with the live collection's reads: a busy bucket is split, down to a few seconds read whole.
- **A failing bucket is deferred, never skipped.** Before any bucket succeeded in a run, a failure stops the run (a source that is down costs one attempt per hour, and the run is reported failed). Once one succeeded, the deferred buckets get their next attempt and the run goes on past a failure; three failures in a row stop it (`backfill_source_failing`). A bucket that keeps failing is halved to isolate the failing span.

- **A bucket cut by the end of its run resumes** at the next run after the last line it wrote; a run stops at *Backfill max seconds per run* (3,570 s). A bucket read while some peers did not answer is listed to be read again, like a live range.
- **Retention edges** come from the sources: the plan stops at the oldest `_audit` and `_introspection` data (`retention_reached`). The introspection retention is usually shorter (about two weeks), so the resource history may end earlier than the audit history.
- **Re-plans carry the coverage forward**: a changed range or bucket size, or *Plan again*, starts a new plan where the previous one stopped; a range already covered completes at once. A complete or cancelled plan un-schedules the report; `backfill_days = 0` disables it.
- The backfill also scans each bucket for Splunk Web logins and automation evidence, so the people and services already active when the tenant was created are classified without waiting. It does not record CSV writer hints, and the inventory is never backfilled.
- Controls in *Collection health* → *Trackers*, on the expanded **Backfill** row: **Pause** (after the current bucket, progress kept), **Resume**, **Cancel** (retires the report; collected buckets stay indexed), **Plan again**, and **Run now**. The receipt carries the buckets done / split / retried / deferred / resumed, the events written, the progress (percent, estimated end from the measured rate) and the plan status. An existing tenant keeps its bucket size: set *Backfill bucket (s)* to 300 to move it to 5-minute buckets; the plan is rebuilt and the coverage already collected carried forward.



Receipts and diagnostics

A receipt is **value-free**: counts, statuses, diagnostic codes and window bounds — never an account name, a search text or a credential. *Collection health* renders the latest receipt of every job and the last seven days of runs from the indexed receipts, each diagnostic explained. A completed run with zero observations is a successful run: absence of activity is not a failure. A completed run is not a lossless-ingestion guarantee — the receipt says what was covered.

The evidence

Evidence events are written to the dedicated `trackme_uam_events.log` under `$SPLUNK_HOME/var/log/splunk` (UAM writes one line per search, so it never shares the state-events file of the other components) and routed by TrackMe's ingest evaluation to the target index of their family.

Sourcetype	Family	One record per	Main content
`trackme:uam:observati`	evidence	Search and window	The account and app, the search id, type and status, the run metrics, the time bounds (the `N/A` all-time marker included) and the grant.
`trackme:uam:resource`	evidence	Search and window	The search's resource usage: CPU seconds (search head and indexers) with their source, peak memory, elapsed time, nodes and samples.
`trackme:uam:inventory`	evidence	Inventory change	The object's fields, the change (added, changed, removed, reappeared, reclassified) and the fields that changed.
`trackme:uam:data_usage`	evidence	Index reference and batch	One fact per joint key (tier, account, app, origin, path, index, sourcetype, read or write, named or unresolved) and audit batch, with its counters and up to five sample search ids. See *Data usage*.
`trackme:uam:search_te`	search text	Reported search	The SPL, written only while *Store SPL search* is on.
`trackme:uam:finding`	findings	Finding transition	The finding with its evidence and investigation state.
`trackme:uam:receipt`	receipts	Tracker run	The outcome of the run.

- **Observation fields.** `account` and `account_source`, `app`, `sid`, `search_type`, `category`, `outcome`, `search_status`, `metrics` (`total_run_time`, `event_count`, `result_count`, `scan_count`, `exec_time`), `time_bounds` (`search_et` / `search_lt` as text) and `granted_time`; use `_time` for the event time. The same sourcetype also carries one `rest_access` summary per account and batch (REST job access counted per kind: `job_poll`, `job_lookup`, `job_dispatch`, `stream`, `remote`, `other`) and the `denied REST:` lines (security evidence).
- **Correlated executions** are not indexed: the Activity tab, the account views, the REST API (`activity` with `kind=execution`) and the AI Agent correlate each search from its audit records when they read it (start and completion observed, ambiguity, the accounts, apps and search types reported). The `trackme:uam:execution` events of earlier versions stay searchable until they age out, and are read too.
- **Resource fields.** `account`, `sid`, `app`, `search_type`, `provenance`, `mode`, `label`, `cpu_seconds`, `peer_cpu_seconds`, `cpu_source`, `peak_mem_mb`, `elapsed`, `nodes`, `samples`, `roles`, `window`.
- **Inventory fields.** Additions, reappearances and removals carry the whole object; a `changed` or `reclassified` event carries only the changed fields, new (`object.<field>`) and earlier (`previous.<field>`), plus the owner.
- **Data usage facts** carry `key` (the JSON list of their dimensions) and the counters `searches`, `index_searches`, `index_completed`, `late_searches` and `matched_events`, written as the indexed fields `uam_data_key`, `uam_data_refs`, `uam_data_n`, `uam_data_ndone`, `uam_data_late` and `uam_data_events`, plus `uam_data_index`, `uam_data_sourcetype` and `uam_data_label` (the saved search that ran). A map over 30 days is one `tstats` over these fields, never a read of raw events.
- **Finding transitions** carry the evidence only when the policies run changes it (`new`, `updated`, `reobserved`); every decision field stays.
- Every event carries `tenant_id` (an **indexed** field) and `environment_id`; the audit and resource records also carry the indexed dimensions `uam_kind`, `uam_environment`, `uam_account`, `uam_sid`, `uam_app` and `uam_status`, so the per-account and timeline reads run through `tstats`. These index-time settings take effect after the splunkd restart of the app installation, on the instances that parse the UAM log; until then, and for older evidence, the readers fall back to slower raw searches.
- **No field is written that nothing reads**, while the fields with investigative value stay.
- Default indexes: the tenant's **summary index** for evidence, search text and receipts, its **notable index** for findings. Each family can be pointed at another index in *Settings → Indexes*.

- **One compact record per search and window**: the grant folds into the completion (`granted_time`), REST job access is summarised per account rather than written line by line, null keys are dropped.
- Searches, dashboards, alerts or custom policies of your own that read `sourcetype=trackme:uam:execution` return nothing for activity collected since 2.4.21: rewrite them on `sourcetype=trackme:uam:observation` (one record per search and window, with `sid`, `outcome`, `granted_time`, `category`, `search_status` and the account fields).

Store SPL search and Fetch SPL

- **Store SPL search** (`store_search_text`) is **off by default**. When on, the SPL of every reported search is indexed as its own `trackme:uam:search_text` record in the search text index. Audit search text can carry literals and secrets: point the search text index at an index restricted to the people allowed to read it **before** you switch this on.
- **Fetch SPL** (account view, Activity tab, saved search view) shows the SPL of one search. It reads the stored `trackme:uam:search_text` record (or older evidence that carried the SPL inline) as the calling user; otherwise it reads the environment's `_audit` record live through the route account, **as the calling user**, and stores nothing. When the text cannot be shown, a reason says why: `not_in_audit`, `account_access_denied` (your roles are not granted the route's remote account), `access_denied` (the environment refused you), `account_resolution_failed`, `authentication_failed`, `transport_error`, `search_incomplete`, `deadline_exhausted` or `audit_lookup_failed`.

The saved search view

Opened from a saved search finding, the *Scheduled searches* tab or an account's owned searches, the **saved search view** shows the inventory definition of the saved search on its tier, its runs (CPU, run time, peak memory, a CPU chart and the 50 latest runs), its findings and its change history. **Fetch definition** reads the current definition live from the saved search's own tier, as the calling user (reasons such as `not_found`, `account_access_denied`, `access_denied` or `tier_not_configured` explain a refusal); nothing is stored. Runs are matched on name, app and owner (a `nobody`-owned saved search runs as `splunk-system-user`); a run of the same saved search by another account is left out.

Licence impact

The evidence is indexed data and counts against the Splunk licence like any TrackMe summary event. Its volume follows the search activity of the monitored environment — one compact record per search and window, one resource record per search and window, the inventory changes, one receipt per run. No row count caps it: UAM collects everything in scope. To reduce it, restrict the **Activity scope** to the search heads you need to monitor, switch off *Collect search resource usage* (the resource policies then stay learning), keep *Store SPL search* off, and size *Backfill days* with the retention of your sources in mind.

Data usage

The **Data usage** tab (*Data usage*) answers which indexes are read, by whom and through which path. This section describes the collection behind it and the rules its views follow.

The collection. The `trackme_uam_data_usage_tracker_tenant_<tid>` report (`4-59/15 * * * *`) has its own checkpoint in the audit trail, its own budget (870 s by default), lock, receipt and Collection health entry. It reads the audit trail through the same bounded, resumable reader as Audit activity, and writes no activity records. What a run cannot finish in its time continues at the next run; a batch whose extraction or writes failed is held and read again, never acknowledged.

- **Resolution.** Each search is parsed for the indexes and sourcetypes it names: literal `index=` and `sourcetype=` terms, `IN` lists, macros (with their arguments), event types, data models (their root constraints) and saved searches (`savedsearch` / `loadjob`), resolved through the **published catalogs of the search's own tier**, with Splunk's private / shared precedence. Wildcards stay patterns. A negated term never makes a read. A late field filter (after the first command) is a reference, not a source read. A `collect` destination is a write reference. So is the target index of a saved search's summary indexing or Log event alert action, read from the published saved search catalog (inherited `alert_actions.conf` defaults included; an empty target means

`summary` or `main`) and recorded on each run on the path `summary_index` or `log_event`. Custom alert actions are never inferred.

- **Unresolved scope.** What cannot be resolved is counted, not dropped: the search is recorded as *scope unresolved* with its reasons (a macro, event type, saved search or data model the catalog does not hold, a dynamic term, a wildcard role default, a truncated SPL, a resolution limit reached). For a search naming no index, the indexes its account's roles give it (the role search filter's indexes, else the default indexes the roles allow) are shown as context, never as reads.
- **Counted once.** A search is counted at its grant in the legacy `Audit:[…]` key=value format, or at its completion in the structured format. A canceled or failed completion counts; a search Splunk refused at its quota (`action=quota info=denied`) is not a read.
- **The indexers' confirmations.** On a distributed deployment, the search peers record in `remote_searches.log` the search they received after Splunk expanded its macros and saved searches. The Data usage run reads those lines from its own cursor and keeps them as a separate facet (*Indexers received*), never added to the search head's counts. A standalone search head has none.
- **Declarations.** Each catalog publication projects which knowledge objects name each index (saved searches, macros, event types, dashboards, data models). A declaration is not a read.
- **History.** When the tenant has a backfill, the Data usage history starts at the backfill depth, upgraded tenants included, but never before the oldest event of the audit trail: what `_audit` no longer holds cannot be read. Without a backfill, a new tenant's history starts where its Audit activity started, and an upgraded tenant's at its first Data usage run.

The rules of the views. Every case, with diagrams and worked examples, is in the *Data usage reference: how each claim is processed*.

- **One indexing layer.** Usage classes and review candidates are decided across every tier of the tenant: an index read on any tier is never a candidate. The indexes TrackMe writes to — the global index settings, every tenant's overrides and this tenant's own families — are never candidates.
- **No absence from too little evidence.** Until the collection covers the selected period, or seven days of it, no index is called unread and no knowledge object *not run*: the views say *so far* and give the date from which the claim can be made. A period with no Data usage run, an incomplete fact read or facts without the rollup key withhold every absence verdict. The first runs of a new tenant, before its first catalog listing, count as progress.
- **Excluded apps** (`trackme` and `Splunk_SA_CIM` by default) are shown, never counted: an index only they read is *Excluded apps only*.
- **Wildcards reach by index name.** `index=cribl_*` is matched against the indexes known for the tier with Splunk's index pattern rule (`*` never matches an internal index), then narrowed to the indexes its reader's roles allow; it is never narrowed by sourcetype. A wildcard reference never makes an index *read by name*.
- **Role search restrictions.** The roles of each reader are read from the published users and roles catalogs when the view is read: allowed indexes, minus the disallowed ones, narrowed by the index terms of the role search filters. A named index the roles do not allow is counted as *denied by roles*, never as a read. The scope is an upper bound, and the current roles apply to the whole period.
- **Not due.** A scheduled saved search that did not run, whose schedule leaves a longer gap than the period covers, is *Not due in this period*, never *Not run*.
- **Least accessed** ranks the indexes read by name with a daily volume above zero by reads per GB/day, and marks the lowest quarter. It needs at least four such indexes.

Volume and cost. A tier is linked to one VOL tenant (index volume) and up to 200 DSM tenants (incoming data), matched automatically whatever account they collect through unless set in *Settings → Data usage*. The cost per day comes from the VOL tenant's costs (its Global license usage configuration), when they are enabled; otherwise no cost is shown, never a guessed one. A link grants nothing: every read repeats the caller's visibility of the linked tenants. An index without a linked volume is counted, not weighed. Each index is weighed by its 30-day average of complete days; while VOL has no average for an index yet (its first day without a backfill), by its last 24 hours, and the views say so.

Reads without a time budget. The map, an index's detail, the knowledge objects and the access timelines run as the **caller's own search jobs**: the start request dispatches them and returns at once, the UI polls them until every

one is done (naming what is still being read), and cancels them when the selection changes or the view closes. Only the 600-second safety timeout applies; a read that reaches it is reported incomplete, never shown as empty data. The start answer fixes the period, and every poll reads the same one. The linked VOL and DSM reads page through every record, each request bounded by `splunkd_timeout`.

Limits. At most 50,000 fact keys and 10,000 catalog indexes per tier are read per map; a larger answer is flagged truncated and withholds every absence verdict. An access timeline has at most 120 clock-aligned buckets and 10,000 aggregated rows, ten lanes per page. Every limit reached is said in the view.

Identity and classification

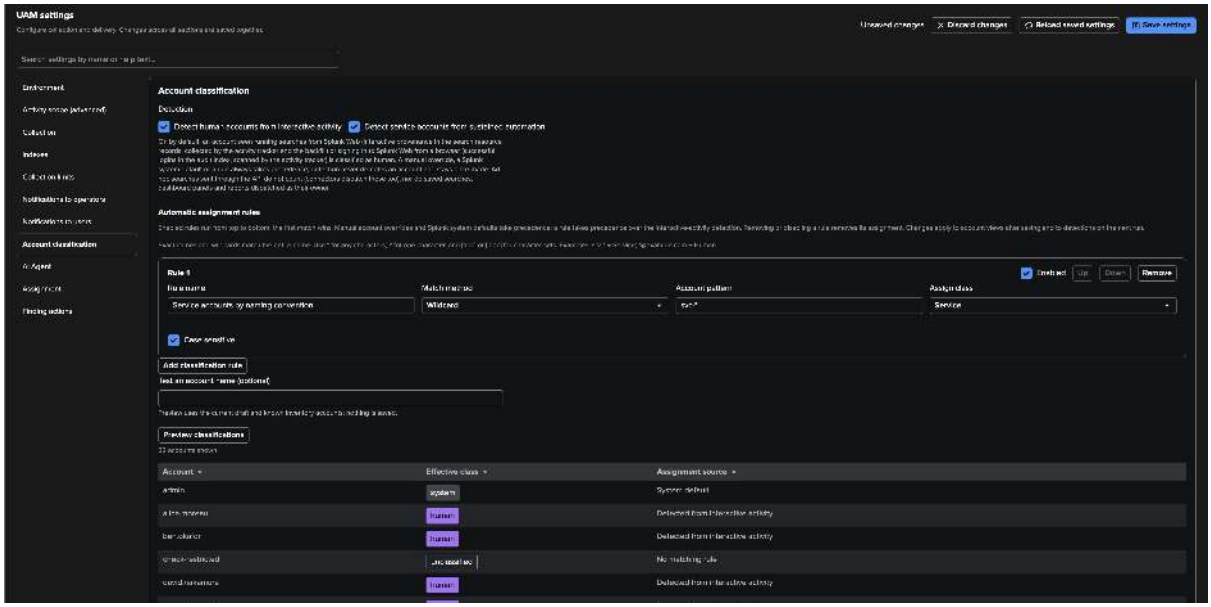
The account. Every observation carries `account` and `account_source` (`legacy_search_user`, `structured_actor` or `unknown`). The legacy `user` header wins when present: it names the caller, while the structured actor is often the system principal. It is a **labelled source claim**, not a verified initiator: UAM never claims that a person sat at the keyboard, and a scheduled search runs under its owner or the system account.

Classes and detection.

Class	Detected when	Limits
`human`	An **interactive search** — a resource record whose provenance starts with `UI:` (`UI:Search`, `UI:Dashboard:<name>`, `UI:Report`) and that carries no saved-search label — or a **successful browser login** to Splunk Web. One is enough; the detection is sticky and never demotes. Switch: *Detection* (human).	Ad hoc alone is not a signal (connectors dispatch ad hoc searches through the API); a labelled dispatch is not either (a dashboard set to run as its owner). Users working only through React apps (TrackMe's UI included) reach splunkd as `rest:jobs` — the login signal covers them.
`service`	**Sustained automation and nothing a person does**: automated searches (REST, scheduler, acceleration, internal) on at least **seven distinct days**, never a Splunk Web search, a splunkjs page, an MCP client or any other provenance a person might use, and not a detected human. Withdrawn as soon as such a search appears. Switch: *Detection* (service).	The automation days come from the legacy key=value `_audit` format (`provenance=` / `savedsearch_name=`): a JSON-only `_audit` gives no service detection, and the seven days must lie inside the audit retention. An account with no activity is never detected.
`system`	Seeded for `nobody`, `splunk-system-user` and the built-in `admin` whenever unset; never detected, never demoted by a detection.	Assign it by hand to the tenant owner and to the administrator accounts that run the platform's own workload.

Rules. Up to 100 ordered **classification rules**, each with a name, an enabled flag, a match type (`exact` or `wildcard` — `*`, `?`, `[abc]`, `[!abc]` on the whole name; no regular expression), a pattern, case sensitivity and the class. No naming heuristic runs unless an administrator saves a rule. **Manual classes** (up to 10,000, from *Settings*, the Users tab or its bulk classification) always win.

Precedence, in every reader (Users tab, account view, inventory, policies): manual class → system default → first enabled matching rule → human detection → service detection. Unmatched, undetected accounts stay **unclassified**. Removing a manual class returns the account to the automatic resolution; disabling a rule stops it at once; switching a detection off ignores its records without deleting them. *Settings → Account classification* previews the draft (up to 1,000 names, the effective class and its source) before saving; the Users tab shows a *detected* marker with the evidence next to the class. Changing a class never rewrites historical evidence nor resolves an investigation: the policies use it at their next run.



Privileged users

The **Privileged users** tab and *Settings → Privileged users* (`privileged` in the configuration) answer which accounts hold high privileges on the monitored tiers, and why.

Definition. An account is privileged when one of its roles, or a role that role imports (`imported_roles`, resolved transitively; a cycle is tolerated), is a **privileged role** or grants a **privileged capability**.

Inheritance. Splunk grants roles and capabilities through direct membership and through inheritance, and a role inherits from roles that inherit further: the assessment resolves the import chain breadth first. An inherited reason keeps its chain (`path`: the role held first, the privileged role last), an inherited capability names the role that grants it itself (`granted_by`, the nearest one; none when only Splunk's `imported_capabilities` knows it), and each role keeps its own definition (its own capabilities and the roles it imports itself) apart from what it inherits. The tab words them: *team_lead imports admin*, *team_lead inherits admin through ops*, *leaf inherits list_settings from base through mid*.

Rule (key)	Default	Behaviour
Role name patterns (`role_patterns`)	`*admin*`	Live, case-insensitive globs (`*`, `?`): a role created later is privileged as soon as its name matches.
Roles added (`roles_include`)	none	A role no pattern matches, made privileged by name.
Roles excluded (`roles_exclude`)	`trackme_admin`	Overrides a pattern. It removes only the name rule: a privileged capability the role grants still counts.
Privileged capabilities (`capabilities`)	`admin_all_objects`, `change_authentication`, `delete_by_keyword`, `edit_roles`, `edit_tokens_all`, `edit_user`, `list_settings`, `list_storage_passwords`, `rest_apps_management`	Granted directly (`capabilities`) or through imported roles (`imported_capabilities` and the capabilities of every role imported).

Up to 500 entries per list. A role name holds letters, digits and `_ . -`; a pattern also `*` and `?`; a capability also `:`; a role cannot be both added and excluded.

Data. No new collection and no call to Splunk: the assessment reads the published users and roles catalogs of every tier (each role's `capabilities`, `imported_roles` and `imported_capabilities`, each user's `roles`), so it

follows *Users and roles every* (60 minutes by default). An account present on several tiers is one account, and each of its reasons names the tier that grants it.

What the tab shows. Tiles for the privileged accounts (and their share of all accounts), the privileged roles, the privileged capabilities in use and the privileged accounts active in the last 24 hours; pies of why accounts are privileged (role, capability or both) and of their classes; a bar of the accounts per privileged capability; the privileged accounts with their reasons in words, last seen and executions over 24 hours; the roles of every tier with their rule, inherited roles and privileged capabilities. The activity is one `tstats` over the audit records, read as you, naming the privileged accounts (up to 1,000; above, it reads every account and keeps the privileged ones); when it cannot be read, the tab says the activity is unavailable, never that the accounts were inactive.

Settings. The patterns in a text area, then two dual lists filled from what the tiers hold: roles (moving a role a pattern matches out of the privileged list adds it to the exclusions; moving another role in adds it by name) and capabilities. The rules apply from the next read of the tab.

The tab describes; the four privileged policies (see *Privileged policies*) raise findings from the same assessment.

The built-in policy catalogue

A UAM tenant evaluates **sixteen built-in policies** in four families. Every policy has:

- **Enabled** — on or off.
- **Severity** — `low`, `medium`, `high` or `critical` (UAM has no informational level). A manual severity set on a Finding group survives later runs; choosing *Members* (the highest severity of its findings) restores the derived one.
- **Excluded owners / accounts** and **Excluded apps** — up to 500 exact, case-sensitive names each (no wildcard). Every policy except the CSV lookup footprint starts with the apps `Splunk_SA_CIM` and `trackme` excluded, so TrackMe's own trackers and data-model acceleration do not flag the monitoring itself. *Exclude owner from this policy* in a finding menu adds the owner to this list.
- **Account scope** (account policies) — `human` (explicitly classified human), `classified` (human or service, never system) or `all`. Accounts outside the scope count as *not applicable*.
- Its **thresholds**, each compared **strictly**: a finding needs *more than* the limit.
- **During bank holidays** — *Hold new findings* or *Keep opening findings* (see *Policies run*). The six inventory policies hold by default: configuration reviews nobody handles on a day off, still there the next working day. The activity and resource policies keep opening findings by default: unusual activity on a day off is more telling, not less. A configuration stored before 2.4.19 reads each policy's default. Changing it never resets the direct user notifications.

The policy editor (*Policies → Edit*) has four tabs: **General settings** (status, *During bank holidays*, severity, scope, thresholds, automatic budgets, exclusions, *Preview policy*), **Email template** (the direct user emails of this policy, see *Notifications and communications*), **Actions** and **Automations** (findings actions, see *Findings actions*).

Inventory: saved searches

Policy	What it detects	Default	Severity
`personal_schedule/v1`	An enabled schedule owned by an account classified human.	On	Low
`unclassified_schedule/v1`	An enabled schedule whose owner has no human or service class.	Off	Medium
`dense_schedule/v1`	More scheduled runs per active hour than the limit.	Off	Medium
`all_time_schedule/v1`	A schedule with no lower time bound (all time).	On	Medium
`realtime_schedule/v1`	A schedule with a real-time dispatch range.	On	Medium

Inventory: accounts

Policy	What it detects	Default	Severity
csv_lookup_footprint/v1	A CSV lookup file too large, or an account's CSV lookups too large in total.	On	Medium

Activity: accounts

Policy	What it detects	Default	Severity
launch_burst/v1	An account launching an unusual number of searches.	Off	Medium
costly_search/v1	An account running repeated long searches.	Off	Medium
all_time_search/v1	An account running all-time searches.	On	High

Resource: accounts

Policy	What it detects	Default	Severity
resource_consumption/v1	An account's search CPU above its allowance.	On	Medium → High
resource_intensity/v1	An account running repeated searches heavy in CPU or memory.	On	Medium
resource_deviation/v1	An account's CPU today unusual for its daily baseline.	Off	Medium

Privileged: accounts and roles

Policy	What it detects	Default	Severity
privileged_account_new/v1	An account that became privileged (reported once per change).	Off	High
privileged_role_capabi/v1	A role whose own definition now grants more privileges (reported once, about the role).	Off	High
privileged_account_doi/v1	A privileged account without activity for the period.	Off	Medium
privileged_reference/v1	A privileged account the reference does not declare, or a stale reference.	Off	High (stale: Low)

Default settings

What each policy applies to, its account scope, what it does on a bank holiday, and its thresholds with their defaults.

Policy	Applies to	Bank holidays	Thresholds and notes (defaults)
`personal_schedule/v1`	Saved search	Hold	No threshold. Common where administrators own every schedule, hence **low**.
`unclassified_schedu v1`	Saved search	Hold	No threshold. A governance gap, not evidence of misuse.
`dense_schedule/v1`	Saved search	Hold	Maximum scheduled runs per active hour 12 (1 to 60). Configured frequency, not observed launches.
`all_time_schedule/v1`	Saved search	Hold	No threshold. `dispatch.earliest_time` of `0` or empty.
`realtime_schedule/v1`	Saved search	Hold	No threshold. An explicit `rt` bound.
`csv_lookup_footprin v1`	Account, scope `all`	Hold	100 MiB per file, 500 MiB per account and tier. No app excluded by default.
`launch_burst/v1`	Account, scope `human`	Keep opening	Maximum distinct searches per window 200.
`costly_search/v1`	Account, scope `human`	Keep opening	Minimum run time 300 s, maximum long searches 3.
`all_time_search/v1`	Account, scope `human`	Keep opening	Maximum all-time searches **0**.
`resource_consumptio v1`	Account, scope `classified`	Keep opening	Allowance 10 % of the search CPU capacity (else 3,600 s). Raised one severity level above a dominant share of 40 %.
`resource_intensity/v1`	Account, scope `classified`	Keep opening	A heavy search uses 2 % of the search CPU or 10 % of the smallest search host memory (else 300 s or 2,048 MB); maximum heavy searches 3.
`resource_deviation/v1`	Account, scope `classified`	Keep opening	3 × the daily p95 over 14 days, floor 3,600 s. Off, in **preview mode**: matches are recorded, no finding and no notification.
`privileged_account_ v1`	Account, scope `all`	Keep opening	No threshold. Splunk-operated accounts left out (*Include accounts operated by Splunk*, off).
`privileged_role_cap v1`	Role	Keep opening	No threshold. Exclusions name roles.
`privileged_account_ v1`	Account, scope `all`	Hold	Days without activity 30 (7 to 365). Splunk-operated accounts left out.
`privileged_referenc v1`	Account, scope `all`	Keep opening	No declared account and no lookup table (the policy stays learning), *Report stale references* on. Splunk-operated accounts left out.

The server supplies the titles, descriptions, bounds and remediation of every policy; the sections below give the full detail.

Inventory policies — saved searches

The subject is one saved search of one tier; the finding keeps the same identity across runs. Explicitly unscheduled or disabled searches are not applicable; a missing flag or an unreadable bound is *unknown*, never assumed. Evidence: the owner and its class (with where the class comes from), the app, the tier, the schedule and the bounds read. UAM never edits nor dispatches the observed searches — the remediation is advisory. These policies follow the catalog cadence: the saved-search listing is daily by default.

Policy	Details
`personal_schedule/v1` *Scheduled search owned by a human account*	• **Counts:** enabled schedules whose owner is explicitly classified **human** (unknown and service owners do not match). • **Thresholds:** none. Common where administrators own every schedule, hence the **low** severity. • **Suggested action:** review whether this schedule should run under an approved service account, or record an owner exception.
`unclassified_schedule/v1` *Scheduled search owner is not classified*	• **Counts:** enabled schedules whose owner has no human or service class. A governance gap, not evidence of misuse. • **Thresholds:** none. • **Suggested action:** classify the owner in Settings after confirming the account's purpose.
`dense_schedule/v1` *Scheduled search exceeds the hourly schedule limit*	• **Counts:** distinct **configured** minute slots in an active clock hour of a standard five-field cron (wildcards, steps, ranges and lists; duplicates count once; named days, macros and extended forms are unknown). Configured frequency, not observed launches. • **Thresholds:** maximum scheduled runs per active hour, 1 to 60 (default 12). • **Suggested action:** review the business need and reduce the frequency, or add a justified exception.
`all_time_schedule/v1` *Scheduled search has an all-time dispatch lower bound*	• **Counts:** enabled schedules whose `dispatch.earliest_time` is `0` or **empty** (Splunk's default: no lower bound). Inline SPL time modifiers may still restrict the search. • **Thresholds:** none. • **Suggested action:** configure a bounded dispatch time range where appropriate.
`realtime_schedule/v1` *Scheduled search uses a real-time dispatch range*	• **Counts:** enabled schedules with an explicit real-time bound (`rt`, `rt-5m@m`, `rt@w0`…). An unsupported `rt` form is unknown, never historical. • **Thresholds:** none. • **Suggested action:** review whether a scheduled historical search can meet the requirement.

CSV lookup footprint

`csv_lookup_footprint/v1` — *CSV lookups attributed to an account exceed its size allowance* — is an inventory policy whose subject is an **account**:

- **What it detects**, separately on every search head tier: **one CSV lookup file** larger than *Maximum individual CSV file size* (default **100 MiB**), or the **cumulative size** of the CSV lookups attributed to one account larger than *Maximum cumulative CSV size per attributed account and tier* (default **500 MiB**). Both 1–1,048,576 MiB.
- **On by default**, severity medium, account scope `all`, no app excluded by default.
- **Attribution: probable writer, recorded owner as fallback.** The Audit activity tracker records, from the audit evidence it already reads, which account last wrote each lookup file. A file is attributed to that **probable writer** when the evidence supports it, else to its **recorded owner** (a shared file owned by `nobody` falls back to its recorded owner unless audit evidence names a writer). The evidence keeps the basis of the attribution and both identities. Attribution is best effort since monitoring began, not proof of authorship: missing audit evidence, ambiguous targets, concurrent writes or later unmatched changes use the owner fallback, and the backfill does not provide writer hints.
- **Size** is the stored file size (a compressed CSV counts at its stored size), not the replicated bundle size. Only the metadata is read — never the contents — and no third-party app is required.
- Only tiers whose lookup-file catalog is **complete and less than an hour old** are evaluated; a missing, partial or stale catalog can never clear a finding.
- *Suggested action*: review the largest files and their generating searches with the probable writer or the owner; reduce retained rows or columns, use the KV store where appropriate, review bundle replication settings with

an administrator. UAM never deletes a file nor changes replication. Direct user emails of this policy list up to 20 of the largest attributed lookups.

Activity policies — accounts

Aggregated from the `trackme:uam:observation` records of the evaluated *Activity policy window* (15 minutes of collected evidence by default, see *Policies run*), one row per search first, then per account and app. The counts are **distinct search ids** the Audit activity tracker observed — a launch-count proxy — labelled with the coverage (`complete` / `partial`). One finding per policy, environment and account: a repeated burst updates the same finding. Evidence: the window, the count, the thresholds, the account class and scope, the top five apps and, for `costly_search/v1`, the maximum and total run time. Excluded apps are removed from the account's aggregate before the threshold is compared.

Policy	Details
`launch_burst/v1` *Account launched an unusual number of searches*	• **Counts:** distinct searches by one account in the window. • **Thresholds:** maximum distinct searches per window, 1 to 100,000 (default 200). • **Suggested action:** confirm whether the burst is expected automation; raise the limit or record an account exception if it is.
`costly_search/v1` *Account ran repeated long searches*	• **Counts:** distinct searches whose reported run time reached the minimum. Run time is the audit completion figure; CPU is not estimated. • **Thresholds:** minimum run time 1 to 86,400 s (default 300); maximum long searches 0 to 100,000 (default 3). • **Suggested action:** review the long searches (run time, scan count); work on time ranges, scheduling or acceleration.
`all_time_search/v1` *Account ran all-time searches*	• **Counts:** distinct completed searches whose reported earliest bound is explicitly unbounded (legacy `search_et=N/A`, structured `0`). A missing bound is unknown. • **Thresholds:** maximum all-time searches, 0 to 100,000 (default **0**). • **Suggested action:** agree on bounded time ranges, or an account exception for approved investigations.

Resource policies — accounts

Read from the `trackme:uam:resource` records (search heads and indexers, ad hoc and scheduled), through one bounded rollup per policies run: CPU adds up across windows, memory keeps its peak. The `system` class is outside the default `classified` scope (data-model acceleration never becomes a finding by default) but its CPU stays in the share denominator: it is real load.

Automatic budgets. With *automatic thresholds* on (the default), the absolute limits are derived from the capacity — the core sum of the search hosts and the memory of the smallest one — and clamped to each threshold's own range:

Policy	Percentage (default)	Derives
`resource_consumption/v1`	Allowance as a share of the search CPU capacity (10 %)	Maximum CPU seconds = search cores × window seconds × percentage
`resource_intensity/v1`	Heavy search CPU as a share of the search CPU capacity (2 %)	Minimum CPU seconds of a heavy search = search cores × window seconds × percentage
`resource_intensity/v1`	Heavy search memory as a share of the smallest search host (10 %)	Minimum peak memory of a heavy search = smallest search host memory × percentage

With automatic thresholds off, the stored absolute values apply. With them on but no usable capacity, the stored values apply and the evaluation says `manual_fallback`. The evidence carries the thresholds source (`auto` / `manual` / `manual_fallback`) and the capacity basis; the policy editor shows the effective values.

Learning period. The resource rules are **learning** — nothing evaluated, no finding created, nothing marked not

observed — until the tenant holds *Resource rules: minimum history* (24 hours by default) of resource history (the backfill counts) and, for automatic budgets, a known capacity. The Policies tab shows the reason.

Policy	Details
`resource_consumption/v1` *Account's search resource consumption exceeded its allowance*	• **Counts:** the CPU seconds of the account's searches in the window, against its allowance. Its share of the environment's search CPU is always in the evidence; strictly above the **dominant share** the severity is raised **one level**. The share never opens a finding on its own. • **Thresholds:** maximum CPU seconds 1 to 10,000,000 (default 3,600, derived when automatic); allowance 1 to 100 % (default 10); dominant share 1 to 100 % (default 40). • **Suggested action:** open the account's most expensive searches; work with the owner on time ranges, acceleration, scheduling or workload rules; raise the allowance or record an exception for approved workloads.
`resource_intensity/v1` *Account ran repeated resource-intensive searches*	• **Counts:** distinct searches whose CPU seconds **or** peak memory reached the per-search minimum (a search spanning several windows is summed; memory keeps its peak). • **Thresholds:** minimum CPU seconds of a heavy search 1 to 1,000,000 (default 300, derived); minimum peak memory 64 to 1,000,000 MB (default 2,048, derived); maximum heavy searches 0 to 100,000 (default 3); automatic percentages 2 % CPU and 10 % memory. • **Suggested action:** review the heavy searches (type, provenance, label); agree on bounded time ranges, acceleration or scheduling.
`resource_deviation/v1` *Account's CPU consumption is unusual for its daily baseline*	• **Counts:** today's accumulated CPU (UTC day) against `max(multiplier × historical daily p95, floor)`, after at least the minimum number of **fully covered** prior days since the account was first seen. Missing coverage is unknown, never zero; today is never extrapolated. • **Thresholds:** historical lookback 7 to 30 days (default 14); minimum complete days 7 to 30 (default 7, at most the lookback); multiplier 1 to 20 (default 3); minimum daily CPU seconds 1 to 100,000,000 (default 3,600). In **preview mode** by default: matches are recorded in the evaluation, no finding and no notification. • **Suggested action:** review the daily baseline, the coverage and the expensive searches; confirm workload changes before adjusting the multiplier.

Privileged policies

The four privileged policies read the privileged assessment (see *Privileged users*) of every tier, from the published users and roles catalogs, in the policies run. They have no excluded apps (they judge roles and accounts, not searches) and never email the account a finding is about.

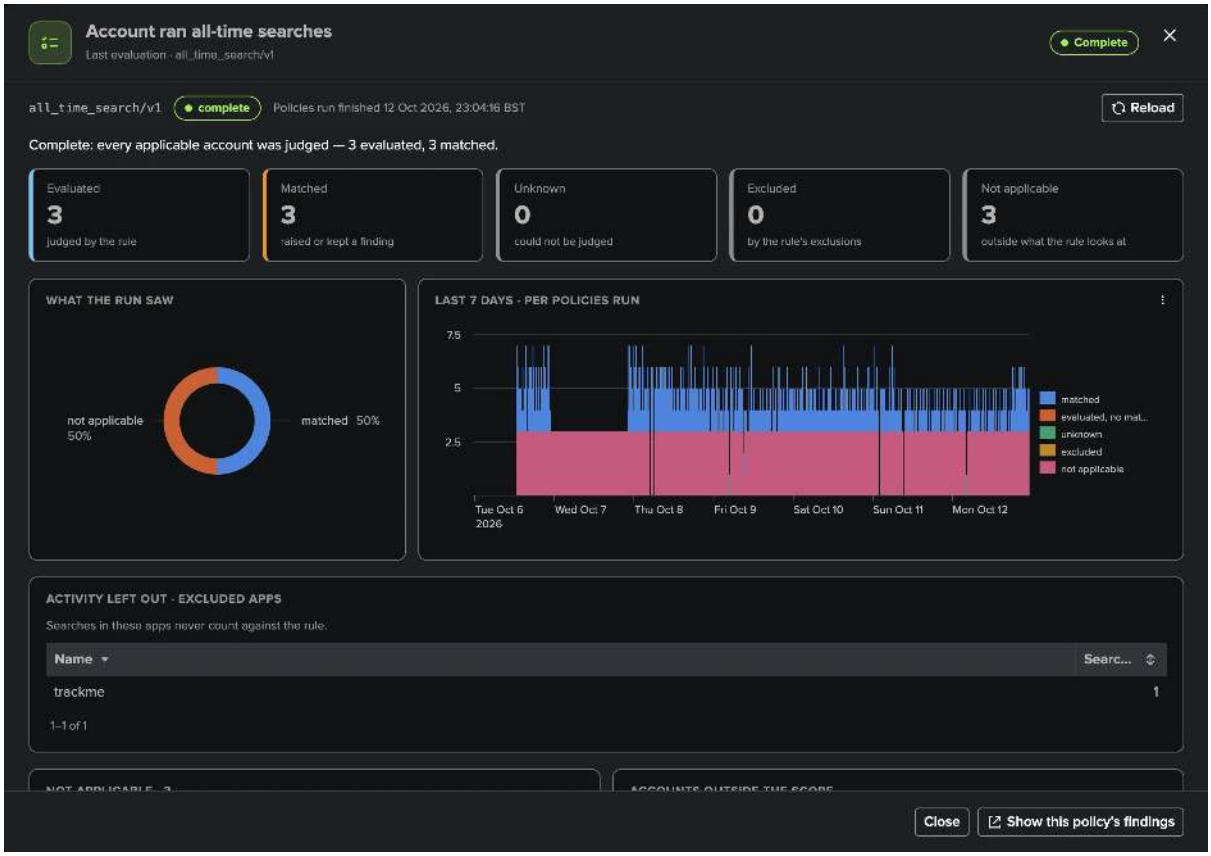
Changes, reported once. The two change policies compare the current assessment with the previous one, which the policies run keeps (a snapshot, per tier). A change is matched by the run that finds it and opened as a finding; the next complete run no longer matches it, so a resolve sticks and a later change opens a new episode. A change held by a bank holiday stays pending and is opened by the first run after it. The first evaluation, a change of the Privileged users rules, and a change policy turned on record the current state without reporting. A partial users or roles catalog never moves the snapshot, never matches and never clears.

Policy	Details
`privileged_account_ne` `v1` *Account became privileged*	• **Matches**: an account privileged now that was not at the previous assessment of its tier, whose own roles changed (`roles_changed`) or that is new (`account_created`). An account made privileged with its own roles unchanged is the role policy's finding; with the role policy off, or the originating role excluded from it, it is this policy's (`privilege_inherited`, naming the roles whose definition changed). • **Evidence**: the roles before and after, the reasons with their chains, and, when the audit trail holds the change (`create_user` / `edit_user`), who made it and when. • **Suggested action**: confirm the grant was approved; otherwise remove the privileged role and review the account's activity since.
`privileged_role_capak` `v1` *Role gained a privileged capability*	• **Matches**: a role whose **own** definition changed — its own capabilities (`capabilities_gained`), the roles it imports itself (`imports_changed`) — so that it grants more privileged capabilities or inherits a privileged role, or a new role created privileged (`role_created`). The roles inheriting it are not reported again: the finding lists them (`descendant_roles_reached`) with every account newly privileged through any of them. A role whose inheritance grew while no role in its chain changed its own definition in the catalog is reported on itself (`inheritance_changed`). • **Subject**: the role, on its tier (a Finding group of its own); findings actions read its name as `$subject.name$`. • **Evidence**: the capabilities gained and the role granting each, the own capabilities and imports before and after, and, from `edit_role`, who made it with the capabilities before and after. • **Suggested action**: confirm the change was approved; otherwise restore the role's capabilities or imports.
`privileged_account_dc` `v1` *Privileged account is dormant*	• **Matches**: a privileged account with no search in the audit evidence (one `tstats` over the period, naming the privileged accounts), no Splunk Web login or interactive search seen by the Account signals tracker, and no successful login Splunk reports on any tier (`last_successful_login`, collected by the users catalog without making it an inventory change), for *Days without activity*. • **Never a guess**: an account in the inventory for less than the period is not applicable; while the tenant's audit evidence (the live history, plus a completed historical backfill) does not cover the period, the account is unknown. • **Not seen**: activity on a search head outside the Activity scope, and REST calls that run no search.
`privileged_reference/` `v1` *Privileged accounts differ from the reference*	• **Reference**: the account names typed in the policy (every tier) and each lookup table, read with `| inputlookup <lookup>` on its deployment — the local search head, or a remote deployment through its TrackMe remote account — from the TrackMe app: the account field, and the tier field when set (an empty tier declares every tier). Matching is case-insensitive; `*` matches any text in typed names and in a lookup set to Wildcard (Exact, the default, ignores a value holding `*`). Up to 20 lookups of 500,000 values each; TrackMe's own lookups are refused. • **Matches**: `undeclared` — privileged on a tier the reference does not declare it for; `stale_reference` (with *Report stale references*, at low severity) — an exact declared name holding no privilege, or absent from every tier (a pattern is never stale). The evidence names the sources that declare the account. • **Never a guess**: a lookup that cannot be read, reads empty, is too large or is not read in time keeps its last good values (diagnostic `privileged_reference_unreadable`, note *reference_lookup_cached*); a lookup with no good values yet, or a reference that declares no account, judges nothing; without a source, the policy is learning. A tier field with no value in any row is treated as unreadable (a renamed column).

Accounts whose collected email address is `support@splunk.com` — the accounts Splunk operates on a Splunk Cloud stack — are left out of the account policies unless *Include accounts operated by Splunk* is on. *How it is evaluated* shows the records judged and, for the dormancy and reference policies and the change author read, the exact searches.

Policy insight and preview

- **Policy insight** — the *Last evaluation* and the count cells of the Policies tab open what the last run saw: a verdict, the population, why records were unknown, excluded or not applicable (`owner_unclassified`, `missing_<field>`, `cron_unreadable`, `excluded_owner` / `excluded_app`, `unscheduled` / `disabled`, `out_of_scope_<class>`…), the owners and apps behind each bucket (owners can be classified in place), up to 25 samples, the run (window, readiness, thresholds source, inventory per tier) and a seven-day history per policies run.
- **Preview policy** (*General settings*) evaluates the draft against the latest stored inventory of the tenant without writing anything and shows the totals and up to 20 matching examples. It needs a collected inventory.



Custom policies

Tenant administrators write their own policies in SPL (*Policies → Create policy*). A custom policy runs on its own schedule and its findings appear with the built-in ones, in the same Finding groups.

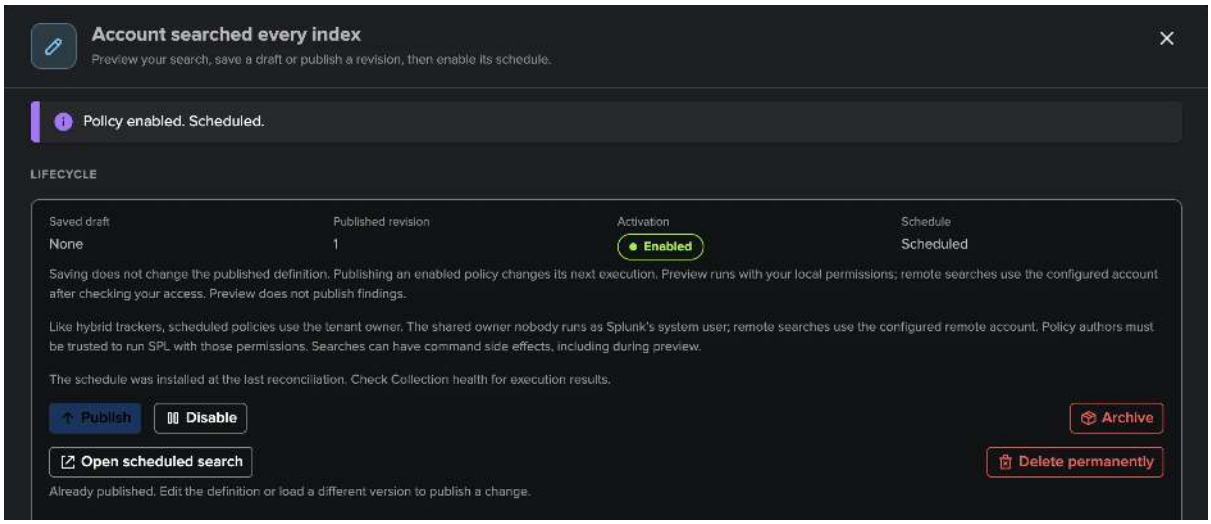
Definition.

- Title, description, default severity and remediation (shown on its findings).
- **Source tier** — a policy about **accounts** reads the route account (the indexing layer); a policy about **saved searches** reads the selected tier. **App context** — the search namespace.
- **SPL** — up to 64 KiB. **Time range** — relative, from `-<n><s|m|h|d|w>` to `now` or an earlier relative bound, at most 31 days in the past; no all-time, real-time, future bound or calendar snap. **Schedule** — a numeric five-field cron.

Map search results to findings.

- **Subject type**: **account** (the result field holding the account) or **saved search** (the fields holding the owner, the app and the name — three distinct fields; alias them in the SPL). The subject places the finding in the right Finding group.
- **Dimensions** (up to eight fields) — distinguish several findings about one subject.
- **Evidence fields** (up to eight), a **count field** (occurrences per row, else one per row) and a **time field** (epoch seconds).
- **Advanced limits**, for example the result rows read (10,000 by default, at most 100,000), the findings per run (1,000, at most 10,000), **25 findings per subject**, the samples and evidence bytes kept per finding.
- Changing the subject mapping or the source requires a higher **identity version** before publication: a new identity, so earlier findings are not reused for a different meaning.
- **Bank holidays** — *Hold new findings* or *Keep opening findings* (`hold_on_bank_holidays`, off when absent). It is not part of the identity, so turning it on needs no new identity version; it takes effect when published. A custom policy holds while a holiday of the tenant's calendars is active at its **anchor**, the end of its search window: a holiday that ended earlier inside a longer window no longer holds. Held results publish no finding and use no findings capacity; a finding already observed is still evaluated. The run's commit records `held` and, when a holiday applied, `bank_holidays` (state and names), shown as *Held N (bank holiday: <names>)* on the run.

Lifecycle.



Step	What it does
Draft	Save keeps a **saved version** of the draft (the 30 most recent are kept). Saving never publishes nor enables.
Preview	Runs the current form — saved or not — as **you**, asynchronously and cancellable (60 seconds, 1,000 result rows), and shows completeness, diagnostics, counts and at most 20 candidate cards. Nothing is published; a zero-row result cannot verify a mapping.
Publish	Freezes an immutable **published revision** (up to 100 per policy). Draft edits never change what is published.
Enable / Disable	Schedules or unschedules the policy's report `trackme_uam_custom_<id>_tenant_<tid>`, owned by the tenant owner.
Archive	Irreversible: the policy stops, its definition and findings stay readable and it can be duplicated.
Delete permanently	Removes the definition, its versions, its scheduled search and its execution history; findings, evidence and notes remain.
Version history	Load, compare, restore (as a new draft) or delete a version; the published revision is protected.

Limits. 100 definitions per tenant (archived ones included) and 25 enabled. A scheduled run has 300 seconds and

10,000 result rows; at most 1,000 findings are kept per custom policy and 10,000 per tenant, separately from the built-in findings limit. Four custom policy runs at a time per installation, two per tenant, one per policy (previews included).

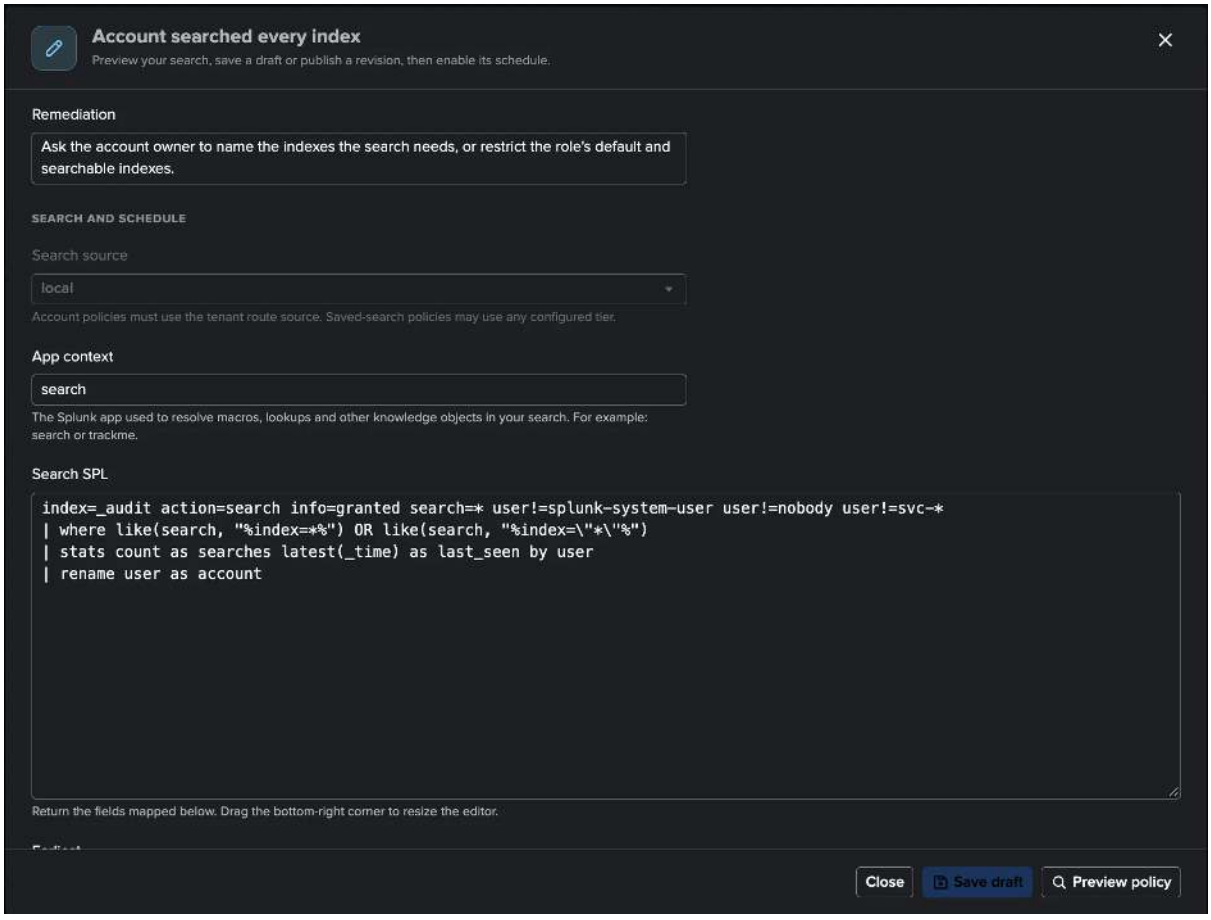
Execution health. *Collection health → Trackers*, family *Custom policies*, shows, per policy, the requested and actual schedule, the cron and next run, the last complete evaluation, the failure count, the recent runs and any running search; states are disabled, never run, healthy, healthy (no match), incomplete, failed, cancelled, capacity deferred, schedule drift, missed schedule and recovery required. *Run now* runs the published revision (findings may be published) and **Recover** frees a run whose searches are verified stopped. The Configuration Guardian reports the problems (see *Configuration Guardian*).

What differs from built-in policies.

- Custom findings are **not** notified: the operator and user notification policy selectors list built-in policies only.
- There is no *Exclude owner from this policy* action: write exclusions in the SPL.
- A custom policy can only map to accounts and saved searches.

Warning

The SPL of a custom policy is arbitrary SPL run on a schedule as the tenant owner (with the `nobody` owner, as Splunk's internal scheduler identity), and a preview runs it as its author: a command or macro with side effects has them, preview included. Only trusted tenant administrators can author policies; give remote accounts least-privilege credentials.



Findings and Finding groups

The shared lifecycle, triage and grouping concepts are explained in *A finding and its lifecycle* and *Finding groups*; this section gives the UAM specifics.

The finding

A finding is one row per policy, environment and subject (a saved search, an account, or a role for the role policy), with a stable id, its `status` (`open`, `investigating`, `resolved`, `dismissed`), its severity (policy or manual), its assignee, a short investigation note, `observed`, first / last seen, `episodes`, `reopened_count`, the dismissal deadline, a bounded history (the 50 most recent records) and the evidence.

Transition	Meaning
`new`	First match: the finding opens.
`updated`	Severity or evidence changed while observed (a threshold edit updates the evidence without changing the identity).
`reobserved`	Matched again after an absence: a new episode; open and investigating findings only gain the history record.
`unobserved`	Not matched by a **complete** evaluation: the finding stays, its *Condition* reads **not observed**. It is never resolved for you; a partial evaluation never marks a finding not observed.
`reopened`	A **resolved** finding observed again returns to `open`.
`expired`	A **temporary dismissal** ended: the finding returns to `open` at the next policies run, observed or not.
`triage`	An operator decision; the policies never overwrite it.
`retired`	The policy no longer exists and its replacement evaluated fully: resolved by the system, not notified.

Decisions

Decisions are made on the **Finding group** (one group, or up to 500 groups at a time), fenced on the group's version (a decision captured on an older version is refused, `finding_group_version_changed`):

- **Status —** *Investigate*, *Resolve*, *Dismiss*, *Reopen*. **Resolve** says the investigation concluded: the policy **reopens** the finding the next time it observes the condition. **Dismiss** says the finding is accepted: it stays dismissed while observed. Dismiss permanently ("until reopened by hand") or for **1, 7, 30 or 90 days** (API: one hour to 366 days); an ended dismissal returns the finding to open. Any status change clears a deadline; a new duration replaces it.
- **Snooze notifications —** 1 hour, 1 day, 7 days or 30 days (API: 60 seconds to 90 days): the operator emails about the group are held; the status does not change. Transitions during the snooze are not sent later.
- **Severity —** a manual severity; *Members* restores the severity derived from the group's findings.
- **Assign —** to a user or an assignment group (see *Assignment and automatic routing*).
- **Notes —** the shared TrackMe Notes (Markdown, permanent or expiring) on the group or on a finding, separate from the short investigation note recorded in the history.

Every change leaves a history record with its author (an operator, the policy, the system or the AI Agent). Decisions on findings and groups (`triage`, `group_members`) require a TrackMe administrator of the tenant; a power user of the tenant can run findings actions, send an email action and set an assignment.

Finding groups

Automatic grouping. All findings about **one account and the saved searches it owns** form one Finding group — for example the two personal schedules of `analyst-a` and its all-time-search finding. Ownership defines the grouping; classification does not. A saved search without an owner keeps its own group. Every tier of the indexing layer shares the account's group; different tenants never do. A role finding (the privileged role policy) keeps a group of its own. Each finding keeps its own subject, tier, policy, evidence and id. An automatic group holds up to **5,000** findings.

The group is the triage unit. A decision applies to every member except a member **dismissed on its own** (*Dismiss only this finding*): that member keeps its own dismissal until it ends or is reopened, and the group's decisions leave it alone. A new kind of problem on a dismissed group reopens the group and keeps the earlier members dismissed on their own: a dismissal never silences a new problem. The group's severity is the highest of its observed members unless an operator set one.

Manual grouping. Select groups on the Findings tab:

- **Merge into one Finding group** — 2 to 25 groups become one manual group (optional title). The most open status wins; a member whose decision differs keeps it on its own.
- **Add to a manual group**, **Remove from the Finding group** (up to 25 findings at a time) and **Ungroup**.
- An object's findings always move together: removing a saved-search finding removes every finding of that object; removing an account returns it with its owned searches.
- A manual group holds up to **50** findings; later findings of a full manual group go back to their automatic group. Automatic grouping never undoes a manual grouping.

Assignment and findings actions

- **Assignment** (*Settings → Assignment*): up to 100 assignment groups (name, description, optional team email) and up to 100 ordered automatic assignment rules (by policy, severity, subject type, owner, app, environment), with optional emails to the assigned group. See *Assignment and automatic routing*.
- **Findings actions** (*Settings → Finding actions*): up to 50 administrator-defined drilldown searches, links, webhooks (through system-wide *Webhook accounts*) and the email action, run by hand from a finding or group menu, and up to 100 automation rules that run them for a policy (*Policies → Edit → Automations*). See *Findings actions*.

Finding events

Every finding transition is indexed as `trackme:uam:finding` in the findings index (the tenant's notable index by default): build your own Splunk alerts, Enterprise Security correlation searches or SOAR playbooks on them.

Notifications and communications

UAM has three email channels, all independent of each other. The shared principles are in *Notifications*.

Notifications to operators

Settings → Notifications to operators (`notifications`), off by default:

- **Events**: *New finding*, *Finding reopened*, *Severity raised*, *Finding resolved* (on by default), *Finding dismissed*, *Finding assigned*. Being observed again or not observed never notifies.
- **Minimum severity** (medium), **Policies** (empty = all built-in policies), **Delivery account** (a TrackMe email account, see *Configuration*; empty = the search head's local mail transport), **Recipients** (up to 50, filtered by the account's allowed domains), **Mode**: **Digest** (one email per policies run, grouped by event then severity) or **Per finding** (one email per transition, threaded per finding in the mail client).
- Transitions are delivered at the end of the next policies run (within about 15 minutes); a failed send is retried at the next runs, and transitions older than 24 hours expire. A snoozed group's transitions are not sent.
- **Send test email** sends a synthetic message with the **saved** settings, even when notifications are off.
- Every email links to the finding (`TenantHome?tenant_id=<tid>&component=uam&tab=findings&finding=<id>` opens its Investigate view).

Notifications to users

Settings → Notifications to users (`user_notifications`), off by default: one email to the **account a finding is about**, on **detection** and when the condition is **no longer detected**.

- **Addresses** come from Splunk's user records, collected per tier by the users catalog and kept in a private store (never in the inventory, the evidence or the findings), or from an administrator's **Override email address** (Users tab). A saved-search or CSV finding uses its own tier; an account finding needs one agreed address across the inventoried tiers, or the **authoritative identity tier** you choose. Missing, stale or conflicting addresses defer the email (at most 24 hours).
- **Who receives**: never a system account; human accounts by default; service and unclassified accounts only when you opt in.
- **Detection and clearing**: a new match opens an episode and sends one detection email. **Two consecutive complete evaluations** without the condition close the episode and send the "no longer detected" email (only after a sent detection, to the same recipient). Partial, unknown or learning evaluations never clear. A recurrence within *repeat hours* (24) does not send a new detection.
- **Baseline**: the first enabled evaluation records the current matches without sending them, unless **Include current detections once** is on.
- **Independent of operator triage**: resolving, dismissing, snoozing, grouping or assigning a finding does not stop or trigger user emails.
- **Content**: a common banner, introduction, footer, reply-to address and an HTTPS support link, plus per-policy subjects and bodies (*Policies → Edit → Email template*; every built-in policy is on except `unclassified_schedule/v1`; the privileged policies never email the account). Plain-text templates with the placeholders `{account}`, `{policy}`, `{search_name}`, `{app}`, `{environment}`, `{summary}`, `{action}` and `{window}`; subjects up to 256 characters, bodies up to 10,000.
- **Limits**: 50 emails per policies run (1–200), 3 per address per hour (1–20), 24 hours between repeat detections (1–168). One recipient per email.
- **Preview** and **Send test email** (to a test recipient, for one policy) use synthetic data and work while the channel is off.

Send email communication

Send email communication (finding and group menus, tenant administrators and power users) prepares a reviewed one-off email about a finding, a group member or a whole Finding group (up to 200 findings, one section per finding): the modal shows the findings, the recipient (which you may change for this email only), a full preview, and asks for explicit confirmation. It is sent once from a search process, never retried blindly: when the outcome is uncertain, check the inbox before sending again. It does not change the findings or the automatic notification state.

The UAM AI Agent

The **UAM AI Agent** reviews UAM findings with the evidence UAM collected; it replaces the UAM Findings Advisor of 2.4.18. Its modes, notes and decisions are those of every findings AI Agent: see *Findings AI Agents*.

- **Inspect** writes one current `[AI Agent]` note per finding (assessment, confidence, recommendation) and changes nothing. **Act** also applies the decisions the tenant allows.
- **Ask the AI Agent** (one finding, from its menu or the Investigate view), **Run a review now** (AI Agent tab) and the **scheduled triage** (hourly, off by default).
- The scheduled triage reviews at most *findings per run* findings, **one per Finding group**, skips a group reviewed within the review interval unless it changed, and never overrides an operator decision. Its selection uses the shared AI filters: by default only **critical and high** findings.
- The AI Agent tab shows the scheduled triage status and the decision log (kept 90 days).
- Requirements: AI enabled with a provider configured; for the scheduled triage, a tenant owner that is not `nobody` or `splunk-system-user` (Guardian `ai_automation_owner_is_system_user`). Launching,

deciding and reviewing need a TrackMe administrator of the tenant; tenant power users can read the settings and the decision log.

Setting (`vtenant_account`)	Default	Meaning
`ai_uam_agent_enabled`	0	Scheduled triage on or off.
`ai_uam_agent_mode`	inspect	Mode of the scheduled triage (`inspect` or `act`).
`ai_uam_agent_provider_name`	empty	AI provider; empty = the first available.
`ai_uam_agent_min_days_betw`	1	Days before a reviewed Finding group is reviewed again (unless it changed).
`ai_uam_agent_max_findings_`	10	Findings reviewed per scheduled run, one per group (1–50).
`ai_uam_agent_max_runtime_s`	3000	Time budget of one hourly run, in seconds.
`ai_uam_agent_allow_investi`	1	Act may mark a group investigating.
`ai_uam_agent_allow_dismiss`	1	Act may dismiss for a time — never a critical or high finding still observed.
`ai_uam_agent_dismiss_max_d`	7	Longest dismissal, in days (1–90).
`ai_uam_agent_allow_resolve`	0	Act may resolve a finding its policy no longer observes.
`ai_uam_agent_allow_classif`	0	Act may set the class (human or service) of an account without an operator class.
`ai_uam_agent_custom_instru`	empty	Plain-English instructions of the tenant administrators, followed by every run of the agent, asked or scheduled (at most 4,000 characters, line breaks kept).
`ai_automated_priority_filt`	critical,high	Shared: the finding severities the scheduled triage reviews.
`ai_automated_filter_expres`	empty	Shared: a filter expression on the finding (`policy_id`, `owner`, `app`, `account`, `subject_type`, `status`…).

These settings are edited in *Settings → AI Agent* of the workspace; *Manage AI Agents* shows the UAM AI Agent of each UAM tenant and edits its schedule, mode, provider, review interval, runtime and custom instructions. A permanent dismissal, an assignment, a severity change and any policy or configuration change are never available to the agent. See also *The AI Advisors*.

Custom instructions and Evaluate. The agent's custom instructions (*Settings → AI Agent → Custom instructions*, also in *Manage AI Agents automation* and the *Configure tenant* dialog) come last in its prompt, after the provider's custom prompt and, for scheduled runs, after the tenant's shared custom instructions (`ai_automated_custom_instructions`, scheduled runs only). They never widen what the agent may do: the allowed decisions and the checks TrackMe makes before every decision still decide. **Evaluate…** runs the agent in inspect mode on the unsaved draft (empty = without instructions), on one open finding or a review of the open findings (at most 10, the most severe first), optionally side by side with a run without custom instructions. It writes nothing — no note, no decision, no review record — and is recorded with the status `evaluation`, so a later act run never starts from it. See *AI Agents for findings*.

Collection health and Configuration Guardian

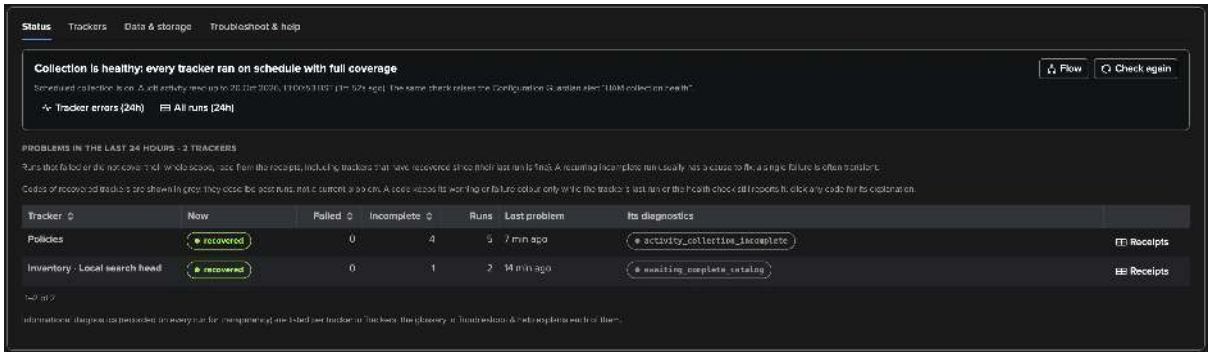
Collection health

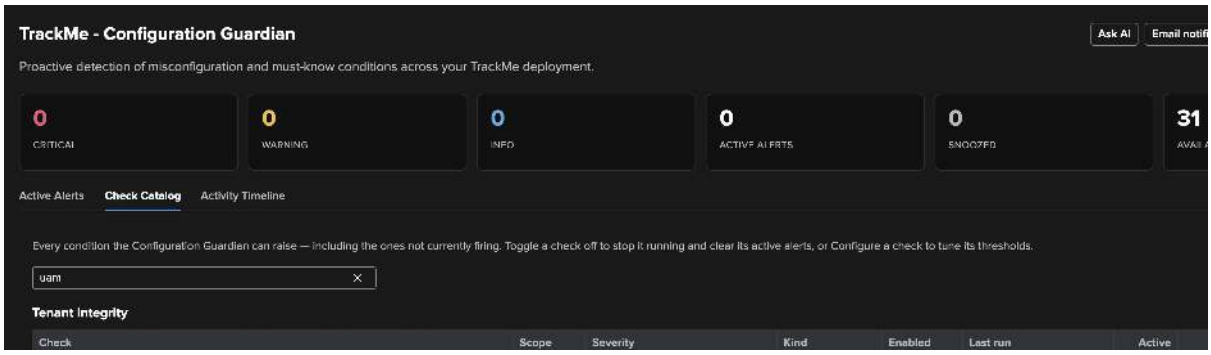
The *Collection health* tab is the first stop when something looks wrong. Everything that says something is wrong comes with its explanation, its evidence and its action, and every artefact UAM writes is named, located and one click away. Four views:

- **Status** — one row per tracker that needs attention, from the same assessment as the `uam_collection_health` Guardian check (so the page and the alert never disagree), plus the tracker's last receipt. Expanded: every reason with its meaning and where it was reported (run, dataset, tier, window), **What to do**, the facts of the last run (status, finish, consecutive failures, search job, report and its live schedule, lock), the policies a policies run could not complete (**Show why** opens the policy insight), the evidence shortcuts (**Receipts**, **Tracker log**, **Search job**, **Report**, **Scheduler log**) and **Run now / Recover**. Below: **Problems in the last 24 hours**, the failed and incomplete runs of each tracker from the indexed receipts, recovered or not (the backfill only while a plan is active or a problem is current). **Flow** opens a read-only topology of the collection pipeline — the tiers and the indexing layer, the trackers, the KV collections and indexes they write, the policies, findings and their consumers — coloured by health.

- **Trackers** — every tracker in one table: status (opens the last-run view), live schedule (read from Splunk, not the defaults), last run, last collected, duration (with the budget applied, see *Run budgets*), diagnostics, actions. Filters: name, family, status (needs attention, failed, running, not scheduled), tier. Expanded: the activity checkpoint and the windows of the last run with their outcome (acknowledged, split, resumed next run, retried) for Audit activity; the resource windows, re-reads and capacity for Resource usage; the scans and their re-reads for Account signals; the datasets of a catalog; the backfill plan and its controls. **Searches of the last run** (Audit activity, Resource usage, Account signals, Policies) lists every search the run sent, exactly as sent — audit windows with the clause that resumes them, recounts, re-reads, resource windows, scan chunks, each policy aggregation per evaluated window — with its time range, **Copy** and **Open in Search**; only searches the run really sent are listed, with a note when the settings changed since or the run read through a remote account. Custom policies have their execution health under the *Custom policies* family.
- **Data & storage** — what UAM writes for the tenant: the events per index and sourcetype (volume over 1 hour to 7 days, latest event, search), the KV collections (records, size, lookup definition, a record viewer with a KV query, what large collections are made of), the logs and every scheduled report with its live state, owner and next run.
- **Troubleshoot & help** — the **diagnostic glossary**: every code UAM can report, with *What it means*, *Where it comes from*, *Possible causes* and *What to do*; searchable (spaces match underscores), the codes the tenant reports now first, codes of earlier versions kept and marked. Then ready-made searches: tracker errors, failed or incomplete runs, every run, skipped scheduled reports, REST calls, who changed UAM.

The view and its filters, and the expanded row, survive a tab switch and the auto-refresh. A diagnostic code is a chip: its short meaning on hover, its full explanation on click; it keeps its warning or failure colour only while its condition is current, and a code of a recovered past run is drawn neutral and names the run it describes. The Status verdict answers in seconds; the 24-hour history and the record counts follow in a second request.





Configuration Guardian

The `uam_collection_health` check (tenant scope, **warning**, see *Configuration Guardian*) runs at every health cycle of each UAM tenant and on Guardian *Run now*. It is skipped for a disabled tenant, an unconfigured workspace or manual collection (which clears a stale alert). The alert names the tenant, lists its problems in the metadata and points at *Collection health*; it clears itself once the conditions are gone. Unreadable inputs leave an existing alert untouched.

Problem code	Condition
`report_missing` / `report_not_scheduled`	A report the tenant expects is absent, or not scheduled.
`no_run_recorded`	A report has no recorded run.
`tracker_stale`	The last run is older than three missed schedule opportunities (plus the listing budget for the catalog reports).
`repeated_failed_runs`	Three or more consecutive failed runs of one report.
`notification_delivery_failed`	Operator notifications are on and the last policies run failed to deliver some.
`user_notification_delivery_`	User notifications are on and the last policies run failed to deliver some.
`listing_overdue`	A catalog was last published more than twice its cadence plus a day ago.
`listing_incomplete`	The last listing or catalog traversal failed or did not complete.
`listing_queued_repeatedly`	A catalog of a tier waited for another listing of the same tier on three due runs in a row and listed nothing.
`checkpoint_stalled`	A checkpoint did not move for three schedules plus one window — the audit activity cursor, the resource usage cursor or an account signals scan. A checkpoint catching up, however far behind, is not stalled. The alert names the cause when one is recorded: a range being written over several runs, or a held range.
`activity_window_held`	An audit range has been held (its search keeps failing) for 15 minutes.
`window_reread_overdue`	A window read while some search peers did not answer has waited more than a day to be read again.
`window_recount_overdue`	A recount of closed ranges has waited more than a day past its time.
`findings_working_set_large`	One policies run can change more than 50,000 findings. Every finding is still evaluated.
`dead_job_lock`	A lock is held by a run whose search has stopped (use *Recover stopped run*).
`lock_owner_unverifiable`	A lock's owner cannot be verified (another member, or no search id).
`definition_capacity`	More custom policies are enabled than the tenant allows.
`schedule_drift`	A custom policy's scheduled report is missing, unscheduled or differs from its published revision.
`repeated_incomplete_runs`	Three or more consecutive incomplete runs of a custom policy.
`recovery_required`	A custom policy run outlived its time limit and needs a verified recovery.
`missed_schedule`	A custom policy missed its scheduled runs.

Tenant lifecycle

Disabling the tenant un-schedules its reports; enabling it reconciles them. Deleting a UAM tenant cancels a running backfill, disables and deletes its reports, lookups and collections, and refuses to run while a job lock is held (a provably stopped lock is recovered first; wait for or recover a live one, then retry). When provisioning is incomplete, the wizard result and the workspace offer **Repair UAM workspace**, which re-provisions the collections, lookups and reports idempotently.

Settings reference

The UAM configuration is one record (`uam_config` at creation, `config` of `POST uam/configure` afterwards), edited from the workspace *Settings* tab and saved at once with a revision check (an older draft is refused). Every limit is a tunable with a validated range, not a product cap, and every limit of a run is a time: there is no row limit. The seven record-count settings of earlier versions (`activity_max_records`, `activity_max_window_retries`, `resources_max_records`, `inventory_max_records`, `findings_max_records`, `backfill_max_records`, `backfill_max_retries`) are ignored: stored values disappear at the next save, and an API client that still sends them keeps working.

Section	Setting (key)	Default	Bounds and meaning
Environment	Search head tiers (`tiers`)	`["local"]`	1–10: `local` and / or remote account names, one indexing layer.
	Route account for indexing-layer searches (`account`)	`local`	One of the tiers; `local` when selected, else the first tier.
Activity scope	Include / exclude (`search_head_scope.include` / `.exclude`)	empty / empty	Up to 20 hostname patterns each (`*`, `?`); exclusions win.
Collection	Scheduled trackers (`scheduled`)	On	Off = collection only on request. Requires a tenant owner.
	Store SPL search (`store_search_text`)	**Off**	Index the SPL of reported searches in the search text index.
	Collect search resource usage (`resources_enabled`)	On	Required by the resource policies.
	Source version assumption (`source_version_assumptic`	On	Parse unverified emitters under the head's version, labelled assumed.
Indexes	`indexes.evidence` / `.findings` / `.receipts` / `.search_text`	empty	Empty = the tenant's summary index (evidence, receipts, search text) or notable index (findings).
Limits · activity	Activity window (`activity_window_seconds`)	300	60–3,600 s: the largest span one audit or resource window reads (a busier window is split and read in full).
	Activity overlap (`activity_overlap_seconds`	60	0–600 s, less than the window.
	Audit activity max seconds per run (`activity_max_seconds`)	270	30–900: the budget of one Audit activity run.
	Resource usage max seconds per run (`resources_max_seconds`)	270	30–900: the budget of one Resource usage run, capacity refresh included.
	Account signals max seconds per run (`signals_max_seconds`)	870	30–900: the budget of one Account signals run (half at most for the login scan).
	Data usage run budget (`data_usage_max_seconds`)	870	30–14,000: the budget of one Data usage run; a scheduled run ends before the next 15-minute slot, a manual run can use the whole budget.
	Activity policy window (`activity_policy_window_s`	900	300–86,400 s: the window of collected evidence the activity and resource policies evaluate.
Limits · inventory	Inventory page size (`inventory_page_size`)	500	50–500 records per REST page.
	Catalog collection every (h) (`inventory_reconcile_hour`	24	1–168: saved-search listing and the ten other families.
	Users and roles every (min) (`inventory_identity_minut`	60	15–1,440.
	Full listing budget (s) (`inventory_listing_max_se`	3,570	300–14,000 per run of a traversal; a longer traversal continues at the next run.
	Listing window start / length (`inventory_listing_start_` / `inventory_listing_window_hour`	1 / 5	0–23 / 1–24 (24 = any time), search head local time.
Limits · policies	Resource rules: minimum history (h) (`activity_min_history_hou`	24	0–720; the learning period of the resource policies.

continues on next page

Table 12 – continued from previous page

Section	Setting (key)	Default	Bounds and meaning
Limits · backfill	Backfill days (`backfill_days`)	30 (the wizard proposes none)	0–90 (0 = no backfill). The wizard always sends its choice; 30 is what a stored configuration without the setting reads.
	Backfill bucket (`backfill_bucket_seconds`)	300	300–3,600 s.
	Backfill max seconds per run (`backfill_max_seconds`)	3,570	600–3,570.
Account classification	Detection (`classification_detect_i` / `_service`)	On / On	Human and service detection.
	Rules (`classification_rules`)	none	Up to 100 ordered exact / wildcard rules.
	Manual classes (`account_classes`)	`nobody`, `splunk-syste` `admin` → system	Up to 10,000 accounts.
Data usage	Supply links (`data_usage.links`)	automatic	Per tier: one VOL tenant (`vol_tenant`) and up to 20 DSM tenants (`dsm_tenants`). A tier without an entry is matched automatically; an explicit entry, even empty, stays as set.
	Excluded apps (`data_usage.exclude_apps`)	`trackme`, `Splunk_SA_CI`	Up to 10 apps whose searches are shown, never counted as reads.
	Internal indexes (`data_usage.include_internal`)	Off	Show the _-prefixed indexes in the views by default.
	Account and sourcetype grain (`data_usage.per_account` / `.sourcetype_facts`)	On / On	Write facts per account and per sourcetype. Changes apply to new facts only.
	Resolution limits (`data_usage.limits`)	65,536 / 128 / 256 / 64	SPL excerpt characters (1,024–262,144), reference depth (1–256), resolution attempts per search (1–4,096) and nested subsearch levels (1–128). A limit reached leaves the search unresolved, never dropped.
Privileged users	`privileged.role_patterns` / `.roles_include` / `.roles_exclude` / `.capabilities`	`*admin*` / none / `trackme_admi` / nine capabilities	Up to 500 entries each; see *Privileged users*.
Notifications to operators	`notifications`	Off; new, reopened, severity raised, resolved; medium; digest	Up to 50 recipients.
Notifications to users	`user_notifications`	Off; human accounts; baseline	50 per run (1–200), 3 per address per hour (1–20), 24 h between repeat detections (1–168).

Table 12 – continued from previous page

Section	Setting (key)	Default	Bounds and meaning
Policies	`policies.<policy id>`	see the catalogue	Enabled, severity, exclusions, scope, thresholds, automatic thresholds, preview mode, bank holidays hold (`hold_on_bank_holidays`); the privileged policies' settings (`inactive_days`, `reference_accounts`, `reference_lookups`, `report_stale`, `include_splunk_operated`).

Stored elsewhere:

- **AI Agent —** the `ai_uam_agent_*` fields of the tenant (see *The UAM AI Agent*).
- **Assignment —** up to 100 assignment groups and 100 routing rules; group emails off by default.
- **Finding actions —** up to 50 definitions and 100 automation rules.
- **Custom policies —** their own definitions (see *Custom policies*).
- **Per viewer —** *Exclude TrackMe activity* on the Users tab (browser storage, off), the Policies view mode (Cards, Compact cards, List), and the three Tenant Home display preferences (Collection monitors, Single stats, Charts).

The tracker schedules, the one-day retention of old catalog generations and the 90-day retention of the AI Agent decision log are fixed.

Roles and licence

Role	Access
TrackMe administrator of the tenant (`trackmeadminoperations` and one of the tenant's admin roles; Splunk `admin_all_objects` also passes)	Everything: the workspace in Tenant Home, triage and grouping, configuration, policies and custom policies, search text and live definitions, the knowledge-object catalogs, collection control, the AI Agent.
Power user of the tenant (`trackmepoweroperations` and one of the tenant's power roles)	**REST API access only** (Tenant Home shows the UAM workspace to tenant administrators): the workspace, findings, Finding groups, counts, activity, accounts, privileged users, inventory, saved search view, policy evaluation and history, tracker history, AI Agent settings and decision log; **Send email communication**; findings actions (run an action, email action, set an assignment).
Read-only user (`trackme_user` only)	No UAM operation.

Licence: any licence beyond the Foundation edition — Enterprise, Unlimited, the trial and Developer licences. Foundation and the Foundation Trial are refused (`uam_not_available_in_foundation`). On an expired licence the workspace stays readable and changes are refused; scheduled collection and custom policy runs continue through the read-only and escalation stages of the licence enforcement ladder and stop with the tenants at the stop stage.

REST endpoints

Resource group `uam`: `/trackme/v2/uam/<operation>` (browse it in **TrackMe REST API Reference**). Every operation is a POST with `tenant_id` in the body, except `GET workspace` and `GET agent_settings`, and answers `describe=true`. "Power" marks the operations also open to tenant power users; the others need a TrackMe administrator of the tenant. Every `earliest` / `latest` accepts what the Splunk time picker produces.

Area	Operations
Workspace reads (power)	`workspace`, `finding_counts`, `activity`, `timeline`, `accounts`, `account`, `privileged` (the privileged users, with `activity: true` for their activity), `inventory`, `saved_search`, `tracker_history`
Data usage (power)	`data_usage` (`view`: `map`, the default, with the value view, or `timeline` for an index or an account), `data_usage_index` (one index), `data_usage_objects` (the knowledge objects), `search_jobs_cancel`; `data_usage_links` (the supply candidates, administrators). The reads accept `search_jobs: "start"` and then the returned jobs to poll; without it they answer synchronously within the safety timeout
Findings and groups	`findings`, `finding_groups`, `finding_group` (power); `triage` (decisions on up to 500 Finding groups, `expected_versions`), `group_members` (`merge`, `add`, `remove`, `ungroup`), `classify` (manual classes of 1 to 200 accounts)
Policies	`policy_evaluation`, `policy_history` (power); `preview` (evaluate a draft configuration without writing)
Custom policies	`custom_policies`, `custom_policy`, `custom_policy_health`, `custom_policy_write` (create, save, restore, publish, enable, disable, archive, delete, delete a version), `custom_policy_execution` (preview or run: dispatch, status, cancel, recover)
Notifications	`notification_test` (operators or users channel); `user_notification_preview` (power); `user_contact_override`; `communication_preview`, `communication_send` (power)
Inventory and catalogs	`saved_search_definition` (Fetch definition), `knowledge_objects`, `search_text` (Fetch SPL)
Collection	`configure` (full configuration with its `revision`), `collect` (`job`: `all` or one job, optional `tier`), `backfill` (`pause`, `resume`, `cancel`, `restart`), `recover`, `collection_health` (optional `parts`: `status` and / or `history`), `storage_counts`, `searches` (the exact searches of a tracker's last run, `job` = `activity`, `resources`, `signals` or `policies`, or of one policy, `policy_id`)
AI Agent	`agent_settings` (GET power, POST saves), `agent_decisions` (power), `agent_findings`, `agent_evidence`, `agent_decide`, `agent_review`, `agent_run`; job control in `/trackme/v2/ai_findings_agent/{agent,agent_status,agent_cancel}`
Findings actions	`/trackme/v2/findings_actions/*` with `component=uam`

The tenant is created with `POST /trackme/v2/vtenants/admin/add_tenant` carrying `tenant_uam_enabled=true` and a `uam_config` object (the wizard sends `tiers`, `scheduled`, `backfill_days` and `search_head_scope`); see *Creating a splk-uam tenant*.

Upgrading to 2.4.22

- **Data usage** arrives with its own report, `trackme_uam_data_usage_tracker_tenant_<tid>`, created on an upgraded tenant by the health tracker's schedule reconciliation, without a configuration save. Its history starts at its first run: the searches before the upgrade are not read. Until the collection covers the selected period, or seven days of it, the views say *so far* and call no index unread.
- The facts' index-time fields (`uam_data_*`) are extracted by the same TrackMe ingest rule as the other UAM dimensions: on a distributed deployment, the instances that parse the UAM log need the upgraded app and its restart. Until then the map falls back to a slower raw read.
- Searches the UI starts on a UAM tenant run as the caller's own search jobs, polled until done: a long range or a heavy account is read completely instead of being cut after 45 to 60 seconds.

Upgrading to 2.4.21

- **Indexing-layer trackers**: the health tracker's report check (every 5 minutes) creates the Resource usage and Account signals reports of an existing tenant, with its owner, ACL and schedule, before the Guardian check of the same cycle (a report it just created is never reported missing). The Activity report keeps its definition and runs the audit only. Resource usage continues from the existing resource cursor, the scans from where the earlier runs stopped; until the first Resource usage run, the policies read the resource usage of the last activity receipt. No schema migration, no settings save.
- **Budgets**: a stored budget still at its earlier default (200 s for the activity, 3,600 s for the full listing, 3,000 s for the backfill) moves to the new default (270 s, 3,570 s, 3,570 s); a value an administrator chose is kept. The report check also refreshes a tracker description left by an earlier build.
- **Retired limits**: the seven record-count settings are ignored and dropped at the next save.
- **Evidence**: correlated executions are no longer indexed, and the UAM events carry fewer fields (see *The evidence*). Rewrite your own searches on `trackme:uam:execution`. The index-time `uam_*` fields of audit and resource records now follow their sourcetype: the rule takes effect at the splunkd restart, and the earlier rule still applies until then.
- **Backfill**: the wizard proposes no backfill and new configurations use 5-minute buckets; an existing tenant keeps its bucket size until you change it.
- **Catalogs**: older catalog generations are deleted after 30 minutes (a day before), which removes many KV records on a deployment with many users. The users catalog also collects `last_successful_login`, kept outside the compared fields (a login is never an inventory change).
- **Privileged users**: the tab and *Settings → Privileged users* appear with the release defaults; the four privileged policies are off, and a change policy turned on starts from a baseline.

Upgrading from 2.4.18

- **Finding groups**: the first policies runs after the upgrade consolidate the existing findings into Finding groups (up to 5,000 findings per run; an account is never split). Triage decisions, notes and history are kept.
- **Inventory**: each tier gets its `listing` and `kos_*` reports. The first saved-search listing runs at the next hourly wake, then on the catalog cadence. The users and roles reports move from 5-minute to 15-minute wakes unless an administrator changed their schedule. *Inventory max seconds*, the fallback listing cadence and the delta object limit of 2.4.18 have no effect any more.
- **UAM AI Agent**: the UAM Findings Advisor report is removed; an enabled advisor's settings (enabled, mode, provider, review interval, runtime capped at 3,000 seconds) are carried to the UAM AI Agent once.
- The indexed `uam_*` dimensions take effect after the splunkd restart of the upgrade.

Troubleshooting and known limits

Start with **Collection health** (each tracker's last run, diagnostics and recovery) and the Configuration Guardian check `uam_collection_health`. The technical logs carry outcomes only, with `tenant_id` index-time extracted: `index=_internal sourcetype=trackme:custom_commands:trackmeuam* tenant_id=<tid>` (`trackme_uam_tracker.log`, `trackme_uam_inventory.log`, `trackme_uam_activity.log`) and `index=_internal sourcetype=trackme:rest_api tenant_id=<tid>` (`trackme_rest_api_uam.log`). `trackme_uam_events.log` is the evidence, not a troubleshooting log.

Symptom	What to check
The inventory is complete but the Activity tab stays empty	The route account cannot read `_audit` on the indexing layer (roles on the remote deployment), the search heads keep their internal indexes local, or the activity scope excludes them. Check the activity receipt in *Collection health* and run `index=_audit action=search` as the route account.
Data usage calls nothing unread, and says *so far* with a date	The collection is younger than the selected period (or than seven days): an absence of reads is claimed from that date. The coverage card of the view gives it.
Data usage shows *Partial coverage* or no volume	The coverage card names the cause: a collection run that did not complete (see the Data usage tracker in *Collection health*), an index catalog that could not be read, facts without the rollup key (the parsing tier lacks the upgraded app), or no VOL / DSM tenant linked to the tier (*Settings → Data usage*).
Most audit lines are unparsed (`unsupported_source_contract`	The emitters' version could not be verified and *Source version assumption* is off: turn it on.
No service account is ever detected	The `_audit` trail is JSON-only (the automation scan reads the legacy key=value format), or its retention is under seven days. Classify the accounts by rule or by hand.
The resource policies say *learning* for days	Less than 24 hours of resource history (*Collect search resource usage* off, or `_introspection` not forwarded), or no capacity record (see the activity receipt).
A policy opened a finding during a bank holiday	The policy keeps opening findings (*During bank holidays*), the tenant does not hold new findings (*Manage Bank Holidays → Tenants & settings*), the holiday is not in the tenant's calendars, or the finding was already observed. The policy insight and the policies receipt say what the run held, or that the holidays could not be read.
Peak memory reads *not measured*	No introspection sample caught the search (short pooled searches on Splunk Cloud). CPU still comes from Splunk's completion accounting.
Fetch SPL shows a reason instead of the text	`not_in_audit`: the record aged out of `_audit`; `account_access_denied`: your roles are not granted the route's remote account; `access_denied`: the environment refused your search. *Store SPL search* keeps the text in an index you control.
A finding keeps coming back after *Resolve*	Expected: the condition persists and the policy reopens a resolved finding. Fix the cause, add an owner / account or app exclusion on the policy, or **dismiss** it.
A CSV finding names the recorded owner, not the writer	No supported audit evidence of the write since monitoring began (or the tier's members could not be discovered: see the policy evaluation's writer diagnostics). The owner fallback is by design.
The Users tab shows a class the settings do not	The class is *detected*; a manual class or a rule always wins, and a detection can be switched off.
Collect now answers that a run is in progress	A scheduled run holds the lock; wait for its receipt. If no run is active, *Recover stopped run* (after five minutes, same search head only).
The backfill reports *waiting for the first activity run*	Normal until the Audit activity and Resource usage trackers set the live start; the backfill plans itself at its next hourly slot.
A custom policy does not run	Check *Collection health → Trackers*, family *Custom policies*: published and enabled, *Scheduled trackers* on, a tenant owner set; the Guardian names `schedule_drift`, `missed_schedule` or `recovery_required`.
The activity checkpoint lag keeps growing	The audit trail grows faster than one run reads it within its budget. Restrict the **Activity scope** to the search heads you monitor (it is applied in the base searches); *Searches of the last run* on the Audit activity tracker shows each window and its outcome. Nothing is dropped meanwhile: the next runs continue.
Audit activity says *Range held*	The search of one range keeps failing: it is retried, then halved to isolate the failing span, never skipped. Open the search job and the tracker log from the Status row; a range held for 15 minutes raises `activity_window_held`.
Windows to read again (informational)	Some search peers did not answer while a window was read. The window is read again once every peer answers, writing only what was missing; after a day of waiting, `window_reread_overdue` is raised: check the peers' state.
The Duration of a run says its budget was capped	The scheduler dispatched the run late (a busy scheduler): the run ended 30 seconds before the next scheduled run so that none is skipped, and the next runs continue through the checkpoint. Frequent caps point at scheduler load on the search head.

Known limits.

- One indexing layer per tenant: keeping the tiers on one layer is the administrator's responsibility.
- A saved search with the same name, app and owner on two tiers shares one set of run figures in the saved search view (resource records carry no tier).
- The knowledge-object catalogs reflect what the collection account can see, and a traversal is not an atomic snapshot.
- Several tenants monitoring the same tier each pay their own collection cost.
- Activity policies judge 15-minute windows of collected evidence by default; inventory policies follow the catalog cadence (a daily saved-search listing by default).
- Custom policies map to accounts and saved searches only, and their findings are not notified.
- A line that becomes searchable more than about ten minutes after its range closed, with no Splunk message, is not recovered; the login and automation scans, the resource usage and the backfill are not recounted. Rows recovered by a re-read after their policy window was evaluated are not evaluated again by the activity policies.
- A one-second range holding 500,000 audit events or more is held.
- A single Splunk call that blocks on a saturated instance is not interrupted inside a run, so such a run can last longer than its budget.

8.3.16 Data usage reference: how each claim is processed

This page is the reference for the **Data usage** tab of a User Activity Monitoring tenant (see *the Data usage section of the UAM guide*). For each kind of claim a search can make about an index, it shows how Data usage records the claim, how the map interprets it when you read the view, worked examples and an explicit list of what it cannot establish.

The same text and diagrams are in the product: every **How this works** link of the Data usage tab opens them, and the **Explain** list selects the topic. The collection behind the tab (its report, facts, limits and REST operations) is described in *Data usage in the UAM in-depth reference*.

To see the facts behind a view, use **Open in Search** in the three-dots menu of any tile, chart or table of the Overview, Value & cost, Knowledge objects and Evidence views. It opens the search over the recorded facts that view reads, with a note on what only the map adds when you read the view: the catalog expansion of wildcards, the role scopes and the VOL volumes.

The examples use generic index and account names (`web`, `fw_*`, `hr_payroll`, `analyst`). Splunk's role search behaviour described here was measured on Splunk Enterprise 10.6 and Splunk Cloud 10.7.

How Data usage works

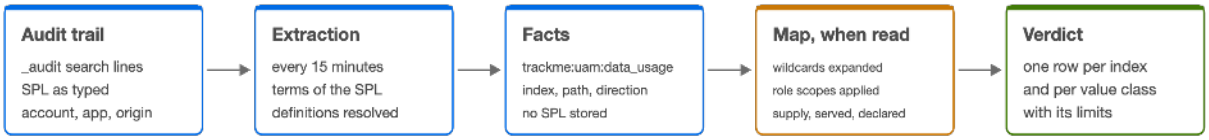
What it means. This view connects known indexes to searches UAM observed. It helps you investigate usage and identify data ingestion worth reviewing.

Where it comes from. The Inventory tracker lists indexes for each monitored search head tier. The dedicated Data usage collector reads audit observations and extracts index references from search text, resolving supported macros, event types, saved searches and data models from collected definitions. Explicitly linked VOL and DSM tenants contribute positive ingestion observations. The map compares these with retained search facts.

What it cannot establish. A reference does not prove that an index returned events, that results were consumed, or that an index has business value. Counts cover the selected period and scope, not all time. Sourcetypes are best effort. The map relies on the UAM contract: every search head tier of a tenant reads the same indexing layer, so one index name is one index. Watch a separate Splunk deployment with its own tenant.

What to do next. Start with Overview, investigate an index in Index activity, or use Value & cost to weigh each index's volume and cost against its reads: indexes no one accessed, indexes only wildcards reach, and the least read for their volume. Check Evidence and Collection health before acting on an absence.

From an audit line to a verdict



Splunk writes an audit record for every search it runs, with the account, the app, the dispatch origin (provenance) and the search text exactly as it was typed. It does not record which indexes the search read. Data usage therefore works from what the search asked for: its index claims.

A dedicated Data usage collector reads the search lines of the audit trail on its own schedule (every 15 minutes by default). It reads the SPL of each search, splits it into its pipeline stages and subsearches, and extracts the index and sourcetype terms of each stage. Macros, event types, saved searches and data models are resolved from the knowledge object catalogs that UAM publishes for the same search head tier. The SPL itself is never stored in the facts; it is held in memory while the batch is extracted.

A search is counted once, by rule: at its grant on the legacy audit format (Splunk writes it when the search starts), otherwise at its structured completion. A canceled or failed search still counts: it ran and read its sources. A search Splunk refused after granting it (a concurrency or disk quota) is not counted. Within one audit batch, each index named by a search receives one unit of weight, whatever the number of paths or sourcetypes that name it.

The collector writes facts (sourcetype trackme:uam:data_usage) to the tenant's evidence index: per window, tier, emitter, account, app, origin, path, index, sourcetype, direction and scope, with their counters as index-time fields. The map reads these facts through one tstats over those fields, so a long period never reads raw events for its counts.

Everything that depends on the current state of the deployment is applied when the map is read, not when the facts are written: wildcard patterns are expanded against the index catalog, role scopes come from the current users and roles catalogs, and incoming data, volume and declarations come from their latest publication. This is why a change of roles or a new index changes the view of past facts.

The map has one row per index for the whole indexing layer: every search head tier of a tenant searches the same indexers, so the same index name on two tiers is one index. A tier filter scopes the facts and the catalog shown; the verdict that decides a review candidate is taken on every tier together.

Limits

- An index claim is what the search asked for, never proof that the index returned events, that the results were looked at, or that the data has value.
- The figures are index claims, not distinct searches: one search that names three indexes counts once on each of them.
- A collector batch retried after a write failure cannot be told apart from the first write by the indexed counts; its receipt reports it.

- Older facts keep the interpretation they were written with: a change of the extraction or of the catalogs does not rewrite them, except for what the map applies when it is read.

Every kind of claim at a glance

Each line of the table below is a kind of claim a search can make about an index, with what Data usage records for it and what it does to the index's verdict. Only two kinds establish that an index was searched: a named source read on the search head side, and a named term in the search the indexers received. Everything else is context: it is shown, never counted as use.

Claim	Example	Recorded as	Verdict effect
Named read	`index=web`	A read of web, path literal	Searched · Read by name
Wildcard reference	`index=fw_*` · `index=*`	The pattern; expanded when the map is read, to the known indexes its reader could search	Indirect only · Wildcard only
Definition	`` `fw_idx` `` · `eventtype=x` · `| savedsearch r` · `| tstats … from datamodel=M`	What the definition names, path macro:… / eventtype:… / savedsearch:… / datamodel:…	As the indexes it yields: named or wildcard
Denied by roles	`index=hr` when the roles do not allow hr	Counted apart as a denied search	None: never a read
Index-less search	`sourcetype=nginx status=500`	Unresolved, path role_default; the role scope shown as context	None: never attributed
Late filter	`… | stats count by index | search index=web`	A late reference of web	None
Negation	`NOT index=web` · `index!=web`	Nothing counted for web	None
Write	`| collect index=summary_web`	A write reference of summary_web	None
Writing alert action	A saved search's summary indexing or Log event action targets summary_web	A write reference of summary_web on each run	None
Indexer confirmation	The search the indexers received names web	A served fact, never added to the search head counts	Searched when the search head side has no named read
Declaration	A saved search definition names web	A declared reference of web	None: a definition is not a run
Incoming data	VOL or DSM saw web receive data	Receiving, with volume and cost from VOL	None: decides which indexes are candidates
Excluded app read	A search of the trackme app names web	Shown, never counted	Excluded apps only, when nothing else reads it

Limits

- The table describes the default view: internal indexes hidden and the configured apps (TrackMe and the CIM acceleration app by default) excluded.

Named reads

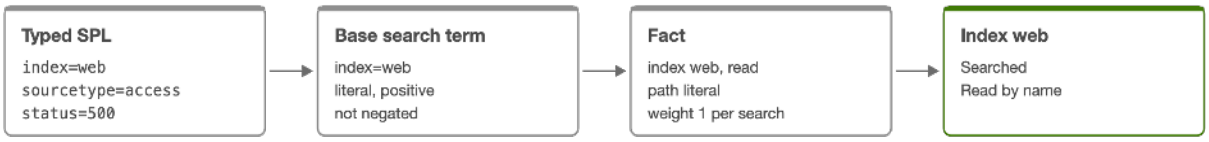
What it means. Source reads count observed search claims that name the index as a source, directly or through a supported definition. They describe the search request, not bytes read or returned events.

Where it comes from. Audit activity extracts source terms such as `index=example_web`. Index totals are deduplicated within each audit batch; path and sourcetype rows describe joint references and may overlap.

What it cannot establish. Do not add path or sourcetype counts to obtain a unique-search total. Older partial claims and later completions can remain in separate collection windows. Last searched is the latest named source claim in the selected evidence.

What to do next. Open Detail to see the account, app, source path and origin together. Fetch SPL examples to inspect the actual retained search text.

A literal index term



A named read is a positive, literal index term in the base search of a search or of one of its subsearches. Every form Splunk accepts is read: `index=web`, `index="web"`, `index::web`, index = web and `index IN (web, auth)`, whose members are one read each. Index names are compared lower-cased, as Splunk stores them.

The commands whose terms select data are the search itself and search, where, tstats, mstats, mcatalog, metadata, dbinspect and eventcount. Their index terms count, so | tstats count where `index=web` and | metadata type=hosts `index=web` are named reads of web.

The extraction reads syntax; it does not evaluate Boolean logic. `index=fw_emea` OR `index=web` records a read of each index. A term inside a subsearch (append, join, a […] argument) is a source term of that subsearch and counts as a read too.

When a search names exactly one literal index in its base search and its extraction is complete, the sourcetypes it matched are paired with that index from the completion's per-sourcetype event counts. With several indexes, a wildcard or a subsearch, no index and sourcetype pair is invented.

Last searched is the latest time a named read of the index was recorded in the selected evidence. Searches counts named reads; Completed counts the reads whose completion was recorded.

Worked examples

Search or case	What Data usage records
`index=web source-type=access_combined status=500`	One named read of web. The completion's event count for access_combined is paired with web.
`index IN (fw_emea, fw_amer) ac-tion=blocked`	One named read of fw_emea and one of fw_amer.
`| tstats count where index=web by sourcetype`	One named read of web: tstats selects data with its where clause.
`index=web [ search index=auth ac-tion=failure | fields user ]`	Named reads of web and of auth (a subsearch's base search is a source).
`index=fw_emea OR index=web`	Named reads of both: the extraction does not simplify Boolean SPL.

Limits

- A named read is a claim from the SPL. A search for an index that held no event in its time range still counts; so do metadata, dbinspect and eventcount, which read no raw event.
- A search whose retained SPL was truncated never yields a named read: its missing suffix could negate a term it kept. It is counted as unresolved.
- A named index the reader's roles do not allow is not a read: see Role search restrictions.
- Counts are per audit batch and per index, not a deployment-wide count of distinct searches.

Wildcard references

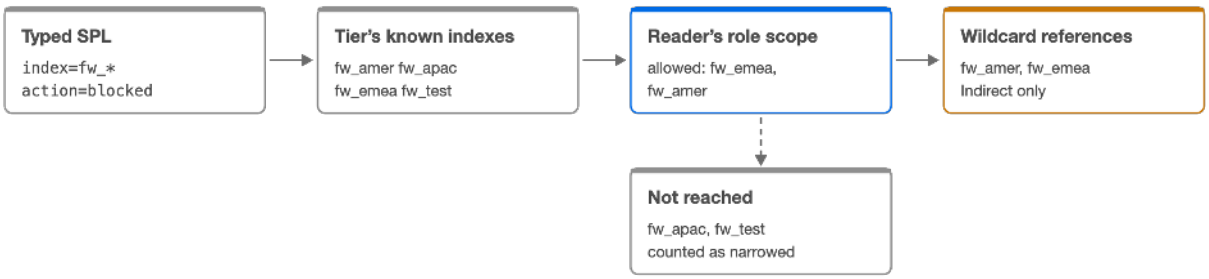
What it means. The index matches a wildcard source term, but UAM has no named source read for it in this selection.

Where it comes from. For example, `index=example_*` is expanded against the collected index catalog for the same search head tier, then narrowed to the indexes the search's account could search: its roles' allowed indexes and the index terms of their search filters. Matching indexes receive indirect references.

What it cannot establish. A broad `index=*` search can reference many indexes without proving that each supplied events or useful results. A field search filter (for example `sourcetype=…`) can still empty an allowed index. Indirect references are not named reads and are not a non-use verdict.

What to do next. Review the original SPL and its owner before judging value. Compare with ingestion volume and operational requirements outside this view.

Expansion, then narrowing to the reader



A wildcard term (`index=fw_*`, `index=*`, `index IN (fw_*, web)`) is kept in the facts as the pattern itself. The collector never knows which indexes matched it, and does not try.

When the map is read, the pattern is matched against the indexes known for the same search head tier: the tier's index catalog, listed by the Inventory tracker, plus any index a linked VOL or DSM tenant or a published knowledge object names for that tier. A new index is matched as soon as one of these sources names it: an index only the catalog will know is matched after the next catalog listing, while one a linked tenant or a published object already names is matched right away.

The matches are then narrowed to the reader's role scope, per account: the same pattern typed by two accounts can reach different indexes. Every remaining match receives one wildcard reference (the Indirect column); the matches the reader could not search are left out and counted in Evidence as wildcards narrowed.

A wildcard is a reference, not a read, because Splunk does not report which of the matched indexes held events in the searched range. Splunk searches every allowed index that matches; whether one of them supplied data is not in the audit.

Every pattern, typed or from a role (allowed, disallowed, filter and default indexes), is matched with Splunk's index pattern rule: case-insensitive, * as the only wildcard, and * never matching an internal index (a name starting with _) unless the pattern itself starts with _. Internal indexes are hidden from the view unless Include internal is on; with it on, `index=*` still does not reach them, while `index=_*` does.

When the source tier of a fact is unknown (its emitter does not map to a single tier), the pattern is kept as recorded, unexpanded, and never assigned to another tier's indexes.

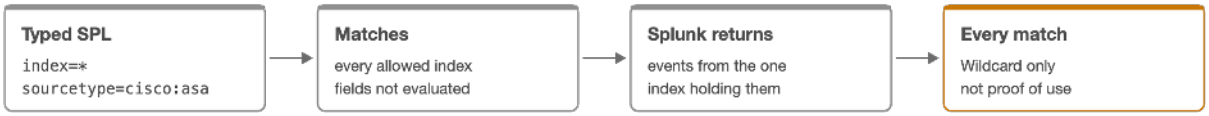
Worked examples

Search or case	What Data usage records
`index=fw_* action=blocked`	By an account allowed fw_emea and fw_amer: wildcard references on fw_emea and fw_amer only. fw_apac and fw_test are not reached (one wildcard narrowed, two matches removed).
`index=* error`	By an account whose roles allow *: a wildcard reference on every non-internal index of the tier.
`index=fw_* | search index=fw_emea`	Wildcard references from fw_*; fw_emea is also a late reference, which is not a read.
`index=_* | stats count by index`	With Include internal on, by an account whose roles allow _*: wildcard references on the internal indexes. `index=*` would reach none of them.

Limits

- An account whose role scope cannot be established keeps every match in the catalog (see Role search restrictions).
- The expansion is bounded per request (3 CPU seconds of the reading thread, 200,000 joint rows). Past the bound the answer is partial (expansion_limit) and candidates are withheld.

Why Wildcard only is never a verdict of non-use



An index reached only by wildcard references has the verdict Indirect only and the value class Wildcard only. It is not proven used: a broad pattern reaches it whether or not it held events. It is not proven unused either: the search may have returned its events. So Data usage keeps it as a review candidate, in a group of its own, and never folds it into No reader.

The role scope is an upper bound. A field term of the search or of the role search filter (`sourcetype=…`, `host=…`) can leave an allowed index without any event, and only the events would show it. Data usage never evaluates field terms per index.

Worked examples

Search or case	What Data usage records
`index=* sourcetype=cisco:asa`	A wildcard reference on every allowed index, although only the indexes holding cisco:asa events returned anything.

Limits

- Accesses (the Overview weight) add wildcard references to named reads: one `index=*` search adds one access to every index it reaches. Read the Wildcard only share before judging a much-accessed index.

Role search restrictions

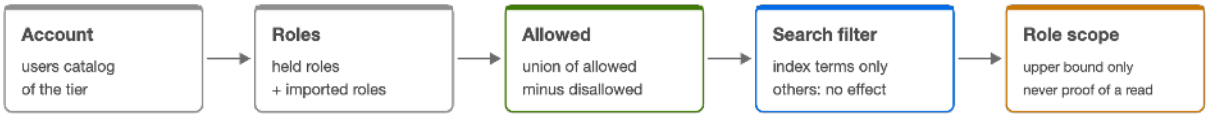
What it means. Splunk searches only what the account's roles allow. A wildcard reaches only the indexes its account could search, and a search naming an index its roles do not allow returned nothing: it is counted as denied, never as a read. A search naming no index can reach the indexes its role search filter names, else its default indexes, within what its roles allow: shown as context on the unresolved searches, never attributed (an index-free command reaches none).

Where it comes from. The published users and roles catalogs of each search head tier: the roles an account holds and imports, their allowed and disallowed indexes, and the index terms of their search filters. Splunk enforces these silently: the audit keeps the search as typed.

What it cannot establish. This is what the roles allowed, an upper bound: a field filter such as `sourcetype=…` can still empty an allowed index. The current roles apply to the whole period. An account or role missing from the catalogs, or a tier whose listing saw only its own account, keeps every wildcard match.

What to do next. Check Evidence for how many accounts were resolved. Before acting on an index reached only by wildcards, compare its readers' roles with the index; a denied read is an index the account asked for and could not read, even when the same search read other, allowed indexes.

How an account's role scope is built



Splunk restricts every search to its account's roles and records none of it: the audit keeps the SPL as typed, the search head appends the roles' search filter to the search it sends the indexers, and the indexers apply the allowed indexes without a message or an error. Data usage rebuilds the restriction from the users and roles catalogs UAM publishes for each search head tier.

The scope of an account is: the union of the allowed indexes of its roles and of every role they import (followed transitively); minus every disallowed index, which wins over any allowance; narrowed by the index terms of the roles' search filters.

Search filters combine as Splunk combines them. An empty filter is ignored, and a role without a filter does not open what another role's filter closes. Filters of several roles are joined with OR. Only positive index terms of a filter narrow the indexes (`index=…`, `index::…`, `index IN (…)`); a negation, a field term or a filter that cannot be read restricts no index.

Patterns are matched as Splunk matches index patterns: case-insensitive, * only, and * never matches an internal index.

The scope is computed when the map is read, from the catalogs as they are now, and applies to every fact of the period. Nothing is written on the facts.

Worked examples

Search or case	What Data usage records
Roles: analyst (allowed fw_*, disallowed fw_test) imports base (allowed web)	Scope: fw_* and web, without fw_test.
Roles: analyst (allowed *) with search filter `index=fw_emea` OR `index=fw_amer`	Scope: fw_emea and fw_amer.
Roles: analyst (allowed *, no filter) and auditor (allowed *, filter `index=audit_*`)	Scope: audit_* only: the unfiltered role does not lift the other role's filter.

Limits

- An upper bound: a field term of the filter (`sourcetype=nginx:*`) can still empty an allowed index.
- Splunk's roles endpoint does not return srchFilterSelecting, so every filter is read as selecting (joined with OR). An eliminating filter (joined with AND in authorize.conf) is widened, never narrowed.
- No scope is established, and every wildcard match is kept, when: the audit did not report the account; the account is not in the users catalog; one of its roles is missing from the roles catalog or was listed before this version; the tier's users and roles listing saw only its own account; the catalogs are not published yet; or the roles catalog holds more than 5,000 roles.

- The current roles apply to the whole period: a role changed last week rewrites the view of the weeks before. A role change also takes a few minutes to reach the indexers (knowledge bundle replication), during which Splunk applies the previous definition.

Denied by roles

A literal index that the reader's role scope does not allow is counted as a denied search on that index (the Denied by roles tile of the index detail), with the accounts that asked. It is never a read and changes no verdict: Splunk served nothing.

Only reads are checked. A write (collect) and a late filter keep their own meaning. An indexer confirmation of a denied index is not counted either.

Worked examples

Search or case	What Data usage records
`index=hr_payroll`	By an account whose roles allow fw_*: one denied search on hr_payroll, no read.
`index=hr_payroll OR index=fw_emea`	By the same account: a denied search on hr_payroll and a named read of fw_emea.

Limits

- A denial follows the roles' definition. It is not corroborated by the search's completion (a zero scan count is also what an empty time range gives).
- A denied search means that the denied index term returned nothing for its account, not that the whole search failed: the same search can read other, allowed indexes (the second example). It is a hygiene signal, never a use of the denied index.

Role filter terms in what the indexers received

Splunk appends the role search filter to the search the indexers receive. When the filter names indexes, the indexers' log shows index terms the account never typed. A served index term equal to one of the reader's own filter patterns is dropped as the role's, not the search's, and counted in Evidence as served filter terms.

Worked examples

Search or case	What Data usage records
Typed: error · role filter: `index=fw_*` · indexers received: litsearch error (`index=fw_*`)	The served fw_* is the role's filter: dropped. The typed search stays index-less.

Limits

- The match is exact, pattern for pattern, after lower-casing.

Macros, event types, saved searches and data models

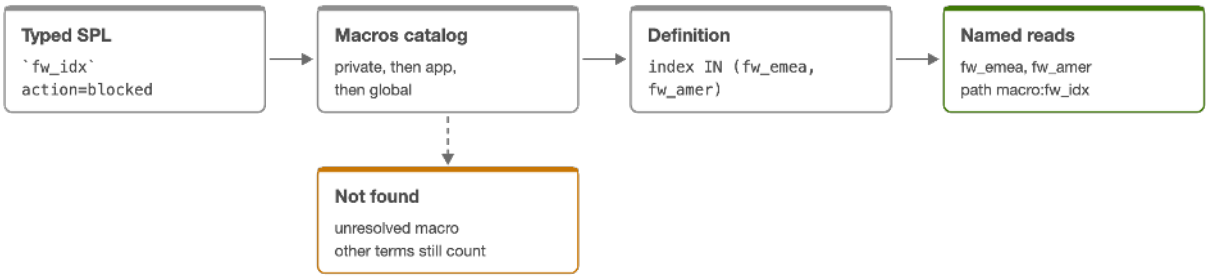
What it means. A search can name its indexes through a knowledge object. Data usage resolves the object from the catalogs of the search head tier and records the indexes its definition names, with the object as their path.

Where it comes from. The macros, event types, saved searches and data models catalogs UAM publishes for each tier. The collector pins the published catalog generations at the start of a run, so a run reads one consistent version of them.

What it cannot establish. An object the catalog cannot see (a private object of another owner, an app not listed) stays unresolved. Tags and custom commands are not expanded. The definition is the one published when the facts were written.

What to do next. Open the index detail's paths to see which objects lead to an index, and the Knowledge objects view for what each object declares and ran.

Resolution from the catalogs



A macro call (`` `name` `` or `` `name(arg1, arg2)` ``) is looked up by name and argument count, with Splunk's namespace order: the search owner's private object in the search's app, then an object shared in that app, then objects shared globally from other apps. Two candidates of the same rank leave the macro unresolved. Arguments replace their exact arg tokens. The definition is then extracted like typed SPL, recursively.

`eventtype=name` is resolved to the event type's search. | savedsearch name, | loadjob savedsearch="owner:app:name" and | from savedsearch:name are resolved to the saved search's SPL; the loadjob owner syntax does not open another owner's private object.

A data model reference (| tstats … from datamodel=Model.Object, | datamodel Model Object search, | from datamodel:Model, | pivot Model Object) is resolved to the root constraints of the model: the constraint of the object's own root dataset (BaseEvent, BaseSearch or BaseTransaction), or of every root when no object is named. Child constraints never widen the scope.

The indexes found are named reads or wildcard references as they would be typed. Their path is the first object of the chain: a macro calling another macro is recorded as macro:<first>.

A macro used inside a command whose arguments are not a search (macro_context), a missing object, a cycle, or a resolution beyond its limits is recorded as an unresolved part of the search; the other index terms of the same search still count.

Worked examples

Search or case	What Data usage records
`` `fw_idx` action=blocked (definition: index IN (fw_emea, fw_amer)) ``	Named reads of fw_emea and fw_amer, path macro:fw_idx.
`eventtype=web_errors (search: index=web status>=500)`	A named read of web, path eventtype:web_errors.
`| tstats count from datamodel=Web.Errors (root constraint: index=web sourcetype=access_*)`	A named read of web, path datamodel:Web.
`` `undefined_macro` index=web ``	A named read of web, and an unresolved part macro:undefined_macro.

Limits

- Resolution limits (Settings → Data usage): depth 128 (1 to 256), 256 resolution attempts per search (1 to 4,096), 64 nested subsearches (1 to 128), and 65,536 characters of SPL (1,024 to 262,144). Reaching one records an explicit diagnostic.
- Tags (`tag=…`) are not resolved; a data model constraint that holds only tags names no index.

- map, foreach, dashboard tokens ($token$) and eval-built index values are dynamic: never resolved.
- Custom commands that run their own searches are not expanded; their inner searches are audited and extracted separately.

Index-less and unresolved searches

What it means. UAM observed searches with an unresolved part: missing source scope, a definition it could not expand, incomplete text or conflicting context. The same search can still have identified source indexes, counted separately. Unknown search head tier is a separate attribution problem.

Where it comes from. Examples include searches with no explicit source index, dynamic expressions or unsupported syntax. Role search defaults use the latest retained snapshot for each reference group, as context only. When the account's roles are resolved, a search naming no index shows what they could let it reach instead: the indexes its role search filter names, else its default indexes its roles allow.

What it cannot establish. An unresolved search may have used an index in your candidate list. Defaults do not tell us which index actually supplied data.

What to do next. Investigate the account and search syntax, and review collection diagnostics. Do not interpret an unresolved search as proof that an index was unused.

Searches that name no index

A search whose base search reads data but names no positive index term (`sourcetype=nginx` status=500, error OR fail*, | tstats count where `sourcetype=x`) is index-less: its scope is unresolved and its path is role_default. Splunk searched the indexes the account's roles give it, and the audit does not say which.

When the account's role scope is established, the unresolved accounts' Role scope column shows what an index-less search could reach: the indexes its role search filter names, when the filter names some (Splunk then searches those, not the default indexes), else its default indexes, always within what its roles allow, and only among the tier's catalog indexes. The table lists three names and counts the rest; the investigation dialog lists up to 50 with the total.

When the scope cannot be established, the default indexes recorded with the facts are shown instead (the latest snapshot per account and app). A default * is flagged as a wildcard default.

This is context only. An index-less search is never attributed to an index, so it never makes an index Searched and never removes one from the review candidates. A searched verdict is always provable from a named term.

A search that starts with a command reading no index (| rest, | inputlookup, | makeresults) makes no index claim at all and is not counted here.

Worked examples

Search or case	What Data usage records
`sourcetype=nginx status=500`	Unresolved, index-less. Role scope: the role filter's indexes, else the default indexes the roles allow.
`sourcetype=nginx [ search index=web | fields host ]`	A named read of web from the subsearch; the base search stays index-less (a subsearch cannot supply its scope).
`| rest /services/server/info`	No index claim: not counted.

Limits

- An index-less search may have read an index in your candidate list: the unresolved count is a reason to investigate before acting on an absence.
- The indexers never see the default indexes: an indexer confirmation cannot resolve an index-less search.

Other unresolved parts

A search is also unresolved, wholly or in part, when its SPL builds index values dynamically (map, foreach, $token$, eval `index=…`), names a macro, event type, saved search or data model the catalogs cannot resolve, holds a cycle or exceeds a resolution limit, has unbalanced syntax, or was truncated. Its path is dynamic. Index terms identified in the same search still count, separately.

A search whose extraction failed (extraction_failed) or whose text the audit did not carry (search_text_unavailable) is counted as unresolved, never dropped.

Each unresolved account keeps up to five sample searches with the reason of each part, so Fetch SPL examples shows what could not be resolved.

Limits

- The reasons are counted per reference group, not per distinct search.

Late filters, subsearches and negations

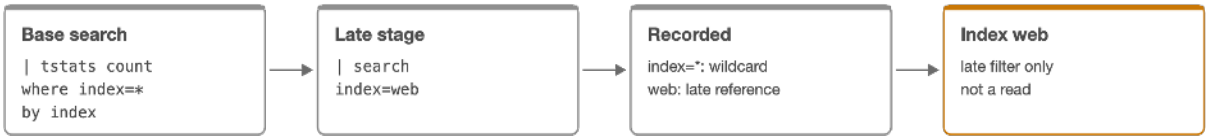
What it means. Where a term appears in the pipeline decides what it means. Only base searches select data; later index terms filter results, and negated terms exclude.

Where it comes from. The extraction splits each search into its stages and subsearches. The first stage of a pipeline is its base; every later stage is late; a subsearch has its own base.

What it cannot establish. Syntax is read, never executed: Boolean expressions are not simplified, and a late term after a stats command filters a field, not a dataset.

What to do next. Use the late references of an index detail to find searches that filter on an index without reading it, and Fetch SPL examples to check the pipeline.

Late filters



An index term after the first pipe (| search `index=web`, | where `index="web"`) filters results that the base search already read. It is recorded as a late reference: shown in the index detail, never counted as a read, never a verdict.

An index counts as late only when every term naming it in that search is late. `index=web` | search `index=web` is a named read.

A late filter never closes an unresolved base: an index-less base followed by | search `index=web` stays index-less.

Worked examples

Search or case	What Data usage records
`| tstats count where index=* by index | search index=web`	Wildcard references from `index=*`; web is a late reference only.
`sourcetype=nginx | search index=web`	Index-less (unresolved) and a late reference of web.

Limits

- A late reference can be the strongest hint of interest in an index, but the base search decided what was read.

Negations

NOT `index=web`, `index!=web` and an index term inside a NOT (…) group are negated: never counted as use. A negated term of an index also cancels a positive term of the same index in the same branch of the search, since the extraction does not simplify Boolean SPL.

Worked examples

Search or case	What Data usage records
`index=* NOT index=web`	Wildcard references from `index=*`; nothing counted for web from the negation.
`index=web NOT index=web`	No read of web.

Limits

- The expansion of `index=*` does not subtract the negated index: an expansion is a reference, not a computed set.

Write references

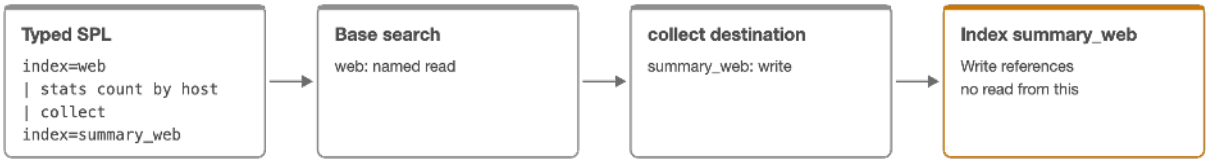
What it means. The search writes to an index: a collect destination in its SPL, for example | collect `index=summary`, or a saved search whose summary indexing or Log event alert action writes its output to an index.

Where it comes from. UAM extracts collect destinations from observed SPL, and reads the summary indexing and Log event targets from the saved search's published definition. Each is recorded with the direction write, separately from source reads.

What it cannot establish. This is evidence of a write reference, not confirmation that events were successfully indexed. A destination can have writes and no observed reads.

What to do next. Inspect SPL examples to understand the producer. Use Splunk ingestion evidence to confirm successful indexing and assess its volume.

collect and mcollect destinations



The index argument of | collect and | mcollect is recorded as a write reference of that index, in the Write references column. A write is never a read: an index only written to has no read from it and stays No reader (or Wildcard only) unless something else reads it.

collect's sourcetype argument labels its output; it is not a read filter and is not recorded. A macro used as collect's arguments keeps its meaning: its index term stays a write.

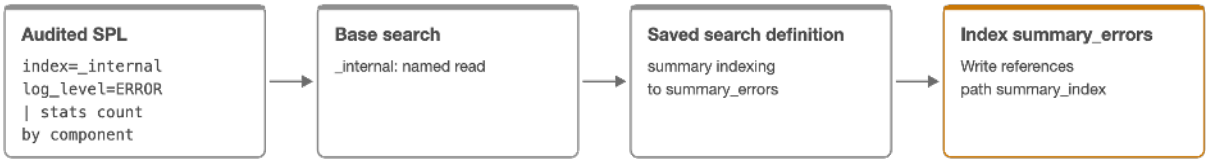
Worked examples

Search or case	What Data usage records
`index=web | stats count by host | collect index=summary_web`	A named read of web and a write reference of summary_web.
`| mstats avg(cpu) where index=metrics span=5m | mcollect index=metrics_rollup`	A named read of metrics (metric) and a write reference of metrics_rollup.

Limits

- outputlookup and outputcsv write lookups and files, not indexes, and tscollect writes namespaces: none is a write reference. Splunk's summary indexing and Log event actions are covered in the next case.
- A write reference is what the SPL asked for, not proof that events were indexed.

Summary indexing and the Log event alert action



A saved search can write its output to an index without any collect in its SPL: with summary indexing enabled (action.summary_index, target action.summary_index._name) or with Splunk's built-in Log event alert action (action.logevent, target action.logevent.param.index). The audit keeps only the saved search's SPL, so neither write appears in the search text.

UAM reads both settings from the saved search's published definition. Each run of that saved search records a write reference of the target index, on the summary_index or log_event path, and the saved search declares the same write in Knowledge objects. Splunk reports the effective target, including a default inherited from alert_actions.conf; when it reports none, the shipped defaults apply: summary for summary indexing, main for Log event.

Worked examples

Search or case	What Data usage records
Saved search "Hourly errors": `index=_internal` log_level=ERROR | stats count by component, summary indexing to summary_errors	Each run: a read of _internal and a write reference of summary_errors (path summary_index).
Alert "Failed logins": `index=auth` action=failure | stats count by user, Log event with an empty index	Each run: a read of auth and a write reference of main (path log_event).

Limits

- A run records the write the action is configured to make. Splunk writes only when the action fires: a summary search with no result or an alert whose condition is not met writes nothing.
- The target is the one Splunk reports for the saved search at the catalog's last listing, including a default inherited from alert_actions.conf. Only when Splunk reports none do the shipped defaults (summary, main) apply.
- Custom alert actions can write anywhere and are not predictable: they are never recorded.

Indexer confirmations

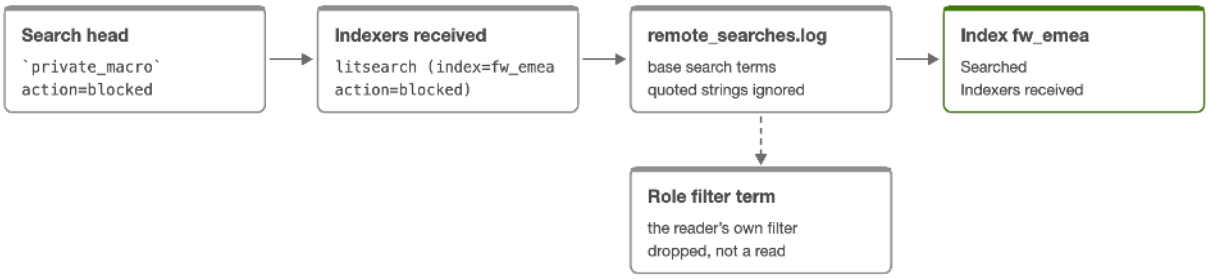
What it means. The search the indexers received, after Splunk expanded its macros, event types and saved searches. Its named index terms confirm reads the search head side could not resolve.

Where it comes from. Each search peer logs Streamed search connection closed in remote_searches.log, with the search it received. The Data usage run reads these lines after its audit windows, up to the audit cursor.

What it cannot establish. Only distributed deployments log them. The indexers never see a role's default indexes, so an index-less search stays unresolved. A served fact never adds to the search head counts.

What to do next. Use the Indexers received column to find indexes read through private macros, apps the catalogs cannot see or dynamic SPL.

What the indexers received



Splunk expands a search's macros, event types and saved-search references on the search head and sends the indexers the expanded search. Each indexer logs it when the connection closes, with the search head, the origin search id, the account, the app and the origin.

Only the base search counts (the text before the first pipe): a later search `index=…` filters results. A quoted string is never an index term. One fact per search head and origin search id.

If the received text holds a wildcard index term, every explicit index term of that text may be Splunk's own expansion of it, so only the patterns are recorded, as wildcard confirmations. A negated index term (NOT `index=…`, a term in a NOT (…) group, or a NOT group nested deeper than three levels) voids the terms of that search.

A served named term makes an index Searched when the search head side has no named read of it, with the verdict text "Named in the search the indexers received". It removes the index from the review candidates: it is the backstop for private macros, apps the catalogs cannot see and dynamic SPL. It is never added to the search head counts.

Served facts follow the reader's role scope like the others, and a served term that is the reader's own role filter is dropped.

Worked examples

Search or case	What Data usage records
`` `private_macro` action=blocked `` (indexers received: litsearch (index=fw_emea action=blocked))	Search head side: unresolved macro. Served: a named confirmation of fw_emea, which makes it Searched.
Received: preeventcount index=* index=_* index=web …	A wildcard text: only `index=*` and `index=_*` are recorded; web is not confirmed by name.

Limits

- A standalone search head usually has no indexers logging what they received.
- A received line cut before its end is marked truncated; the terms of the text it kept stand.
- A search whose indexers log in two adjacent read ranges counts once per range.
- The access timeline shows search head accesses only: served facts are not in it.

Declared references

What it means. The published knowledge objects that name an index: saved searches, macros, event types, dashboards and data models. A declaration says an object names the index, not that anybody ran it.

Where it comes from. Each time a tier's knowledge object catalogs are published, their definitions are extracted with the same grammar as typed SPL and reduced per index: objects, writes and unresolved objects.

What it cannot establish. Declarations never make an index Searched and never remove it from the candidates. Wildcard declarations are not expanded onto index rows. Unscheduled and disabled objects remain declarations.

What to do next. Use the declared objects of an index detail, and the Knowledge objects view, to find who to ask before acting on an index nobody reads.

Definitions that name an index

The definitions read are: the search of saved searches and event types, the definition of macros, the search and query bodies of dashboards (Simple XML and Dashboard Studio), and the root constraints of data models. A dashboard query with tokens, or a chained search, is dynamic.

Each index row carries its declared objects (objects naming it, objects writing to it, unresolved objects); the index detail lists up to 50 sampled objects per tier with their app, owner, sharing, schedule and disabled state.

The Knowledge objects view compares what each object declares with what it ran in the period.

Worked examples

Search or case	What Data usage records
Saved search "Daily firewall report": `index=fw_*` | stats count by action	A declared wildcard reference fw_* (not expanded onto index rows).
Macro web_idx: `index=web`	A declared reference of web, one object.

Limits

- Private objects the catalog cannot see are not declarations.
- A collect in a saved search's SPL, and its summary indexing or Log event action, are declared writes.
- A declaration is the definition at the last publication, not at the time of a run.

Incoming data and review candidates

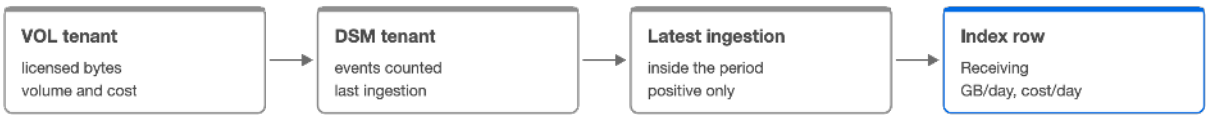
What it means. By default, candidates have positive linked VOL or DSM ingestion evidence in the selected period, but no named source reads. Wildcard-only references remain candidates because they do not establish that each matching index supplied data.

Where it comes from. Value & cost compares the linked incoming-data observations with the retained search references of every monitored tier. Account, app, class and path filters from Index activity do not apply to it.

What it cannot establish. This does not mean never used or safe to delete. Retention, incomplete collection, unresolved searches and excluded activity can hide usage. Write references may still exist. Volume and cost come from the linked VOL tenant: without one, no volume or cost is shown.

What to do next. Choose a representative period, check coverage and unresolved searches, then consult owners and ingestion or storage measurements. Treat the list as candidates for investigation, not an automatic deletion recommendation.

Incoming data from VOL and DSM



Each search head tier can be linked to one VOL tenant and to DSM tenants (Settings → Data usage). Every enabled VOL and DSM tenant you can read is listed, whichever account it collects through. Without an explicit link, the map selects them automatically when it is read: the first VOL tenant by tenant identifier (more than one is not expected) and every DSM tenant.

An index is receiving when its latest ingestion observation lies in the selected period: for VOL, the last time its licensed volume was positive; for DSM, an entity with a positive event count and a last ingestion time. Incoming data is evidence that data arrived, never that it was read.

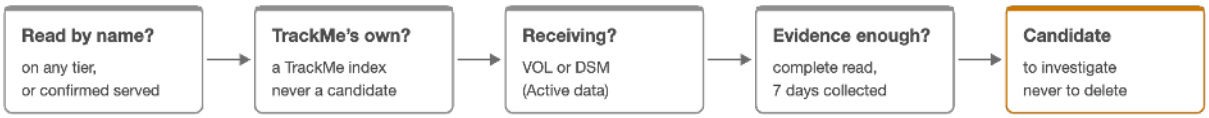
Volume is VOL's 30-day average of complete days (or the last 24 hours while the index has no complete day), with the cost of VOL's license view. The same index seen through two links is one volume: the larger.

Links grant no access: every read rechecks that you can read the linked tenant, and that it is enabled.

Limits

- These are latest observations: an index that stopped receiving before the period does not count as receiving, and an older period cannot be reconstructed.
- A linked tenant that could not be read completely leaves the candidates in place but withholds their volume and cost totals.
- Indexes are matched by name, so a tenant that measures other indexers can add incoming data or volume to an index of the same name. Unselect any tenant that measures other indexers than the ones this UAM tenant searches.

How a review candidate is decided



An index is a review candidate when no search head tier reads it by name and no indexer confirmation names it, it is not one of TrackMe's own indexes and, with Active data on (the default), it receives data. An index read on another tier is never a candidate.

Wildcard only and Excluded apps only indexes remain candidates and are shown apart: a broad pattern, or a TrackMe tracker reading an index, is not use of its data.

TrackMe's own indexes are never candidates: the global index settings, every tenant's index overrides and this UAM tenant's own indexes. They are written and read by TrackMe.

Candidates, and their volume and cost, are withheld while the evidence cannot support an absence of reads: when the fact read was incomplete, when no Data usage run read the audit trail in the period, or while the collection covers less than the period and less than seven days of it (Collecting, with the date the list will be available).

Limits

- A candidate is an index to investigate, never a recommendation to delete it: retention, collection gaps, index-less searches and excluded apps can hide reads.

Verdicts and value classes

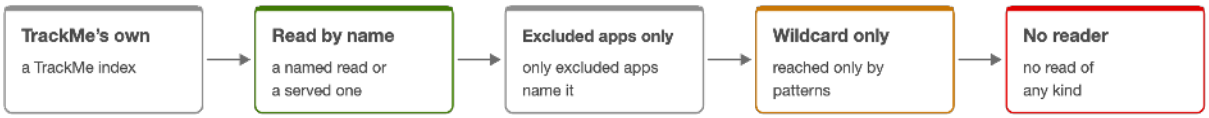
What it means. Each index has a verdict for the selected tier (Searched, Indirect only, No observed reads) and a value class on the indexing layer (Read by name, Wildcard only, No reader, Excluded apps only, TrackMe's own).

Where it comes from. The verdict comes from the named and wildcard reads, on the search head side or served. The value class adds the excluded apps' reads and TrackMe's own indexes, and is taken on every tier together.

What it cannot establish. No verdict claims an absence of use: No observed reads and No reader describe the evidence held for the period, nothing more.

What to do next. Use the verdict to investigate a tier, the value class to weigh volume and cost against reads.

Verdicts and value classes, in order



Verdicts. Searched: at least one named read on the search head side, or a named term in the search the indexers received. Indirect only: reached by wildcard references only. No observed reads: neither. Late filters, writes, denied searches, index-less searches and declarations never decide a verdict.

Value classes, decided in this order. TrackMe's own: an index TrackMe writes to for a tenant, whatever reads it. Read by name: Searched on any tier. Excluded apps only: only the excluded apps read it by name (TrackMe and the CIM acceleration app by default), even if wildcards also reach it. Wildcard only: reached only by wildcard references. No reader: no read of any kind.

Reads by excluded apps are shown, never counted: the verdict text says "Read only by excluded apps: … (N searches)". Only their literal reads count there (no wildcard, write or served fact).

Accesses, the Overview weight, are an index's named reads (or its served named reads when the search head side has none) plus its wildcard references. Low use marks the quarter of the Read by name indexes with a volume read the least per GB/day, when there are at least four of them.

Limits

- With a tier selected, a verdict describes that tier; an index read on another tier says so in its detail.
- Before seven days of collection, the counts describe the evidence collected so far, dated "since collection began".

Paths, origins and source types

What it means. Path explains how a dataset was referenced. Origin reports where the search was dispatched. Sourcetype is the source type named in the observed search, when it can be established.

Where it comes from. Literal means a direct source term; macro, eventtype, savedsearch and datamodel identify a definition UAM resolved. A wildcard is a kind of term, matched against the catalog when the map is read. UI:Search and UI:Dashboard identify dispatch provenance reported by Splunk.

What it cannot establish. A later SPL field filter is only a reference, not a source read. Role defaults describe possible scope and never count as observed usage. Missing app, origin or sourcetype values are unknown, not inferred.

What to do next. Use the joint detail rows rather than combining separate totals. Open the account to investigate its activity, and fetch SPL examples to inspect the syntax.

The values you can meet

Paths: literal (a term typed in the search, a wildcard pattern included), macro:<name>, eventtype:<name>, savedsearch:<name>, datamodel:<name> (the first object of a resolution chain), role_default (an index-less search), dynamic (any other unresolved part) and served (received by the indexers).

Origins: UI:Search, UI:Dashboard:<view>, scheduler, rest, rest:jobs, summary_director, subsearch:…; other UI origins are grouped as UI:*, and a missing one is N/A.

Index totals give one unit per search to each index. Path and sourcetype rows count references: one search through two paths counts once on each path, so their sum is not a number of searches.

Limits

- A sourcetype is recorded only for a search whose base names one literal index and whose extraction is complete: the sourcetypes its completion counted, else the sourcetype terms of its base search. Any other search records none.

Coverage and uncertainty

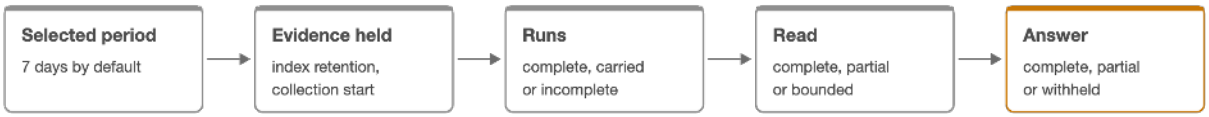
What it means. The selected range bounds the retained facts used for this answer. Retained facts dates show the evidence returned, not proof that every moment or index was observed.

Where it comes from. The map reads tenant-scoped evidence, collection receipts and index catalogs using your access. The catalog describes the monitored search head tier; it is not proof of which indexer served a search.

What it cannot establish. Missing or stale catalogs, collection gaps and read limits can make an answer partial. Even a complete response cannot establish lifetime non-use. An active Exclude TrackMe setting also narrows usage evidence.

What to do next. Check Collection health and the selected tier and period before interpreting missing reads. Data usage stays still until you change the selection or use the global Refresh button; the workspace health indicator can update independently.

What bounds an answer



Retention: the facts live in the tenant's evidence index. A period longer than its retention holds only what remains. A new tenant reads the audit trail from where its collection began (and, with a backfill, from the backfill depth, never before the oldest audit event held).

Collection start: until the collection covers the period, or seven days of it, the counts are dated "since collection began" and the candidates are withheld (Collecting).

Runs: a run that stopped on its time budget carries its range over to the next run (carried, nothing lost). A run that could not extract (incomplete) makes the period partial (extraction_coverage).

Catalogs: a tier's index catalog older than 48 hours is stale; a missing one leaves wildcards unexpanded. A catalog still being listed on a new tenant is pending, not a fault.

Reads: at most 50,000 fact keys and 10,000 catalog indexes per tier are read. Past a bound, or when a search failed or was cut, the answer is partial and the candidates are withheld. Facts written before the rollup key existed are reported and not counted.

Roles: the current users and roles catalogs apply to the whole period.

Limits

- Even a complete answer covers the evidence held for the period, never a proof of lifetime non-use.
- Exclusions (Settings → Data usage, and the Exclude TrackMe switch) narrow the evidence counted, never collection.

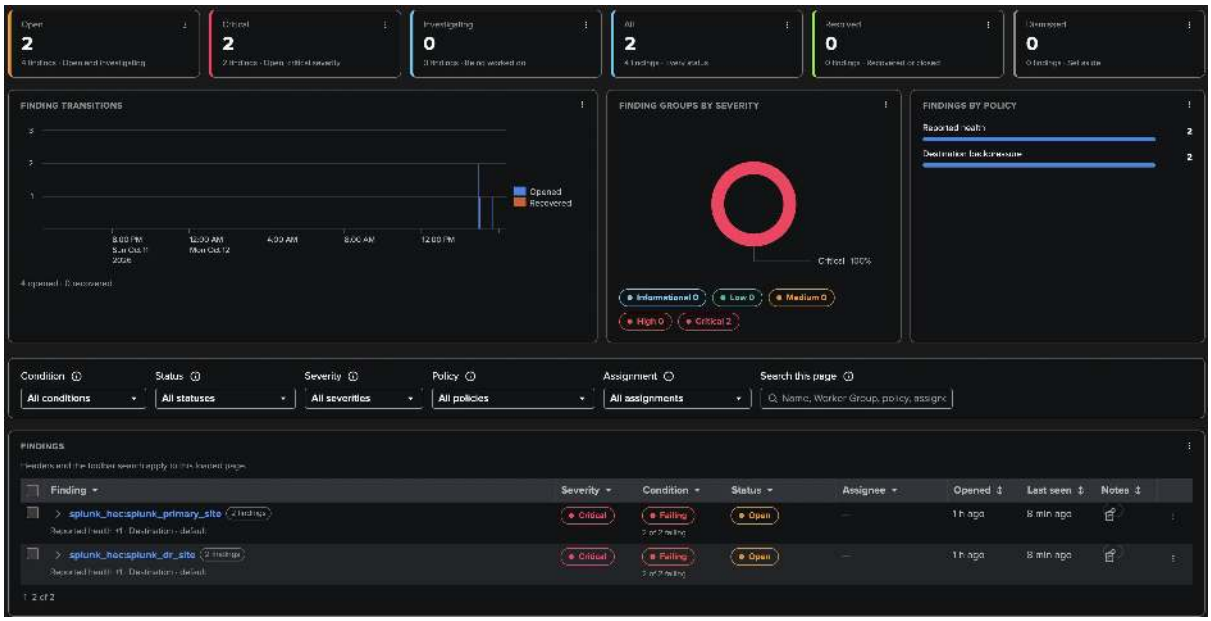
8.3.17 Findings, Finding groups and findings actions

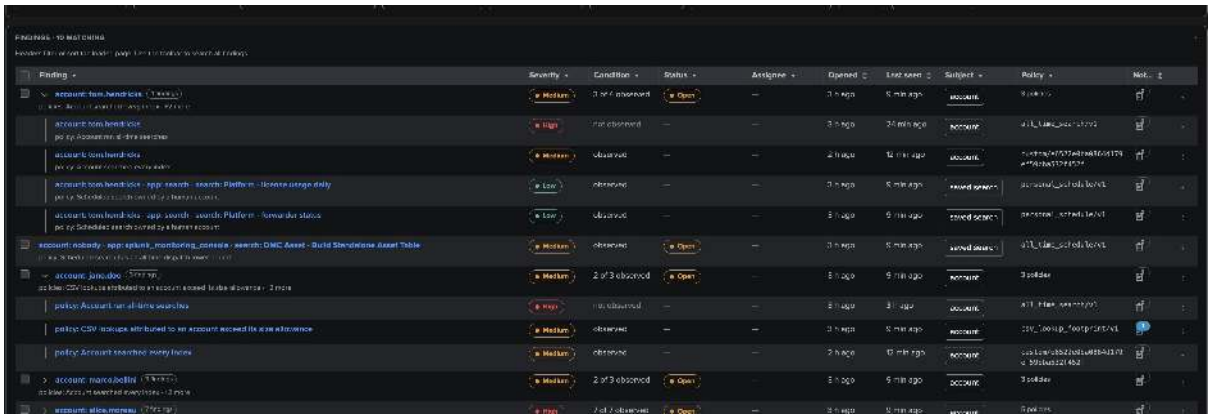
Four tenant types in TrackMe do not track entities with a state colour: **User Activity Monitoring (UAM)**, **Cribl Stream**, **Cribl Edge** and **Splunk HEC**. They are **dedicated findings tenants**. Each one collects what it monitors on a schedule, evaluates a catalogue of **policies** against it, and raises a **finding** whenever a policy detects a condition on one subject: an account running all-time searches, a Worker Group under backpressure, an Edge Node that stopped reporting. A healthy object has no finding at all; the work queue only ever contains what needs a look.

This page explains the concepts the four tenant types share: what a finding is and how it lives, how findings are triaged together as **Finding groups**, how they are assigned and routed to teams, notified, acted upon with **findings actions** and **Webhook accounts**, and reviewed by the **AI Agents**. The pages of each tenant type document what they monitor, their policies and their own differences:

- *User Activity Monitoring* — User Activity Monitoring
- *Cribl Stream* and *Policy catalogue* — Cribl Stream

- *Cribl Edge* and *Built-in policies* — Cribl Edge
- *Splunk HEC* and *Built-in policies* — Splunk HEC
- *Splunk S2S* and *Built-in policies* — Splunk S2S
- *Splunk UF Fleet* and *Built-in policies* — Splunk UF Fleet





From policies to findings

The flow is the same in the three tenant types:

1. **Collection jobs** (scheduled reports run by TrackMe search jobs) build the inventory of the monitored objects and read their activity or their measurements.
2. **Policies** — built in, each one enabled or not, with a default severity, a scope and its own settings — are evaluated against what was collected. UAM also lets you write your own **custom policies** in SPL.
3. Every condition a policy detects on one subject is a **finding**. The same condition on the same subject is always the same finding: it keeps its identity, its evidence, its notes and its history across the collection runs.
4. Findings about the same object are triaged together as one **Finding group**.
5. Around that core: email notifications, assignment to users or teams, findings actions (drilldown searches, links, webhooks), the AI Agent, indexed finding events for your own Splunk alerts, Enterprise Security or SOAR, and a **Collection health** tab that tells you whether collection runs as configured.

Bank holidays. A findings tenant uses the *bank holiday calendars* like every tenant. While a holiday of its calendars is active, the policies **set to hold** open no new finding; each policy chooses it in its editor (*During bank holidays*: **Hold new findings** or **Keep opening findings**), with a default that suits it: the configuration reviews of UAM, Traffic

outliers on Cribl Stream, Fleet connectivity and Fleet coverage on Cribl Edge, the traffic policies and Token silence on Splunk HEC hold; every other policy keeps opening findings, so a real failure on a holiday still opens its finding. A finding already open keeps being evaluated and can recover and close, a resolved or dismissed finding is not reopened by a held condition, and a calendar that cannot be read holds nothing. After the holiday, a condition that is still there opens its finding as on any other day.

How a findings tenant differs from an entity tenant

	Entity tenants (DSM, DHM, MHM, FLX, FQM, WLK, VOL)	Findings tenants (UAM, Cribl Stream, Cribl Edge, Splunk HEC)
What you look at	Entities that always exist and always have a state	Findings: they exist because a policy detected something
Health	A state colour (green, orange, red, blue) driven by thresholds, outliers and an impact score	A finding has a **severity** and an investigation **status**; there is no score and no state colour
Alerting	Stateful alerts (opened / updated / closed emails), notable events, acknowledgements	Email notifications from the finding transitions, finding events, webhook automation rules
Configuration	Thresholds per tenant and per entity, priority / tag / SLA policies	A policy catalogue with severities, scopes and settings
Good at	The continuous health of many similar things, at a glance, with SLA and KPI history	Sparse, varied conditions that need an investigation, evidence, an owner and a recorded decision

A tenant is either an entity tenant or one of the four findings tenant types, never a mix: each findings tenant type is created from its own card in the tenant creation wizard.

Which tenant types

	User Activity Monitoring	Cribl Stream	Cribl Edge
Findings are about	Accounts and the saved searches they own (and other knowledge objects)	The Leader, Worker Groups, Workers and Worker processes, Sources, Destinations, Pipelines, Routes	The Leader, Fleets, Sources and Destinations, Edge Nodes
A finding is	One policy on one subject (an account or a saved search)	One policy and one measurement on one object	One policy and one measurement on one object
When the condition goes away	The finding reads **not observed**; it is never resolved for you	A measured recovery **resolves** the finding automatically	Same as Cribl Stream
Automatic Finding group	One per account: its findings plus those of the saved searches it owns	One per object (a Worker machine with its processes)	One per object (a Fleet, a node, a Source or Destination)
Severities shown	Low, Medium, High, Critical	Informational, Low, Medium, High, Critical	Informational, Low, Medium, High, Critical
Dismiss until it recovers	—	Yes (the default)	Yes (the default)
Email action, direct user notifications	Yes	—	—
AI Agent	UAM AI Agent	Cribl Stream AI Agent	Cribl Edge AI Agent
Bank holidays (effects that apply)	Suppress new alerts	Suppress new alerts, Exclude from ML training	Suppress new alerts
Licence	Any edition except Foundation	Enterprise, Unlimited, trial and Developer licences	Same as Cribl Stream

A **Splunk HEC** tenant (*Splunk HEC*) reads like the Cribl Edge column: its findings are about HEC endpoints, pools and tokens, one policy and one measurement on one object; a measured recovery resolves the finding; each object has one automatic Finding group; it has its own AI Agent, the Splunk HEC AI Agent; and it needs the same licences as Cribl Stream.

Splunk S2S (*Splunk S2S*) and **Splunk UF Fleet** (*Splunk UF Fleet*) tenants read the same way: their findings are about receivers, intermediate forwarders, pools and destinations, or about agents, groups, the fleet, Deployment Servers and destinations; a mass event is one cohort finding holding the findings of its members; each has its own AI Agent, and they need the same licences as Cribl Stream.

Note

Every finding transition is also written as an indexed **finding event** in the tenant's notable index — `sourcetype=trackme:uam:finding` for UAM, `sourcetype=trackme:cribl:finding` (and `trackme:cribl:finding_group` for the Finding group transitions) for Cribl Stream, Cribl Edge, Splunk HEC, Splunk S2S and Splunk UF Fleet, with `object_category=cribl_edge` on Edge, `splunk_hec` on Splunk HEC, `splunk_s2s` on Splunk S2S and `splunk_uf` on Splunk UF Fleet. Build your own Splunk alerts, Enterprise Security correlations or SOAR playbooks on them.

A finding and its lifecycle

Identity

A finding is identified by **its policy and its subject**. On UAM the subject is an account or a saved search of the monitored environment; on Cribl Stream and Cribl Edge it is an object and the measurement the policy watches (a Worker process and its CPU, a Destination and its backpressure, an Edge Node and its connectivity). The identity is stable: when the same condition comes back on the same subject, it is the same finding again, with its earlier notes and history.

Each finding carries:

- its **evidence**: what the policy measured or saw, and when (first seen, last seen);
- a **severity** and an investigation **status**;
- an optional **assignee**, **notes** (Markdown) and a full **history** of what changed, who changed it and why — an operator, the policy itself, TrackMe or the AI Agent.

Episodes: opens, recovers, reopens

A finding has two independent axes: whether the **policy still sees the condition**, and the **status** an operator gave it. How the first axis behaves follows the nature of the data, and that is the main difference between the tenant types.

Tenant type	What happens when the condition goes away and comes back
User Activity Monitoring	A finding is **observed** while the policy sees the condition. After a complete policy evaluation that no longer sees it, the finding reads **not observed** — it is never resolved for you, because a configuration or a behaviour that disappears from one evaluation deserves a human decision. A resolved finding that is observed again is **reopened**. An evaluation that could not cover everything may add findings, never clear them.
Cribl Stream and **Cribl Edge**	The **condition** of a finding is *failing*, *recovered*, *unknown* or *ended*, and each failure is a numbered **episode**. A measured recovery **resolves** an open or investigating finding; a new failure **reopens** it as a new episode. An unknown measurement never counts as a recovery. TrackMe also closes findings automatically, always with a reason: the object was not evaluated for 24 hours, was removed from Cribl or is no longer listed, monitoring was turned off, the source of the tenant changed.

Severity

The three tenant types use one severity scale. Every policy has a default severity, which you can change in the policy settings, and an operator can override the severity of a finding or a Finding group by hand (**Set severity**). **Use policy severity** (on a Finding group: **Use member severity**) removes the override.

Severity	Meaning and use
Critical	Act now: an outage, a component that stopped, a change with an immediate impact.
High	Act soon: a degradation or a risk that is likely to become an outage.
Medium	Investigate: a deviation or a misconfiguration. The default severity of most policies and the default minimum severity of notifications.
Low	Worth knowing: a small drift, a hygiene topic.
Informational	Cribl Stream and Cribl Edge only: how a finding (or a Finding group) is **shown** once it recovered, its episode ended or it was resolved. The finding keeps the severity it reached, which the tooltip of the Informational pill names, so you can still sort and filter on the real level.

How each tenant type uses the scale:

- **UAM** shows Low, Medium, High and Critical. Most built-in policies default to Medium; a personal schedule defaults to Low, an all-time search to High, and the resource consumption policies raise the severity with the share of the environment an account consumes. A Finding group carries the highest severity of its observed findings.
- **Cribl Stream** and **Cribl Edge** add the Informational display for settled findings. Leader availability defaults to Critical; the other availability and connectivity policies mostly default to High, most others to Medium (each policy page lists its default, and some policies raise a finding to Critical while the condition is severe). A Finding group carries the highest severity of its failing findings.

In the example below, a Worker that went down and came back is shown **Informational**, **Recovered** and **Resolved**; hovering the severity names the severity it reached while it failed (*Recovered or resolved; it reached High*).

Statuses and triage

The status is the **operator axis**: what a person (or the AI Agent) decided. The same four statuses exist in the three tenant types.

Status	Meaning
Open	New, or back for another look. Every finding starts open.
Investigating	Someone is on it.
Resolved	The problem is fixed. On Cribl Stream and Cribl Edge, a measured recovery resolves the finding automatically.
Dismissed	No action is needed, even while the condition holds — for a time, until it recovers, or permanently (see below).

Triage decisions, available from the finding menu, the Finding group menu, a selection of rows and the investigation view:

Dismiss
Choose how long the dismissal holds:

- **Until it recovers** (Cribl Stream and Cribl Edge, the default): the dismissal holds while the object keeps failing; if it fails again after recovering, the policy reopens the finding.
- **For a time**: 1, 7, 30 or 90 days. When the time is up the finding returns to open, whether or not the condition still holds, so you get another look at it.
- **Until reopened by hand (permanent)**: no later detection reopens it.

Snooze
Holds the emails without changing the status. On UAM, **Snooze notifications** pauses the email notifications for 1 hour, 6 hours, 1 day, 7 days or 30 days. On Cribl Stream and Cribl Edge, **Snooze** (1 hour to 30 days) also holds the automation rules, and a snoozed finding no longer colours its object in Topology Studio: the object reads blue when nothing else is wrong.

Resolve, Mark investigating, Reopen
The status decisions above, with an optional note recorded in the history.

Assign
To a Splunk user or an assignment group — see *Assignment and automatic routing*.

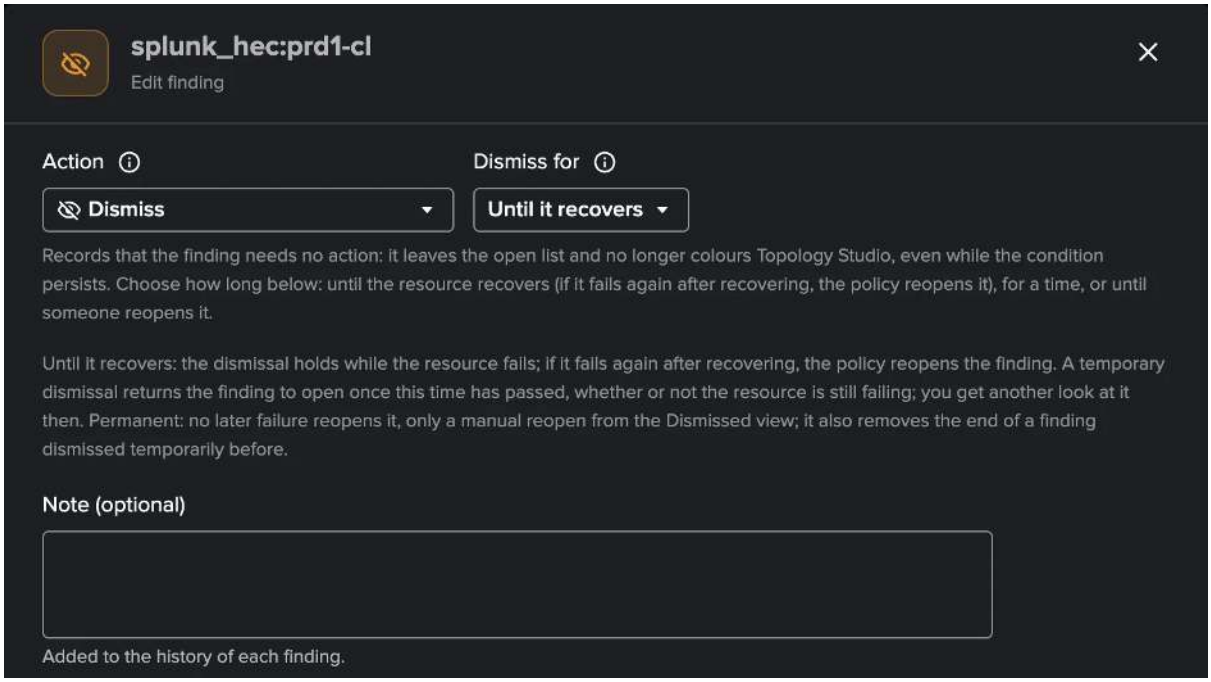
Set severity
A manual override that survives the policy runs.

Notes
Markdown notes on the finding or the Finding group, visible to everyone who can read the tenant. The AI Agent keeps one current note of its own per finding, signed `[AI Agent]`.

Some decisions belong to one tenant type:

Tenant type	Its own decisions
User Activity Monitoring	**Set class** of an account (human, service, system) and **Exclude owner from this policy**; **Dismiss only this finding** inside a Finding group (see *Finding groups*).
Cribl Stream	**Not an anomaly** (a traffic outlier finding: its model relearns without that period), **Stop monitoring this object**, **Forget this object** (an object removed from Cribl).
Cribl Edge	None beyond the shared decisions.

Every decision is recorded in the history of the finding (and of its Finding group) with the actor, the time and the note. Decisions are protected against concurrent changes: if someone changed the Finding group after you opened it, your decision is refused and you are asked to reload rather than overwriting their work.



splunk_hec:prd1-cl
Edit finding
Action
Dismiss for
Dismiss
Until it recovers
Records that the finding needs no action: it leaves the open list and no longer colours Topology Studio, even while the condition persists. Choose how long below: until the resource recovers (if it fails again after recovering, the policy reopens it), for a time, or until someone reopens it.
Until it recovers: the dismissal holds while the resource fails; if it fails again after recovering, the policy reopens the finding. A temporary dismissal returns the finding to open once this time has passed, whether or not the resource is still failing; you get another look at it then. Permanent: no later failure reopens it, only a manual reopen from the Dismissed view; it also removes the end of a finding dismissed temporarily before.
Note (optional)
Added to the history of each finding.

Finding groups

One problem, one decision

A single problem rarely raises a single finding. A Worker that runs out of memory may raise CPU, memory and availability findings on the machine and on each of its Worker processes; an employee who leaves may own a dozen saved searches, each raising a personal-schedule finding. Deciding on each finding separately is slow and error-prone. A **Finding group** gathers the findings of one object so that you investigate it once, decide once and assign it once.

The **Finding group carries the triage decision**: its status, dismissal, assignee, snooze and severity override apply to every finding in it, and a finding that joins the group later takes the group's state.

Automatic grouping

Finding groups form automatically; you do not need to do anything.

Tenant type	What one automatic Finding group holds
User Activity Monitoring	**An account and the saved searches it owns**: every finding about the account (all-time searches, resource consumption) together with the findings about its saved searches (personal schedules, real-time schedules). A saved search without an owner keeps its own group. An automatic group can hold up to 5,000 findings.
Cribl Stream	**One object**: a Source, a Destination, a Worker Group, the Leader — and a Worker machine together with its Worker processes. Up to 50 findings.
Cribl Edge	**One object**: a Fleet, an Edge Node, a Source or Destination of a Fleet, the Leader. Up to 50 findings.

On Cribl Stream and Cribl Edge, a new failure on a resolved Finding group reopens the group. On UAM, a new kind of finding on a dismissed group returns the group to open with the new finding, while the findings the dismissal covered stay dismissed: a dismissal never silences a new kind of problem.

A finding keeping its own decision (UAM)

On UAM, an account group may mix an accepted situation and a real problem — for example a personal schedule you approve and a real-time schedule that must be fixed. **Dismiss only this finding** on a member sets that one finding aside, dismissed on its own (for a time or permanently), while the rest of the group stays open. The expanded row says so ("Dismissed on its own until …"); later decisions on the group leave it untouched. **Reopen this finding** brings it back into the group's state. On Cribl Stream and Cribl Edge, remove the finding from the Finding group instead.

Manual grouping

Sometimes you know better than the automatic grouping: two Destinations failing because of the same upstream outage, or several accounts belonging to one project. The Finding group menus and the selection toolbar offer:

Action	What it does
Merge into one Finding group	Merges 2 to 25 Finding groups into one manual group (up to 50 findings).
Add to the Finding group	Adds findings or groups to an existing manual group.
Remove from the Finding group	Takes up to 25 findings out of a group; they keep the decisions of the group. On Cribl Stream and Cribl Edge each removed finding gets a group of its own; on UAM the findings return to their account's automatic group, and the findings of one account always move together.
Ungroup	Dissolves a manual group; every finding returns to its automatic group.

Manual groups stay as you made them: automatic grouping never undoes a deliberate merge. On UAM, manual grouping is reserved to the tenant administrators; on Cribl Stream and Cribl Edge, to the roles that can triage (the tenant's power and admin roles).

How the Findings tab lists Finding groups

The **Findings** tab lists **one row per Finding group**, with the finding, its severity, its condition or observation, its status, its assignee and when it was opened and last seen. A group of more than one finding has an expander that shows its members, each with its own policy, severity and condition. The tiles above the table count Finding groups and drive the filters. Filters, sorting and selections act on **whole Finding groups**: a filter that matches one member returns its group, and a member hidden by a filter can never become the target of a bulk decision.

Assignment and automatic routing

A Finding group is assigned to **one destination**: a Splunk user, or an **assignment group**. Assignment lives in the workspace **Settings → Assignment**.

Important

An **assignment group** is a team destination — "Platform team", "Security operations" — not to be confused with a **Finding group**, which gathers related findings. An assignment group has a name, an optional description and an optional **team email** address. It has no members and grants no access: being "in" a team is not a TrackMe concept, and an assignment never changes who can read the tenant.

Assignment groups

Create up to 100 assignment groups per tenant. A group can be disabled (it then receives no new assignment and no email) but never deleted, so the history of past assignments stays readable.

Routing rules

Routing rules assign new Finding groups automatically. They are **ordered**: TrackMe evaluates them from the top and the **first enabled rule that matches** wins. Within a criterion, the values are alternatives (OR); the criteria of a rule must all match (AND), on the same finding of the group. An empty criterion matches everything; text criteria accept case-sensitive `*` and `?` patterns.

Tenant type	Routing criteria
Every tenant type	Policy, severity, subject type
User Activity Monitoring	Owner or account, app, environment
Cribl Stream	Worker Group, object name
Cribl Edge	Fleet, object name (a Leader finding has no Fleet; its name is *Cribl Leader*)

Automatic routing runs in the tenant's own collection job, a few Finding groups at a time (25 per run, in rotation). It only assigns Finding groups that are **unassigned and under automatic assignment**; it never changes an existing owner. Two buttons help you tune the rules before relying on them:

- **Preview matches** shows which open Finding groups the draft rules would assign, without saving anything;
- **Apply to selected groups** applies the saved rules to up to 25 Finding groups now.

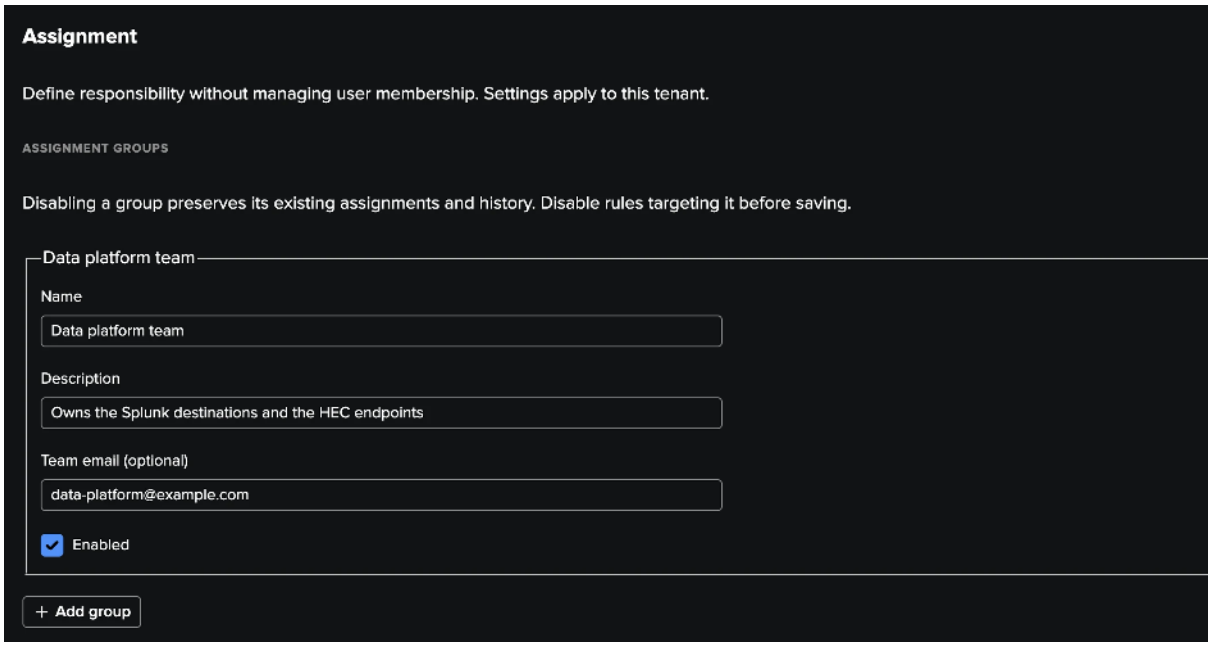
Assigning by hand

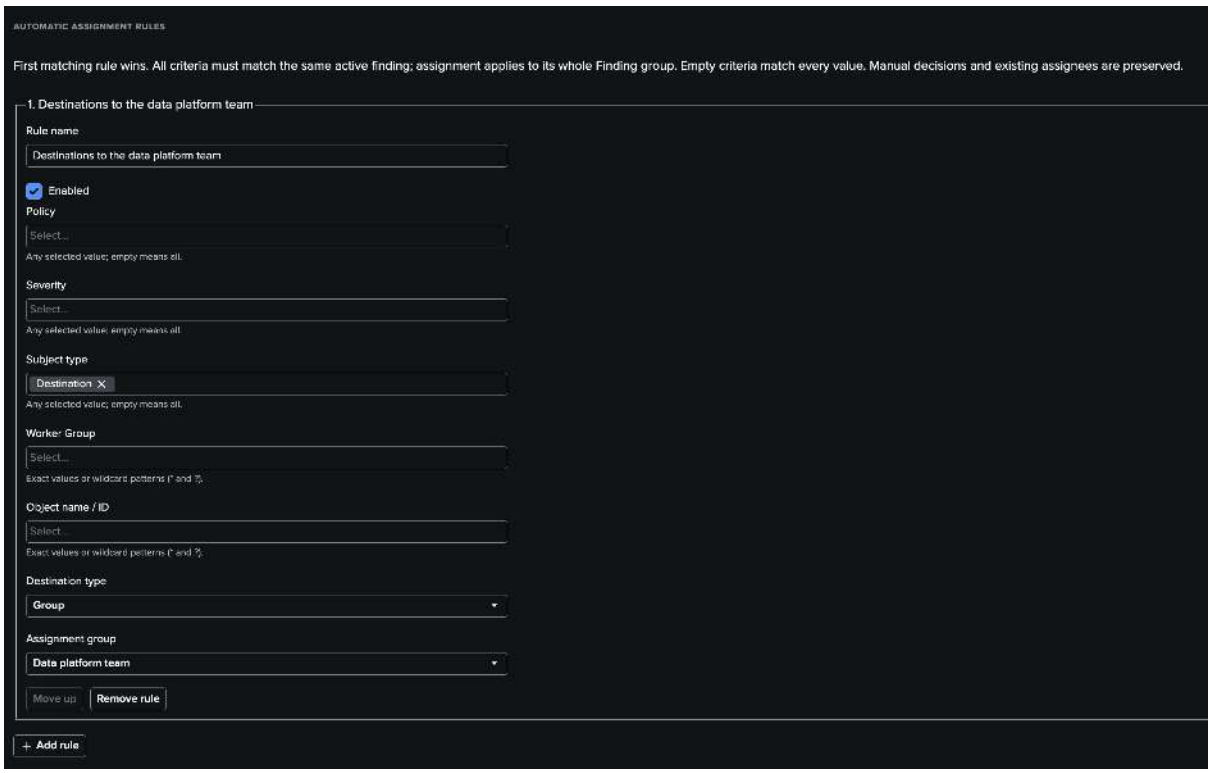
Assign to me, **Assign to…** and **Unassign** are in the finding and Finding group menus, the selection toolbar and the investigation. A manual assignment always wins over the rules; an explicit unassignment also holds until you choose **Use automatic assignment**. On UAM the user picker searches the accounts of the monitored environment; on Cribl Stream and Cribl Edge you type the Splunk username. A group assignment shows the group name; an automatic one names its rule in a tooltip; the AI Agent keeps its purple **AI Agent** pill. The findings filters tell user and group assignments apart, including **Assigned to me**.

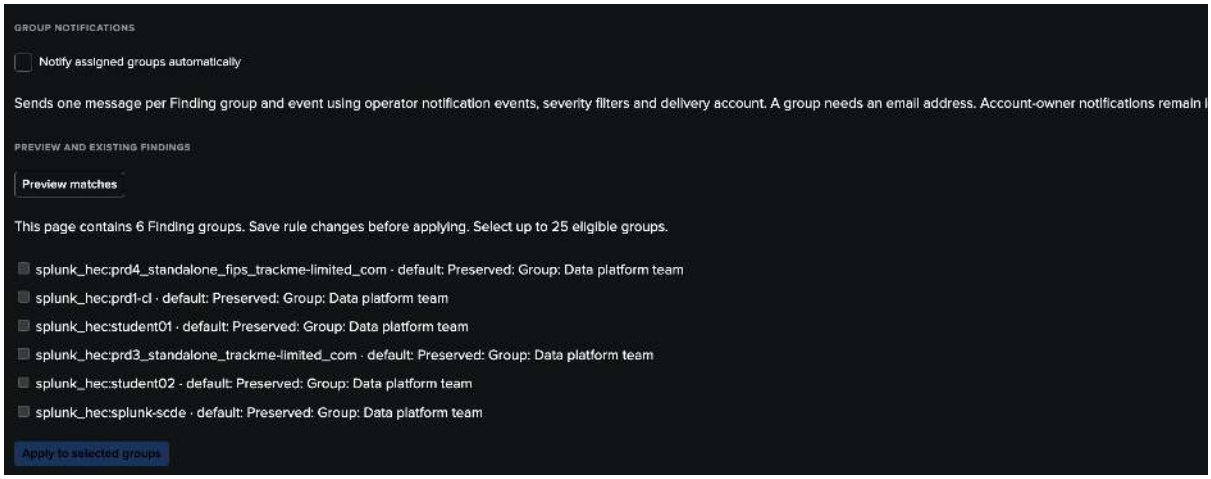
Team email

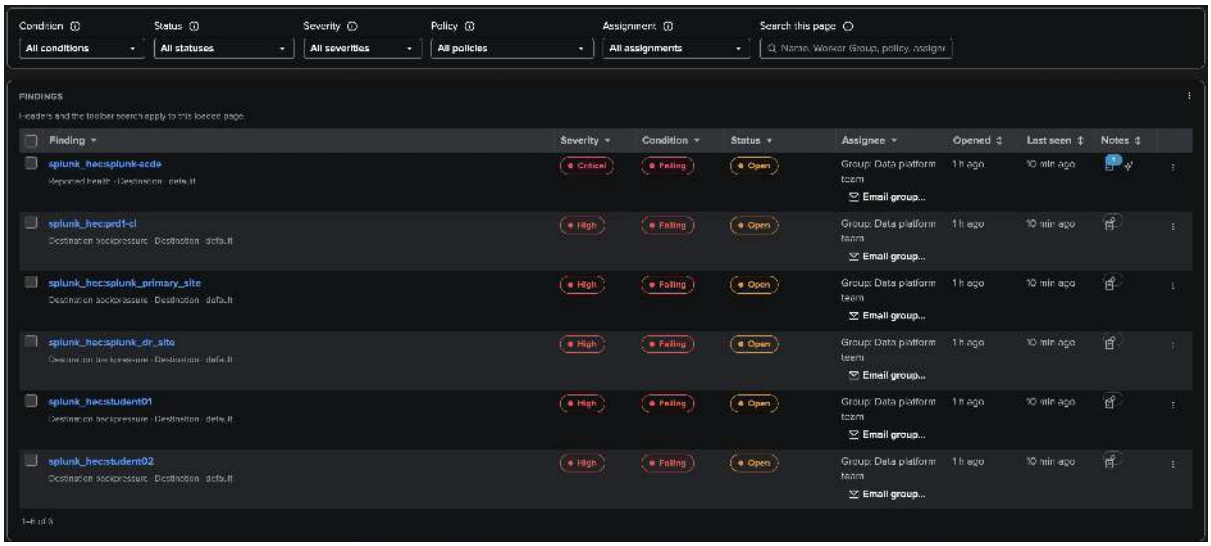
When **team email** is turned on, each Finding group event (with the event, severity and policy filters of the tenant's notifications) is mailed to the address of the assignment group it is assigned to — one message per Finding group and event, through the tenant's email delivery account. Snoozed Finding groups receive no automatic mail. You can also send a team email by hand: **Email group…** opens an HTML preview of the message and the findings it includes; **Confirm and send email** sends it. An email whose delivery could not be confirmed is reported as such and never resent automatically.

Who may do what: the assignment settings, the rule preview, **Apply to selected groups** and team email are for the TrackMe administrators of the tenant. Assigning a Finding group needs the triage permission on Cribl Stream and Cribl Edge (the tenant's power and admin roles) and the administrator permission on UAM. Users who can only read the tenant see the group names, never their email addresses or the rules.









Notifications

Email notifications to operators

Each findings tenant can email its operators when findings change. Configure it in the workspace **Settings → Notifications** (UAM: **Notifications to operators**); it is off by default.

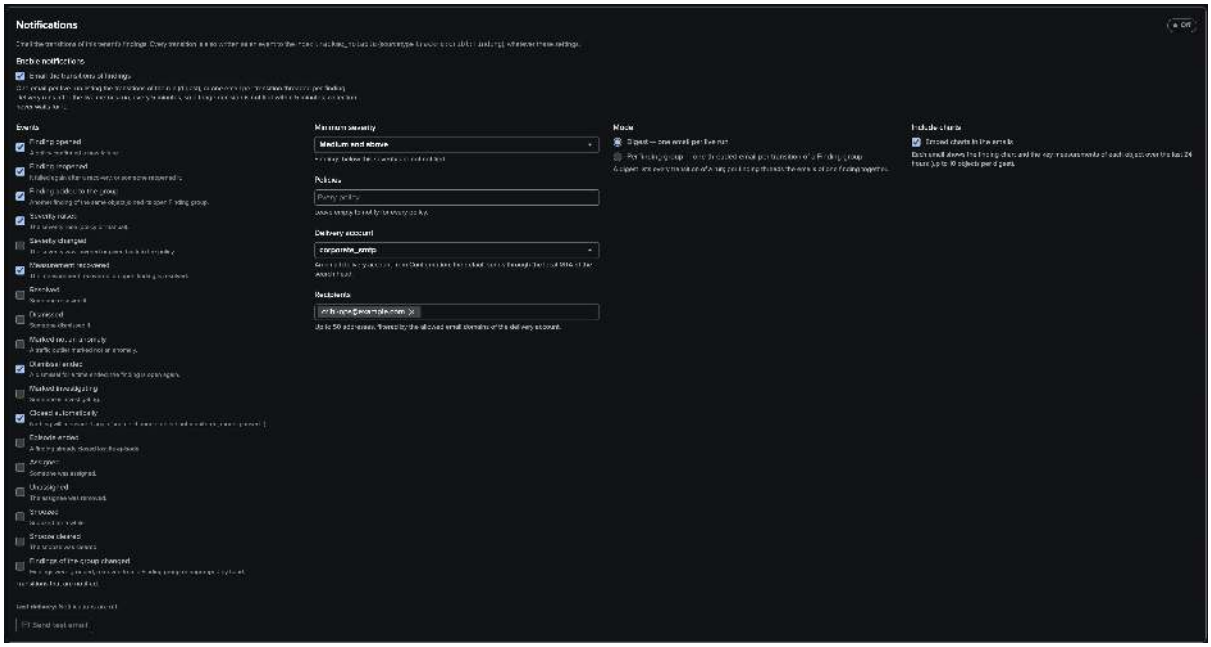
- **Events**: choose the transitions that send an email.
  - UAM: New finding, Finding reopened, Severity raised, Finding resolved, Finding dismissed, Finding assigned.
  - Cribl Stream and Cribl Edge: Finding opened, Finding reopened, Finding added to the group, Severity raised, Measurement recovered, Dismissal ended, Closed automatically, and the operator decisions.
- **Minimum severity** (Medium by default) and **policies** (all by default).
- **Delivery account**: one of the TrackMe email delivery accounts (Configuration → Manage Email delivery accounts), and up to 50 **recipients**.
- **Mode**: a **digest** (one email per run) or one threaded email **per finding** (UAM) or **per Finding group** (Cribl Stream, Cribl Edge, Splunk HEC, Splunk S2S and Splunk UF Fleet, with the finding chart and the key measurements of the last 24 hours as inline images). In per Finding group mode, when more than 10 Finding groups have updates to send at once (a fleet event such as a patch wave or a site recovering, or a delivery catching up), they are sent as one digest that says so, never one email each.
- **Send test email** sends a test message with the saved settings, even while notifications are off.

Emails are sent by the tenant's collection job, never by the browser: within about 15 minutes on UAM (the policies run), after each live run on Cribl Stream and Cribl Edge. They link straight to the finding in the workspace. A delivery that keeps failing shows up in the **Collection health** tab.

Direct notifications to users (UAM)

UAM can also email **the account a finding is about**: on a new detection and when the condition cleared, with per-policy subjects and bodies (Policies → Edit → **Email template**), reply-to and support details, and rate limits. Human accounts are notified by default, service accounts on opt-in, system accounts never. **Send email communication** sends a reviewed, one-off message about a finding or a Finding group, with a preview and an explicit confirmation. See *User Activity Monitoring* for the details.

Cribl Stream and Cribl Edge have no direct user notifications: see *Cribl Stream* and *Cribl Edge* for their notification settings.



Findings actions

Findings actions turn a finding into the next step of your workflow: open the right search, jump to your runbook or CMDB, or call an external system. A TrackMe administrator of the tenant defines them once; everyone who works the findings then finds them in the menus, already filled in with the finding's values.

Type	What it does	Available on
Drilldown search	Opens Splunk Search with a search built from the finding (as the clicking user), with a time range around the finding, a fixed relative range, the workspace range or all time. Optional preview of the rendered search.	UAM, Cribl Stream, Cribl Edge
Link	Opens an external page (`https://`) or a Splunk page in a new tab: a runbook, a CMDB record, a Cribl UI page.	UAM, Cribl Stream, Cribl Edge
Webhook	Sends an HTTPS request through a *Webhook account*: to a ticketing system, a chat channel, an on-call service, a SOAR or another Splunk. Sent by hand, or automatically by automation rules.	UAM, Cribl Stream, Cribl Edge
Email	Sends the policy's Email template to the account a finding is about, after a preview and confirmation (by hand only).	UAM

Defining actions

Where the editors live

Tenant type	Settings → **Finding actions**	Policy editor tabs **Actions** and **Automations**
User Activity Monitoring	Every definition and every automation rule	Yes, for that policy
Cribl Stream	Every definition and every automation rule	Yes, for that policy
Cribl Edge	Every definition and every automation rule	— (use Settings → Finding actions; a rule still names its policies)

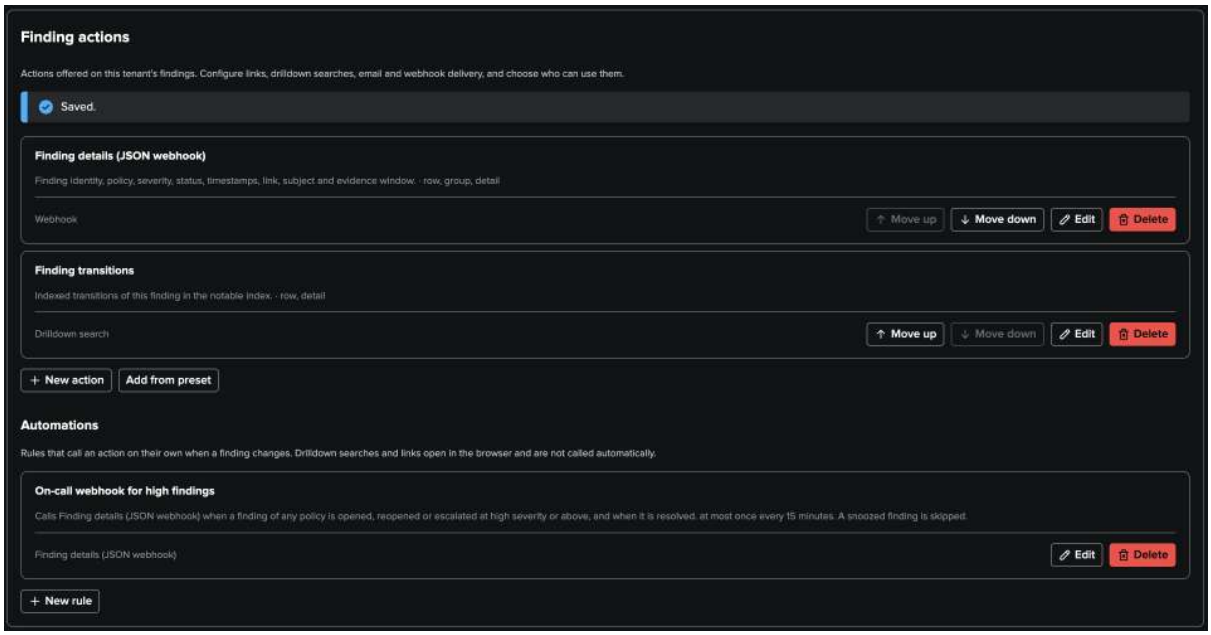
Add from preset inserts a ready-made definition, **disabled** until you review and enable it:

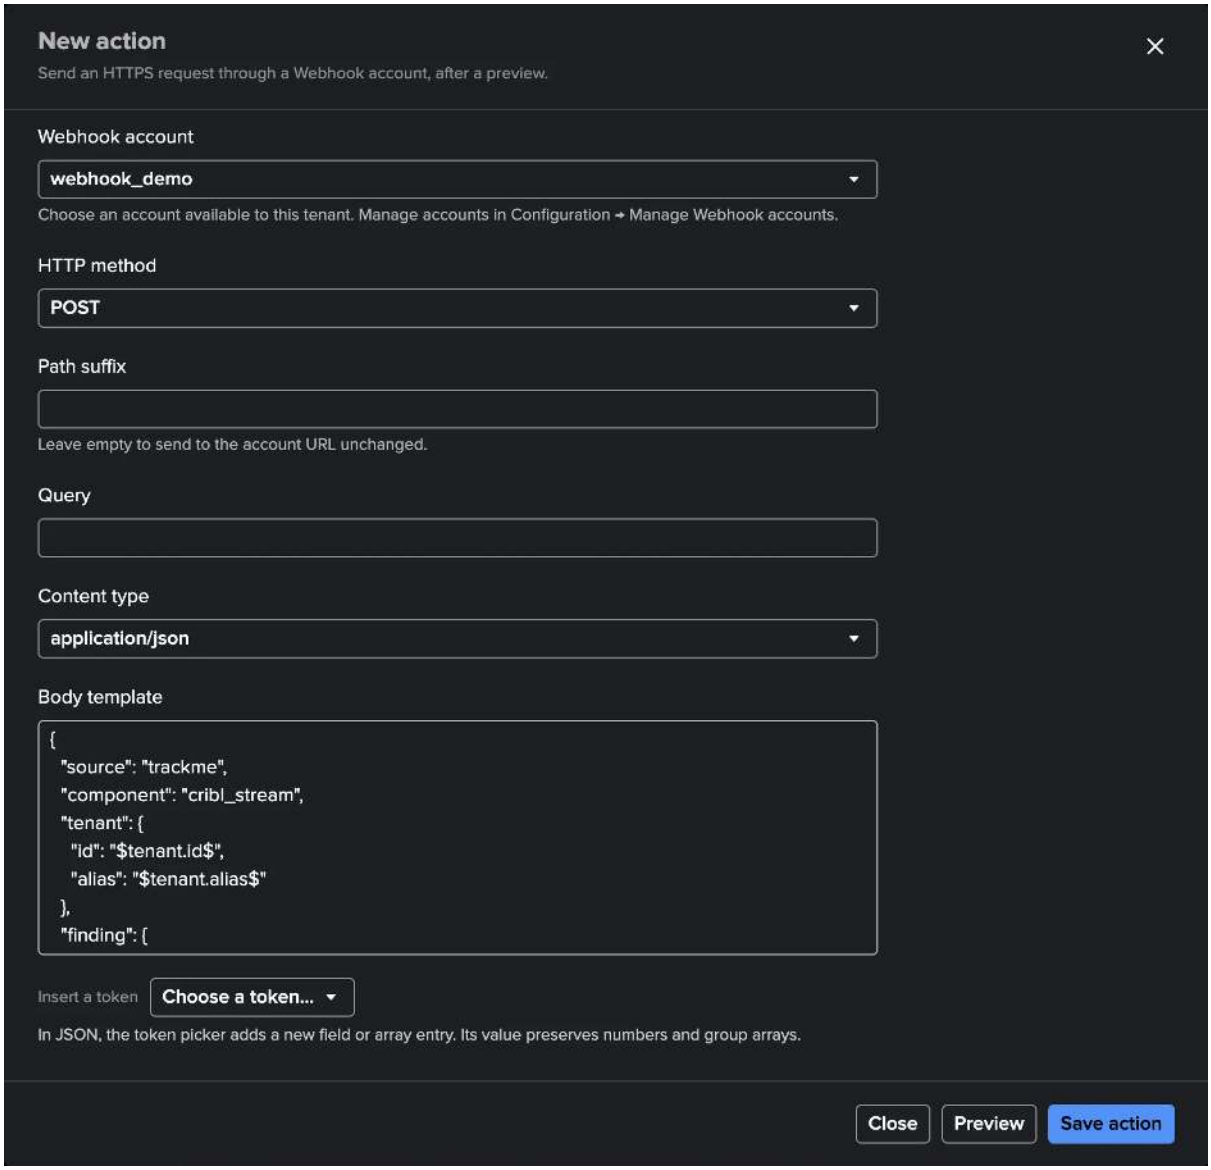
- UAM: *Audit activity of this account*, *Scheduler runs of this saved search*, *Finding transitions*;
- Cribl Stream: *Metrics of this object* (set your Cribl metrics index first), *Finding transitions*;
- Cribl Edge: *Finding transitions*, *Findings of this Fleet*;
- every tenant type: *Finding details (JSON webhook)* and *Finding summary (text webhook)*.

Every definition has a label, an optional description, and:

- a **scope** — the policies, subject types, severities and statuses it applies to (empty = all), so a "Open the Cribl Destination page" link is only offered on Destination findings;
- **where it appears** — the finding menu, the Finding group menu, the selection toolbar, and up to three buttons on the investigation;
- a **minimum role** — drilldowns and links are offered to everyone who can read the tenant, webhooks and emails to the roles that can triage; a definition can raise its minimum role, never lower it.

Up to 50 definitions and 100 automation rules per tenant. Drilldown searches refuse commands that write or send data (`delete`, `outputlookup`, `collect`, `sendemail`, `map` and similar) unless the definition explicitly allows them.





Tokens

A template refers to the finding with **tokens** written `$namespace.field$` — `$finding.title$`, `$subject.account$`, `$tenant.id$`. Write `$$` for a literal dollar sign. The editor's **Choose a token…** picker lists the tokens of the tenant type, and an unknown token is refused when you save.

Tokens	Available on
`tenant.id`, `tenant.alias`, `finding.id`, `finding.title`, `finding.policy_id`, `finding.policy_title`, `finding.severity`, `finding.status`, `finding.first_seen`, `finding.last_seen` (and `_iso` variants), `finding.group_id`, `finding.link` (the workspace link), `finding.assignee`, `finding.assignment_type` (`user` or `group`), `actor.user`, `action.label`, `action.request_id`, `now`	Every tenant type
`subject.type`, `subject.account`, `subject.owner`, `subject.app`, `subject.name`, `subject.environment`, `evidence.window_start`, `evidence.window_end` and the numeric evidence of the policy	User Activity Monitoring
`subject.worker_group`, `subject.entity_kind`, `subject.entity_id`, `subject.label`, `subject.kpi`, `finding.condition`, `connection.name`, `evidence.value`, `evidence.unit`	Cribl Stream
`subject.fleet` (instead of `subject.worker_group`), `subject.entity_kind`, `subject.label`, `subject.kpi`, `finding.condition`	Cribl Edge

Search text and secrets are never tokens.

Encoding is automatic. A finding's values come from names you do not control — a saved search title, a Cribl object name — so inserting them raw would let a crafted name inject SPL, break a URL or a JSON document. TrackMe encodes every token **for the place it sits in**: SPL string, URL path or query, HTTP header, JSON, plain text or form. You cannot turn this off. A few **filters** tell TrackMe how you want the value:

Filter	Meaning
`|s`	In SPL: the value as a quoted string, quotes included.
`|in`	In SPL: a list of values in parentheses, for `field IN …` on a Finding group or a selection.
`|n`	In SPL: the raw value, accepted only for numbers, times, identifiers and fixed lists of values.
`|json`	In a JSON body: the whole JSON value (a number stays a number, several values become an array).
`|default:<text>`	A fallback when the value is empty.

In SPL a string token must sit **inside double quotes**, or use `|s`. On a Finding group or a selection, a value the findings share stays one value; a value that differs becomes the list of the distinct values — use `|in` in SPL, an array in JSON; URLs and headers refuse it.

Example 1 — a drilldown search on a UAM account (the token inside quotes):

```
index=_audit action=search user="$subject.account$"
```

Example 2 — a drilldown on a whole Finding group, every finding of the group at once:

```
sourcetype="trackme:cribl:finding" tenant_id=$tenant.id|s$ finding_id IN
↪$finding.id|in$
```

Example 3 — a JSON webhook body with typed values and a fallback (the `"$…|json$"` string is replaced by the JSON value itself):

```
{
  "summary": "[TrackMe] $finding.title$",
  "severity": "$finding.severity|json$",
  "first_seen": "$finding.first_seen|json$",
  "owner": "$finding.assignee|default:unassigned$",
  "link": "$finding.link|json$"
}
```

Running actions by hand

The finding menu and the Finding group menu carry a **Custom actions** submenu listing the actions whose scope matches and whose minimum role you hold. The investigation shows up to three drilldown and link buttons. A selection of rows offers **Run action** for drilldowns (up to 200 findings).

- **Drilldown search**: with preview on, the rendered search and its time range are shown, then **Open in Search**.
- **Link**: opens in a new tab.
- **Send webhook…**: shows the request as it will be sent (secrets masked), then sends it after you confirm, and follows its status: *sent*, *failed* or *unconfirmed* (the receiver may have received it; a manual send is never repeated automatically). On a Finding group, one request carries the group's values.
- **Email** (UAM): a preview of the message, an optional one-time recipient change, then confirmation.

Sending is done by a TrackMe search job, never by the browser or a REST request.

Automation rules

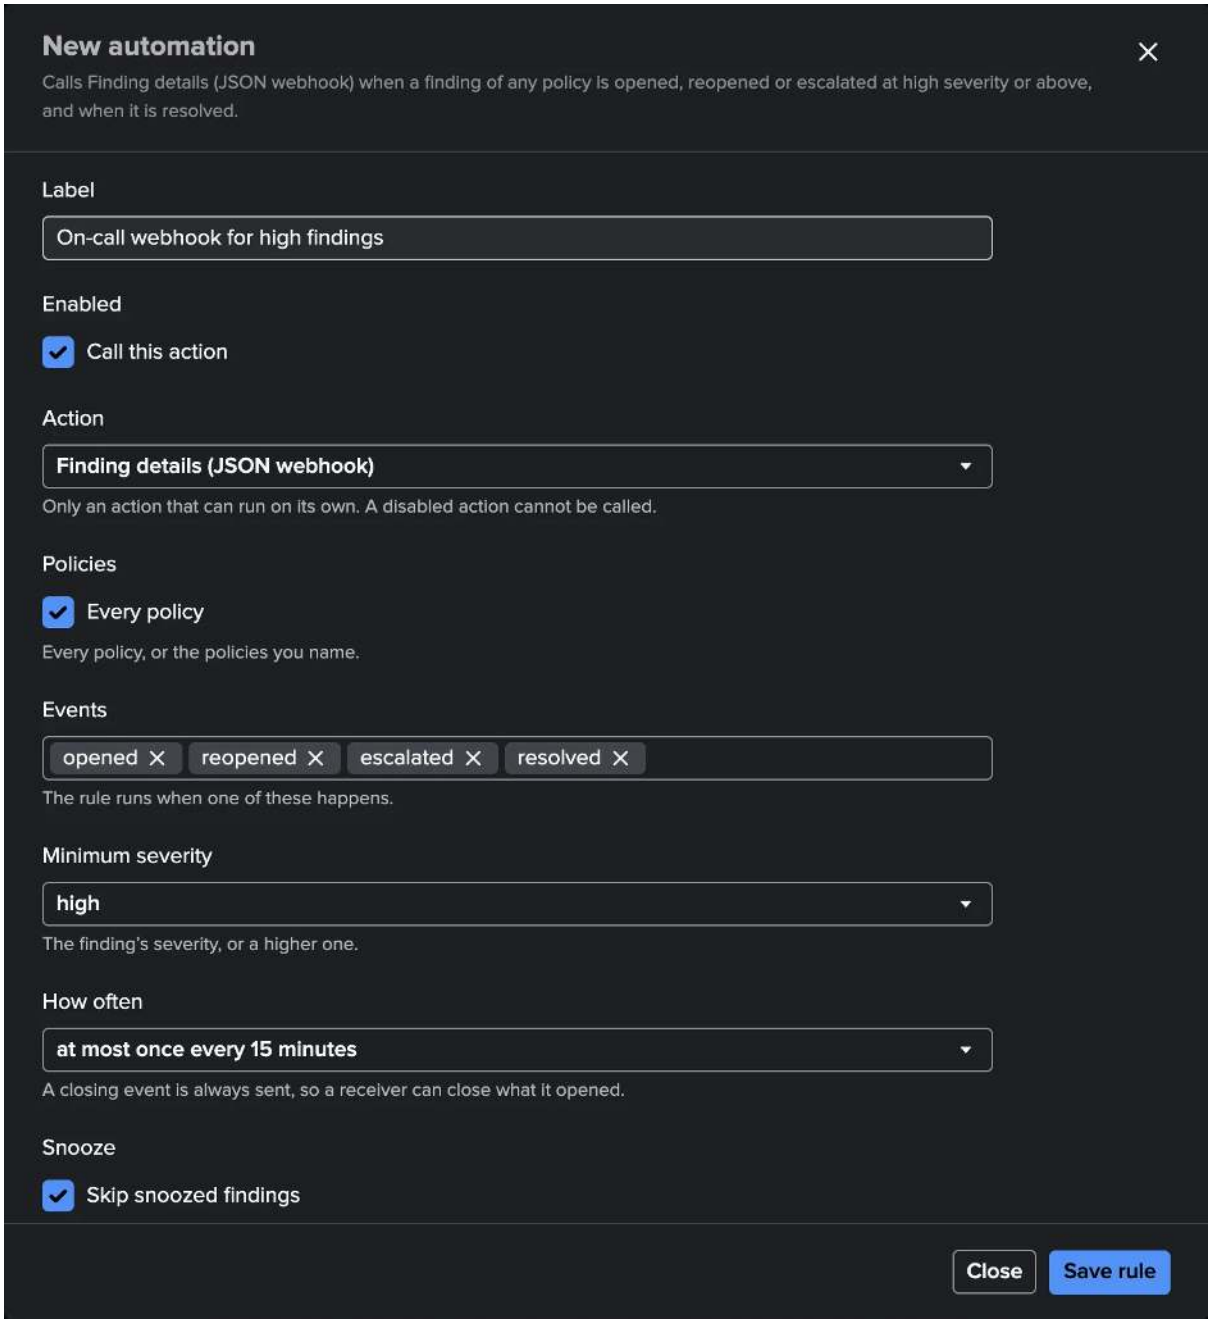
An **automation rule** sends a webhook definition automatically when a finding changes.

Field	Meaning
Which policies	The policies the rule applies to, or every policy.
Events	The transitions that trigger it (see below).
Minimum severity	Low (default) to Critical.
Action	The webhook definition it sends (only webhooks can be automated).
How often	The throttle per finding: from 0 to 86,400 seconds, 900 by default.
Snooze	Respect snooze (default): a snoozed finding sends nothing.

Tenant type	Events
User Activity Monitoring	new, reopened, escalated, resolved, dismissed, assigned
Cribl Stream, Cribl Edge	opened, reopened, member added, escalated, recovered, resolved, dismissed, dismissal expired, closed

Throttling. A rule sends at most once per finding per throttle period. **Closing events** (resolved, dismissed — and on Cribl recovered and closed) are never throttled, so the receiver can always close what it opened.

The queue. Matching transitions are queued in the tenant (at most 5,000 deliveries) and sent by the tenant's own collection job: the policies run on UAM (about every 15 minutes), the live run on Cribl Stream and Cribl Edge (every 5 minutes). Each run sends at most 200 deliveries; a failed delivery is retried up to 6 times with an increasing delay (30 seconds to 20 minutes) and dropped after 24 hours. Every automatic send carries a stable `webhook-id` header, so the receiver can recognise a retried request it already processed. Disabling or deleting a definition disables the rules that use it.



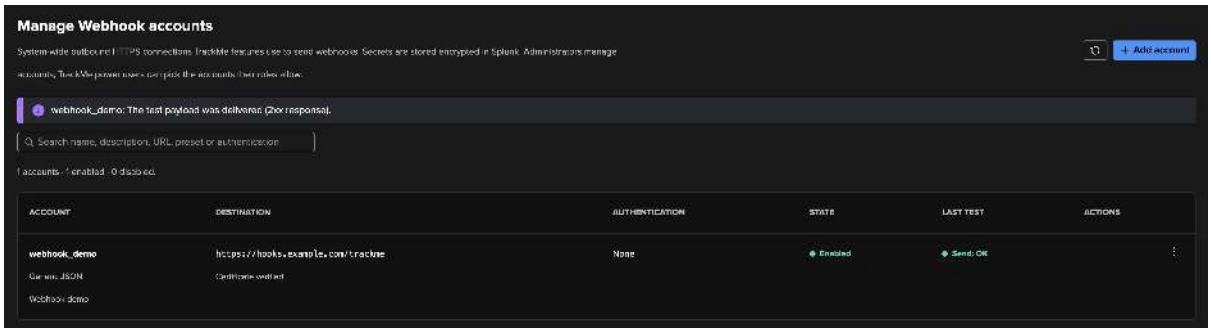
Checking deliveries

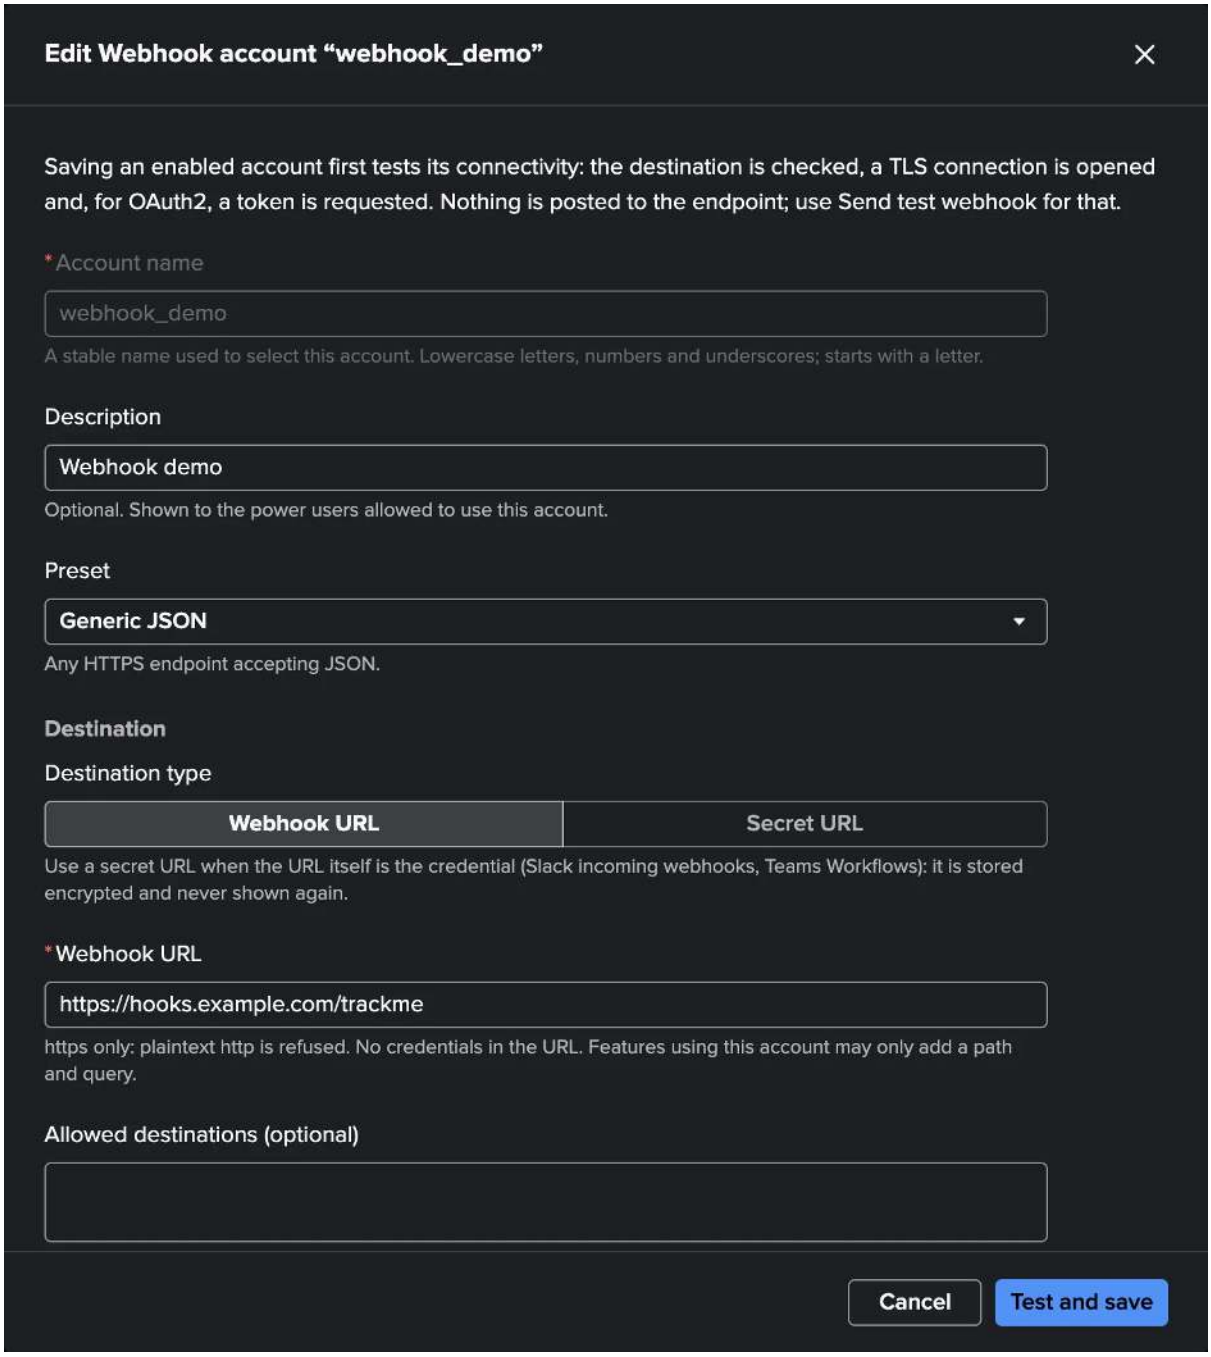
- The Configuration Guardian check **findings_action_delivery_failing** warns when a queued delivery of a tenant was attempted three times or waited more than 30 minutes — see *Configuration Guardian*.
- Manual sends are logged in `index=_internal sourcetype=trackme:custom_commands:trackmefindingsaction`.
- On UAM, the receipt of each policies run (`sourcetype=trackme:uam:receipt`) carries the counts of the automatic sends.
- Changes to definitions, rules and assignment settings are audited in the TrackMe audit index.

Webhook accounts

A **Webhook account** is a reusable, **system-wide** outbound HTTPS connection: where to send, how to authenticate, which certificates to trust, through which proxy. Webhook definitions only name the account and add a path, a query, headers and a body — so the destination and its credentials are managed once, by an administrator, and never copied into each tenant.

Manage them in **Configuration → Manage Webhook accounts**.





Edit Webhook account “webhook_demo”
Saving an enabled account first tests its connectivity: the destination is checked, a TLS connection is opened and, for OAuth2, a token is requested. Nothing is posted to the endpoint; use Send test webhook for that.
*Account name
webhook_demo
A stable name used to select this account. Lowercase letters, numbers and underscores; starts with a letter.
Description
Webhook demo
Optional. Shown to the power users allowed to use this account.
Preset
Generic JSON
Any HTTPS endpoint accepting JSON.
Destination
Destination type
Webhook URL
Secret URL
Use a secret URL when the URL itself is the credential (Slack incoming webhooks, Teams Workflows): it is stored encrypted and never shown again.
*Webhook URL
https://hooks.example.com/trackme
https only: plaintext http is refused. No credentials in the URL. Features using this account may only add a path and query.
Allowed destinations (optional)
Cancel
Test and save

Fields

Field	Notes
Account name, **Description**, **Account state**	The name is how definitions select the account (lowercase letters, digits and underscores). A disabled account is never used and saves without a connectivity test.
Preset	Generic JSON, Slack, Microsoft Teams Workflows, PagerDuty Events v2, ServiceNow, Splunk HEC, Splunk SOAR, Cribl HTTP source. A preset pre-fills the empty fields with the receiver's usual settings; it is informational afterwards. The message itself (a Slack text, a Teams card, a PagerDuty event) is written in the webhook definition, starting from the JSON preset.
Webhook URL or **Secret URL**	HTTPS only: `http://` is refused, and so are credentials in the URL. Use a **Secret URL** when the URL itself is the credential (Slack, Teams): it is encrypted and never displayed again. The host is fixed: a definition may only append a path and a query.
Allowed destinations	Optional: host names, `*.example.com`, IP addresses and CIDRs. Addresses in private, loopback, link-local and other special-purpose ranges are refused unless an allowed IP or CIDR covers them; cloud metadata, multicast and reserved addresses are always refused, and so are the Splunk management ports of non-public addresses.
Authentication type	None, Basic, Bearer token, API key header (header name and an optional one-word prefix such as `Splunk` for HEC), HMAC signature (Standard Webhooks or GitHub SHA-256), OAuth2 client credentials (token URL, client ID, client secret, optional scope and audience). Secrets are stored in Splunk's encrypted storage.
Verify SSL certificate, **CA certificate chain**	On by default. For a private CA or a self-signed certificate, keep verification on and add the CA chain (paste it or **Upload PEM file**). Turning verification off keeps the traffic encrypted but stops checking the destination's identity.
Proxy URL, user name, password	Optional, `http://` or `https://`. The request stays TLS to the destination inside the proxy tunnel. Environment proxies are never used.
Default headers	A JSON object of non-secret headers sent with every request; reserved and credential headers are refused.
Timeouts, **Maximum retries**, **Retried HTTP statuses**, **Maximum body size**	Connect 5 s (up to 30), read 15 s (up to 60), 2 retries (up to 5) on 429, 502, 503 and 504 by default, bodies up to 256 KiB (up to 1 MiB). Redirects are never followed.
Allowed roles, **Allowed tenants**	Who may use the account: comma-separated roles whose TrackMe power users may select it (empty: every TrackMe power user; TrackMe administrators always may), and the tenants allowed to use it (empty: every tenant). Checked when a definition is saved and again before every send.

Every address a destination resolves to is checked before **every** attempt, and the connection is pinned to the address that was checked. Through a proxy the proxy resolves the name, so the name is checked but the address cannot be pinned.

Testing an account

- **Saving** an enabled account runs a connectivity test — destination checks, the TLS handshake and, for OAuth2, the token request — and **sends nothing** to the receiver (a test message in a Slack channel or a PagerDuty incident would be noise). A failure rejects the save with its reason; save the account **disabled** to keep it while you fix the destination.
- **Test connectivity** in the row menu runs the same test again.
- **Send test webhook** (with a confirmation) posts one `trackme.webhook.test` message, so you can see what the receiver gets. **View last result** shows the outcome.

Who manages and who uses them

- TrackMe **administrators** (`trackmeadminoperations`, Splunk `admin` or `sc_admin`) create, edit, test and delete Webhook accounts.
- TrackMe **power users** only see the list of accounts their roles and tenant may use, without any secret, when they edit or send a webhook definition.
- Other users see nothing.

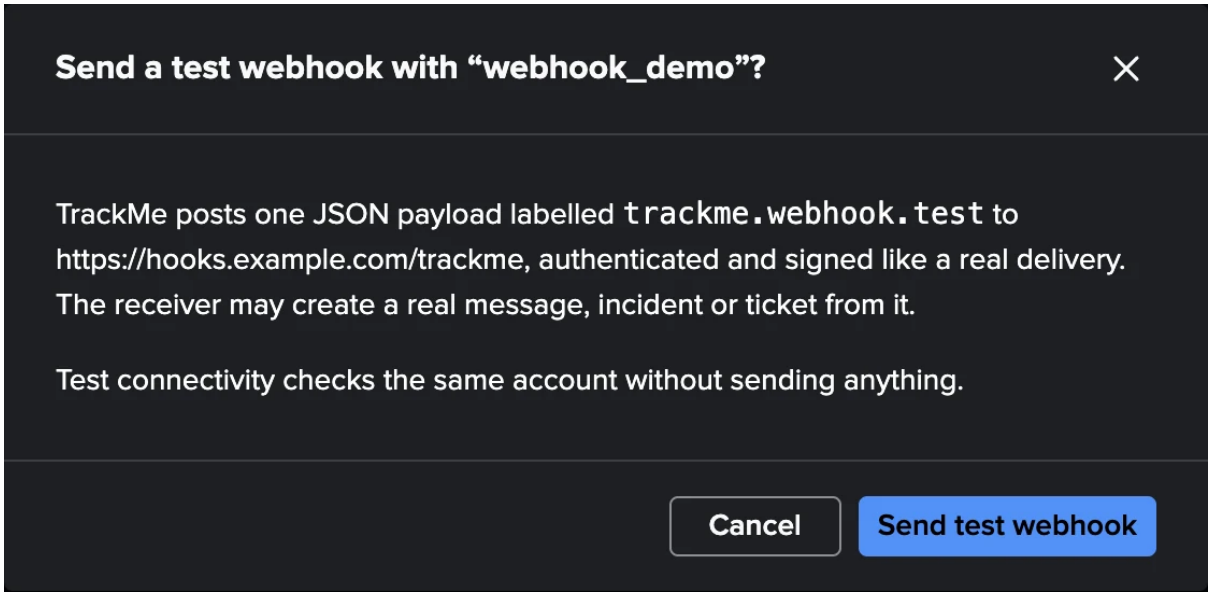
Warning

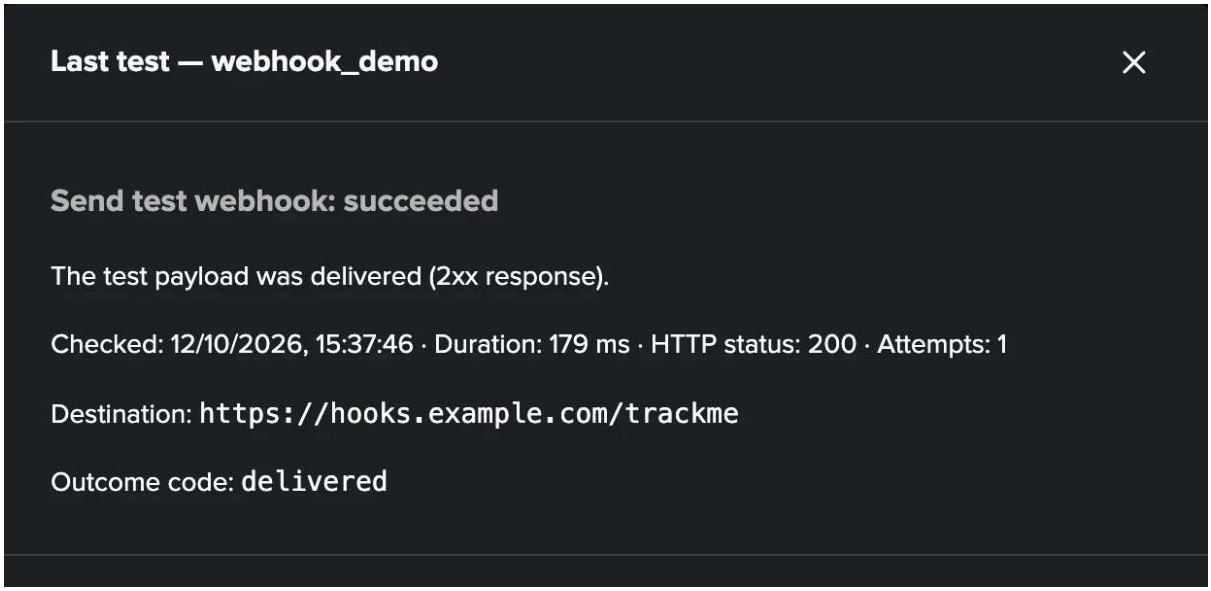
While an enabled account has **Verify SSL certificate** turned off, the Configuration Guardian raises the warning **webhook_account_tls_unverified**. Turning verification off is allowed on every platform, Splunk Cloud included, but prefer adding the CA chain of the destination.

Worked example: from an account to an automatic webhook

This example uses a test endpoint such as a request-inspection service, which shows every request it receives — the quickest way to see exactly what TrackMe sends before you point it at a real receiver.

1. **Create the account.** In Configuration → Manage Webhook accounts, **Add account**: name `webhook_demo`, preset **Generic JSON**, the HTTPS address of your test endpoint as **Webhook URL**, authentication **None**, **Verify SSL certificate** on. Save: the connectivity test runs, and the row reads *Connectivity: OK*.
2. **Check what the receiver gets.** Row menu → **Send test webhook** → confirm. The test endpoint shows a `trackme.webhook.test` JSON message.
3. **Define the action.** In a Cribl Stream workspace, Settings → **Finding actions** → **Add from preset** → *Finding details (JSON webhook)*. Select the Webhook account `webhook_demo`, review the body template, enable the definition and save.
4. **Send by hand.** On a finding, open **Custom actions** → **Send webhook…**, review the request preview and confirm. The test endpoint shows the finding as JSON: its id, title, policy, severity, status, subject, condition and the link back to the workspace.
5. **Automate.** Open a policy → **Automations** → **New rule**: events *opened* and *recovered*, minimum severity Medium, the action you just created, the default throttle. The next time the policy opens or recovers a finding, the live collection run sends it.
6. **Watch the deliveries.** If the endpoint stops answering, the deliveries are retried and the Guardian check **findings_action_delivery_failing** warns after three attempts or 30 minutes.





Findings AI Agents

An **AI Agent** reviews findings the way an operator would: it reads the evidence TrackMe collected, writes an assessment as a note, and — when you allow it — applies the decisions the tenant permits. Three agents share one framework:

Tenant type	AI Agent
User Activity Monitoring	**UAM AI Agent** — it replaces the UAM Findings Advisor of TrackMe 2.4.18; on upgrade, an enabled advisor's settings are carried over to the agent.
Cribl Stream	**Cribl Stream AI Agent**
Cribl Edge	**Cribl Edge AI Agent**

Inspect and act

Mode	What it does
Inspect	Reads the evidence and writes **one current note per finding**, signed `[AI Agent]`, with its assessment, confidence and recommendation. It changes nothing. A later review refreshes the note when the assessment is unchanged and replaces it otherwise.
Act	Inspects, then applies the decisions the evidence supports **and** the tenant settings allow. Act must be chosen explicitly.

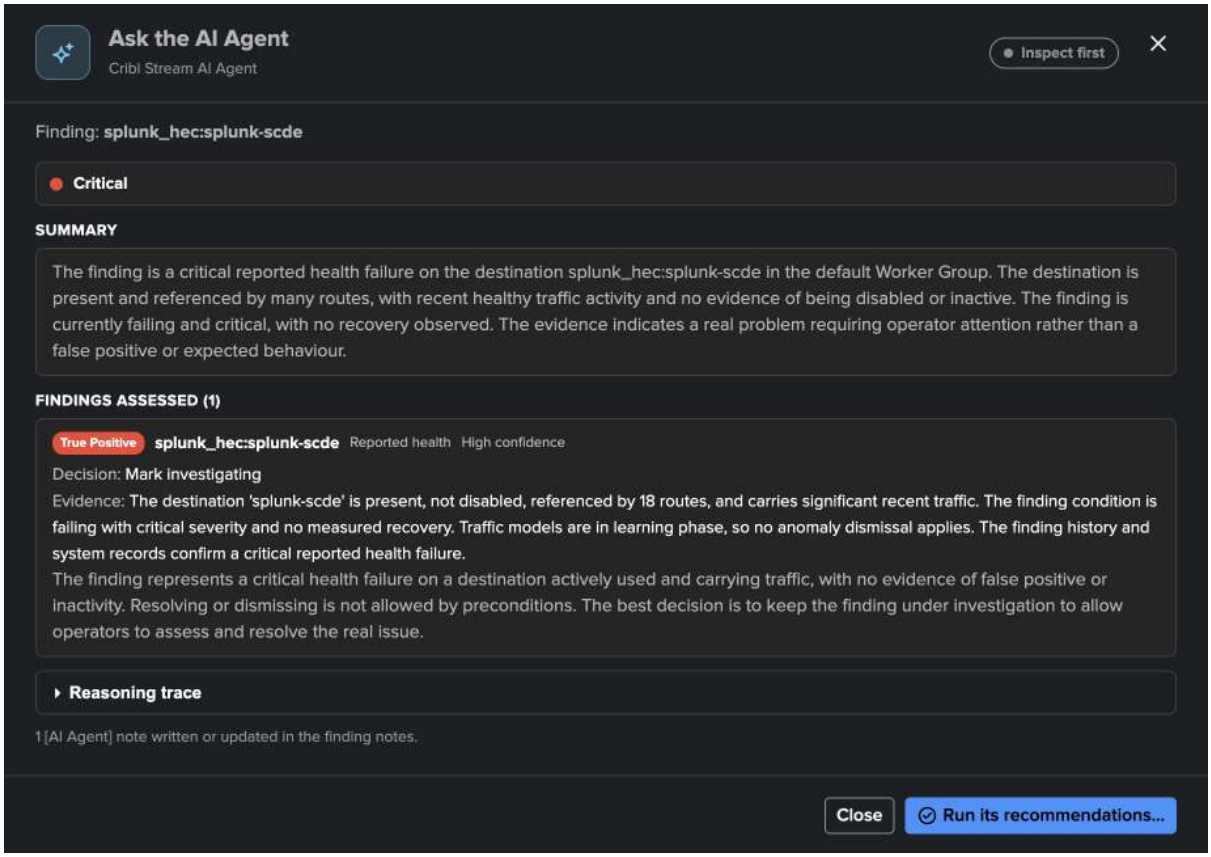
What act may do, depending on the settings:

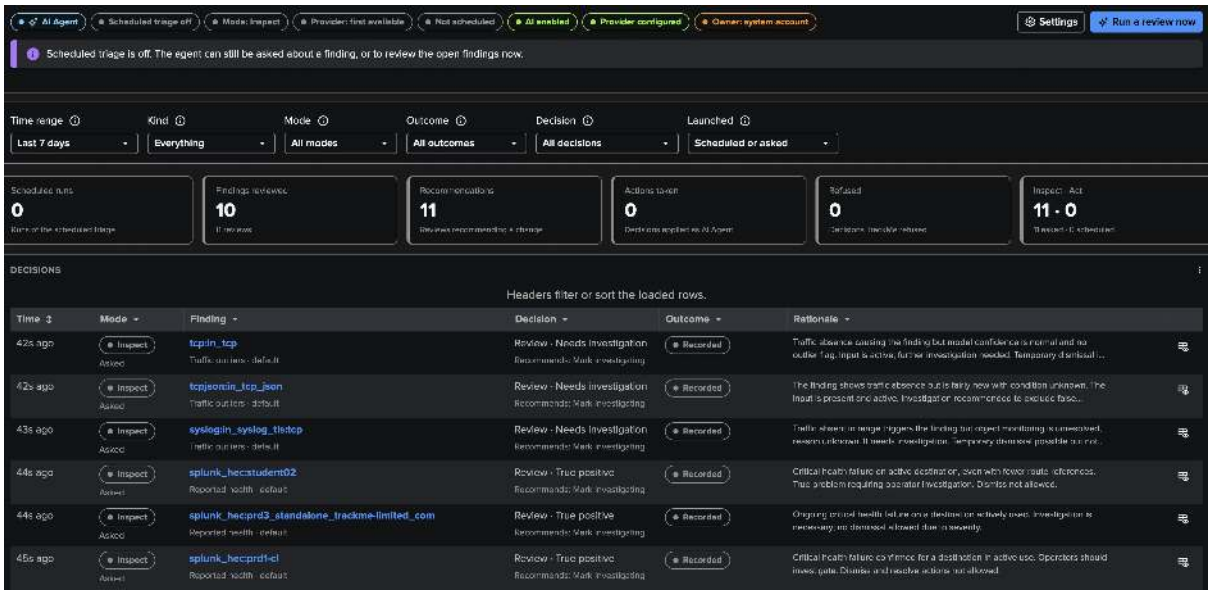
Decision	Default	UAM	Cribl Stream	Cribl Edge
Mark investigating	On	Yes	Yes	Yes
Dismiss for a time (up to 7 days by default, at most 90)	On	Yes, never a critical or high finding still observed	Yes, a critical failing finding only with proof that the object is disabled, missing or inactive	Yes, a critical or high finding still failing only when its node or Fleet is gone from the node directory
Not an anomaly (a traffic outlier)	On	—	Yes	—
Resolve	Off	Only a finding its policy no longer observes	Only after a measured recovery	Only after a measured recovery
Classify an account	Off	Only an account without an operator class	—	—
Stop monitoring an object	Off	—	Only with proof of inactivity (7 days by default)	—

The agent **never** dismisses permanently, assigns or unassigns, changes a severity, or changes a policy or a setting. Every decision it applies is recorded under the actor **AI Agent** (a purple pill in the history), never under the person who asked; the decision log also records who asked, the AI provider and whether the run was scheduled.

Asking the AI Agent

Ask the AI Agent… is in the finding and Finding group menus, the investigation and the **AI Agent** tab. The agent first inspects; you read its assessment and can then let it **act** on that inspection within 30 minutes. The AI Assistant of the workspace can also propose an AI Agent review in the chat. Asking needs AI to be enabled with at least one AI provider; on UAM it is reserved to the TrackMe administrators of the tenant, on Cribl Stream and Cribl Edge to the roles that can triage.





Scheduled reviews

The agent can also review the open and investigating findings every hour on its own. This is **off by default**. A scheduled run only starts when:

- the AI Assistant is enabled and at least one **AI provider** is configured;
- the tenant is enabled and its AI Agent is enabled (Settings → **AI Agent**);
- the tenant owner is a real account, not `nobody` or `splunk-system-user` — the Guardian check **ai_automation_owner_is_system_user** warns otherwise. On Cribl Stream and Cribl Edge the owner of the scheduled report must also be a Splunk administrator.

Each run reviews up to 10 findings (one per Finding group, most severe first), skips the findings it reviewed recently, and **never overrides a person**: a finding or a Finding group that an operator decided on, or that has an assignee, is left to the operators. By default the scheduled selection only includes **critical and high** findings: the shared filters of the automated AI reviews apply, with the finding severity as priority.

Settings

In the workspace **Settings → AI Agent** (each agent is also in **Manage AI Agents automation**, for enabling, mode, provider, review interval, runtime and custom instructions):

Setting	Default	Notes
Enabled	Off	Scheduled reviews only; asking the agent needs only AI to be available.
Mode	Inspect	Inspect or act, for scheduled runs.
AI provider	First available	
Review interval (days)	1	A finding is not reviewed again within this interval unless it changed.
Maximum runtime (seconds)	3000	Fits the hourly cadence.
Findings per run	10	1 to 50.
Custom instructions	Empty	Plain English the agent follows on every run (at most 4000 characters).
Allowed decisions and longest dismissal	See above	Per decision.

Custom instructions tell the agent what to treat as expected, what to look at first and how to word its recommendations, for example "The accounts named `svc_*` are service accounts." They never widen what it may do: the allowed decisions and the checks TrackMe makes before every decision still decide. **Evaluate…**, next to the field, runs the agent in inspect mode with an unsaved draft, on one open finding or a short review, optionally side by side with a run without instructions; an evaluation writes nothing (see *AI Agents for findings*).

Everything the agents do is in the **AI Agent** tab, the finding history, the `[AI Agent]` notes and the **Review AI Advisor activity** and **Review Scheduled AI Advisor activity** dashboards. The AI side of the agents — how a review works, the evidence, the data sent to the provider and the audit — is in *AI Agents for findings*. See also *The AI Advisors* and *AI Assistant & Concierge*.

The shared workspace conventions

The three workspaces look and behave alike, so what you learn on one applies to the others.

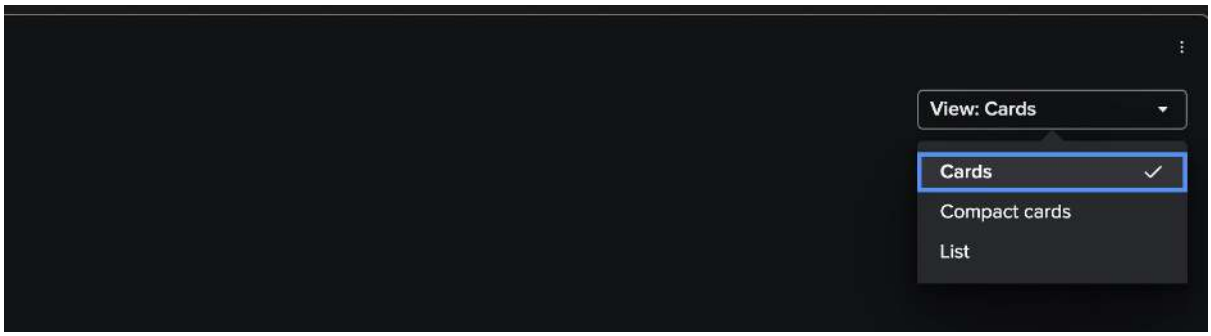
Table header filters and sorting
: Text and category columns have a filter in their header: search the values, select exact values, or type a "contains" match. Numeric and date columns sort, with empty values always last. On the Findings tab these filters act on whole Finding groups. On tables loaded page by page (Cribl Edge nodes, UAM catalogs), header controls act on the loaded page, while the toolbar filters search everything. Header controls never change data or permissions.

Policy view modes
: The Policies tab shows **Cards** (default), **Compact cards** or a sortable **List**. The choice is remembered per user and per tenant type (Cribl Stream and Cribl Edge share it) and writes no configuration.

Menus
: Finding, Finding group and selection menus stay within the screen and scroll. **Set severity** and **Custom actions** are submenus (Right Arrow opens, Left Arrow returns). An entry you cannot use stays listed, disabled, with its reason.

One Save in Settings
: Every Settings section — Notifications, Assignment, Finding actions, AI Agent and the tenant's own sections — is saved with one **Save**, **Discard** or **Reload**.

Deep links
: Notification emails and the `finding.link` token open the finding (or its Finding group) in place in the workspace; Cribl Edge links can also open a node or a Fleet.



8.3.18 Cribl Stream and Cribl Edge

TrackMe monitors Cribl with two **dedicated tenant types**, generally available since TrackMe 2.4.19:

- a **Cribl Stream** tenant follows one Cribl Stream deployment end to end: the Leader, the Worker Groups, the Workers and their machines, and the Sources, Destinations, Pipelines and Routes, with traffic machine learning models on every data object;
- a **Cribl Edge** tenant follows the Fleets of a Cribl Edge Leader: connectivity, version and configuration drift, the health of the Sources and Destinations reported by the nodes, and the disk, CPU and memory of every Edge Node, at any fleet size.

Like User Activity Monitoring, a Cribl tenant has no entities: its policies raise **findings**, which you triage, group, assign, act on and notify — see *Findings, Finding groups and findings actions*.

The Cribl documentation lives with the third party integrations:

Cribl Stream & Cribl Edge Which Cribl tenant to use, how they work, and the Cribl connections.

Cribl Stream & Cribl Edge Cribl Stream Create a Cribl Stream tenant and explore its workspace.

Cribl Stream Cribl Edge Create a Cribl Edge tenant and explore its workspace.

Cribl Edge To monitor the data sources and hosts whose logs pass through Cribl, with the DSM and DHM components, see *Monitor data sources and hosts with Cribl signals*.

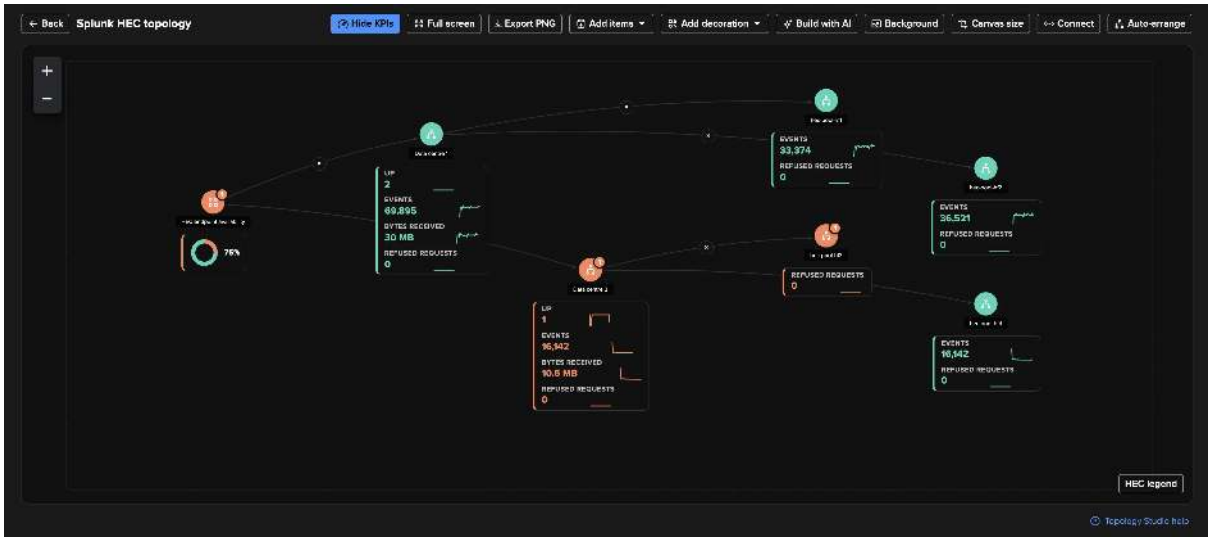
8.3.19 Splunk HEC

The **Splunk HEC tenant** monitors the **HTTP Event Collector** (HEC) endpoints of one Splunk deployment: the heavy forwarders, indexers or Splunk Cloud indexers that receive HEC traffic, the **pools** they form behind a load balancer, and the **tokens** senders use. It answers the questions a Splunk administrator asks about HEC: *are all my HEC endpoints up and receiving? are senders being refused, and why? where is the bottleneck when HEC answers "Server is busy"? which tokens send data Splunk rejects? did a business-critical token stop sending? is my load balancer spreading the traffic over every member of the pool?* The answers are **findings**, raised by built-in policies, with the same triage, Finding groups, notifications, assignment and findings actions as the Cribl Stream and Cribl Edge tenants, and a findings AI Agent of its own, the Splunk HEC AI Agent.

A Splunk HEC tenant is a **dedicated tenant type**: it has no entities and no state colour, and one tenant follows the HEC endpoints of one Splunk deployment. It reads the telemetry Splunk **already writes** about HEC — the HEC metrics in `_introspection` and the HTTP input, queue and output messages in `_internal` — on the local

search tier or through a TrackMe remote account. Nothing is installed on the endpoints, no new data is ingested, and TrackMe never changes a HEC setting, a token or anything else on Splunk: the tenant only reads.

The Splunk HEC tenant is generally available since TrackMe 2.4.21.



The view above is the **HEC topology** of a deployment with two pools of two heavy forwarders, generated from the workspace in one click and saved to Topology Studio (see *Generated topologies*). One heavy forwarder of *Data centre 2* was stopped: the endpoint and its pool turned orange with the findings they opened, and the endpoint availability fell to 75 %.

For a guided tour on a live deployment, see the hands-on walkthrough *Splunk HEC*.

What it monitors

Object	What TrackMe watches
Endpoints	Every Splunk instance whose HEC heartbeat reaches the search tier. **Availability** (an endpoint writes its HEC metrics every minute, traffic or not: no heartbeat means it is down), **refused requests** (server busy, refused tokens, rejected data), **back pressure** along its ingestion pipeline and the stage that cannot keep up, its **output** to the indexers, **indexer acknowledgment** under pressure or never polled, and optionally its host's **CPU and memory**.
Pools	The endpoints behind one load balancer or with one role. **Capacity** (members up against the expected size), **imbalance** (a member up but starved of traffic), a **traffic drop** against the same hour of the previous days, **traffic outliers** against a traffic model, and, between the members, **token consistency** and **configuration drift** (Splunk versions, global HEC settings).
Tokens	The HEC inputs by name, whatever pool receives them. **Rejected data** (invalid format, incorrect index, missing or blank event, indexed fields, oversized events), **silence** of the tokens you select, and **traffic outliers** against each busy token's traffic model.

A token is always known by its **name**: TrackMe never reads, stores, logs or shows a token value.

How it works

Splunk's own telemetry is the source. Every HEC instance writes, every metrics interval (60 seconds by default, `limits.conf [http_input] metrics_report_interval`), its HEC metrics to `_introspection` (`sourcetype=http_event_collector_metrics`): an instance series, written even when the endpoint is idle (a heartbeat), and a series per token while the token receives data. It logs each refused request to `splunkd.log` (`component=HttpInputDataHandler`, with the token name, the client address and the HEC reply code), and its queues, thread activity and forwarding to `metrics.log`. Splunk forwards its internal indexes by default, so TrackMe sees every HEC endpoint with **no agent, no network path to the endpoint and no credential to it**.

Bounded searches, whatever the fleet size. The collection runs a fixed number of searches per run, aggregated by host and token, over what Splunk **indexed** since the previous run (by index time, in settled 5-minute windows): its cost does not grow with one search per endpoint.

Job (Collection health label)	What it does
HEC activity (every 5 minutes)	Reads the last settled 5-minute window: the HEC metrics of every endpoint and token, the refused requests by reply code, token and client, the ingestion queues and their threads, the output and its receivers, and the host's CPU and memory. It publishes the window (endpoints, pools, tokens), writes the history points to the tenant's TrackMe metric index, then evaluates the policies (**Monitoring policies**) and sends the notifications.
Endpoint directory (every 10 minutes; rebuilt about once an hour)	The endpoints (those seen in the last 24 hours, kept while they reported in the last 7 days) and the token names seen in the last 24 hours, their identity (Splunk version, OS, CPUs, memory) and the pool each one joins. With remote accounts bound, it also reads the optional splunkd API (see *The splunkd API enrichment*).
Traffic models (twice an hour)	Learns the incoming traffic of each pool and token per hour of the week, from the HEC metrics (see *Traffic models*).
Monitoring policies (after every HEC activity run; on demand)	Evaluates the policies on the newest window. **Run now** in Collection health evaluates them again.

Endpoint states. In each window an endpoint is **up** (a heartbeat in the window), **late** (no heartbeat this window, but one in the last 5 minutes), **stalled** (no heartbeat, and its output was in trouble: its own telemetry waits behind the same blocked output) or **silent**. An endpoint silent for longer than the dormancy period of Endpoint availability (7 days by default) is **dormant**, a retired instance: it opens nothing. The directory keeps the endpoints that reported in the last 7 days.

Why "Server is busy". HEC writes every request into one input queue, shared by every token, then into the ingestion pipeline (parsing, merging, typing, indexing) and, on a heavy forwarder, the output to the indexers. When a stage cannot keep up its queue fills, then the queues before it, until HEC's own queue is full and HEC refuses requests with HTTP 503. The tenant reads every queue of that path and names the **bottleneck**: the stage after the furthest-downstream saturated queue, or the **output** when the backup reaches the indexing queue and an output queue is saturated too, and whether that stage's thread was busy (working at its limit) or waiting on the next stage.

Before you start

A licence. A valid **Enterprise**, **Unlimited**, Unlimited trial or **Developer** licence. The Splunk HEC tenant is not available with the Foundation edition or the Foundation trial.

A source. The search tier that sees the HEC endpoints' internal indexes:

- **local**, this search tier, when it searches the indexers that hold the endpoints' `_internal` and `_introspection`;
- or a **TrackMe remote account** (*Remote Splunk deployments*) to the search tier of another deployment, a Splunk Cloud stack included. The tenant's scheduled searches run as the tenant owner, so the **tenant owner must hold one of the remote account's roles**: the wizard and the Settings refuse the account otherwise (`remote_account_refused`).

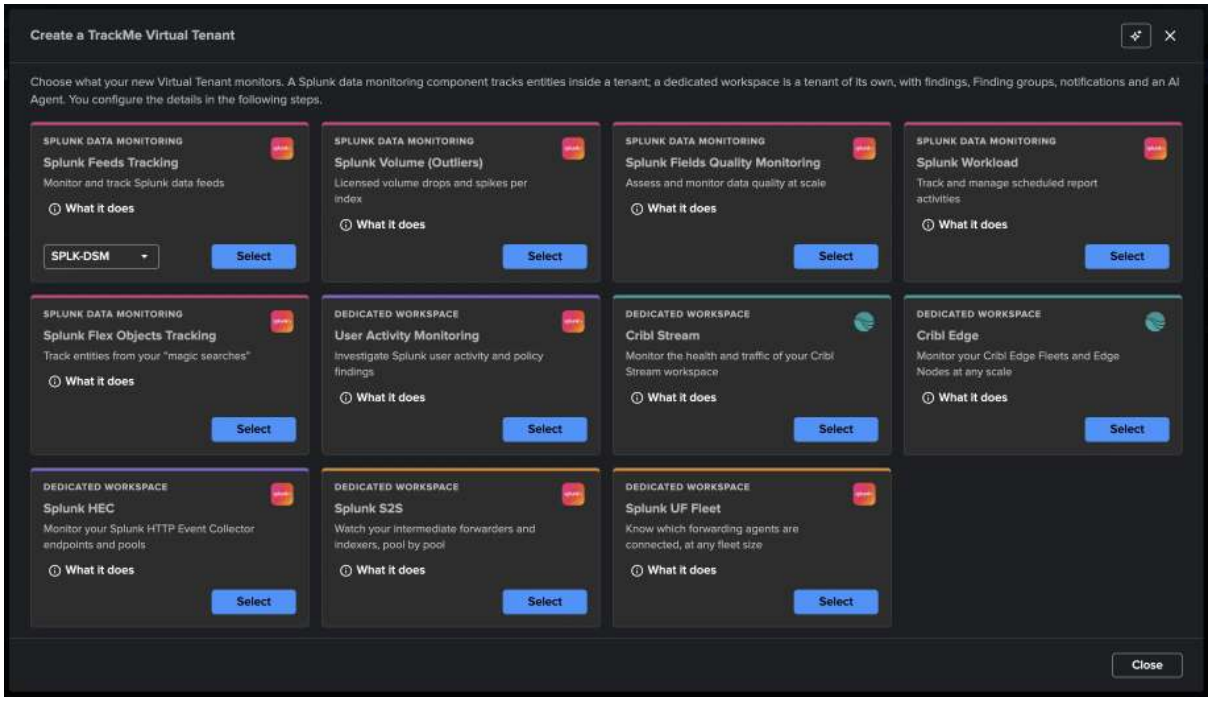
HEC telemetry that reaches the indexers. The endpoints forward their `_internal` and `_introspection` indexes (the default forwarding of internal indexes does it). On Splunk Cloud, `_introspection` and `_internal` are searchable and HEC runs on the indexers; the tenant works the same way.

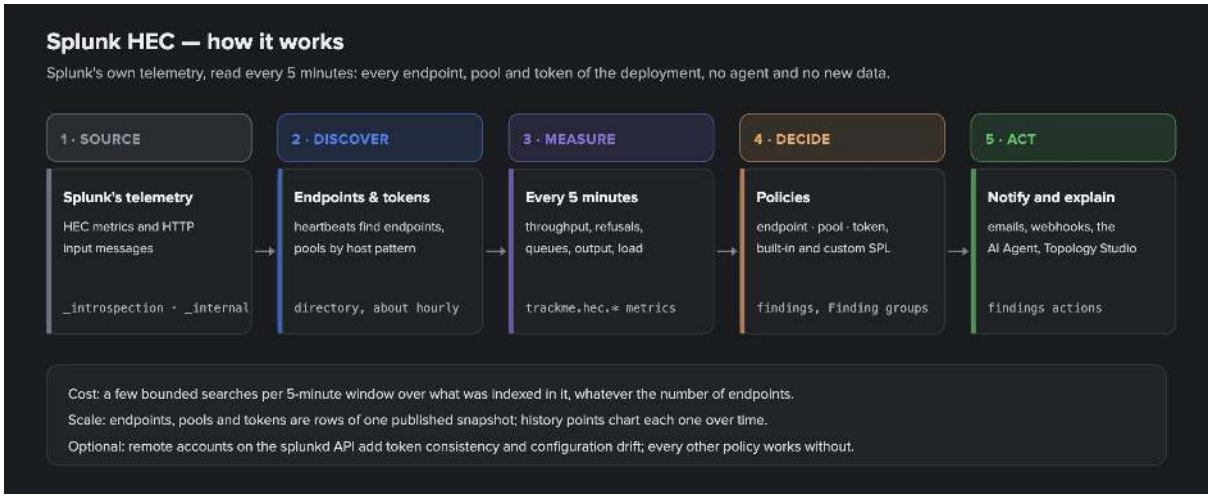
A tenant owner: `nobody`, or an account (typically a service account) holding the capabilities the creation wizard lists, so that the tenant's scheduled reports run. The scheduled triage of the Splunk HEC AI Agent needs a Splunk administrator account as owner (see *The Splunk HEC AI Agent*).

Optionally, remote accounts on the endpoints' splunkd API, for the two policies that compare the configuration of pool members (see *The splunkd API enrichment*). Every other policy works without them.

Creating the tenant

From the *Virtual Tenants* page, open **Actions → Create a tracking tenant** and choose the **Splunk HEC** card ("Monitor your Splunk HTTP Event Collector endpoints and pools"). Its first screen explains what the tenant does, with a **How it works** diagram on demand. The wizard has four steps.



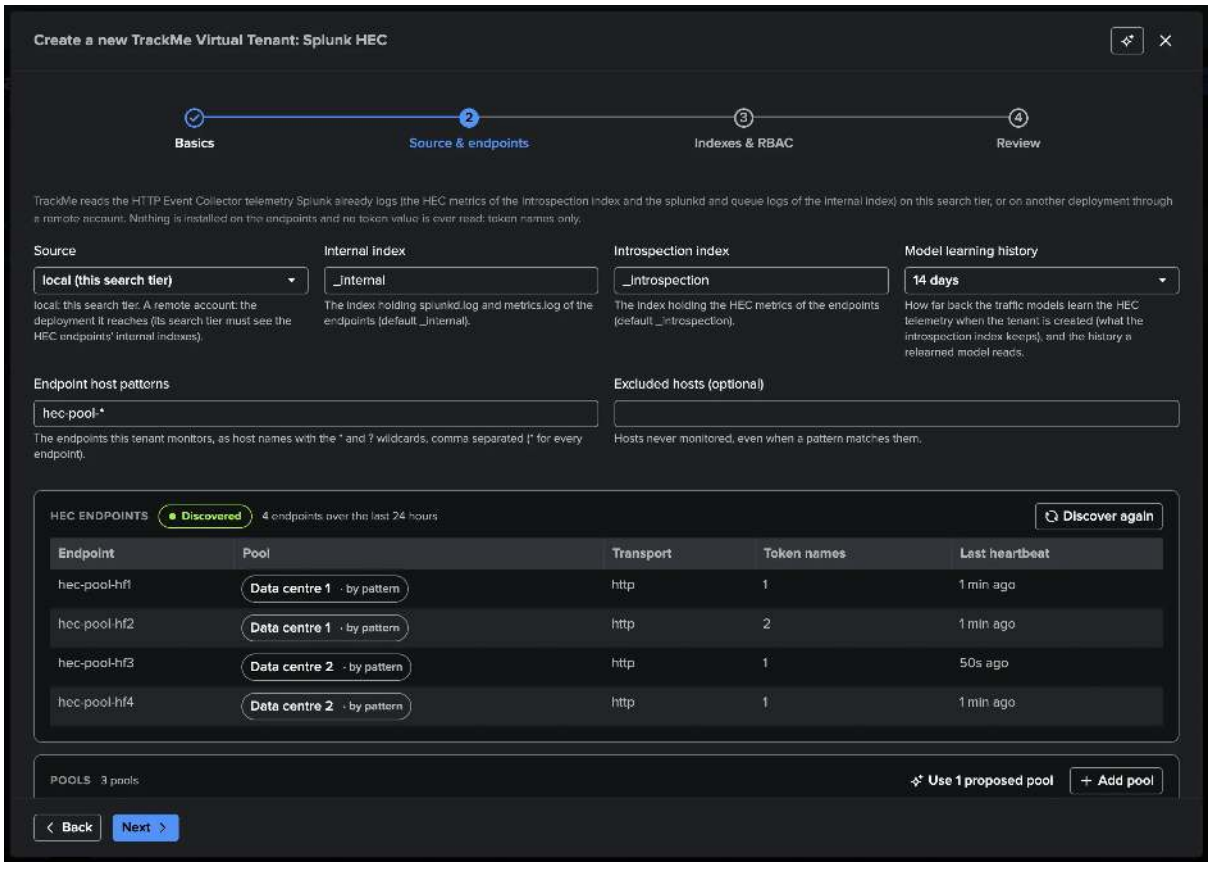


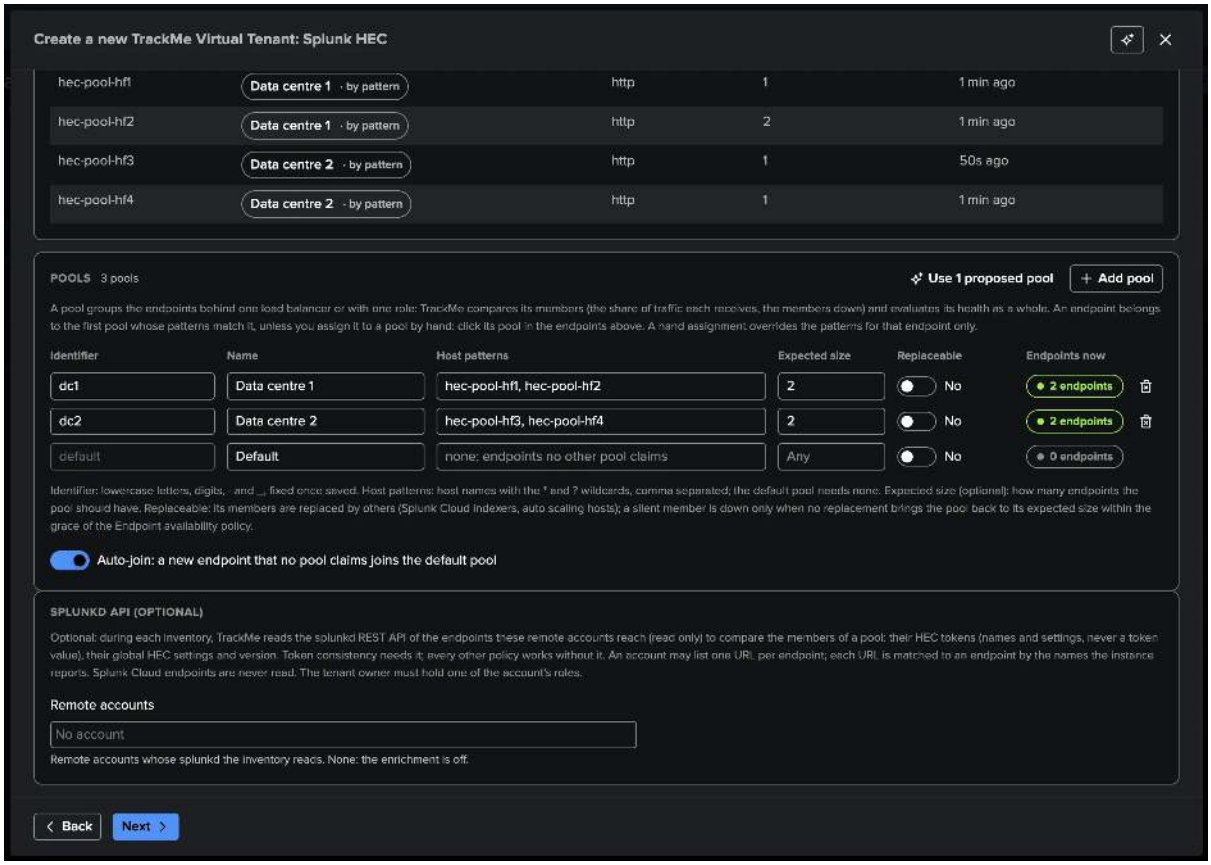
1. Basics. The **tenant identifier** (lowercase letters, digits and hyphens, up to 20 characters, for example `example-hec`; it cannot be changed afterwards), an optional **alias** and **description**.

2. Source & endpoints.

- **Source**: `local` (this search tier) or a remote account. It is locked once the tenant exists: another deployment takes another tenant.
- **Internal index** (default `_internal`) and **Introspection index** (default `_introspection`): where the endpoints' `splunkd.log` / `metrics.log` and their HEC metrics are. Locked once the tenant exists.
- **Model learning history** (14 days by default; *from today on*, 7, 14, 30, 60 or 90 days): how far back the traffic models learn the HEC telemetry when the tenant is created, and what a relearned model reads. `_introspection` must keep that much (Splunk's default retention is 14 days). Changed later in *Settings → Collection*.
- **Endpoint host patterns**: the endpoints this tenant monitors, as host names with the `*` and `?` wildcards (`*` for every endpoint, the default), and **Excluded hosts**, never monitored even when a pattern matches them.

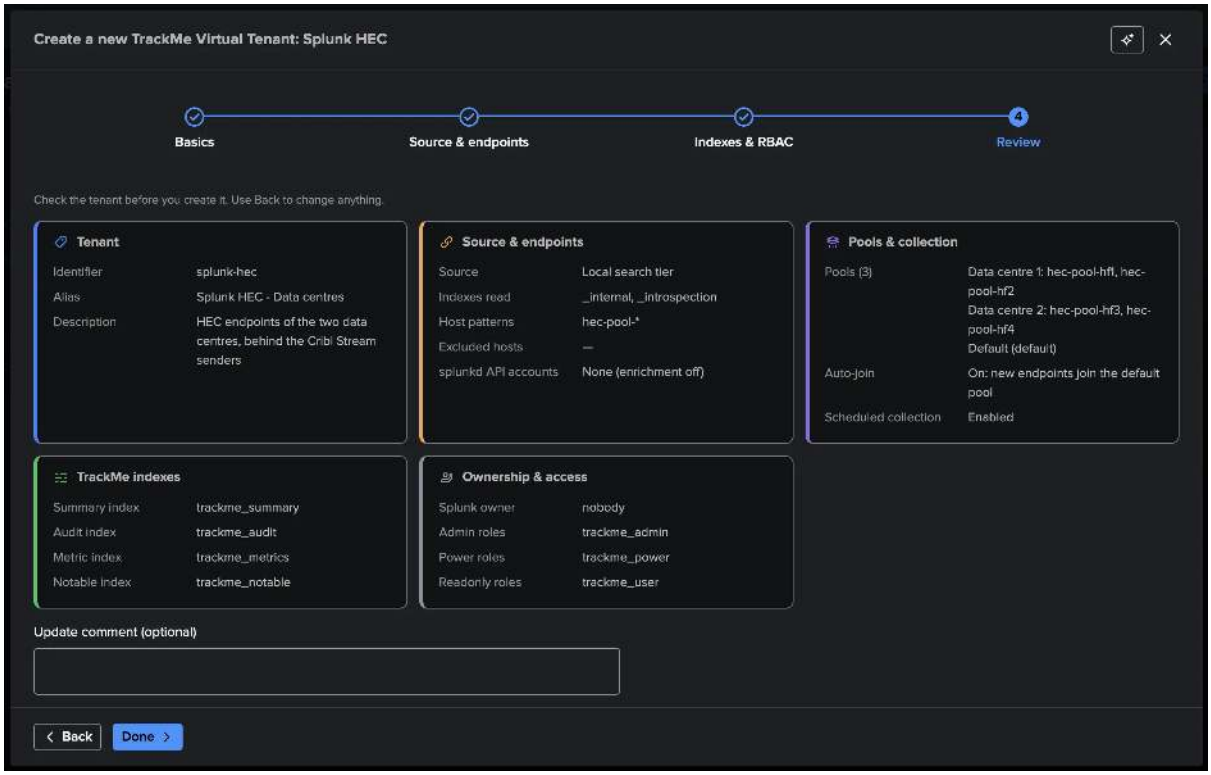
- **HEC endpoints**: TrackMe searches the HEC telemetry of the source and lists every endpoint that reported in the last 15 minutes (an endpoint reports a heartbeat every minute, traffic or not), with its transport, the token names active in those 15 minutes and its last heartbeat: two searches of 5 minutes at most. **Discover again** repeats the search. When nothing reported, the tenant can still be created: endpoints join it as soon as they report.
- **Pools**: **Use the proposed pools** applies the pools TrackMe proposes from the host names (see *Pools*), or **Add pool** defines your own. Each endpoint's pool is shown; click it to assign the endpoint to another pool by hand.
- **Splunk Cloud**: when the discovery finds Splunk Cloud indexers (`*.splunkcloud.com`), the wizard adds the **Splunk Cloud indexers** pool on its own, before the default pool: one per stack, matching `idx-*.<stack>.splunkcloud.com`, with **replaceable** members, because Splunk Cloud replaces its indexers under new host names. A card in the Pools section says so. The other endpoints of the deployment stay in their pools, and a pool of yours that already claims those indexers is left alone. Remove the pool or turn Replaceable off and the wizard keeps your choice; the card then warns that every replaced indexer would be reported down, with a button that adds the pool back.
- **Auto-join** (on by default): a new endpoint that no pool claims joins the default pool. Off, it waits as *discovered*: listed, but not evaluated by the pool policies.
- **splunkd API (optional)**: the remote accounts whose splunkd the directory reads (none: the enrichment is off).

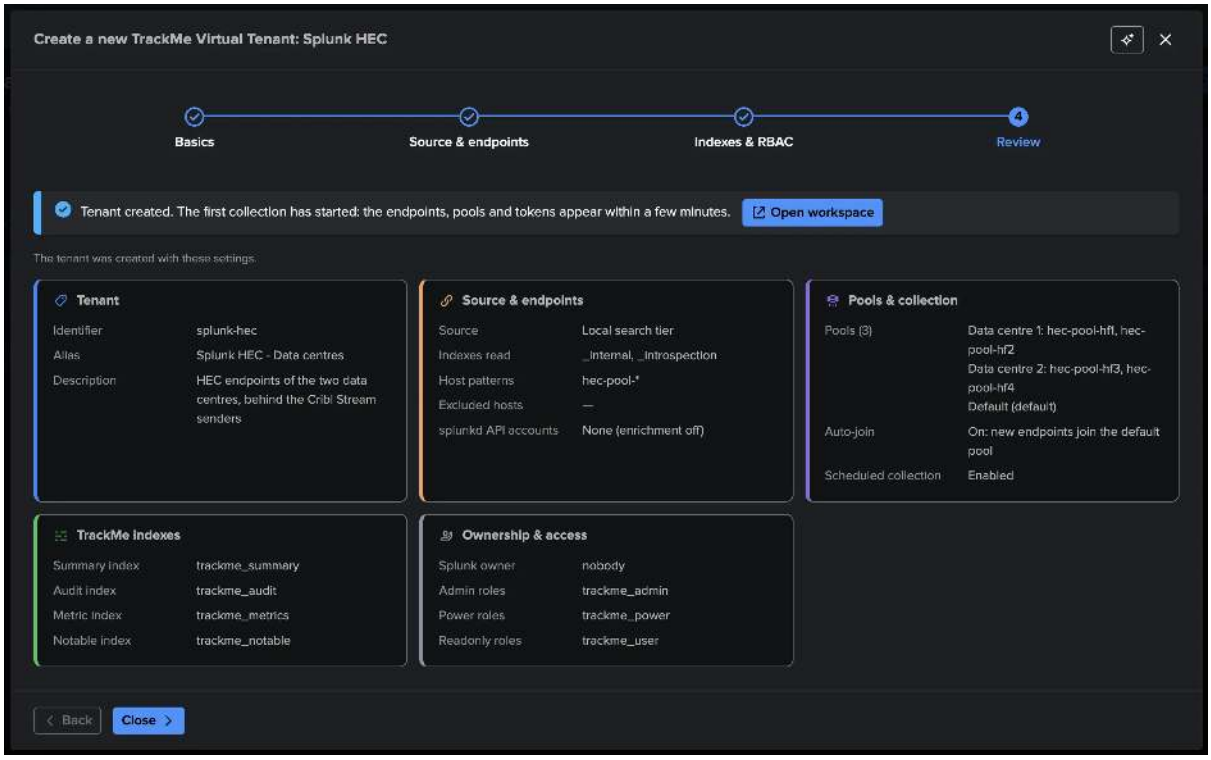




3. Indexes & RBAC. The tenant's indexes (summary, audit, metric, notable), its admin, power and user roles, and its owner, as for any tenant.

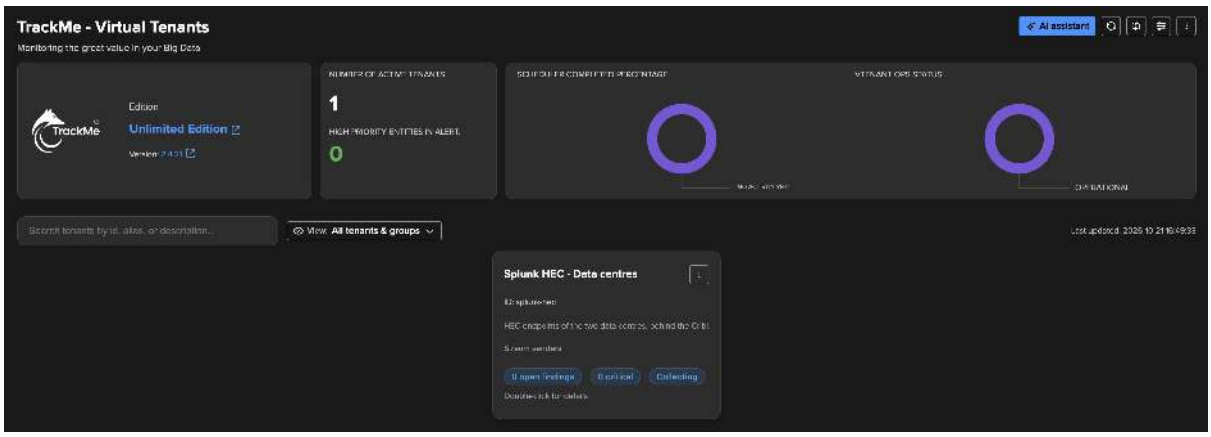
4. Review. Check the summary — source, indexes read, host patterns, pools, auto-join, splunkd API accounts, indexes and roles — and create the tenant. TrackMe creates the tenant's collections and reports and starts the first collection: the endpoints, pools and tokens appear in the workspace within a few minutes (**Open workspace**).





Collection is scheduled from the start: the HEC activity is read and the policies evaluated every 5 minutes, the endpoint directory rebuilt about once an hour, the traffic models trained twice an hour. To pause it, turn off **Scheduled collection** in **Settings → Collection**.

The workspace



Open the tenant from Virtual Tenants: Tenant Home shows the **Splunk HEC** workspace, built with the same components as the Cribl workspaces. **The status strip** shows the source, the last run of **HEC activity**, **Endpoint directory** and **Traffic models**, **Refresh** and, for the TrackMe administrators of the tenant, **Collect now**.

Tab	What it is for
Findings	The open findings and Finding groups of the tenant, their triage, assignment and findings actions.
Overview	The tiles of the deployment, the traffic over time, the pools, the endpoints needing attention, the discovered endpoints and the busiest tokens.
Endpoints	Every endpoint, by pool, filtered and paged by the server. Opens the endpoint.
Tokens	Every token name seen in the last 24 hours. Opens the token.
Traffic models	The traffic model of each pool and token, its state and expected range; opens a model and tunes one or several (see *Traffic models*).
Policies	The built-in policies and the custom policies of the tenant.
Collection health	Whether collection runs as configured, job by job, the source and the traffic models.
AI Agent	The Splunk HEC AI Agent: whether it can run, its totals, **Run a review now** and its decision log.
Settings	Source & pools, Collection, Notifications, AI Agent, Assignment, Finding actions.

The last five minutes

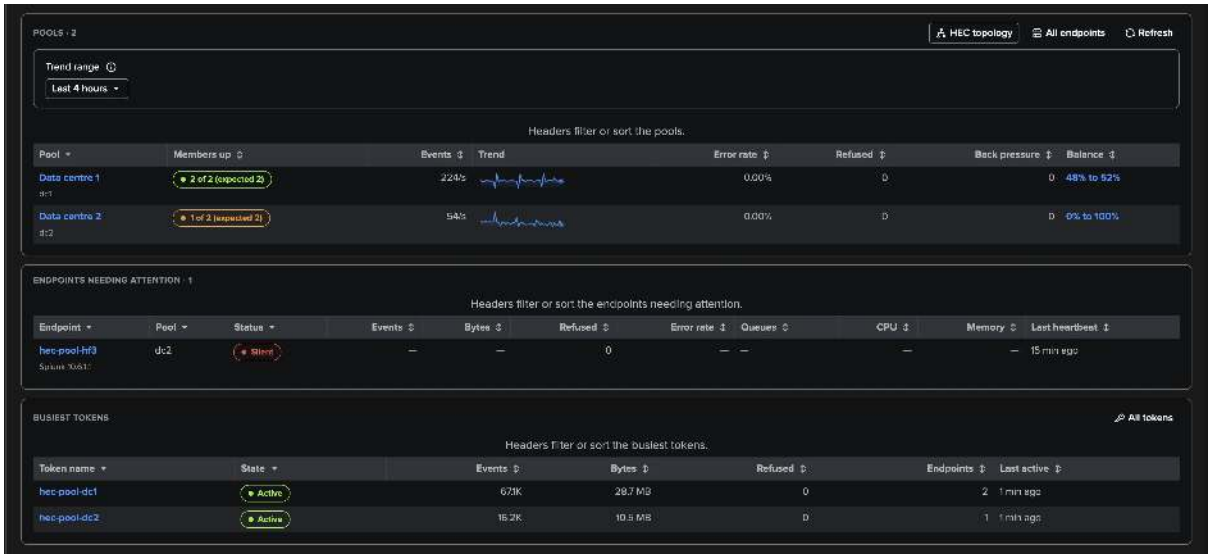
The states, findings and history come from the collected windows, which are settled on purpose (a window is read once its telemetry is indexed). The figures you look at are more recent: when the workspace opens, and at every refresh (automatic or manual), TrackMe also reads the **statistics of the last five minutes up to now** from Splunk and lays them over the collected rows. The badge says **Last 5 minutes · as of HH:MM:SS**; when that read fails, the workspace shows the collected window with the reason (**Collected window**). This read is an ordinary historical search over fixed bounds, run with your own rights: it never changes a state, a finding or the history. It runs at most two searches at a time, and a read still running is never started twice.

The large charts (the Overview traffic, the endpoint, pool and token drilldowns, a finding's history) also read their **latest buckets** from Splunk when the last collected window is behind, and say so under the chart.

Overview

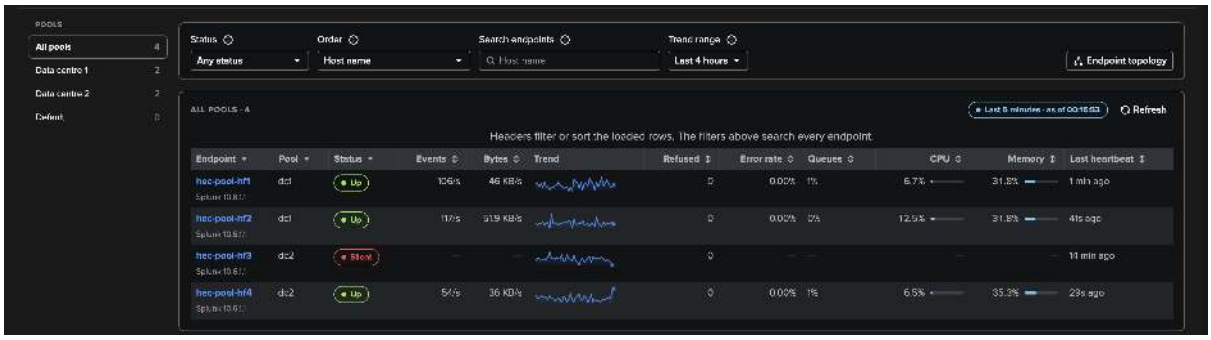
The tiles answer the HEC questions at a glance: **Endpoints up**, **Events** and **Bytes** per second, **Active tokens**, **Refused requests** (load balancer probes excluded), **Server busy** (HTTP 503: HEC could not queue the request), **Back pressure** (endpoints whose queues backed up), and when it happens **Stalled** endpoints and **Oversized events**. Refused requests, server busy, back pressure and stalled open the Endpoints tab sorted or filtered on them.

Below them: **Traffic over time** (events and bytes per second, refused requests and server busy replies per bucket, over a range you choose), the **Pools** (members up, traffic, refusals, back pressure, a trend, and the pool's traffic distribution), **Endpoints needing attention** (not up, refusing, backed up, dropping oversized events, failing destinations), the **Discovered endpoints** waiting for a pool, and the **Busiest tokens**. **HEC topology**, on the Pools panel, draws every pool and its endpoints with their live status (see *Generated topologies*).



Endpoints

A sidebar selects **All pools**, one pool (with its members in the latest window), or the **Discovered** endpoints. The table, paged by the server, filters by **status** (up, stalled, late, silent) and host name, and sorts by host name, most events, most refused requests, most server busy replies, highest error rate, most failed requests or back pressure first. Each row shows the pool, the status, the traffic, the refused requests, the fullest ingestion queue (or the bottleneck), a trend over the **Trend range**, and the host's **CPU** (user and system, average over the window) and **Memory** used (the peak over the window), as a percentage with a bar that turns amber from 75 % and red from 90 %. Both are host-wide (the introspection `Hostwide` data: every process on the endpoint's host); a dash means the window holds no host resource telemetry for the endpoint, as for a silent one. **Endpoint topology** draws the endpoints the tab selects (see *Generated topologies*).



The endpoint drilldown shows its status and last heartbeat, events per second, refused requests and its queues, then:

- **Latest window**: events, bytes received, requests, refused requests (with the server busy share), the error rate (excluding the empty probe requests of a load balancer), the events **accepted, then refused** (a request stops at its first error: the events before it are indexed, and the sender's retry duplicates them), oversized events dropped, active tokens, CPU, memory, first seen and last heartbeat;
- **Refused requests** by HEC reply code;
- **Ingestion pipeline**: each queue of the HEC path with its stage, its fill (90th percentile and maximum), its blocked samples, the bottleneck and how busy its thread was;
- **Output to receivers**: each destination with its longest pause, connection failures and timeouts, and, when their own logs are searchable from the source, the **Receivers** and whether they stopped listening;
- **History** (events per second, refused requests, fullest queue, CPU) and, when bound, the **Configuration (splunkd API)**.

Why it was flagged. A refused-requests or back-pressure figure in the tables, the tiles of the drilldown or a pool row opens a screen that shows *why*, from Splunk's own logs, over the last hour, 4 hours or 24 hours: the summary (the refused total with its top reply codes and clients, or the saturated queues and the stage after the furthest-downstream one, with the output pauses that caused it), the timeline, the breakdown and the raw lines (at most 50, token-shaped values masked), each with **Open in Search**.

Pools

A **pool** groups the endpoints behind one load balancer or with one role. TrackMe compares its members — the members up, the share of the traffic each one receives, their versions and settings — and judges its capacity and its traffic as a whole. A tenant has up to 200 pools, and always a **default** pool.

Membership. An endpoint belongs to the pool it is **assigned** to by hand, else the first pool whose **host patterns** match it (case-insensitive `*` and `?` wildcards, for example `hf-*.example.com`), else the default pool's own patterns, else the default pool when **auto-join** is on. Otherwise it is listed as **discovered**: shown, evaluated by the endpoint policies, but by no pool policy. An endpoint excluded or outside the tenant's host patterns is in no pool, whatever its assignment.

- **Assignments** (up to 500) pin one endpoint, by its exact host name, to a pool; **By pattern** removes the assignment. An assigned endpoint the discovery did not report stays listed as *Not seen in 24 hours*.
- **Proposed pools**: the discovery proposes one pool per host-name family (the host names with their trailing digits or cloud instance id removed; a family of one host joins the default pool) and one **Splunk Cloud indexers** pool per Splunk Cloud stack.
- **Expected size** (optional, 1 to 10,000): how many endpoints the pool should have. Without it, Pool capacity learns the size from the pool's own history.
- **Replaceable**: the pool's members are replaced by others with new host names (Splunk Cloud indexers, auto scaling groups, containers). A silent member is then judged through its pool: while the pool is back at its

expected size, it was **replaced** and opens nothing; when no replacement arrives within the **replacement grace** of Endpoint availability (30 minutes by default), it is down as in any pool. A replaced member's open findings close as *endpoint replaced* (never as recovered), it leaves the directory at its next rebuild, and the pool drilldown lists the last replaced members. The discovery turns it on for the Splunk Cloud pools it proposes, and the creation wizard adds those pools on its own (see *Creating the tenant*). A replaceable pool takes no hand assignment.

Pools are configuration: a pool change applies at the next HEC activity run. Moving an endpoint moves its findings: those under the old pool close and open under the new one if the condition holds; its history is kept by host.

The pool drilldown (from a pool's name or **Balance** in the Overview, the Endpoints tab or a pool finding) shows the latest window, then the **Traffic distribution** over a range: **Balance** (100 for an even split over the members up, 0 when one member takes everything), the members carrying traffic, the smallest share against the fair share, the members up that received nothing, the share of each member over time, the balance over time and the members table, then the pool history and its replaced members.

Tokens

The **Tokens** tab lists every token name seen in the last 24 hours: the pools and endpoints that received it, its last activity, its events, bytes and refused requests. A token name in this tab, the Overview's busiest tokens, an endpoint or a token finding opens the **token drilldown**: its state in the latest window (active or idle), events per second, refused requests and error rate, its last 24 hours, an alert naming the index when Splunk refused its events for an **incorrect index**, its **Traffic over time**, the **Endpoints involved** (each endpoint that received or refused it, its share of the token's events against an even split), and the **Errors** (classes, HTTP statuses, reply codes in plain words, indexes refused, client addresses). **Token topology** draws the tokens the tab lists under the pools that received them (see *Generated topologies*).

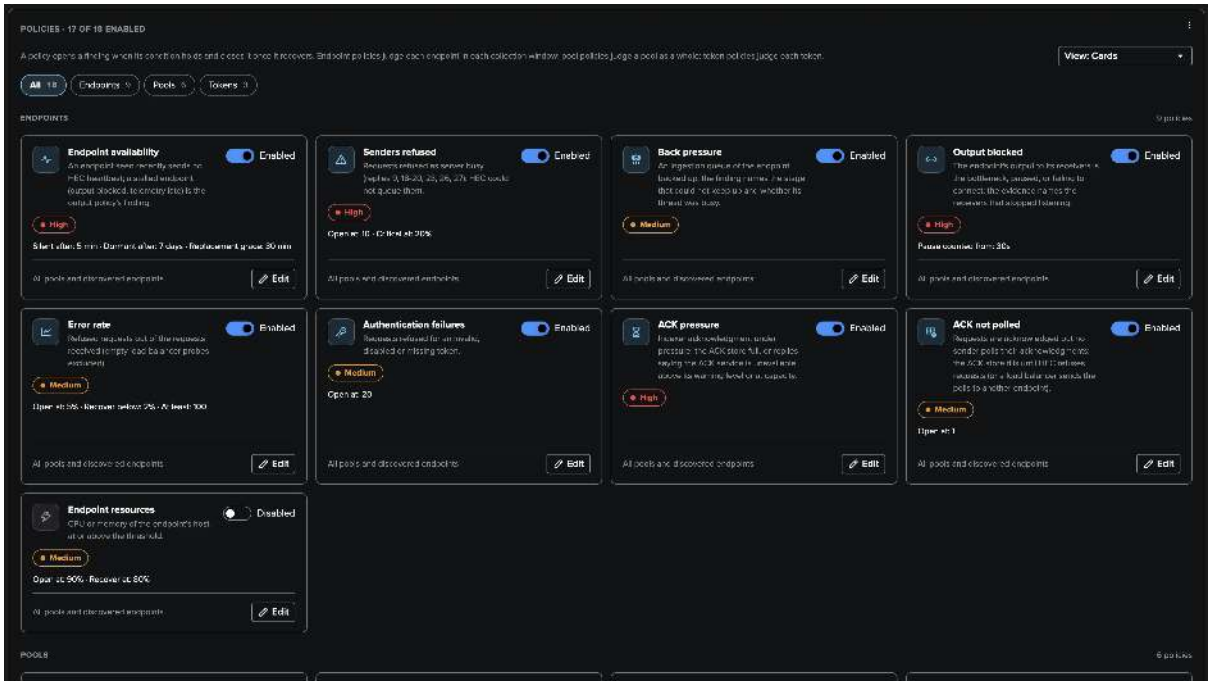
The traffic history of a token is written for the 50 busiest tokens of each window, with 10 places kept for tokens with refused requests: a window where a token was outside them is a gap in its chart, not a zero.

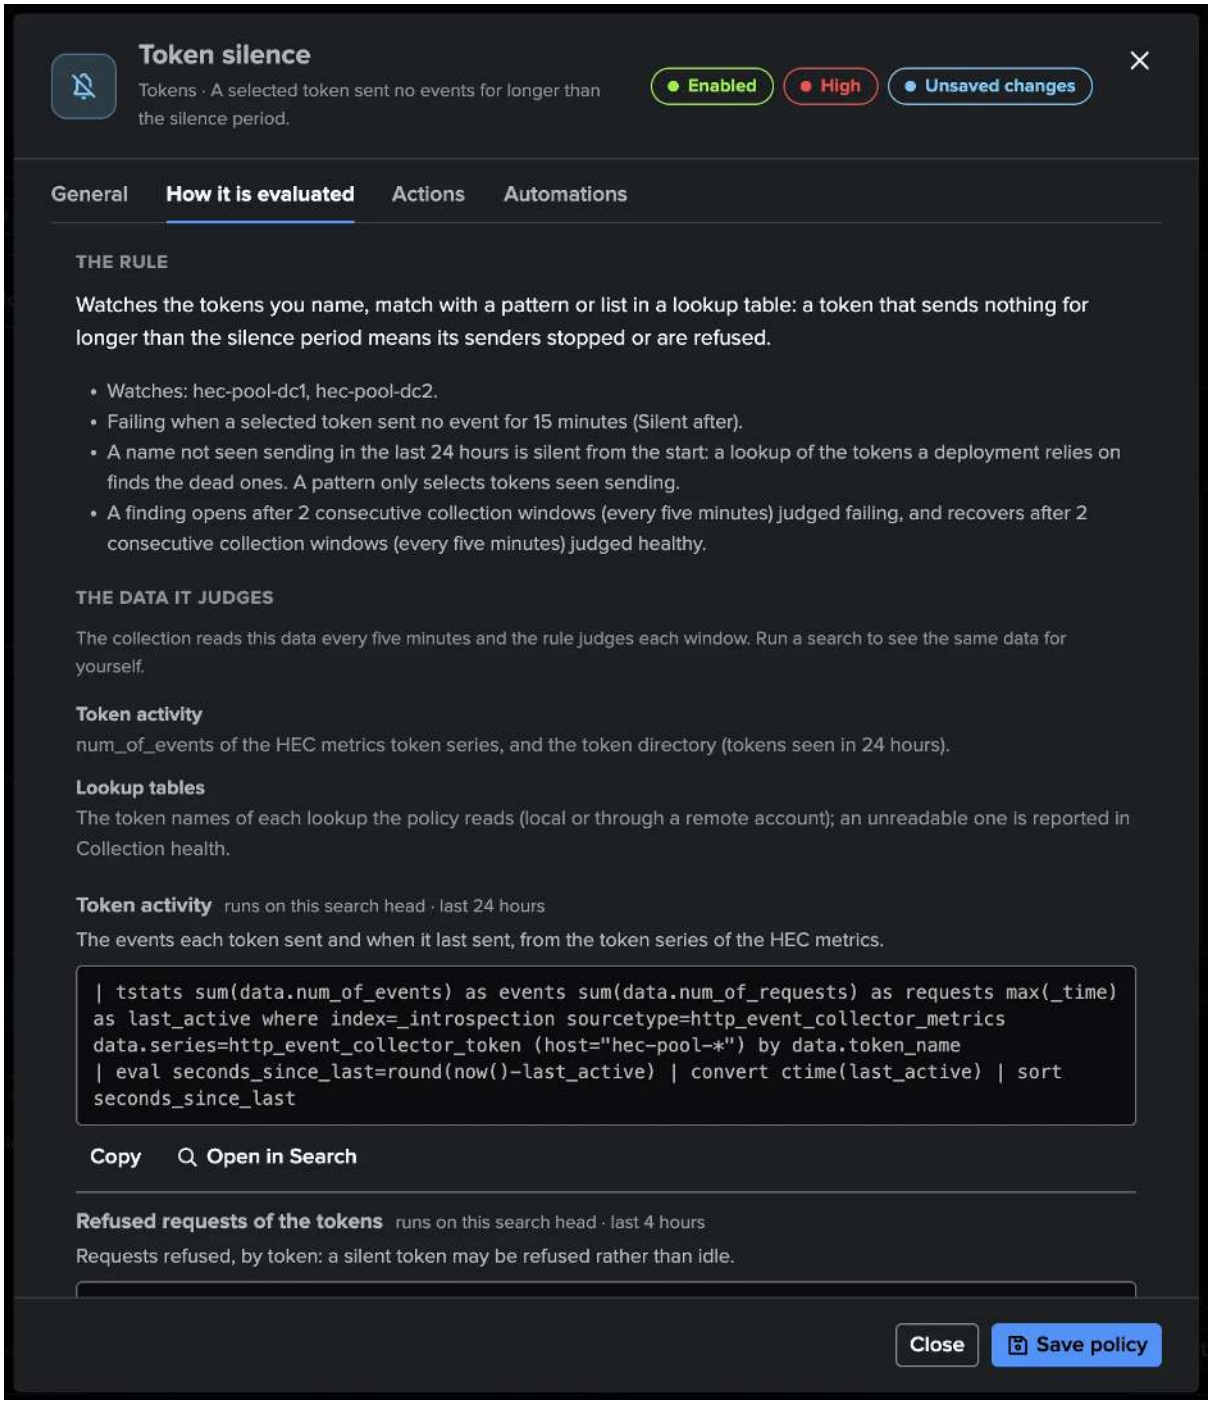
Policies

The catalogue of the **eighteen** built-in policies, in three categories: **Endpoints**, **Pools** and **Tokens**. Seventeen are on out of the box; **Endpoint resources** is off (it watches the host, not HEC). **Token silence** is on but decides nothing until you select tokens, and **Token consistency** needs the splunkd API.



Show them as cards, compact cards or a list. A TrackMe administrator of the tenant turns a policy on or off and opens its editor:

- **General**: on / off, severity, the **checks to open** (consecutive failing 5-minute windows) and **to recover**, the policy's own conditions with their help, **During bank holidays** (see *Bank holidays*) and the **Pools** it applies to (empty: every pool; the endpoint policies also cover the discovered endpoints). A token policy has no pool scope: a token goes to every pool that accepts it.
- **How it is evaluated**: what the policy does and how it decides **with its current settings**, the data it reads, **ready-to-run searches** built from the tenant's own source (its indexes, host patterns and remote account), each with **Open in Search** and **Copy**, how to investigate, the causes and resolutions, the related policies and notes. The same help opens from a finding's investigation, with the searches narrowed to its endpoint or token.
- **Actions** and **Automations**: the findings actions offered on this policy's findings and the rules that call them.



Every policy, its settings and defaults are in *Built-in policies*.

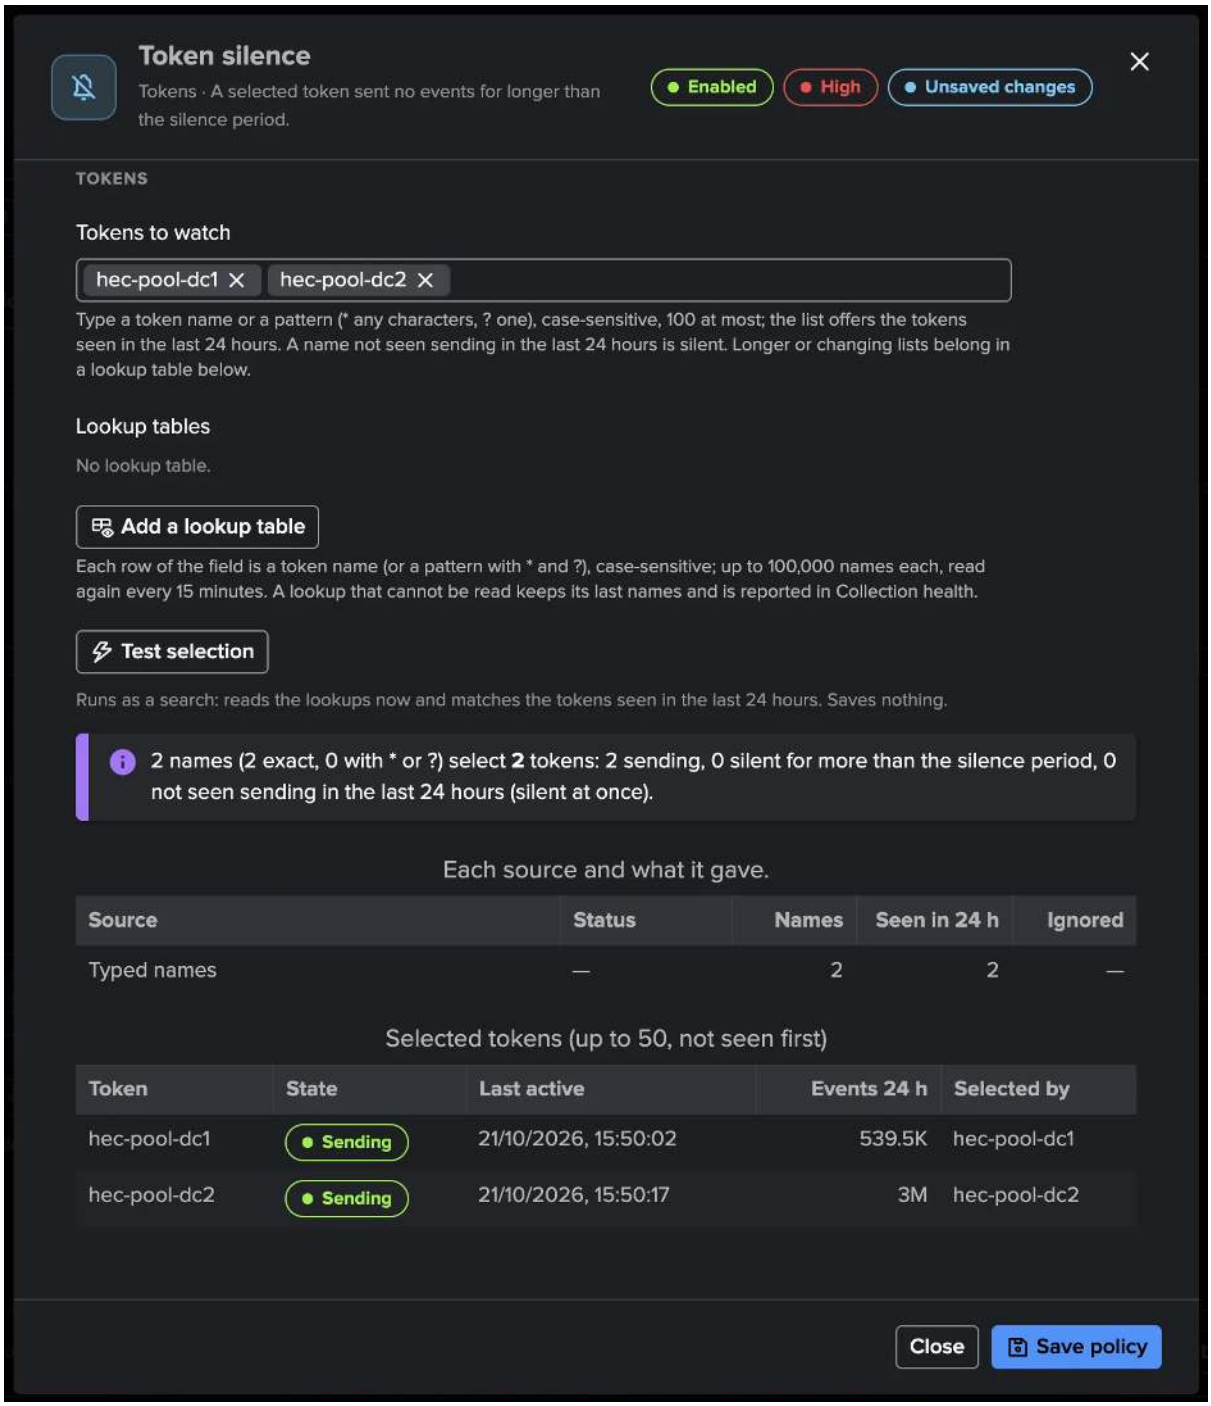
Tokens that must keep sending

Token silence opens a finding when a token you select sends no event for longer than the silence period (15 minutes by default). Its editor, **Tokens to watch**, selects them from two sources that add up:

- **Token names** typed in the policy (the list offers the tokens seen in the last 24 hours), up to 100 names or patterns, case-sensitive, with `*` (any characters) and `?` (one character), for example `app.prod` or `payments-*`;
- **Lookup tables** from Splunk, for long or changing lists such as the tokens a deployment relies on: up to 20 lookups, on the local search tier or on a remote deployment through a TrackMe remote account, each with the field holding the token names and a **match mode**, **Exact** (the default) or **Wildcard**. A lookup holds up to 100,000 distinct names and is read again every 15 minutes; one that cannot be read keeps its last good names, and Collection health says so (`token_lookups_failing`).

A name selected exactly that was **not seen sending in the last 24 hours is silent at once**: this is how a lookup of the tokens you rely on finds the dead ones. A pattern selects only the tokens seen sending.

Test selection checks the selection before you save: it runs as a search, reads every lookup now and matches the latest token directory and window. It shows the tokens selected by state (sending, silent, not seen in 24 hours), up to 50 examples with the entry that selected each, what each source gave, and the patterns that select nothing. It saves nothing.



Custom policies

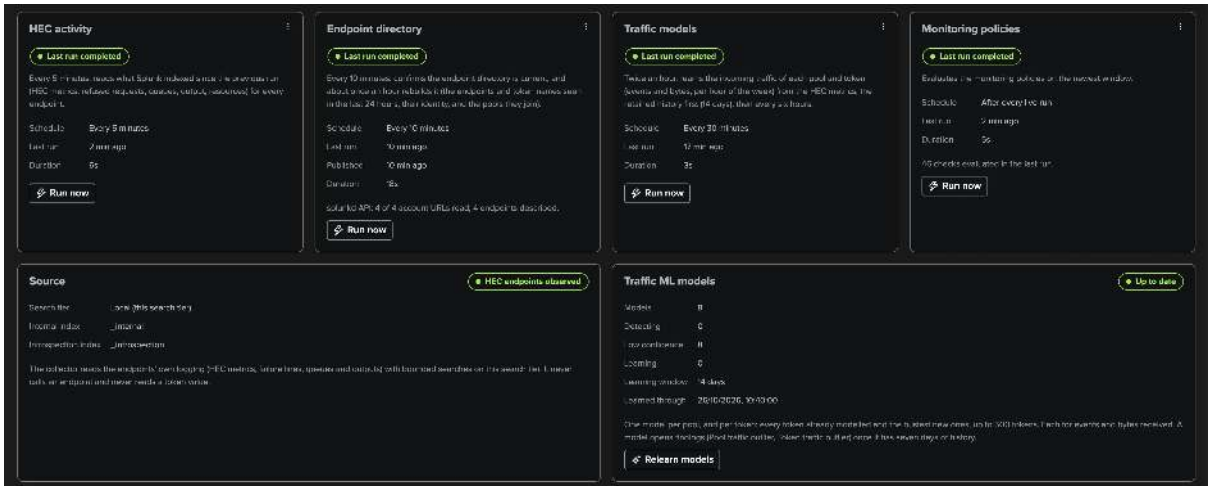
When no built-in policy covers a rule of your own, write it as an SPL search on the tenant's Splunk data: **Policies → Custom policies → Create policy**. On a Splunk HEC tenant each result row names an **endpoint** (a host name within the tenant's host patterns), a **pool** (a pool id of the tenant) or a **token** (a token name). A custom finding joins the Finding group of its object and is triaged, notified, offered findings actions and reviewed by the AI Agent like a

built-in one. A host outside the tenant's host patterns, or a pool it does not define, is not monitored: the row is skipped and its earlier findings recover.

The editor, the preview, the version history and the lifecycle are the same as on a Cribl Stream tenant (see *Custom policies*). Only the tenant's TrackMe administrators see and edit custom policies, because they hold SPL; their execution health is in *Collection health → Custom policies*.

Collection health

One card per job — **HEC activity**, **Endpoint directory**, **Traffic models** and **Monitoring policies** — with its schedule, its last run and its outcome, the next run and **Run now**. A run that Splunk completed short, or whose searches carried Splunk messages, says so: those messages are recorded, never a failure. The **Endpoint directory** card also says what the splunkd API enrichment read. The **Source** panel shows the search tier and indexes the tenant reads and whether HEC endpoints were observed; the **Traffic ML models** panel shows the models, their confidence and the learning history.



When collection does not run as configured, the tab lists the problems in plain words, and the Configuration Guardian raises **Splunk HEC collection needs attention** (`cribl_collection_health`). Every condition is in *Splunk HEC reference*.

Settings

One Save covers every section:

- **Source & pools**: the source, the two indexes (locked once configured), the host patterns and excluded hosts, the pools with their patterns, assignments, expected size and replaceable members, auto-join, and the **splunkd API** accounts. **Changing the host patterns or excluded hosts starts a new source revision**. **Repair workspace** checks the tenant's collections and reports and keeps findings and settings.
- **Collection**: **Scheduled collection** on or off, and the **Model learning history**.
- **Traffic ML models**: the defaults every traffic model of the tenant follows (see *Traffic models*).
- **Notifications**: finding emails (events, minimum severity, policies, delivery account, recipients, digest or one email per Finding group, charts, test email).
- **AI Agent**: the Splunk HEC AI Agent (see *The Splunk HEC AI Agent*).
- **Assignment**: assignment groups, their team email, ordered routing rules and manual overrides.
- **Finding actions**: drilldown searches, links and webhooks offered on findings, and the **Automations** that call an action automatically.

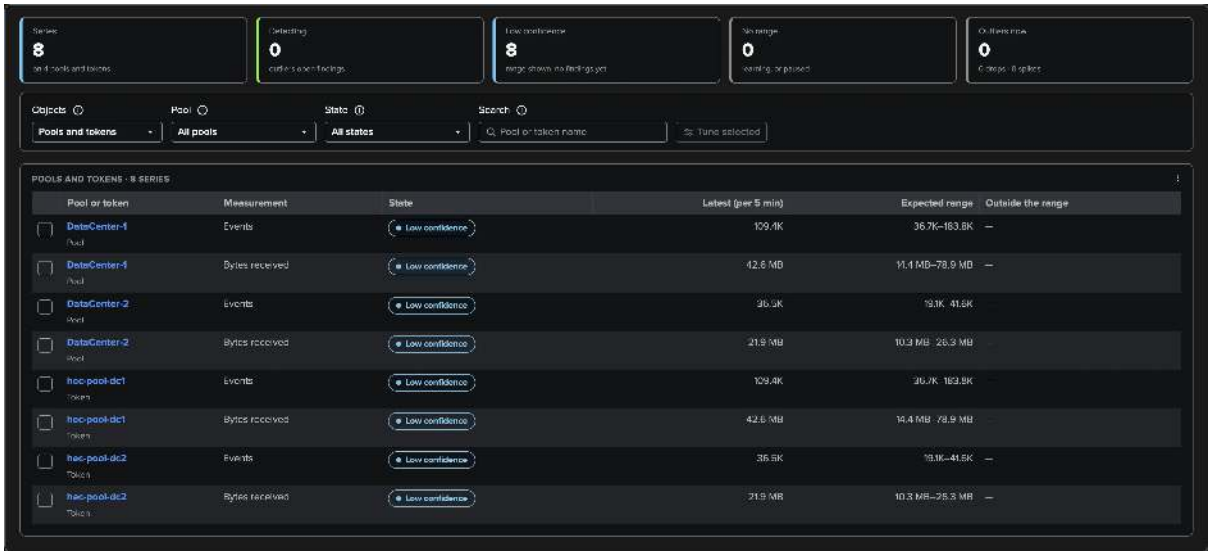
A TrackMe administrator of the tenant manages these settings; other roles read them.

Traffic models

The Splunk HEC tenant learns what each **pool** and each **token** usually receives — its **events** and its **bytes received** — per hour of the week, with the model arithmetic of the Cribl Stream tenant's traffic models (*Traffic ML models and Expected traffic*): recent weeks count more, the hour of the day first, then the weekday and hour once four weeks are learned, and an expected range of the usual value plus or minus three standard deviations, never tighter than 10 % of it. Endpoints get no model: load balancing moves traffic between the members of a pool, and Pool imbalance already watches their shares.

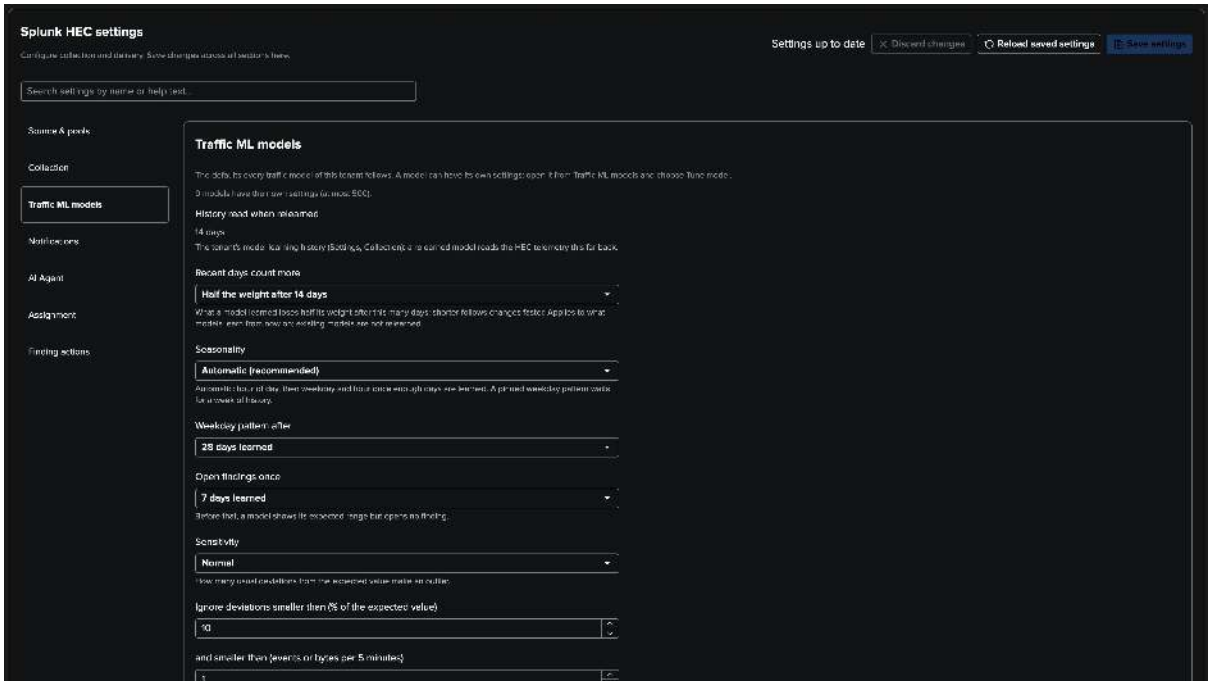
- **Learned from the HEC telemetry itself**, not from the history TrackMe writes: on its first runs, a new tenant learns the history the source keeps in `_introspection`, as far back as its **Model learning history** (14 days by default, chosen in the wizard; see *Creating the tenant*), so its models can reach normal confidence within the first runs. Then the models learn new traffic every six hours.
- **One model per pool, and per token for the 500 busiest tokens**, admitted busiest first. A modelled token that sends nothing is learned at zero; a series without traffic for 14 days is retired.
- **Confidence**: *learning* (less than a day: no expected range), *low confidence* (1 to 7 days: the range is drawn, no finding), *detecting* (7 days and more, normal confidence).
- **Bank holidays**: the training leaves out the hours of the tenant's bank holidays when the *Exclude from ML training* effect applies to the tenant (on by default; see *Bank holidays*), as for Cribl Stream.

The Traffic models tab counts the series, how many detect, how many have a range but low confidence, how many have no range yet (learning or paused) and the outliers now (drops and spikes). Its table lists every model — pool or token, measurement, state, the latest value per five minutes, the expected range and how far outside it the value is — filtered by object, pool, state or name. A name opens the **model view**: its state, the days learned, its seasonality, the expected range now, and the measured traffic against the expected band.



The expected range on the charts. The pool and token histories, and the trend of a Pool or Token traffic outlier finding, draw the measured traffic (events, bytes received) against the range its model expects, with the spikes and drops marked, a **Traffic ML model** pill with the model's state and the number of buckets outside the range. The **Expected range** toggle shows or hides the band (remembered per browser, as on Cribl Stream), and the **Traffic ML model** button opens the model.

Tuning. A TrackMe administrator of the tenant sets the defaults every model follows in *Settings → Traffic ML models* (how much more recent days count, seasonality, when the weekday pattern starts, when findings open, sensitivity, the smallest deviation that counts), and gives one model, or several of one measurement (**Tune selected** in the Traffic models tab), **its own settings** with **Tune model**: the same settings plus the training days, the direction (drops, spikes or both), a pause and **excluded periods** the model must not learn from. The tuning screen simulates the current and the proposed range over the last 24 hours, 7 or 30 days, with the drops and spikes each would have raised, before anything is saved. A paused model keeps learning but gives no range; pausing the measurement a finding is judged on closes that finding.



Not an anomaly. When a Pool or Token traffic outlier finding was expected — a maintenance, a load test, a migration of senders — a power or admin role of the tenant marks it **Not an anomaly**, from the finding or from a chart interval of the model view: the period is excluded from what the model learns, the model relearns without it at the next training run, and the finding is dismissed with your reason as its note.

Relearn. *Collection → Relearn models* forgets every model and learns the history again on the next training run; **Open models in search** lists them. A model relearned on 14 days of history goes back to hour-of-day seasonality until it learns four weeks again.

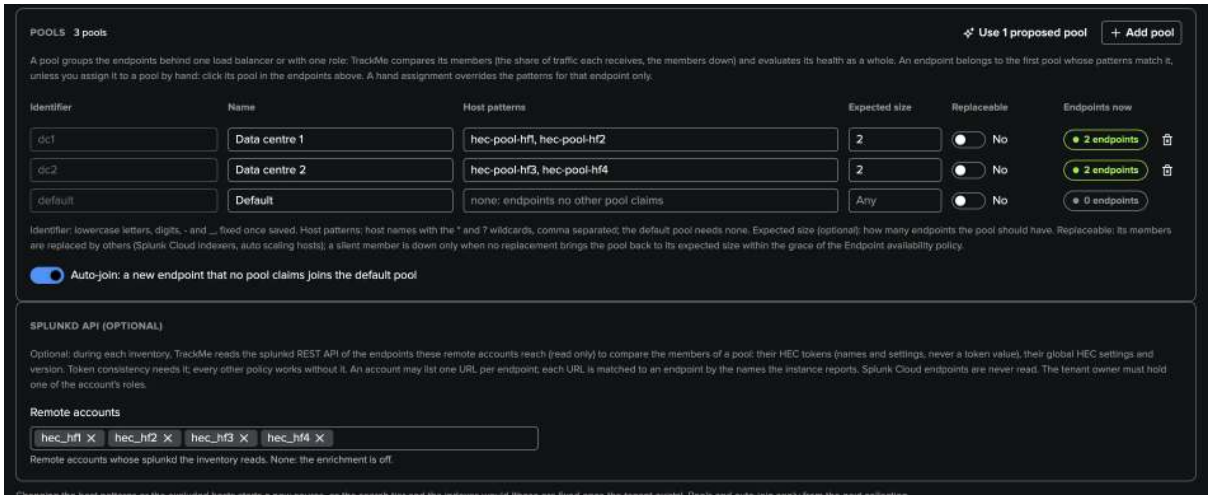
Two policies use the models: **Pool traffic outlier** and **Token traffic outlier** open a finding when the window's events (or bytes) fall below or rise above the model's range for that hour, once the model reaches normal confidence (or low confidence, if you choose), and only when the window or the model reaches the **At least** amount per five minutes (100 by default). A modelled token absent from the window is judged at zero: the drop that matters most.

Pool traffic drop is the simpler check that needs no model: the pool's rate against the median of the same hour of the day over the previous 7 days.

The splunkd API enrichment

The telemetry tells what HEC does, not how it is configured. Two policies compare the configuration of the members of a pool, and need the **splunkd REST API** of the endpoints: **Token consistency** (a token missing on some members, or with a different status, index, allowed indexes or ACK) and the HEC settings part of **Configuration drift** (the Splunk versions are compared without the API). The enrichment is **optional** and **read only**.

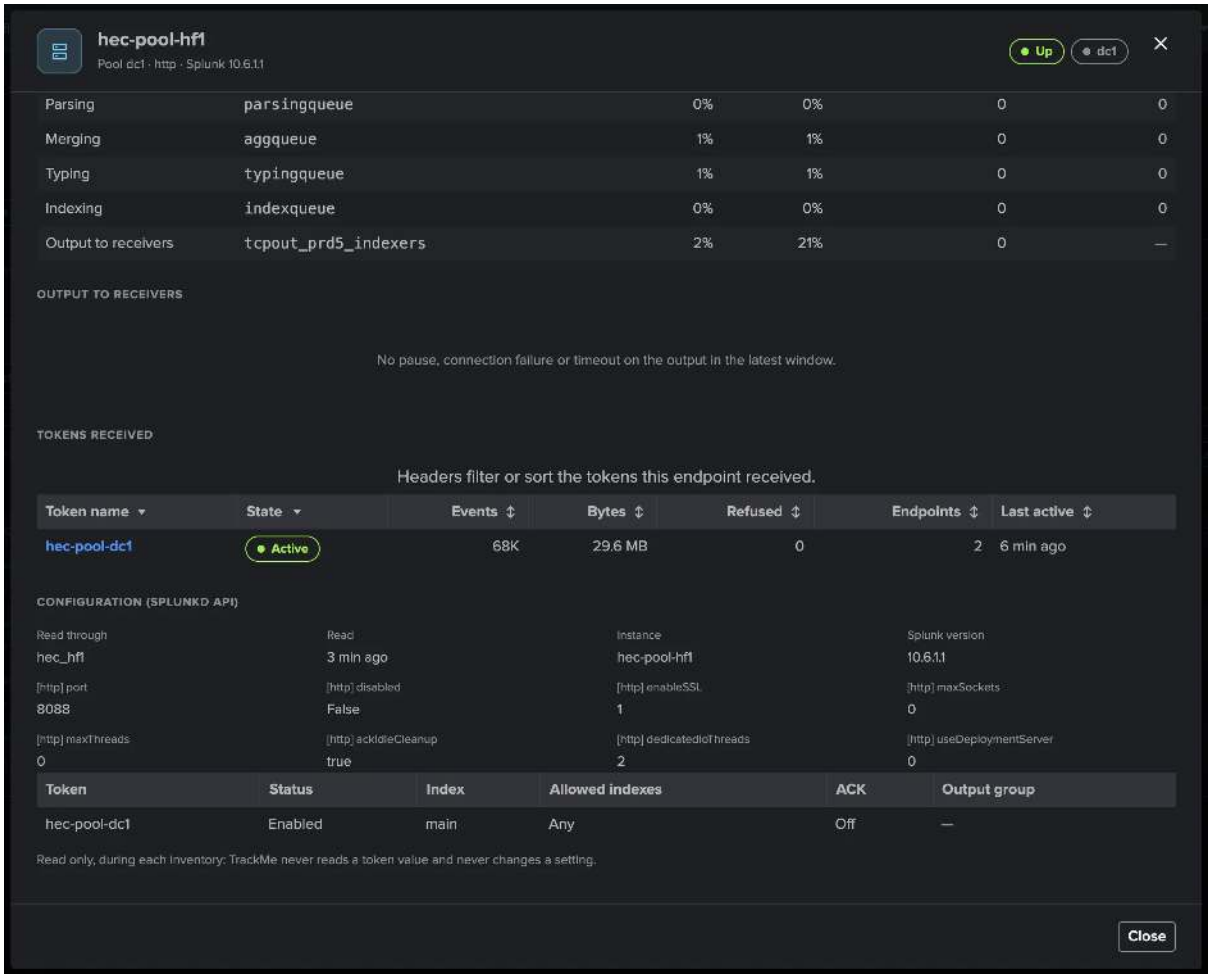
Setting it up. In *Settings → Source & pools → splunkd API (optional)*, choose up to 20 TrackMe remote accounts (*Remote Splunk deployments*) whose URLs reach the endpoints' management port. An account may list one URL per endpoint (up to 50 HTTPS URLs). The tenant owner must hold one of each account's roles.



What is read. At each rebuild of the endpoint directory, for every URL: `/services/server/info` (the instance's names and version), `/services/data/inputs/http/http` (the global `[http]` settings) and `/services/data/inputs/http` (the HEC tokens by name, up to 200 per endpoint: disabled, index, allowed indexes, ACK, output group). **The token value is dropped while the answer is parsed**: it is never stored, logged or returned. Each URL is matched to an endpoint of the directory by the names its instance reports; two URLs matching one endpoint bind neither.

Splunk Cloud is never read: an account URL on `*.splunkcloud.com` is skipped and a Splunk Cloud endpoint is never described or compared (Splunk Cloud indexers have no customer-reachable management port). The rest of the tenant works on Splunk Cloud from `_introspection` and `_internal`.

Failures never fail the directory. A URL that cannot be read is counted, and its endpoint keeps its earlier facts while they are fresh (3 hours). The **Endpoint directory** card in Collection health says what was read and why the rest was not, per account: for example *splunkd API: 3 of 4 account URLs read, 3 endpoints described, 1 could not be read (api_hf: connection failed)*. The reasons are *connection failed*, *timed out*, *access denied (check the account token)*, *HTTP error*, *answer too large*, *unexpected answer*, *out of time this run* and *read failed*; the card also counts URLs that matched no endpoint, Splunk Cloud URLs skipped, accounts the tenant owner may not use and accounts unavailable. The endpoint drilldown shows the facts in **Configuration (splunkd API)**.



Note

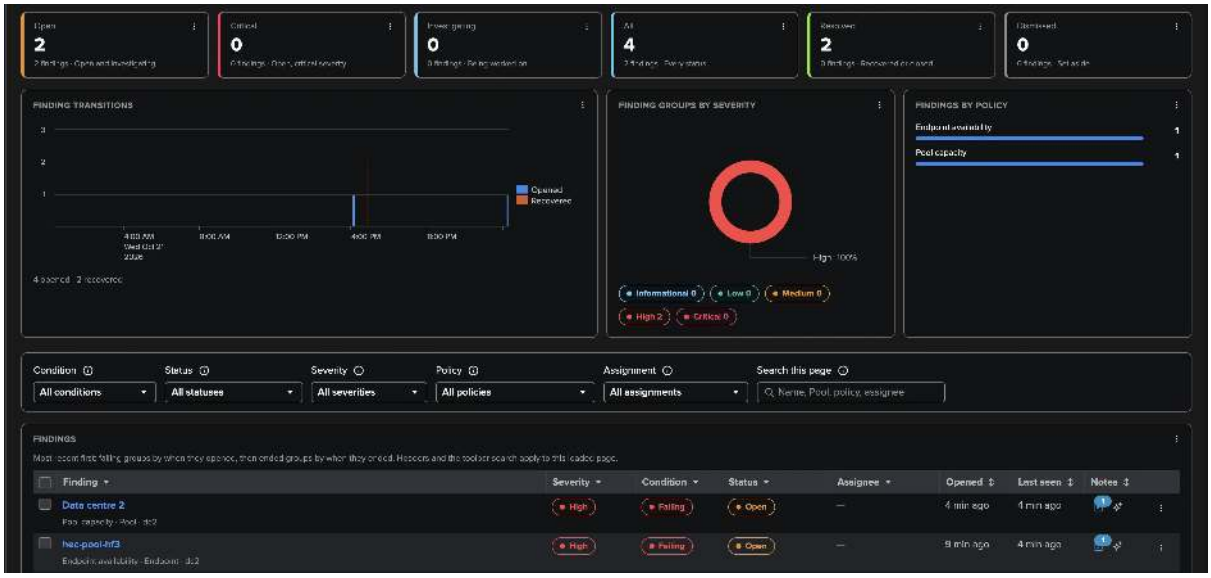
The reads follow the trust model of every TrackMe remote-account read: the remote account has no certificate verification setting. Bind accounts whose management port is reached over a trusted network.

Findings in practice

A Splunk HEC finding is about one object and one policy:

The finding is about	Raised by
An endpoint	Endpoint availability, Senders refused, Back pressure, Output blocked, Error rate, Authentication failures, ACK pressure, ACK not polled, Endpoint resources.
A pool	Pool capacity, Pool imbalance, Pool traffic drop, Pool traffic outlier, Token consistency, Configuration drift.
A token	Rejected data, Token silence, Token traffic outlier.

Findings work as on Cribl Stream and Cribl Edge. Each object gathers its findings in one automatic **Finding group**, the unit you triage and get notified about. A finding **recovers by itself** when the measured condition clears, and closes by itself when its object leaves the tenant's scope, when its endpoint was replaced, or when nothing evaluated it for 24 hours. Triage, notes, snooze, dismissal, the severity override and assignment are the same as for every findings tenant; a Pool or Token traffic outlier finding can also be marked **Not an anomaly** (see *Traffic models*). The investigation of a HEC finding gives the decision in plain words, the measurement and what it was compared with, the recorded facts, the trend of the KPIs its policy judges, and **How it is evaluated**; **Open resource** opens the endpoint, pool or token drilldown in place.



The shared concepts are described once:

- *Findings, Finding groups and findings actions* — findings, statuses, triage, severity, notifications;
- *Finding groups* — Finding groups, automatic and manual;
- *Findings actions* — drilldowns, links, webhooks and automation rules;
- *Webhook accounts* — the accounts a webhook action posts with;
- *Assignment and automatic routing* — assignment groups, routing rules and team emails.

Links into the workspace. An email, an action or a dashboard can open the workspace on an object: `TenantHome?tenant_id=<tenant>&tab=endpoints&host=<host>` opens an endpoint, `tab=overview&pool=<pool id>` a pool and `tab=tokens&token=<token name>` a token.

An endpoint that stops: what you see

Take a pool of four heavy forwarders, `hf-1.example.com` to `hf-4.example.com`, behind a load balancer, and stop splunkd on `hf-2`:

1. In the next window, `hf-2` is **late** (no heartbeat this window, one in the last 5 minutes): no finding yet, and Topology Studio draws it green with a *Late* cue.
2. Once it has sent no heartbeat for 5 minutes (**Silent after**, 300 seconds), it is **silent**: **Endpoint availability** opens a **High** finding on it at the first silent check. Had every member of the pool stopped, the finding would be **Critical**.
3. **Pool capacity** compares the members up (3) with the pool's expected size (4, set or learned) and opens a **High** finding on the pool after two checks (**Critical** below half the expected size).
4. The other members now take its share: Pool imbalance stays quiet, since no member up is starved.
5. When `hf-2` reports again, both findings recover after two healthy checks.

The screens below come from a deployment with two data centres, a pool of two heavy forwarders each, where `hec-pool-hf3` of *Data centre 2* was stopped: **Endpoint availability** opened on it at the first silent check, then **Pool capacity** on its pool, 1 of 2 members up, after two checks. On the generated HEC topology, both turn orange with their finding badge, and the endpoint availability falls to 75 % (the view at the top of this page).

Had the forwarder's **output** been blocked instead (indexers not accepting data), its own telemetry would wait behind the same output and arrive late: the endpoint is **stalled**, Endpoint availability holds, and **Output blocked** opens a finding naming the destinations, their pauses and, when their logs are searchable, the receivers that stopped listening.

Notifications

Finding notifications work as for the Cribl tenants (*Findings, Finding groups and findings actions*): turn them on in **Settings → Notifications**, pick the events, a minimum severity, the policies, a delivery account and recipients, and choose a **digest** or **one email per Finding group**, with charts. Emails are sent after the policy evaluation and link to the finding in the workspace. **Send test email** checks the delivery.

Every transition is also written as an indexed event (`trackme:cribl:finding` and `trackme:cribl:finding_group`, `object_category=splunk_hec`), whatever the notification settings, for your own Splunk alerts, Enterprise Security or SOAR: see *Splunk HEC reference*.

Bank holidays

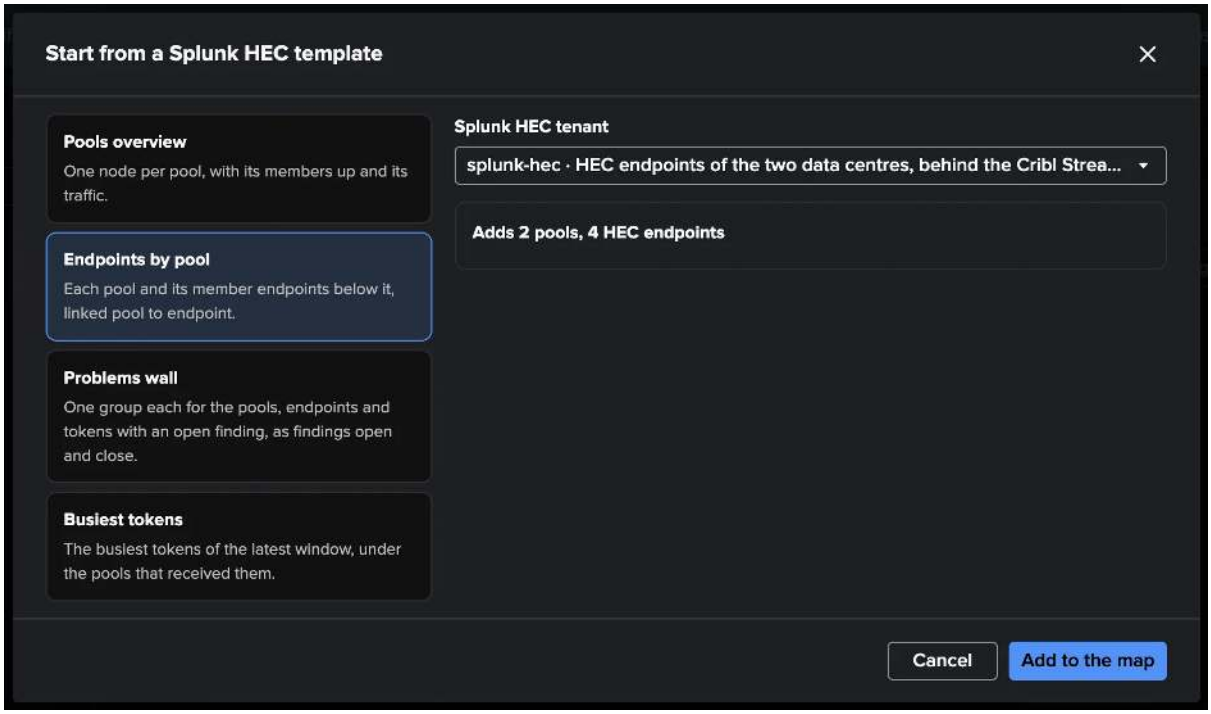
A Splunk HEC tenant uses the *bank holiday calendars* of its scope: the system default calendars, unless it selects its own or none. While a holiday of its calendars is active, the policies **set to hold** open no new finding. Each policy decides it in its editor (*During bank holidays*: **Hold new findings** or **Keep opening findings**). By default the policies that judge **traffic** hold **— Pool traffic drop**, **Pool traffic outlier**, **Token traffic outlier** and **Token silence —** since traffic is expected to change on a holiday; every other policy keeps opening findings, so an endpoint down on a holiday still opens its finding.

While a holiday holds a policy, a failure opens no new finding and sends no notification; a finding already open is still evaluated and can recover and close; a resolved or dismissed finding is not reopened by a held failure. When the calendars cannot be read, nothing is held.

Topology Studio

Splunk HEC objects are Topology Studio objects (*Topology Studio*): the **pools**, **endpoints** and **tokens** of a HEC tenant.

- **Add entities**: pick pools, endpoints (by pool, searchable, the discovered ones included) and tokens, each with its live status.
- **Groups** (*Add an aggregate node*, **Follow a selection**): a group of pools, endpoints or tokens, narrowed by pool (the *discovered* endpoints included), by a name that contains a text, and optionally to the objects with a finding. Start from **Endpoints of a pool**, **Every token** or **Anything failing**. A group follows its objects as they come and go (up to 2,000 objects per kind) and shows its health and healthy share; groups carry no summed KPI.
- **Templates**, offered when you can read a Splunk HEC tenant (on the empty canvas and in the *Add items* menu): **Pools overview** (one node per pool), **Endpoints by pool** (each pool over its endpoints, up to 10 pools of 12 endpoints), **Problems wall** (three groups: pools, endpoints and tokens with open findings) and **Busiest tokens** (the 12 busiest tokens under the pools that received them).
- **Status**: findings first (red or orange; blue when only snoozed). Otherwise, while the collected window and the policy evaluation are current: an endpoint up is green, a **late** endpoint green with a *Late* cue (Endpoint availability has not decided yet), a silent, dormant or stalled endpoint without a finding **quiet grey**; a pool at or above its expected size green, below it without a finding quiet; a token with events green, an idle one quiet. Quiet objects are disclosed and stay outside a group's healthy share.
- **KPIs**: for an endpoint, up, events, bytes, rates, requests, refused, error rate, fullest queue, ACK-enabled requests, CPU, memory; for a pool, members up, members, down, stalled, back pressure, traffic, refused, error rate, fullest queue; for a token, events, bytes, requests, refused, error rate. Endpoints, pools and tokens have 24-hour sparklines.
- **The integrity linter** reports a pool removed from the tenant's configuration or an endpoint no longer in the directory; a token is never reported removed.
- **Topology Alerts** (*Topology Alerts*) work on HEC objects and groups.
- **Build with AI** (*Build with AI — a topology from a description*) lists HEC tenants ("· Splunk HEC") with three starting points: **HEC endpoints by pool**, **HEC problems wall** and **Busiest HEC tokens**. The builder knows the pools, endpoints, busiest tokens and open findings by name, never a token value.
- Opening an object from a view opens the HEC workspace on it.

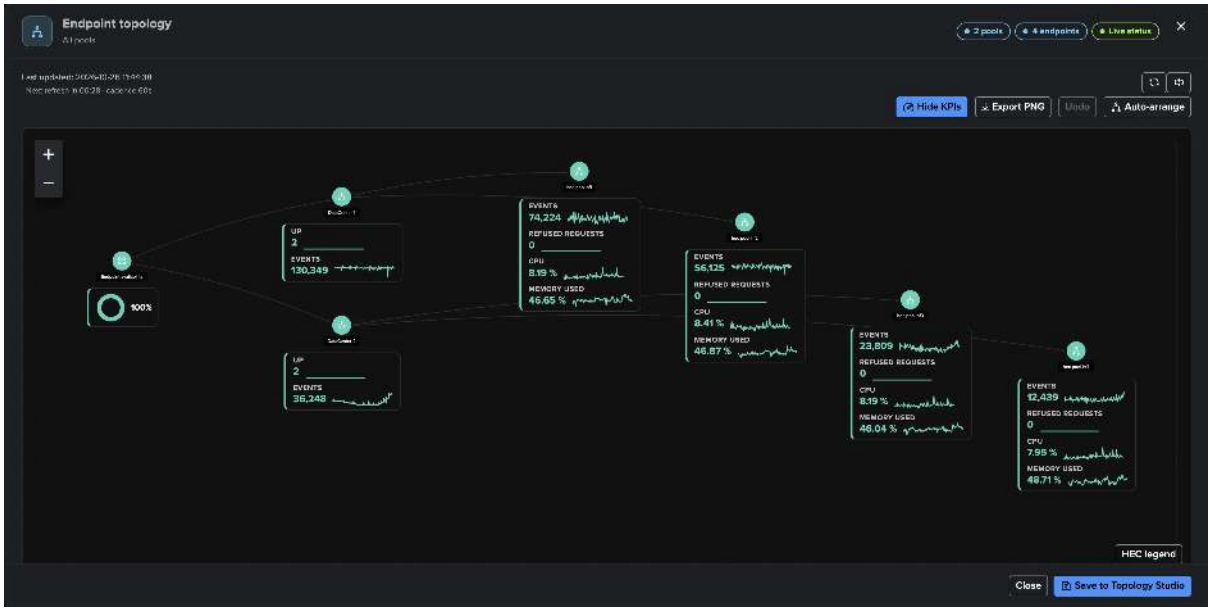


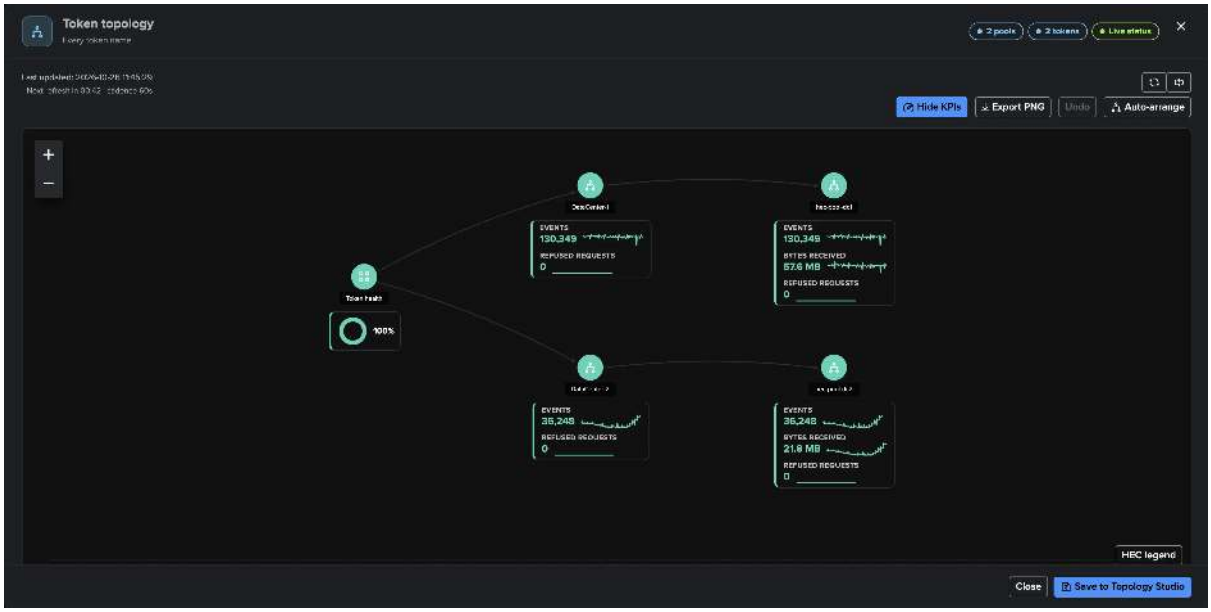
Generated topologies

Each workspace tab draws its own map on the Topology Studio canvas, the way the Cribl Stream Worker and Flow topologies do. **HEC topology** is on the Overview's Pools panel, **Endpoint topology** in the Endpoints toolbar and **Token topology** in the Tokens toolbar.

- **HEC topology**: the endpoint availability (a donut over every endpoint), each pool with its members up, events, bytes received and refused requests, and each endpoint below its pool with its events and refused requests.
- **Endpoint topology**: the endpoints the tab selects (its pool, status, search and order) under their pool, each with its events, refused requests, **CPU** and **memory**. Endpoints no pool claims sit under a *Discovered endpoints* group.
- **Token topology**: the tokens the tab lists under the pools that received them (a token sent to several pools is linked from each, one no pool received sits under a *No pool* group), with their events, bytes received and refused requests.

Every node shows its live status and its 24-hour sparklines, refreshed every minute; the canvas keeps the positions you give it, and **Auto-arrange**, **Hide KPIs** and **Export PNG** work as in Topology Studio. A topology draws up to 50 endpoints or tokens: when the tab selects more, it draws the first 50 and says how to narrow the selection. **Save to Topology Studio** saves it as a view, proposing its name and description, with the roles that can view and edit it. From then on it is a view like any other: edit it, share it, add Topology Alerts.





The Splunk HEC AI Agent

The **Splunk HEC AI Agent** reviews HEC findings the way an operator would, from facts TrackMe already holds. It is its own agent, built on the same framework as the other findings AI Agents (*AI Agents for findings*). It assesses each finding — **true positive**, **likely false positive**, **expected behaviour**, **endpoint or pool not in use** or **needs investigation** — recommends a decision, and keeps one current **[AI Agent]** note on the finding.

- **Inspect** only recommends: nothing changes but the note.
- **Act** applies the recommendation, but only what the tenant allows.

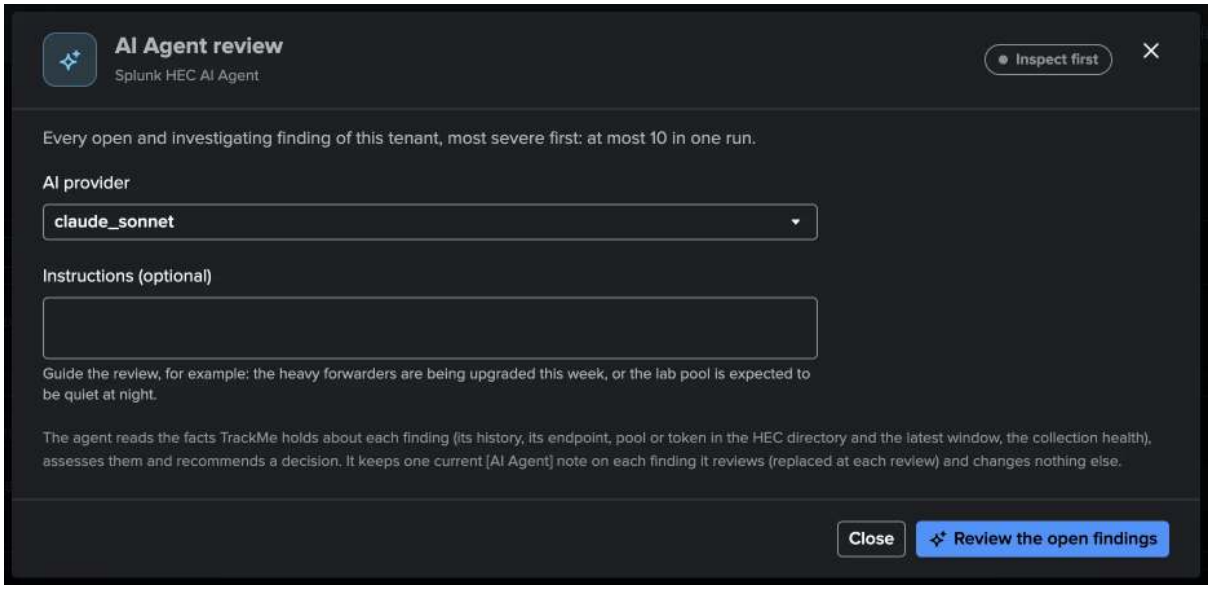
What it reads. The finding (its policy, settings, evidence, history, episodes and Finding group), and its object in the published directory and latest window: an **endpoint**'s status, last heartbeat, refusals, queues and bottleneck, output, version, resources and splunkd API status; a **pool**'s definition (expected size, replaceable) and its members; a **token**'s latest window, last 24 hours and endpoints, by name only. It also reads whether the endpoint or pool is still there (only a current directory can prove an endpoint gone, once the finding has not been evaluated for an hour; a token is never gone), the tenant's Collection health and its own past decisions. It runs no search.

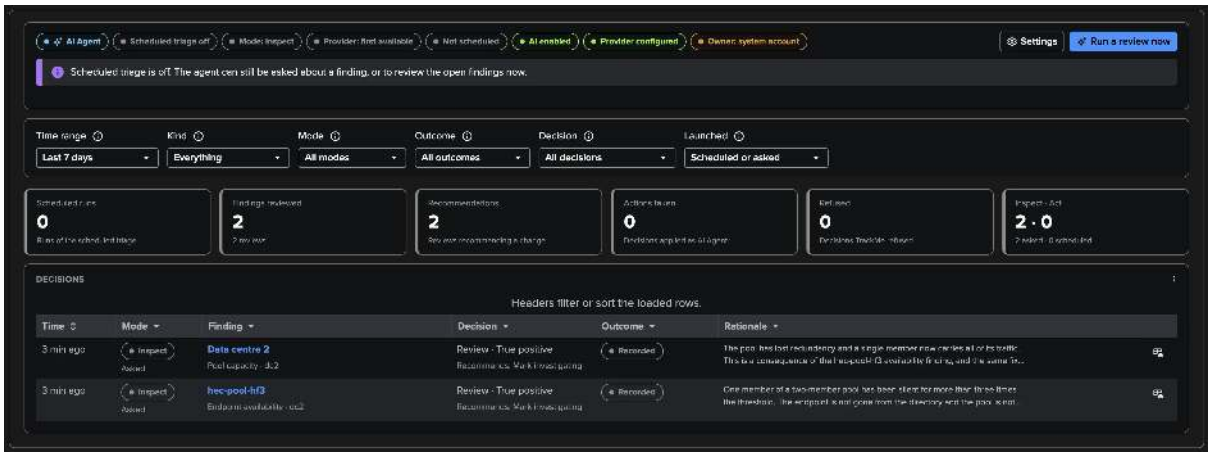
What it may decide (act mode, each decision with its own setting, checked again by TrackMe before it is applied):

Decision	Default	Condition checked by TrackMe
Mark investigating	Allowed	The finding is open.
Dismiss for a time	Allowed, 7 days at most (up to 90)	A **critical** or **high** finding that is still failing only when its endpoint is no longer in the directory (retired, dormant or replaced) or its pool is no longer defined.
Resolve	Not allowed	Only after a measured recovery.

The agent never dismisses permanently, assigns, or changes a severity, a policy, the pools or the source. A scheduled run never overrides an operator decision, and the agent makes at most one decision per Finding group in a run.

Asking and scheduling. Ask the AI Agent… is in the finding and Finding group menus and the investigation view, and **Run a review now** on the **AI Agent** tab reviews the open findings: the agent inspects first, then **Run its recommendations…** lets it act on that inspection. Scheduled triage is **off by default**: turned on in *Settings → AI Agent*, it reviews up to 10 findings an hour (one per Finding group, the most severe first, by default only critical and high), skips a finding reviewed in the last day unless it moved, and needs the AI Assistant enabled, an AI provider, the tenant enabled and a tenant owner that is a Splunk administrator account (not `nobody`). **Custom instructions** and **Evaluate…** work as for the other findings agents (*AI Agents for findings*). The settings and their defaults are in *Splunk HEC reference*; the **Manage AI Agents automation** page (*AI Agents automation*) lists the tenant with its agent.





AI Assistant

On a Splunk HEC tenant's Tenant Home, the AI Assistant (*AI Assistant & Concierge*) knows what the tenant is, its configuration, its policies and their settings, the pools, the endpoints needing attention, the busiest tokens and the open findings: ask it why an endpoint refuses requests, what a policy checks, or what to do about a finding. When a finding or the open findings would benefit from a review, it proposes a **Splunk HEC AI Agent** review as a consent card: nothing runs until you confirm. It proposes no Concierge action.

Troubleshooting

Symptom	What to check
The wizard lists no HEC endpoint	No endpoint reported HEC metrics on this source in the last 24 hours. Check that HEC is enabled, that the endpoints forward `_internal` and `_introspection` to indexers the source searches, the index names, and the host patterns.
The source is refused: `remote_account_refused`	The tenant owner holds none of the remote account's roles: its scheduled searches would be refused. Add one of the owner's roles to the account, or choose another owner.
The workspace shows no endpoint	The first collection has not published yet: **Collect now**, then **Collection health**.
Collection health: `no_hec_endpoints`	No endpoint for an hour after configuration: HEC disabled, internal indexes not searchable from the source, or host patterns matching nothing.
An endpoint is **late** or **stalled** but no finding opened	Expected: a late endpoint has reported in the last 5 minutes; a stalled one's telemetry waits behind its blocked output, and **Output blocked** says why.
Error rate is high but nothing is busy	Open the refused requests (*Why it was flagged*): the reply classes say whether senders use refused tokens (Authentication failures) or send data Splunk rejects (Rejected data). Empty load balancer probes (reply 5) are never counted.
Rejected data: incorrect index (reply 7)	The sender writes to an index the token may not use or that does not exist: create the index, add it to the token's allowed indexes, or fix the sender. The token drilldown names the index refused.
ACK not polled	A sender uses indexer acknowledgment but never polls `/services/collector/ack`, or a load balancer sends the polls to another endpoint: make it poll, disable `useACK` on its token, or make the load balancer sticky per channel.
Token consistency or the HEC settings of Configuration drift decide nothing	They need splunkd API accounts bound in *Settings → Source & pools*, with fresh facts from two members up of the pool. Splunk Cloud members are never compared. The **Endpoint directory** card says what the API read and why the rest was not.
Token silence decides nothing	No token is selected: type token names or add a lookup table, then use **Test selection**.
Collection health: `token_lookups_failing`	A Token silence lookup table could not be read, is too large or is empty. Check that the lookup exists, is shared with the TrackMe app, that the owner can read it and, on a remote deployment, that its remote account connects.
Pool or Token traffic outlier opens nothing	The models need 7 days of history (normal confidence) by default, and the traffic must reach the **At least** amount per five minutes.
Splunk Cloud indexers keep opening Endpoint availability findings	Mark their pool **replaceable** (the discovery proposes it for Splunk Cloud pools): a replaced indexer then opens nothing while the pool is at its expected size.
"Last 5 minutes" falls back to **Collected window**	The read of the last five minutes failed (the badge gives the reason). The collected data always shows; the next refresh tries again.
A run failed and the reason is unclear	The collector log, `index=_internal sourcetype=trackme:custom_commands:trackmecriblcollect` (file `trackme_cribl_collect.log`): one summary line per run, with the Splunk messages of a failed search.

What the Splunk HEC tenant does not do

- **No writes to Splunk**: TrackMe never changes a HEC setting or a token, and never restarts anything.
- **No token values and no event content**: tokens are known by name; the raw lines shown as evidence have token-shaped values masked.
- **No per-request tracing**: Splunk logs refused requests, not successful ones.
- **No health probe of the endpoints**: TrackMe never calls an endpoint's HEC port; the splunkd API enrichment is optional and never reads Splunk Cloud.
- **No Stop monitoring this object** on findings: narrow the host patterns or exclude the host instead.
- **No Concierge actions**: the AI Assistant answers questions and can propose a Splunk HEC AI Agent review.

Next: the reference

Every policy with its settings and defaults, the jobs and their schedules, the limits, the settings, the AI Agent, the indexed finding events, the permissions, the Configuration Guardian conditions and the run reasons: *Splunk HEC reference*.

8.3.20 Splunk HEC reference

The reference of the Splunk HEC tenant: the built-in policies and their defaults, the HEC reply codes, the collection jobs, the limits, the history TrackMe keeps, the settings, the AI Agent, the indexed finding events, the permissions, the Configuration Guardian conditions, the run reasons and the REST endpoints. The user guide is *Splunk HEC*; the findings model shared with User Activity Monitoring, Cribl Stream and Cribl Edge is *Findings, Finding groups and findings actions*.

Built-in policies

A Splunk HEC tenant has **eighteen** built-in policies. **Seventeen are on** out of the box; **Endpoint resources** is off (it watches the host, not HEC). **Token silence** is on but decides nothing until tokens are selected, and **Token consistency** decides only with the optional splunkd API. Your own SPL policies on endpoints, pools and tokens are described in *Custom policies*.

Endpoints

Policy	What it detects	Default	Severity
Endpoint availability	An endpoint seen recently sends no HEC heartbeat.	On	High → Critical
Senders refused	Requests refused as server busy (replies 9, 18–20, 23, 26, 27): HEC could not queue them.	On	High → Critical
Back pressure	An ingestion queue of the endpoint backed up; the finding names the stage that could not keep up and whether its thread was busy.	On	Medium → High
Output blocked	The endpoint's output to its receivers is the bottleneck, paused, or failing to connect.	On	High
Error rate	Refused requests out of the requests received (empty load-balancer probes excluded).	On	Medium
Authentication failures	Requests refused for an invalid, disabled or missing token.	On	Medium
ACK pressure	Indexer acknowledgment under pressure: the ACK store full, or replies saying the ACK service is unavailable, above its warning level or at capacity.	On	High
ACK not polled	Requests are acknowledged but no sender polls their acknowledgments.	On	Medium
Endpoint resources	CPU or memory of the endpoint's host at or above the threshold.	Off	Medium

Pools

Policy	What it detects	Default	Severity
Pool capacity	Fewer pool members up than expected.	On	High → Critical
Pool imbalance	A pool member up but receiving a very small share of the pool's events.	On	Low
Pool traffic drop	The pool receives far fewer events than it usually does at this hour of the day.	On	High → Critical
Pool traffic outlier	The pool's events (or bytes) outside what its traffic model expects at this hour of the week.	On	Medium
Token consistency	A token configured on some pool members only, or with a different status, index, allowed indexes or ACK from one member to another (splunkd API).	On	High
Configuration drift	Pool members running different Splunk versions or, with the splunkd API, different HEC settings, for longer than the grace period.	On	Medium

Tokens

Policy	What it detects	Default	Severity
Rejected data	Requests of a token refused for their content, or events dropped as oversized.	On	Medium → High
Token silence	A selected token sent no events for longer than the silence period.	On	High
Token traffic outlier	A token's events (or bytes) outside what its traffic model expects at this hour of the week.	On	Medium

Default settings

What each policy applies to, its checks to open and to recover (one check per collected 5-minute window), and its own settings with their defaults and ranges.

Policy (id)	One finding per	Open / recover	Settings and notes (defaults)
Endpoint availability (hec_endpoint_av	Endpoint	1 / 2	**Silent after** 300 s (300–86,400): no heartbeat for that long. **Dormant after** 7 days (1, 7 or 30): a longer silence opens nothing. **Replacement grace** 1,800 s (300–86,400): in a pool of replaceable members, a silent member waits that long for a replacement (see *Splunk HEC*, Pools). A late endpoint (a heartbeat in the last 5 minutes) and a stalled one (its output blocked) are held. Critical when every member of the pool is down.
Senders refused (hec_server_busy	Endpoint	2 / 3	**Open at** 10 busy refusals in a window (1–1,000,000,000). **Critical at** 20 % of the requests (1–100). Busy replies 9, 18–20, 23, 26, 27, and the HEC queue insertion failures when the endpoint reports them. Decided for an endpoint up in the window.
Back pressure (hec_queue_satur	Endpoint	3 / 3	No setting. A queue of the HEC path is saturated when its 90th percentile fill reaches 80 % or it was reported blocked in 30 % of its samples or more; back pressure is a saturated queue or busy refusals. High when the endpoint also refuses requests as busy.
Output blocked (hec_forwarding_	Endpoint	2 / 2	**Pause counted from** 30 s (1–3,600): an output pause that long in the window; a failing destination or the output as the bottleneck counts too, and so does a stalled endpoint.
Error rate (hec_error_rate)	Endpoint	3 / 3	**Open at** 5 % refused (0.01–100), **Recover below** 2 % (below the open threshold), **At least** 100 requests in the window (1–1,000,000,000). Load balancer probes (reply 5) excluded.
Authentication failures (hec_auth_failur	Endpoint	2 / 3	**Open at** 20 token refusals in a window (1–1,000,000,000): replies 1, 2, 3, 4, 21, 22. The detail names the reply codes and the clients refused most.
ACK pressure (hec_ack_pressur	Endpoint	3 / 3	No setting. The ACK service logged its store full (HttpInputAckService), or requests were refused with replies 19, 20, 25 or 27.
ACK not polled (hec_ack_unpolle	Endpoint	6 / 2	**Open at** 1 request acknowledged (1–1,000,000,000) in a window that received no ACK poll; after 6 checks (30 minutes), so a sender polling every few minutes never opens it. Decided where Splunk reports both counters (9.4 and 10.x); on 10.x the detail names the tokens acknowledged with no poll.
Endpoint resources (hec_endpoint_re	Endpoint	3 / 3	Off by default. **Open at** 90 % CPU or memory (0–100), **Recover at** 80 % (below the open threshold).
Pool capacity (hec_pool_capaci	Pool	2 / 2	**Critical below** 50 % of the expected members (1–100), or with none up. Expected size: the pool's own, else learned (the second highest daily peak of members up over 7 days). Nothing is decided while the size is being learned.
Pool imbalance (hec_pool_imbala	Pool	6 / 3	**Smallest share** 5 % of the pool's events (0.01–50), **At least** 10,000 events in the window (1–1,000,000,000,000), at least two members up. A member first seen less than 15 minutes ago is skipped (warm-up).
Pool traffic drop (hec_pool_traffi	Pool	3 / 2	**Open below** 10 % of the usual traffic (1–90): the median rate of the same hour of the day over the last 7 days, from 3 days at least. **At least** 1,000 usual events an hour (1–1,000,000,000,000). Critical when the pool received no event. Holds on bank holidays by default.
Pool traffic outlier (hec_pool_traffi	Pool	2 / 2	**Traffic judged**: events (default) or bytes received. **Direction**: drops and spikes (default), drops only, spikes only. **At least** 100 per five minutes (0 or more): below it in both the window and the model, nothing is judged. **Open from**: normal confidence (7 days learned, default) or low confidence (1 day). Holds on bank holidays by default.
Token consistency (hec_token_consi	Pool	2 / 2	No setting. Compares the members up of a pool with fresh splunkd API facts (two at least, else nothing is decided): a token missing on some members (only when no member's token list was cut at 200), or differing in status, index, allowed indexes or ACK.
Configuration drift	Pool	2 / 2	**Grace** 60 minutes (5–10,080): a difference lasting that long opens a finding. Splunk versions (from the telemetry) and, with

Settings every policy has. On / off; **severity** (Low, Medium, High, Critical; the policies above raise it in the cases listed); **checks to open** and **checks to recover** (1 to 12 consecutive windows, one every 5 minutes); **During bank holidays** (**Hold new findings** or **Keep opening findings**; see *Bank holidays*); and for the endpoint and pool policies, a **pool scope** (empty: every pool; the endpoint policies also take the *discovered* endpoints). A token policy has no pool scope.

How a check works. A check is one collected 5-minute window: the policies run after every **HEC activity** run, on the window it published. A window older than 20 minutes is not judged (`hec_live_stale`). The counter policies judge only the endpoints measured in the window.

How findings close by themselves. A finding recovers when the measured condition clears for the checks to recover. It closes automatically when its object leaves the tenant's scope (a host pattern or pool changed, a policy turned off or out of scope), when its endpoint was replaced in a replaceable pool (closing reason *endpoint replaced*, never a recovery), or when nothing evaluated it for 24 hours. A condition TrackMe cannot decide (*unknown*, for example a pool still learning its size) is never written as a recovery.

HEC reply codes

The reply code Splunk logs for each refused request (`reply=` in `HttpInputDataHandler`), and how the tenant counts it:

Class	Reply codes	Counted by
Busy	9, 18, 19, 20, 23, 26, 27	Senders refused, Back pressure, Error rate
Token refused	1, 2, 3, 4, 21, 22	Authentication failures, Error rate
Rejected data	6, 7, 12, 13, 15	Rejected data, Error rate
ACK	19, 20, 25, 27	ACK pressure
Channel, configuration	10, 11, 14, 16	Error rate
No data (load balancer probes)	5	Counted and shown, **never** a sender error
Capacity warning	24, 25	Shown (only with Splunk's `warn_at_80` back pressure state)

`num_of_errors` of the HEC metrics is collected but never used: it does not count refusals. The error rate is the refused requests (every class but the probes) over `num_of_requests`, which includes the refused requests.

Bank holidays

A Splunk HEC tenant uses the bank holiday calendars of its scope (*Bank holidays*). While a holiday is active, the policies set to hold open no new finding; a finding already open is still evaluated and can recover and close.

Policy	Default
Pool traffic drop, Pool traffic outlier, Token traffic outlier, Token silence	Hold new findings
Every other policy	Keep opening findings

A rule saved before this setting existed reads its default. When the calendars cannot be read, nothing is held. The traffic models leave the hours of the tenant's holidays out of their training when the *Exclude from ML training* effect applies to the tenant; a run that cannot read the holidays learns nothing and fails with `ml_holidays_unavailable` (the next run retries).

Custom policies

A custom policy is an SPL search on the tenant's Splunk data whose result rows each name a HEC object. How to write one: *Splunk HEC*, section Custom policies.

Object type	Resolution
Endpoint	A host name within the tenant's host patterns; its pool is the one the configuration assigns (*discovered* when none).
Pool	A pool id of the tenant.
Token	A token name.

- A custom finding takes the subject of the built-in findings on the same object, so it joins that object's Finding group.
- A host outside the tenant's host patterns or a pool the tenant does not define is **not monitored**: skipped, counted in the run's receipt, and its earlier findings recover. Only a value that cannot name an object is unresolved; a run with an unresolved row recovers nothing.
- **Runs, lifecycle and limits**: the same as on a Cribl Stream tenant, see *Custom policies*.
- **Health**: *Collection health → Custom policies*, and the `custom_*` problems of the Configuration Guardian check `cribl_collection_health`.

Collection jobs

Each Splunk HEC tenant has its collection reports, named `trackme_splunk_hec_<job>_<generation>_tenant_<tenant_id>` run as the tenant owner, and the AI Agent report (below). Each tenant's schedule runs at a minute offset of its own.

Job (Collection health label)	Schedule	What it does
`live` (**HEC activity**)	Every 5 minutes	Reads the last settled 5-minute window by index time, in two waves of searches dispatched together (wave 1: the instance and token series of the HEC metrics; wave 2: the refused requests, the queues and thread duty cycles, the output, the host resources), then the receivers of the endpoints whose output was in trouble. Publishes the window, writes the history points, evaluates the policies, sends the notifications.
`inventory` (**Endpoint directory**)	Every 10 minutes; rebuilt about once an hour	Rebuilds the endpoint and token directory (the endpoints seen in the last 24 hours, kept while they reported in the last 7 days; the token names seen in the last 24 hours; the identity from `Host-wide`) and, with accounts bound, reads the splunkd API. Between rebuilds, confirms the directory is current. A manual run always rebuilds.
`mltrain` (**Traffic models**)	Twice an hour	Learns the traffic models of the pools and tokens from the HEC metrics, then projects the expected ranges of the next 24 hours.
`policies` (**Monitoring policies**)	After every live run; on demand	Evaluates the policies on the newest window (**Run now**).
`trackme_hec_agent_` (AI Agent)	Hourly, when enabled	Scheduled triage by the Splunk HEC AI Agent. Off by default: the report stays unscheduled until the triage is turned on.

Run budgets. Each job runs at most its interval less 30 seconds (the live and policies jobs 270 s, the directory 570 s, the traffic models 1,770 s), and a scheduled run ends 30 seconds before its next scheduled run, however late the scheduler started it: a late run reads less and the next one carries on. A run started with less than 15 seconds left does nothing and says so (`collection_time_budget`). The tenant's reports carry no scheduler skew (`allow_skew = 0`, set again at every schedule reconciliation).

Windows. A live run reads what became searchable since the previous run, up to the last 5-minute boundary at least 120 seconds old (the settle delay, never less than 60 seconds), and scans 30 minutes of event time to find it: telemetry more than 30 minutes late is not counted. After missed runs, at most three windows are read (one history point each); older windows stay gaps. A window already counted is never read again. Rates are per second of measured activity.

Searches. A search is judged by its job state: Splunk messages attached to a search are recorded on the run (never a failure), and a search Splunk completed short is used and flagged. Only a failed job, a time limit or a broken read fails the run. The searches name the directory's endpoints (up to 500, else the host patterns).

Scheduled collection off (*Settings → Collection*) unschedules the reports; **Collect now** and **Run now** still work. A live run never builds the directory: a new tenant's first live run answers `hec_directory_pending` and starts the directory job beside it (2.4.23). A search may use what is left of its job's budget: there is no fixed per-search timeout. The reports run `| trackmesplunkcollect` (log `trackme_splunk_collect.log`).

Limits and history

Bound	Value
Endpoints per run	5,000 (beyond, counted as truncated; Collection health says so)
Tokens per run	20,000
Refused-request rows, output rows, receiver rows per run	20,000 each
Queue rows per run	50,000
Receivers read per run	200
Client addresses kept per endpoint	20
Indexes refused kept per token	10
Endpoints listed per token	200
Pools per tenant	200 (host patterns per pool: 50)
Tenant host patterns	100
Hand assignments	500
Expected size of a pool	1 to 10,000
splunkd API accounts / URLs per account / tokens read per endpoint	20 / 50 / 200
Token silence: typed names / lookup tables / names per lookup	100 / 20 / 100,000
Token silence: tokens selected	20,000; at most 250 new silence findings started per run (the others start at the next runs)
Token traffic models	500 tokens (busiest first)
Traffic model history learned on the first runs (**Model learning history**)	14 days by default; from today on, 7, 14, 30, 60 or 90 days (at most what `_introspection` keeps: 14 days by default)
Traffic models with their own settings	500
Endpoints, pools or tokens in one Topology Studio group	2,000 per kind (narrow the group beyond)
HEC references per tenant in one Topology Studio view	100 (use groups for more)
Rows per page of the Endpoints and Tokens tabs	Up to 100 (the viewer's preference)

History kept by TrackMe. At every live run, in the tenant's TrackMe metric index (through `trackme_hec_metrics.log`):

- `trackme.hec.endpoint.*` per endpoint (dimension `endpoint`, the host): `up`, `requests`, `events`, `bytes_received`, `errors`, `parser_errors`, `auth_failures`, `busy_replies`, `refused`, `failures`, `probe_noise`, `waiting_ack`, `oversized_events`, `worst_queue_fill`, `queue_insertion_failures`, `back_pressure`, `output_paused_seconds`, `cpu_pct`, `mem_used_pct`;
- `trackme.hec.pool.*` per pool (dimension `pool_id`): `members`, `up`, `down`, `stalled`, `requests`, `events`, `bytes_received`, `auth_failures`, `busy_replies`, `refused`, `failures`, `oversized_events`, `waiting_ack`, `worst_queue_fill`, `back_pressure`;
- `trackme.hec.token.*` (dimension `token_id`, a digest of the name, never the name): `events`, `bytes_received`, `requests`, `refused`, for the 50 busiest tokens of the window with 10 places kept for tokens with refused requests.

Every point carries `tenant_id` and the end of its window. They draw the trends of the workspace, the drilldown histories and the Topology Studio sparklines. `waiting_ack` is the ACK-enabled requests of the busiest minute, a count per interval, not a backlog.

Settings reference

Setting (where)	Default	Meaning
Source (wizard; Settings → Source & pools)	`local`	This search tier, or a TrackMe remote account to the search tier that sees the endpoints' internal indexes. The tenant owner must hold one of the account's roles. Locked once configured.
Internal index, **Introspection index** (same)	`_internal`, `_introspection`	Where the endpoints' `splunkd.log` / `metrics.log` and HEC metrics are. Locked once configured.
Endpoint host patterns, **Excluded hosts** (same)	`*`, none	The endpoints in scope (`*` and `?` wildcards). Changing them starts a new source revision; an excluded host is never monitored.
Pools (same)	A `default` pool	Identifier (lowercase letters, digits, - and _, up to 40 characters, fixed once saved; never `discovered` or `tokens`), name (up to 80 characters), host patterns (the default pool needs none), expected size, replaceable.
Assignments (same, the endpoint's pool pill)	None	An endpoint pinned to a pool by its host name; never to a replaceable pool.
Auto-join (same)	On	A new endpoint no pool claims joins the default pool; off, it waits as discovered.
splunkd API accounts (same)	None	Up to 20 remote accounts (never `local`) whose splunkd the directory reads. See *Splunk HEC*, The splunkd API enrichment.
Scheduled collection (Settings → Collection)	On	Runs the live job every 5 minutes, the directory about hourly, the traffic models twice an hour.
Model learning history (wizard; Settings → Collection)	14 days	How far back the traffic models learn on the first runs, and what a relearned model reads: from today on, 7, 14, 30, 60 or 90 days.
Traffic ML models (Settings → Traffic ML models; a model's **Tune model**)	Recent days half the weight after 14 days, automatic seasonality, weekday pattern after 28 days, findings once 7 days are learned, normal sensitivity, deviations under 10 % ignored	The defaults every traffic model follows; a model's own settings add the training days, the direction, a pause and excluded periods. See *Splunk HEC*, Traffic models.
Bank holidays (Manage Bank Holidays; Configure tenant → Bank Holidays)	The system default calendars	The tenant's calendars. See *Bank holidays*.
Notifications (Settings → Notifications)	Off	Finding emails: events, minimum severity, policies, delivery account and recipients, digest, charts.
Assignment (Settings → Assignment)	None	Assignment groups, team email, ordered routing rules, manual overrides. See *Assignment and automatic routing*.
Finding actions (Settings → Finding actions; a policy's Actions and Automations)	None	Drilldown, link and webhook actions, and the Automations that call them. See *Findings actions*.
AI Agent (Settings → AI Agent)	Scheduled triage off	See *AI Agent*.
Policies (Policies tab)	See *Built-in policies*	Saved for the tenant with their own revision.

The span of a window (300 seconds) and the settle delay (120 seconds, up to 600) are part of the source configuration.

The tenant's indexes, roles and owner are set in the wizard and edited like any tenant's.

Token silence selection

Token silence watches the tokens that must keep sending, from two sources that add up:

Source	Rules
Typed token names	Up to 100 names or patterns, case-sensitive (a token name is the HEC input's name), 1 to 256 characters without a control character, a quote or a backslash. `*` matches any characters and `?` one character.
Splunk lookup tables	Up to 20 per policy, each a lookup shared with the TrackMe app, on the local search tier or on a remote deployment through a TrackMe remote account (never a TrackMe KV store lookup), with the field holding the token names. Up to 100,000 distinct names per lookup; a larger one is refused (`too_large`), never truncated. Values are trimmed; values that cannot be a token name are counted as ignored.
Match mode (per lookup)	**Exact** (default): whole token names; a value holding `*` or `?` is ignored. **Wildcard**: `*` and `?` match.

Decisions. Every name selected exactly — typed or from an Exact lookup — is selected whether seen or not: a name not seen sending in the last 24 hours is silent at once. The patterns select the known names they match (the latest window, the 24-hour directory, the tokens already followed). At most 20,000 tokens are selected, exact names first.

Refresh. The policies run reads each lookup again every 15 minutes, the oldest first, and keeps its names between reads. A lookup that cannot be read keeps its last good names; a lookup never read successfully selects nothing. Collection health reports `token_lookups_failing` when a lookup is unreadable, too large or empty.

Test selection runs as a search: it reads every lookup now and matches the published token directory and the latest window, then shows the tokens selected by state (sending within the draft's silence period, silent, not seen in 24 hours), up to 50 examples (not seen first) with the entry that selected each, each source's names, and the patterns selecting none. It saves nothing. Token names are selectors: they are not copied into the evidence of the findings.

AI Agent

The Splunk HEC AI Agent triages the tenant's findings from what TrackMe holds: the finding and its HEC detail, history, episodes and Finding group; its endpoint, pool or token in the published directory and latest window; whether the endpoint or pool is still there; Collection health; and its own past decisions. It runs no search. The user guide is in *Splunk HEC*; the shared model in *AI Agents for findings*.

Assessments: true positive, likely false positive, expected behaviour, endpoint or pool not in use, needs investigation.

Settings (*Settings → AI Agent*; the core ones also in **Manage AI Agents automation**, *AI Agents automation*, and in *Configure tenant*), stored in the tenant record:

Setting	Field	Default	Range and notes
Scheduled triage	`ai_hec_agent_enabled`	Off (`0`)	Asking the agent needs only AI to be available.
Mode	`ai_hec_agent_mode`	Inspect	`inspect` (recommend only) or `act` (apply allowed decisions); scheduled runs.
AI provider	`ai_hec_agent_provider_name`	First available	An AI provider account name.
Review interval (days)	`ai_hec_agent_min_days_betwe`	1	0 reviews every run; a new episode is reviewed at once.
Findings per run	`ai_hec_agent_max_findings_pe`	10	1 to 50, most severe first.
Time budget per run (seconds)	`ai_hec_agent_max_runtime_se`	3,000	60 to 86,400.
Custom instructions	`ai_hec_agent_custom_instruct`	Empty	At most 4,000 characters, line breaks kept; followed by every run; never widen what the agent may do.
Allow Mark investigating	`ai_hec_agent_allow_investig`	Allowed (`1`)	An open finding only.
Allow Dismiss for a time	`ai_hec_agent_allow_dismiss_t`	Allowed (`1`)	A critical or high finding still failing only when its endpoint is no longer in the directory (retired, dormant or replaced) or its pool is no longer defined.
Longest dismissal (days)	`ai_hec_agent_dismiss_max_da`	7	1 to 90.
Allow Resolve	`ai_hec_agent_allow_resolve`	Not allowed (`0`)	Only after a measured recovery.

The shared filters of the automated AI reviews, `ai_automated_priority_filter` (by default critical and high findings) and `ai_automated_filter_expression`, apply to the scheduled selection with the finding severity as the priority.

Gone from the directory. An endpoint is gone only when a **current** directory no longer lists it and the finding has not been evaluated for an hour; a pool is gone when the tenant no longer defines it. A token is never gone.

Scheduled triage runs the report `trackme_hec_agent_tracker_tenant_<tenant_id>` hourly when all of these hold: the AI Assistant is enabled, an AI provider is configured, the tenant is enabled, and scheduled triage is on. The report runs as the tenant owner, which must be a Splunk administrator account (a member of `admin` or `sc_admin`), not `nobody`: the run records itself in a store only they can write. Saving the settings schedules or unschedules it, and the tenant health tracker checks the same conditions every five minutes.

Audit. Every run is indexed to the tenant summary index with the sourcetype `trackme:ai_agent:hec_agent:inspect` or `trackme:ai_agent:hec_agent:act`; decisions appear in the finding's history under the actor **AI Agent**, and the reviewed finding carries one current `[AI Agent]` note.

```
index=trackme_summary sourcetype="trackme:ai_agent:hec_agent:*"␣
↪tenant_id="example-hec"
| table _time, sourcetype, launched_by, automated, status
```

Indexed finding events

Every transition of a finding and of a Finding group is written as an event, whatever the notification settings:

Item	Value
Index	The tenant's notable index (`trackme_notable` by default)
Sourcetypes	`trackme:cribl:finding` (a finding) and `trackme:cribl:finding_group` (a Finding group), shared with the Cribl tenants
`object_category`	`splunk_hec` (with `tenant_id`)

Example: the HEC findings opened or reopened in the last day.

```
index=trackme_notable sourcetype=trackme:cribl:finding object_category=splunk_hec␣
↪tenant_id="example-hec"
    transition IN ("opened", "reopened")
| table _time, policy_name, entity_name, severity, reason, finding_id
```

Permissions

Each tier needs the TrackMe capability **and** one of the tenant's matching roles; a Splunk administrator (`admin`, `sc_admin`) holds every tier on every tenant.

Action	Who
Read every tab, the drilldowns, the last five minutes and *Why it was flagged*; run drilldown and link actions	Any role of the tenant (`trackmeuseroperations`). The reads run with your own rights: a remote source also checks the remote account's roles.
Triage findings and Finding groups (investigate, assign, snooze, dismiss, resolve, change the severity, group by hand), notes; ask the AI Agent and let it act on its inspection	The tenant's power and admin roles (`trackmepoweroperations`)
Policies (on / off, severity, conditions, scope, bank holidays), the Token silence lookups and Test selection, custom policies	A TrackMe administrator of the tenant (`trackmeadminoperations` and a tenant admin role)
Source & pools, Collection, **Collect now** / **Run now**, Repair workspace, Notifications, AI Agent settings, Assignment settings, Finding actions and Automations	A TrackMe administrator of the tenant
Create or delete the tenant; manage remote accounts and Webhook accounts	TrackMe administrators (see *Remote Splunk deployments* and *Webhook accounts*)

The **scheduled** AI Agent needs a tenant owner that is a Splunk administrator account (not `nobody`). A remote account used as the source or for the splunkd API must be usable by the tenant owner (one of its roles).

Configuration Guardian

The tenant check `cribl_collection_health` raises **Splunk HEC collection needs attention** (warning) when collection does not run as configured, and clears by itself on the first run without a problem. The Collection health tab shows the same conditions.

Condition	In plain words
`live_never_ran`, `live_not_running`	No live HEC run since the source was configured, or none for 20 minutes. Check that the reports exist, are scheduled and that their owner can run searches.
`live_failing`, `inventory_failing`, `policies_failing`	A job keeps failing (30 minutes for live and policies, 90 minutes for the directory). Search the collector log, and check that the tenant's remote account connects.
`inventory_never_ran`, `inventory_not_running`	No endpoint directory since the source was configured, or none for 3 hours.
`no_hec_endpoints`	No endpoint for an hour after configuration: HEC disabled on the endpoints, the internal and introspection indexes not searchable from the source, or host patterns matching nothing.
`capacity_reached`	A collection limit was reached (more endpoints or rows than a run keeps). Narrow the host patterns or exclude hosts.
`token_lookups_failing`	A Token silence lookup table could not be read, holds more than 100,000 names, or is empty, at the last policies run. A lookup that cannot be read keeps its last names. Check the lookup, its sharing with the TrackMe app, and the remote account when it is on a remote deployment.
`custom_schedule_drift`, `custom_policy_failing`, `custom_missed_schedule`, `custom_recovery_required`, `custom_health_unavailable`	A custom policy's report or runs need attention: the same conditions as on a Cribl Stream tenant (see *Custom policies*).
`notification_delivery_failing`	Notifications are on and the emails have failed for 30 minutes. Collection never waits for delivery.

Each alert carries its recommended actions. See *Configuration Guardian*. Also relevant: `ai_automation_owner_is_system_user` warns when the AI Agent's scheduled triage is on and the tenant owner is `nobody` or a system account.

Run reasons

The outcome each job records, shown on its Collection health card:

Reason	Meaning
`live_published` / `window_current`	The latest HEC window was collected / was already collected.
`directory_published` / `directory_current`	The endpoint directory was rebuilt / is up to date.
`hec_policies_evaluated`	The policies were evaluated on the latest window.
`hec_live_not_published`	No HEC window published yet.
`hec_live_stale`	The latest window is more than 20 minutes old: it is not judged.
`hec_policy_time_budget`	The policies ran out of time.
`hec_scope_changed`, `source_revision_changed`	The source changed during the run; the next run reads the current settings.
`hec_snapshot_changed`	A new window was published while reading; the next run evaluates it.
`hec_policies_unavailable`	The policies could not be evaluated.
`remote_account_refused`	The remote account refused the tenant owner. Add one of the owner's roles to the account, or change the owner.
`search_failed`, `search_timeout`	A collection search failed or exceeded its time limit. The collector log carries the Splunk messages of the failed search.
`models_current`, `training_continues`	The traffic models are up to date / are still learning the history (the next run continues).
`ml_holidays_unavailable`	The tenant's bank holidays could not be read: the training waited.
`job_lock_busy`	Another run of the same job was running; logged as information.

The collector log is `index=_internal sourcetype=trackme:custom_commands:trackmecriblcollect` (file `trackme_cribl_collect.log`).

REST endpoints

The workspace uses the `/trackme/v2/cribl/tenant/*` endpoints shared with the Cribl tenants (`workspace`, `configure`, `collect`, `collect_result`, `repair`, `policies`, `policy_save`, `findings`, `finding`, `triage`, `finding_groups`, `group_triage`, `group_members`, `notifications`, `notification_test`, the custom policy and AI Agent operations) plus the HEC reads below, which answer `splunk_hec_tenant_required` on another tenant. An operation a HEC tenant does not have answers `not_available_for_splunk_hec`. Every endpoint documents itself with `describe=true` and is listed in the REST API Reference page.

Endpoint	Purpose
`hec_overview`	The summary of the latest window, the pools, the endpoints needing attention, the discovered endpoints and the busiest tokens
`hec_endpoints`	A page of endpoints (up to 200), filters host, pool and status (`up`, `stalled`, `late`, `silent`), sorts by host, events, failures, error rate, busy, queue or refused
`hec_endpoint`	One endpoint, with its pipeline, output and receivers, and its splunkd API facts
`hec_tokens`	A page of token names
`hec_token`	One token by `token_name`: its latest window, its last 24 hours, its endpoints, its errors, the indexes refused and the client addresses
`hec_lookups`, `hec_lookup_preview`, `hec_token_selection_prev` `hec_token_selection_stat`	The Token silence editor: the lookups of a deployment, one lookup's preview, and Test selection (start, then poll)

Example:

```
| trackme url="/services/trackme/v2/cribl/tenant/workspace" mode="get"␣
↪body="{\"tenant_id\":\"example-hec\"}"
```

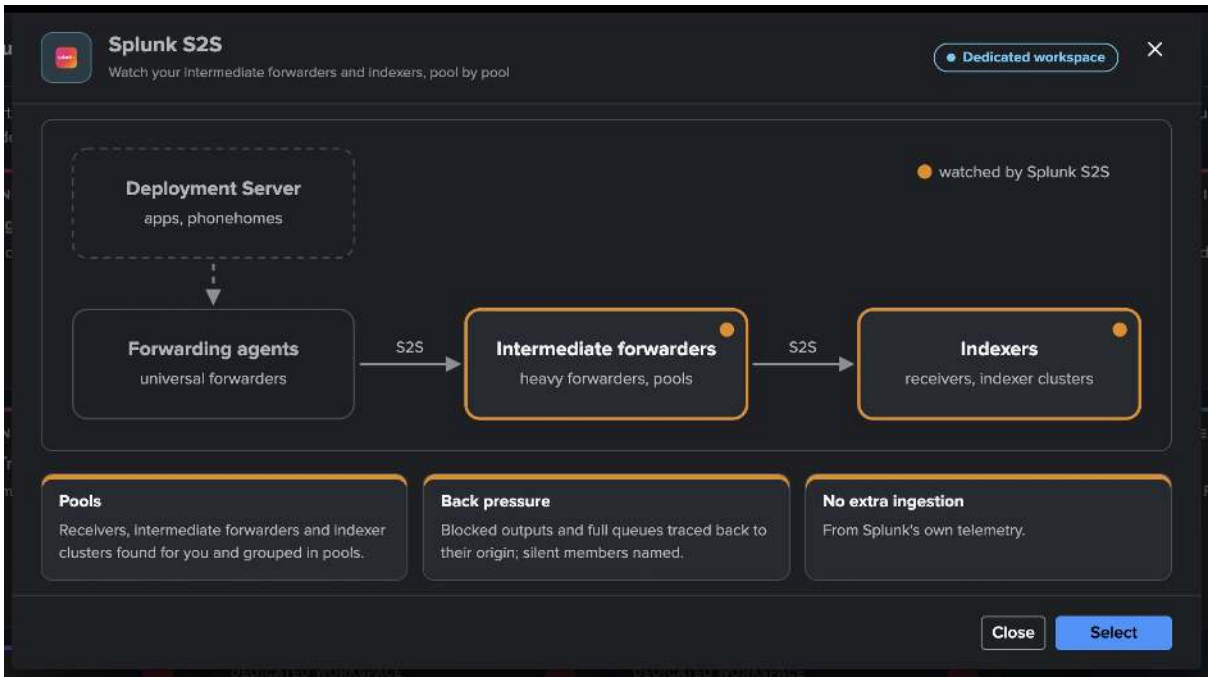
8.3.21 Splunk S2S

The **Splunk S2S tenant** watches the **Splunk-to-Splunk receiving side** of one Splunk deployment: the **receivers** (indexers, standalone instances, Splunk Cloud indexers), the **intermediate forwarders** (heavy or universal forwarders that receive S2S and forward it) and the **pools** they form, and the data path between them. It answers the questions a Splunk administrator asks about forwarding: *is every receiver accepting and keeping up? is my intermediate tier blocked, backed up, silent, or load balancing over fewer destinations than usual? when senders are held back, which tier is the bottleneck, and is the cause downstream, local or an upstream surge? how much flows into each pool, from how many senders of which type and version, with which TLS and acknowledgement posture?* The answers are **findings**, raised by built-in policies, with the same triage, Finding groups, notifications, assignment and findings actions as the other dedicated tenants, **traffic ML models** on every receiver pool, and a findings AI Agent of its own, the Splunk S2S AI Agent.

A Splunk S2S tenant is a **dedicated tenant type**: it has no entities and no state colour, and one tenant follows the S2S receiving side of one Splunk deployment. It reads the telemetry Splunk **already writes** — the receivers' and intermediates' `metrics.log` connection lines, queues and throughput, their `splunkd.log` input and output messages, their health report and `_introspection` — on the local search tier or through a TrackMe remote account. Nothing is installed on any Splunk instance, no new data is ingested, no forwarder is ever called: the tenant only reads.

The **senders** (universal forwarders, heavy forwarders, search heads, Deployment Servers) are context here: counted, typed and versioned per receiver and pool, never findings. The forwarding agents and their Deployment Servers have their own tenant type, *Splunk UF Fleet*.

The Splunk S2S tenant is generally available since TrackMe 2.4.22.



For a guided tour on a live deployment, see the hands-on walkthrough *Splunk S2S*. Every policy, setting, job and command is described in the *Splunk S2S reference*.

What it monitors

Object	What TrackMe watches
Receivers	Every host that receives S2S and indexes it. Whether it **accepts** its senders (a receiver whose queues stayed blocked stops its listening ports), whether it is **silent** while the other members of its pool report, **back pressure** along its ingestion path and the stage that cannot keep up, its share of the pool's senders (**imbalance**), **connection churn**, and the **TLS and acknowledgement posture** and **Splunk versions** of its senders.
Intermediate forwarders	Every host that receives S2S and forwards it: a heavy forwarder tier, or a universal forwarder used as a relay. Its **output paused** (the senders behind it held back), **back pressure** and its origin (downstream, local or an upstream surge), **silence**, failing destinations, a **single destination** where it usually load balances over several, what it receives against what it forwards (**in / out anomaly**), the TLS posture of its senders, and a universal forwarder **relaying** universal forwarders.
Pools	The receivers of an indexer cluster, one pool per site of a multisite cluster (found without configuration), the intermediate forwarders grouped by host-name family (also automatic), or receivers and intermediates grouped by host patterns, output groups or hosts you assign. **Capacity** (members up against the expected size), **not receiving** (every member silent), a **traffic drop** against the same hour of the previous days, **traffic outliers** against a traffic ML model, and a **back pressure cascade**: one finding naming the receivers that back up and the intermediates paused towards them.
Destinations	A receiver that **many senders fail to reach** without a break: one finding on the destination listing the senders, never one per sender.

Indexer clusters are found without configuration. Each indexer cluster the source search head is attached to becomes a receiver pool, its members and expected size from the cluster. A **multisite** cluster forms **one pool per site**, named `<cluster>:<site>` (`idxc1:site1`, `idxc1:site2`): each site is judged on its own peers, so a site that loses its indexers is a capacity finding even while the other site carries the load. A single-site cluster, or one whose peers' sites are not all known, stays one cluster-wide pool. An optional remote account on the cluster manager adds its view of **planned work**: while a cluster is in maintenance mode or a rolling restart, the availability, capacity, balance, churn and traffic findings of its pools wait. A cluster's own health (peers, replication and search factors, buckets) is shown in the workspace, never judged here.

The intermediate tier is grouped for you too. The intermediate forwarders no pool claims form one **automatic pool per host-name family** (`hec-pool-hf1` to `hec-pool-hf4` form `hec-pool-hf`). **Configure** an automatic pool to rename it, give it its output groups and an expected size: it becomes a configured pool and keeps its id, its findings and its history.

How it works

Roles are read from signatures, never configured. Over the last 24 hours, a host that receives S2S (`group=tcpin_connections` lines) and indexes is a **receiver**; a host that receives and forwards (`group=tcpout_connections` or cooked output) is an **intermediate forwarder**. An intermediate's type comes from how its own receivers see it: `fwdType=full` is a heavy forwarder, `uf` a universal forwarder. Host patterns and excluded hosts bound which hosts may be receivers or intermediates; they never apply to senders.

Bounded reads, whatever the deployment size. Every read is an aggregation over indexed terms or metric dimensions (`tstats` with `TERM()` and `PREFIX()`, `mstats` on the `_metrics` mirror), never a search per host. The live job reads index-time windows of five minutes with catch-up (never the same window twice), and every view of a window is published under one id, so two views never mix two windows.

Job (Collection health label)	What it does
Inventory (every 10 minutes; the directory is rebuilt about hourly, always on a manual run)	The roles over a day, the intermediates' type, the indexer clusters (the search head's view every run, the manager's through its account), the pools, and a probe that chooses the telemetry form. Publishes the directory.
Live (every 5 minutes)	Per receiver and intermediate: the inbound connections (senders by type and version, TLS and acknowledgement mix, volume), an intermediate's output groups and destinations, output pauses and connection failures; assembles the latest facts of the jobs below. Per pool: the sums, the members up and the balance. Writes the series to the tenant's metric index, then **evaluates every policy**. A live run never builds the directory: before the first inventory it waits for it.
Pipeline, **Health report**, **Destinations** (every 5 minutes each)	Dedicated jobs, each with its own report, schedule, time budget and Collection health line (2.4.23): the pipeline queues and their threads, stopped listening ports, the intermediates' output trouble, churn, CPU and memory; the health report, with the detail for the flagged hosts only; the destinations the senders fail to reach and the cluster peers restarting. A job that misses a slot makes the policies hold, never count twice.
Traffic ML models (twice an hour)	Learns each receiver pool's models when due (see *Traffic ML models*).
Policies (on demand)	Evaluates the policies again on the latest live window (**Run now** in Collection health).

Host statuses. In each window a host is **not accepting** (it stopped its listening ports), **silent** (no connection line in the live window), **output paused** (an intermediate), **back pressure**, or **up** — the first that applies.

Why senders are held back. A receiver writes every S2S connection into its input queue, then into the ingestion pipeline (`splunktcpin` → `parsingqueue` → `aggqueue` → `typingqueue` → `rulesetqueue` for parsed data → `indexqueue`); a heavy intermediate adds its output queues (`tcpout_<group>`). When a stage cannot keep up, its queue fills, then the queues before it, until the receiver pauses its senders or stops its listening ports. The tenant reads every queue of that path, names the **bottleneck** — the stage after the furthest-downstream saturated queue — and whether that stage's thread was busy (working at its limit) or waiting on the next stage. On an intermediate it names the **origin**: *downstream* (its output paused, or a receiver pool it feeds backs up), *upstream surge* (inbound above 1.5 times its learned volume) or *local*.

Note

An intermediate's own `tcpout` count is **compressed bytes on the wire**, not comparable with what its receivers count (uncompressed). The workspace labels it **Sent on the wire (compressed)** and shows the receivers' side as the relayed volume: never compare the two.

Before you start

A licence. A valid **Enterprise**, **Unlimited**, Unlimited trial or **Developer** licence. The Splunk S2S tenant is not available with the Foundation edition or the Foundation trial.

A source. The search tier that sees the receivers' and intermediates' internal indexes:

- **local**, this search tier, when it searches the indexers that hold their `_internal` (and `_metrics` / `_introspection` when used);
- or a **TrackMe remote account** (*Remote Splunk deployments*) to the search tier of another deployment. The tenant's scheduled searches run as the tenant owner, so the **tenant owner must be allowed to use every remote account the tenant reads**: the wizard and the Settings check it before saving and name the fix.

The three index names are configurable (defaults `_internal`, `_metrics`, `_introspection`).

Reading the indexer clusters. The cluster reads (`/services/cluster/searchhead/generation` and each peer's `/services/cluster/peer/info`, through `| rest`) need the **read-only** `list_indexer_cluster` capability for the reader: the tenant owner on the local search tier, or the source account's user. Without it Splunk

answers nothing, and Collection health reports `cluster_read_refused`. A deployment with no indexer cluster can set **Indexer clusters as pools** to Off.

Optionally, a manager account per indexer cluster. A TrackMe remote account on the cluster manager's management port lets the tenant read the manager's maintenance mode and rolling restarts, which **Hold during planned work** then follows. Give it a **read-only** role:

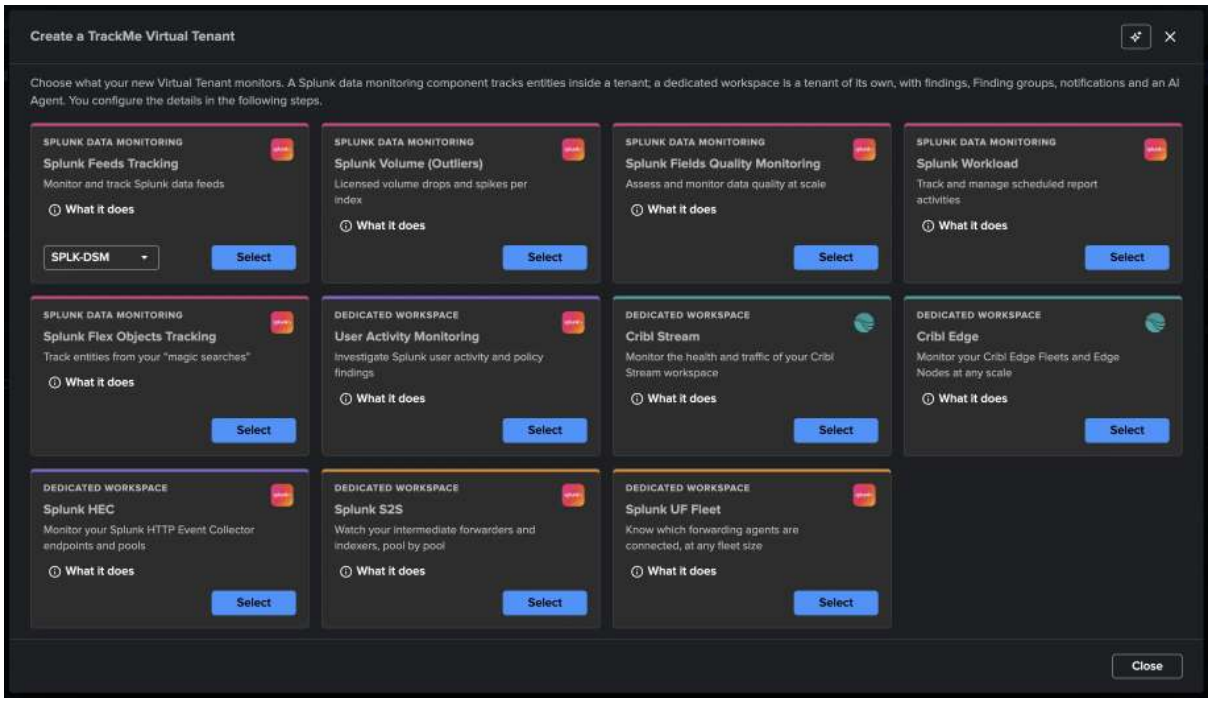
```
[role_trackme_cluster_reader]
importRoles =
search = enabled
rest_properties_get = enabled
list_indexer_cluster = enabled
```

The account is checked as soon as it is chosen, and an account that could change the cluster gets an advisory: TrackMe only reads, a read-only role is recommended.

A tenant owner: `nobody`, or an account (typically a least-privilege service account) holding the capabilities the wizard lists (`trackmeuseroperations`, `trackmepoweroperations`, `trackmeadminoperations`, `schedule_search`, `list_settings`, `list_storage_passwords`, `admin_all_objects`). The scheduled triage of the Splunk S2S AI Agent needs an owner that is not `nobody` (see *The Splunk S2S AI Agent*).

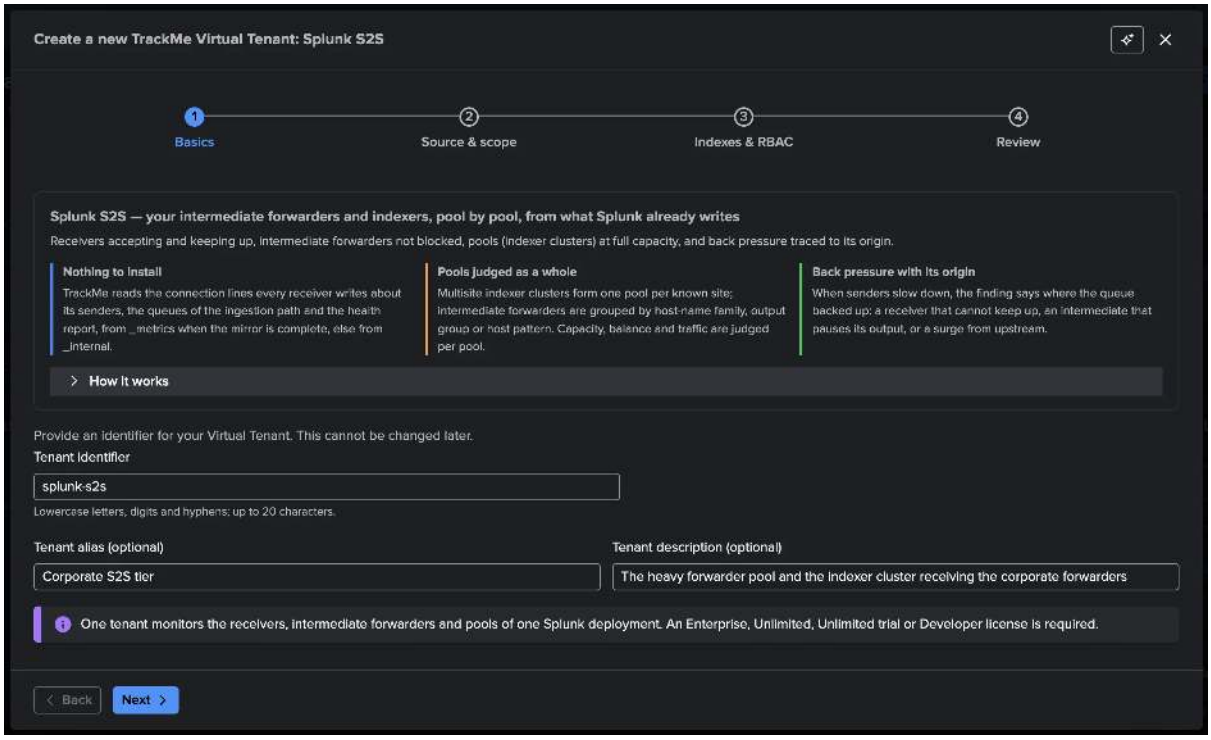
Creating the tenant

From the *Virtual Tenants* page, open **Actions → Create a tracking tenant** and choose the **Splunk S2S** card ("Watch your intermediate forwarders and indexers, pool by pool"). **What it does** opens the dialog shown at the top of this page.

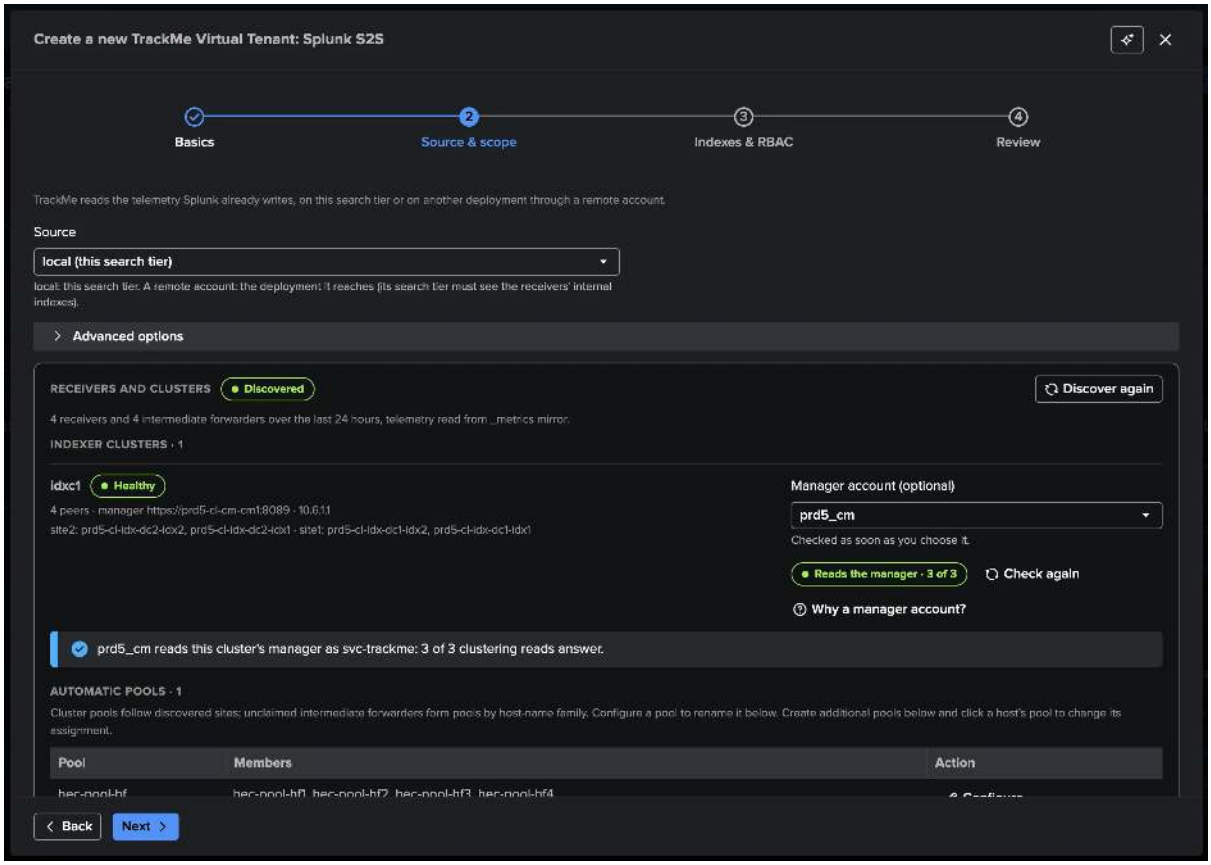


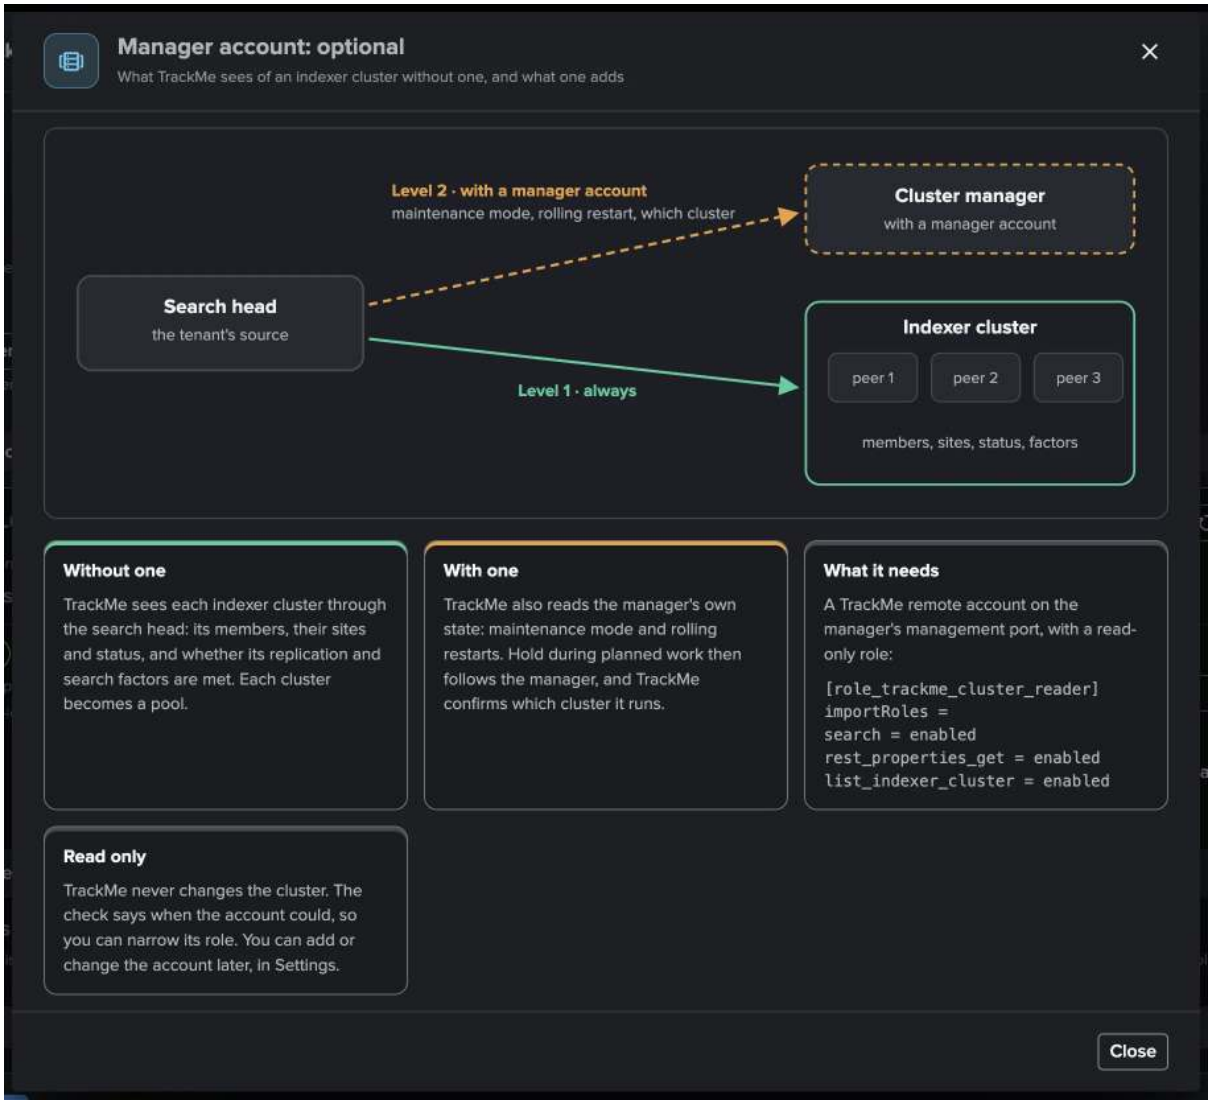
The wizard has four steps.

1. Basics — an introduction to what a receiver, an intermediate and a pool are, then the tenant identifier (lowercase letters, digits and hyphens, up to 20 characters, fixed once created), an alias and a description. One tenant monitors the receivers, intermediate forwarders and pools of one Splunk deployment.

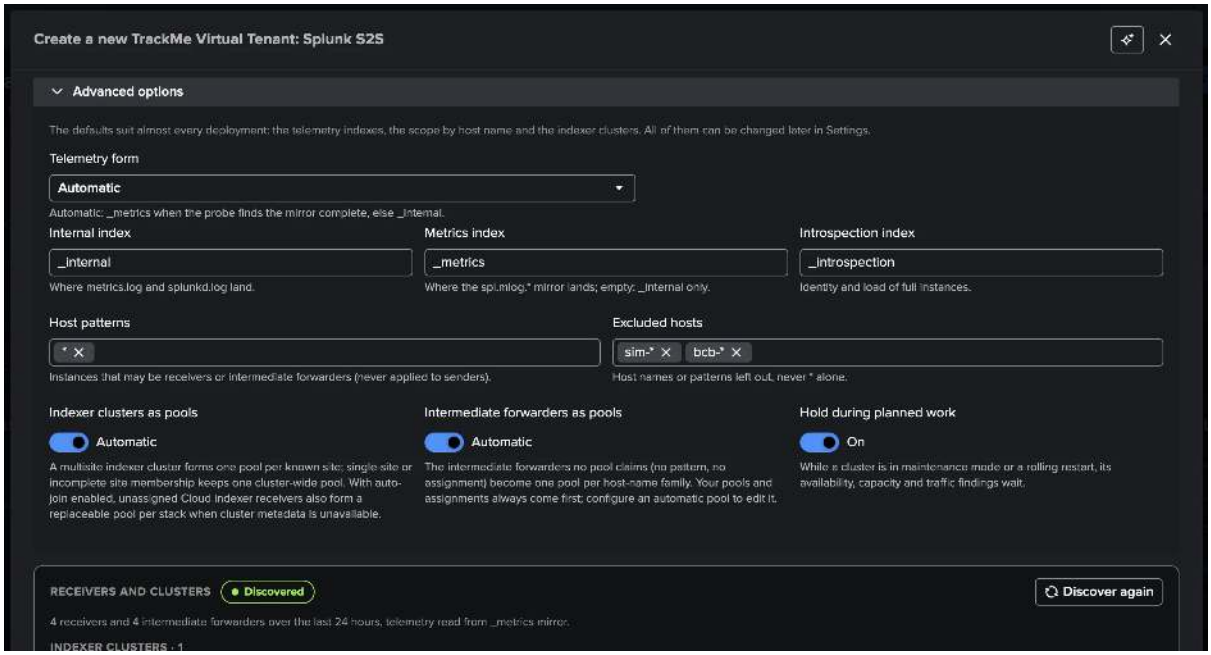


2. Source & scope — the **Source** (this search tier, or a remote account), then **Receivers and clusters**, a short discovery of the receivers and intermediate forwarders found over the last 15 minutes (at most two searches of 5 minutes: one row per receiver with its role, its senders counted on the indexers and its inbound volume, then the indexer clusters): each indexer cluster with its sites, its health and its peers, and beside it the cluster's optional **Manager account**. The account is checked as soon as you choose it ("Reads the manager · 3 of 3"); each refused read says what TrackMe cannot read, what it costs and the role to create, and an account that could change the cluster gets an advisory recommending a read-only role. **Why a manager account?** explains the two levels.

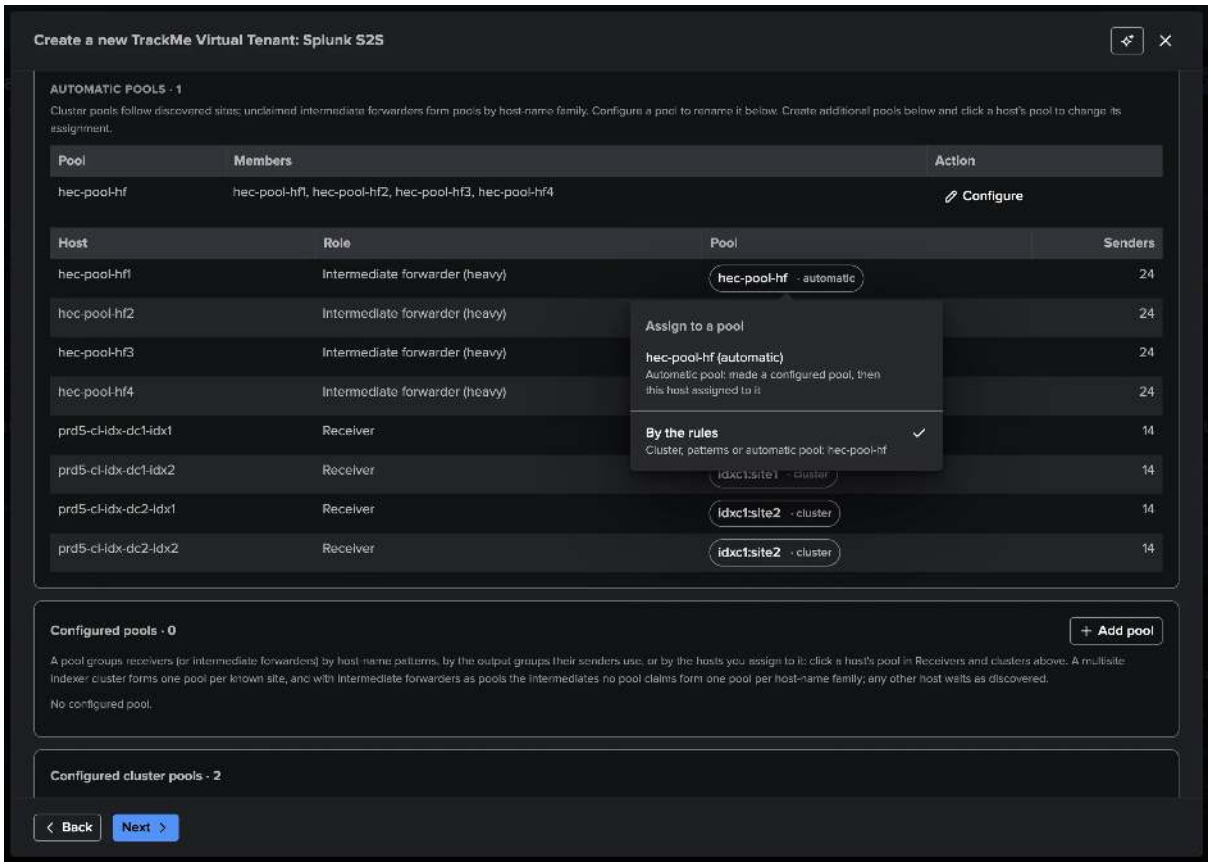




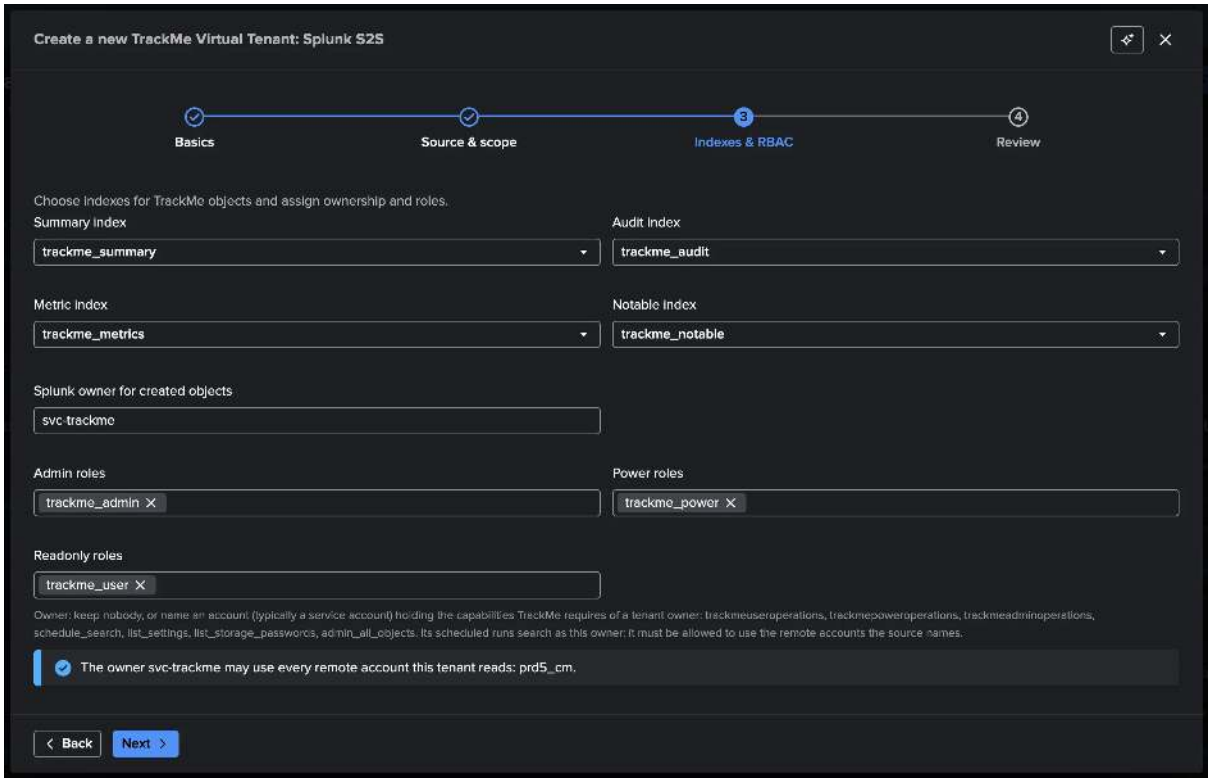
Advanced options (folded; opened when one of its settings needs a fix) hold the telemetry form (*Automatic*: the `_metrics` mirror when the probe finds it complete, else `_internal`; or forced), the three index names, **Host patterns** and **Excluded hosts** (type a host name or a pattern and press Enter: each becomes a token; a pasted comma-separated list is split), **Indexer clusters as pools** and **Intermediate forwarders as pools** (Automatic / Off) and **Hold during planned work** (On / Off). The defaults suit almost every deployment. Set an exclusion here rather than later: the first backfill (14 days) never reads the hosts it leaves out. Below, two families of test receivers sharing the same indexes are left out: `sim-*` and `bcb-*`.



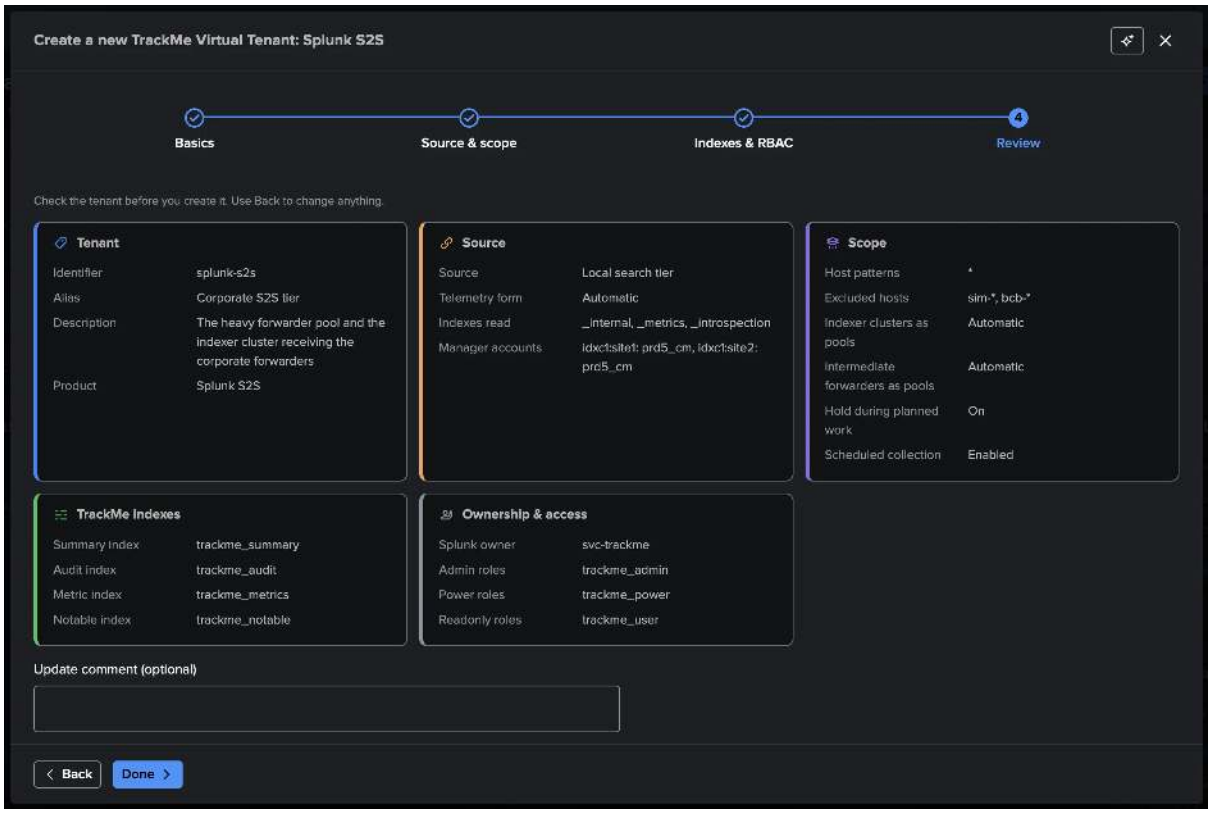
Below the clusters, the step shows the pools the tenant will start with, the same editor as **Settings → Pools**: the **automatic pools** (each site of a multisite cluster, and one pool per host-name family of the intermediates no pool claims, each with **Configure**), every host with its **pool pill**, and the **configured pools**. Click a host's pool pill to **assign it to a pool**, or choose **By the rules** to give it back to the cluster, the patterns or its automatic pool. Nothing needs configuring here: the indexer cluster and the heavy forwarder tier below are pools from the first run.

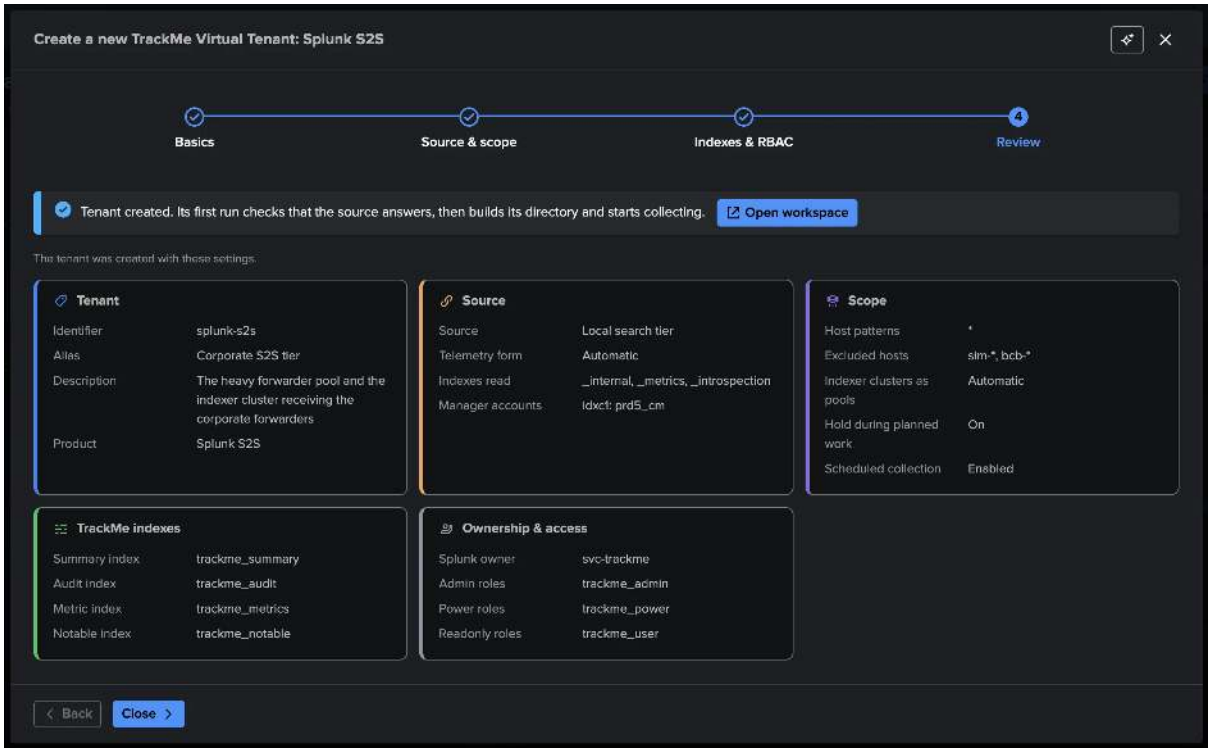


3. Indexes & RBAC — the tenant's TrackMe indexes (summary, audit, metric and notable), the owner and the admin, power and read-only roles. The wizard checks that the owner may use every remote account the tenant reads, the manager accounts included.



4. Review — the tenant, its source with the manager account of each site pool, its scope and its pool settings, then **Done**. The first live run starts at once: it checks that the source answers, then builds the directory and starts collecting. **Open workspace** opens the tenant.

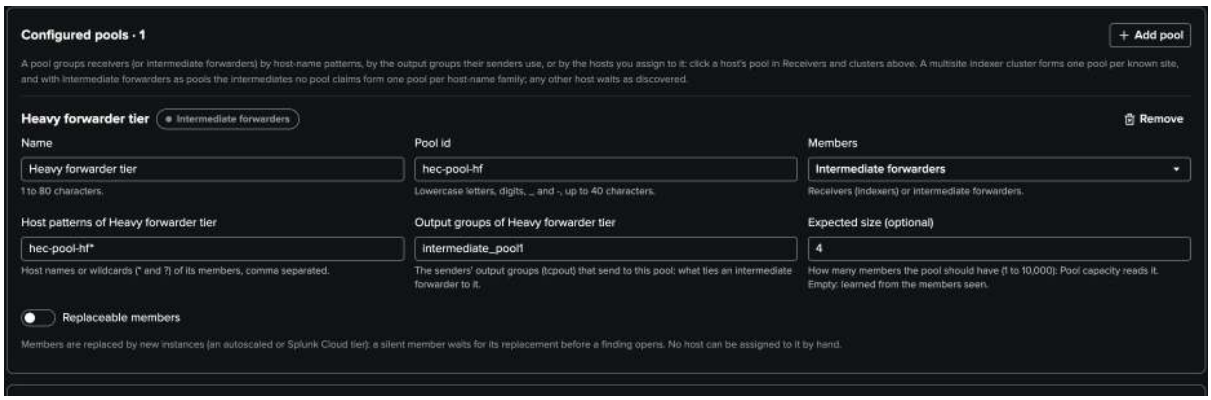




Configuring pools

An indexer cluster (one pool per site of a multisite cluster) and the intermediate tier (one automatic pool per host-name family) are pools from the first run. **Settings → Pools** shows the same editor as the wizard: the **automatic pools**, every host with its **pool pill**, and the **configured pools** (up to 200 pools in all). Make a pool your own when it needs a name, its output groups or an expected size; group receivers no cluster claims (standalone indexers, Splunk Cloud indexers) in a configured pool of their own.

Configure on an automatic pool turns it into a configured pool with the **same id**, so its findings and history continue; on the lab tenant, the automatic pool `hec-pool-hf` became the **Heavy forwarder tier**. A configured pool has a name, an id (fixed once saved: its findings and history follow it), its **members** (receivers or intermediate forwarders), **host patterns**, the **output groups** that send to it, an optional **expected size**, and **Replaceable members** for a tier whose members are replaced by new instances (an autoscaled tier, Splunk Cloud indexers): a silent member then waits for its replacement before a finding opens. A site pool of an indexer cluster can be renamed too (its members always come from the cluster); removing a configured pool gives its hosts back to the automatic pools.



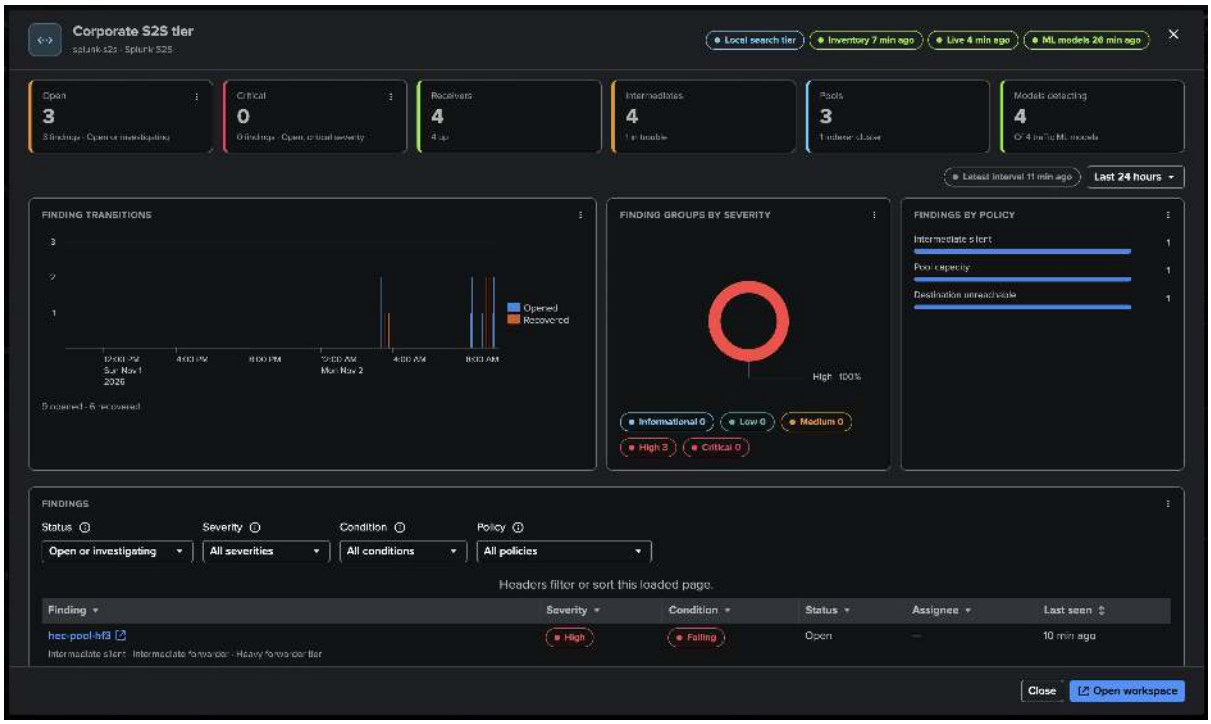
Output groups tie an intermediate tier to what it feeds. The output groups are the senders' `tcpout` group names that send to the pool (here the forwarders' `intermediate_pool1`). They are how an intermediate is tied to the receiver pool it feeds, and how a sender's traffic is placed on the data path; an intermediate is never tied by guessing from a destination address.

A host is placed by the first rule that applies: a host **assigned by hand** (from its pool pill), then the **indexer cluster**

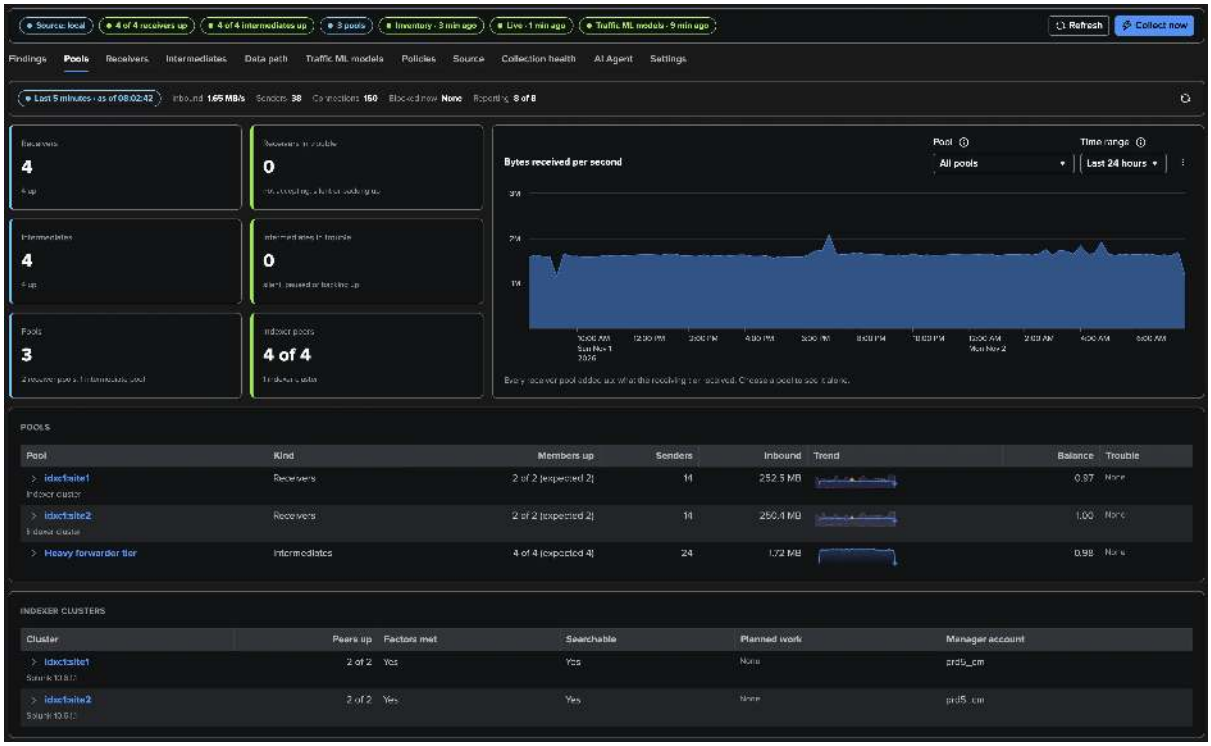
it is a peer of (its site's pool on a multisite cluster), then a configured pool whose patterns match (when **Auto-join** is on), then the **automatic pool** of its host-name family (an intermediate), else **discovered** (no pool). An intermediate never joins a cluster pool, and your pools and assignments always come before the automatic ones. A pool may hold hand-picked hosts only, with no pattern. A pool change applies from the next inventory; to see it at once, **Run now** the inventory in Collection health, then **Collect now**.

The workspace

The preview. On the *Virtual Tenants* page, a double-click on the tenant card opens its preview before the workspace: the source and the collection pills, the **Open** and **Critical** figures, **Receivers** and **Intermediates** (with how many are in trouble), **Pools** and **Models detecting**, the finding transitions and severities of the last 24 hours, the findings by policy and the findings table, read-only. A finding opens in the workspace; **Open workspace** opens the tenant. Before the first live run, the figures read as dashes.

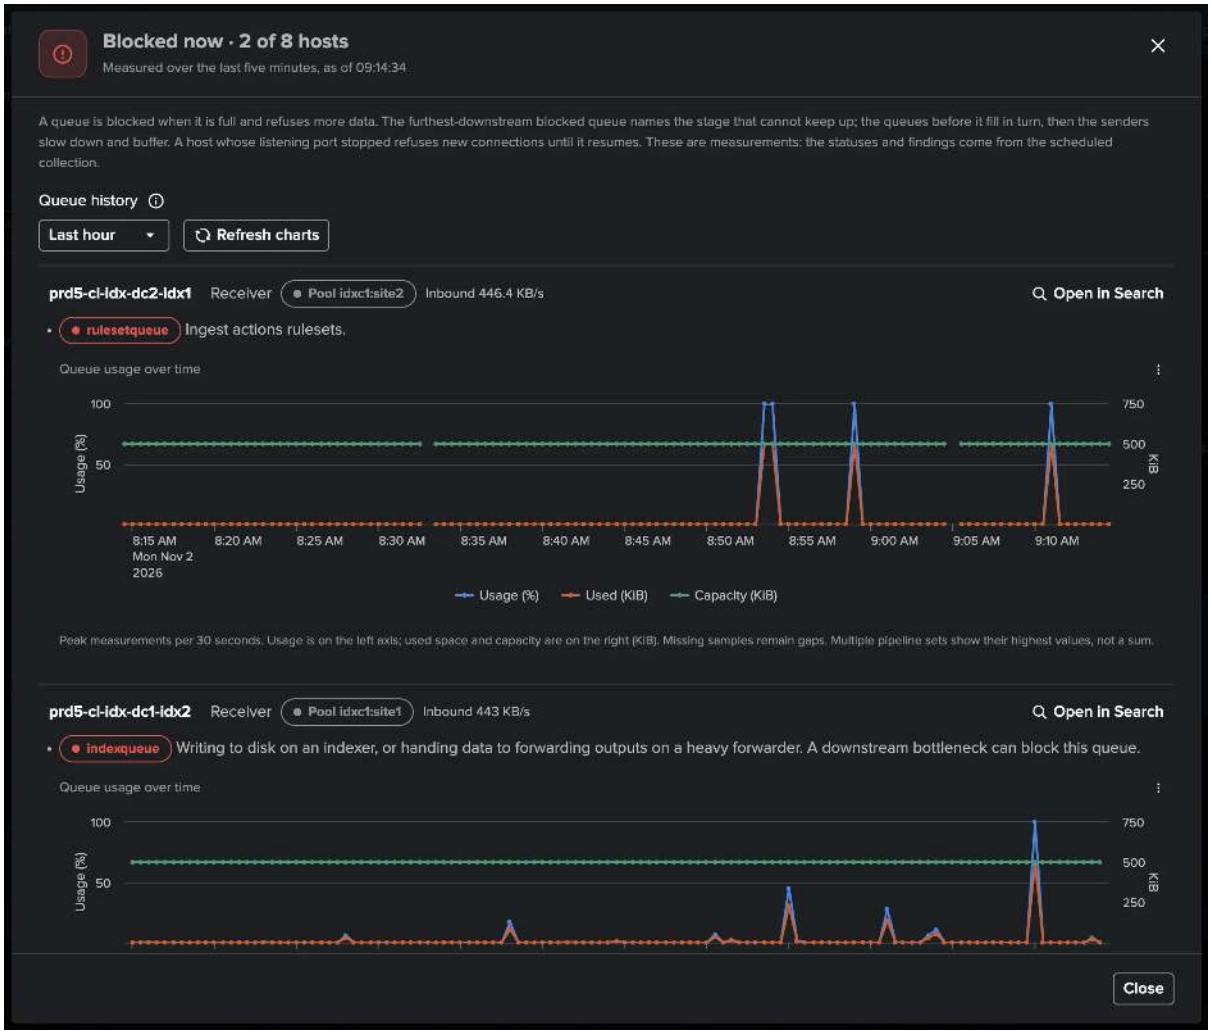


The workspace is the Tenant Home of the tenant. A **status strip** sits above the tabs: the source, "N of M receivers up", "N of M intermediates up", the pools, and the **Inventory**, **Live** and **Models** job pills (each opens Collection health), with **Refresh** and **Collect now** (runs the live job).

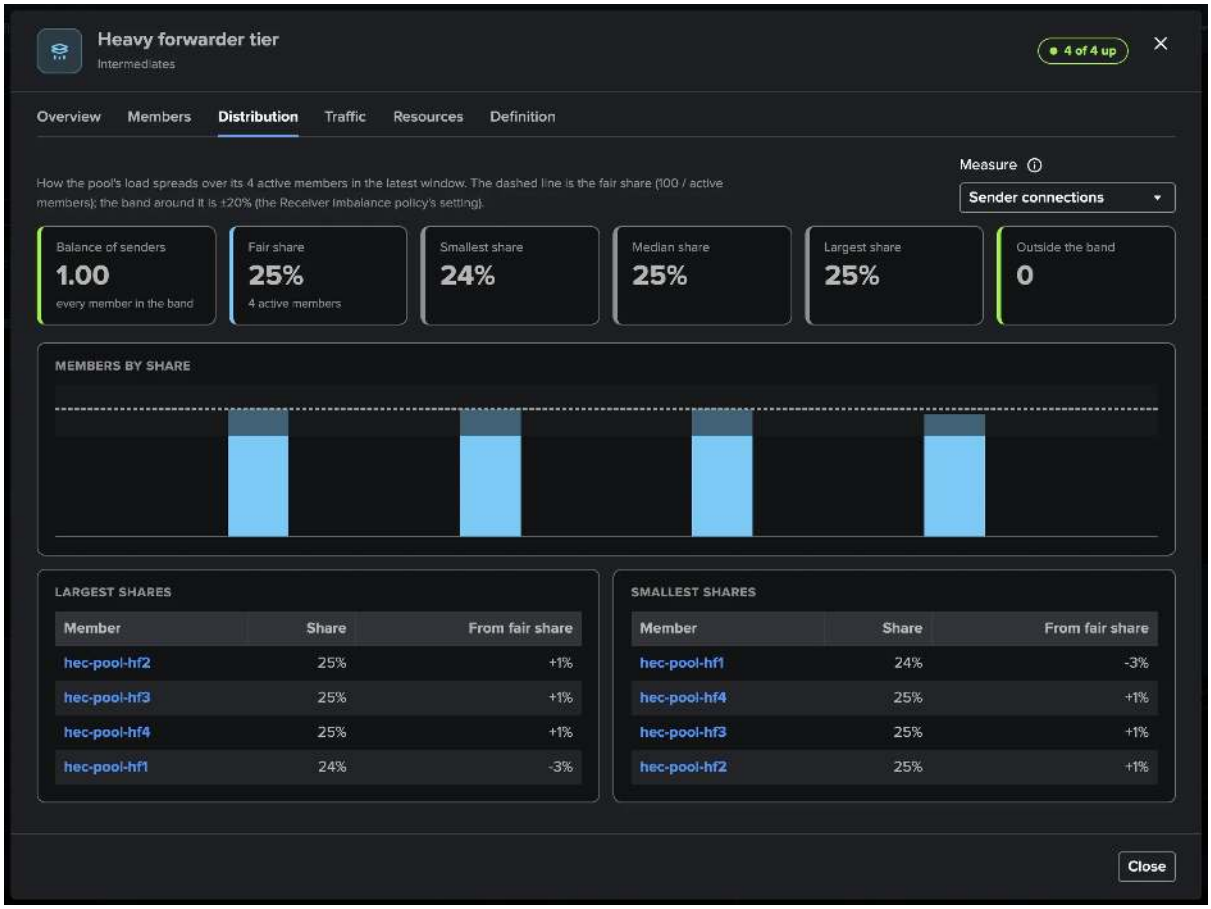


Tab	What it shows
Findings	The findings centre shared by every dedicated tenant (see *Findings, Finding groups and findings actions*). Families: Receivers, Intermediate forwarders, Pools, Destinations. The findings of one object (a host, a pool, a destination) form one Finding group; the pool is the policy scope (`discovered` for a host in no pool).
Pools	The **Last 5 minutes** strip (inbound per second, senders, connections, **Blocked now**, hosts reporting), host tiles beside **Bytes received per second** (every receiver pool added up, or one pool alone, over the chosen time range), the pools table (each row expands to its members, an indexer cluster pool to its peers), the indexer clusters, one row per site pool (peers up, factors met, searchable, planned work, manager account), the Splunk versions of the hosts, the intermediate types, and the hosts needing attention.
Receivers, **Intermediates**	Every host, paged on the server, with filters on status, pool and name. **Signal pills** (back pressure and its bottleneck, destinations paused, origin, red or yellow health, without TLS) open the facts and their evidence. A host opens its modal.
Data path	The generated three-column topology: sender types → intermediates → receivers, a pool as one node, edge width by volume, with a Flows table.
Traffic models	Every receiver pool's models, their state, the model view, tuning and relearning.
Policies	The policy catalogue, custom policies, and **How it is evaluated** for every policy.
Source	The search tier, the qualification, the telemetry form, and the collection runs with their outcome and receipt.
Collection health, **AI Agent**, **Settings**	See below.

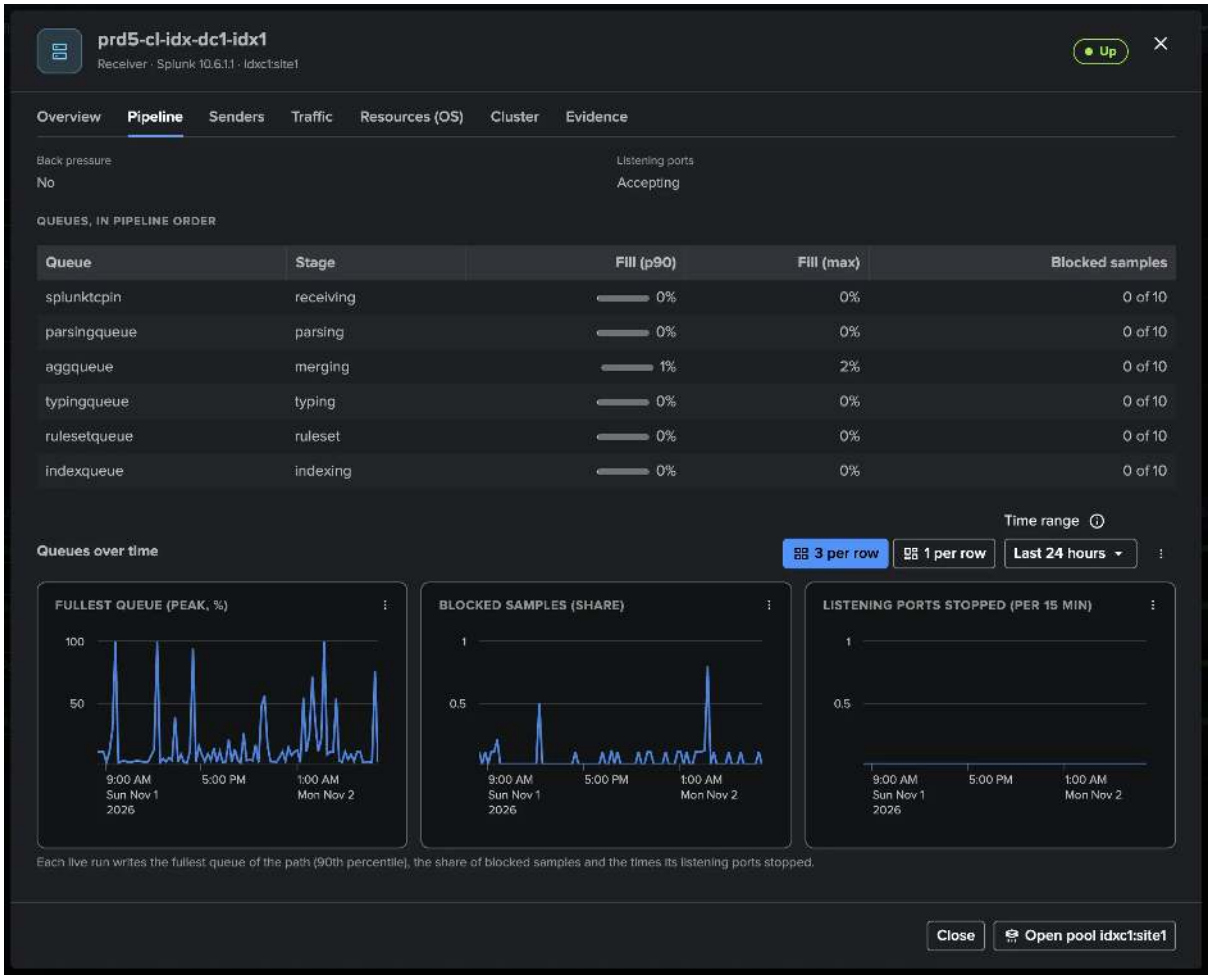
Blocked now. When a host of the last five minutes has a blocked queue, the strip's **Blocked now · N of M hosts** opens what is blocked: each host with its role, its pool and its inbound, every blocked queue with what that stage of the pipeline does, a stopped listening port, **Open in Search** on the host's queues, and the **queue history** of each blocked queue (usage, used and capacity, last 15 minutes to 24 hours, two hosts per page). These are measurements: the host statuses and the findings come from the scheduled collection, so a queue blocked for a few samples shows here without any finding opening.



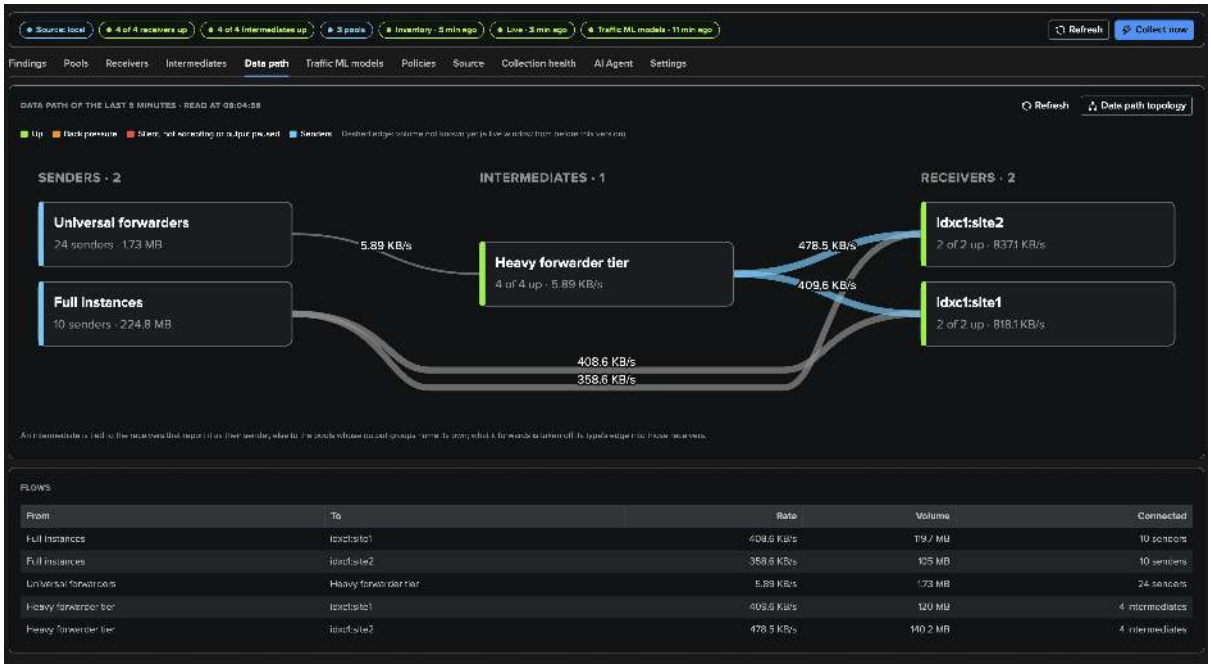
The pool modal has tabs Overview, Members, **Distribution** (one bar per active member's share of the pool, the fair-share line and the imbalance band of the Receiver imbalance setting; switch between sender connections and volume; Jain's fairness index), Traffic (with the traffic model's band on a receiver pool), Cluster (an indexer cluster pool), Resources (the members' CPU and memory) and Definition.



The host modal has tabs Overview (status, senders, inbound, worst queue, the last 5 minutes, and what needs attention with its open findings), **Pipeline** (the queues in pipeline order with fill bars and over time, the listening ports, an intermediate's output groups and destinations), Senders (posture tiles, senders by version, the senders table), Traffic, Resources, Cluster (an indexer peer) and Evidence.



The Data path tab draws the forwarding path of the last five minutes from what the receivers report: the sender types, the intermediates and the receivers, edges sized by volume, and a Flows table that states every edge in words. An intermediate is tied to its receivers by its output group, never by guessing from a destination address; **Data path topology** saves it to Topology Studio.



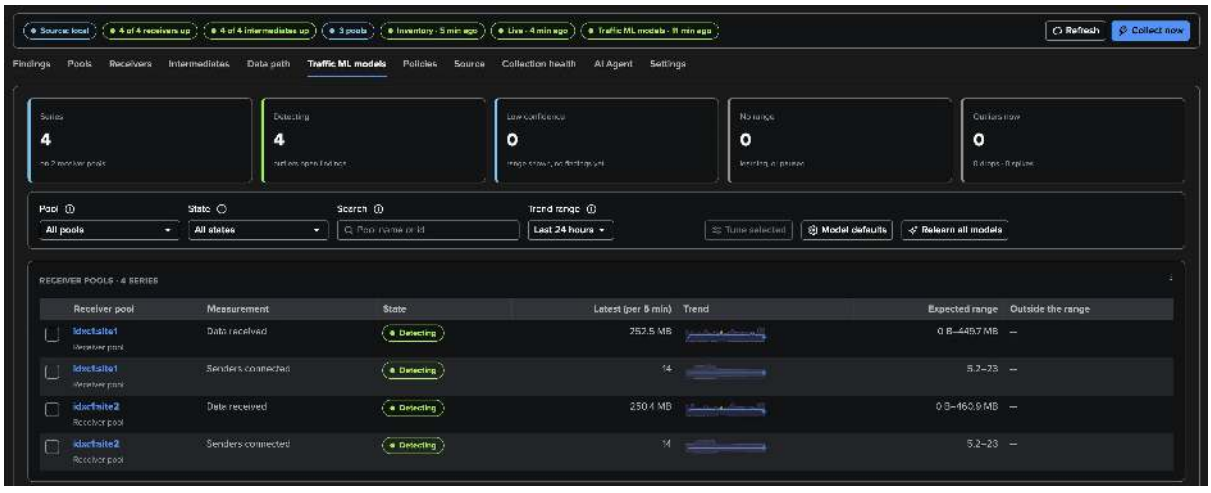
What the figures mean

Figure	Meaning
Inbound	The KB of the host's (or pool members') connection lines in the live window, by index time.
Senders	Distinct sender GUIDs, exact: a sender load balancing over N members counts once for the pool, never as a sum of per-member counts.
Connections	Sender connections: a sender connected to N receivers counts N times.
Worst queue	The highest 90th-percentile fill of the host's path queues (the output queue excluded).
Back pressure	A queue saturated: 90th-percentile fill of 80 % or more, or blocked in 30 % or more of its samples.
Balance	Jain's fairness index of the volume of every member up (1 is an even split).
Expected size	A cluster's registered peers (a site pool: the peers of its site), else the configured size, else the second-highest daily peak of members up over 7 days.

Traffic ML models

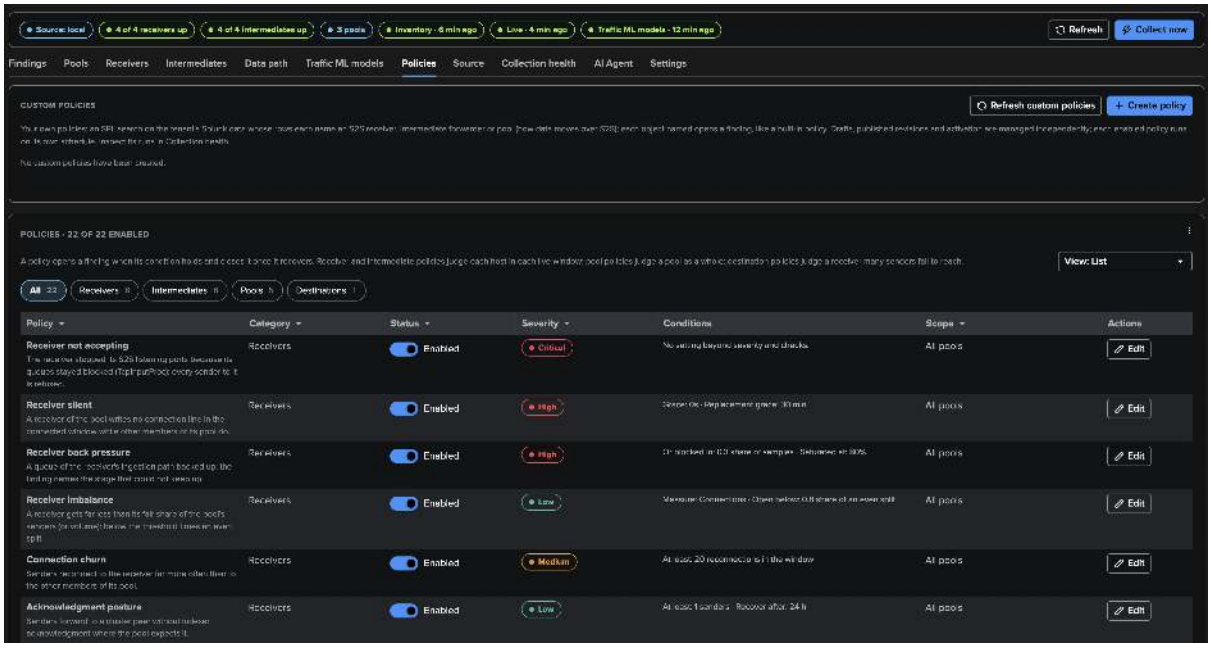
Every receiver pool (each site pool of a multisite cluster) has two traffic models: **KB received** (per five minutes) and **connected senders** (the distinct senders of each member, summed over the members). They are learned per weekday and hour from the members' connection lines over the tenant's model learning history (14 days by default; 0, 7, 14, 30, 60 or 90 days), refreshed every half hour. A five-minute bucket in which a member reported and the pool received nothing counts as zero.

The **Traffic models** tab lists every model with its state, opens the model view (the expected range against the observed traffic), **Tune model** with a simulation of past windows, **Not an anomaly** on a finding, and, for TrackMe administrators, **Model defaults** and **Relearn all models**. These are the traffic model features of the Splunk HEC and Cribl Stream tenants: see *Traffic ML models and Expected traffic*. The **Pool traffic outlier** policy uses them; **Pool traffic drop** is a plain statistic (the same hour's median over 7 days) and needs no model. Intermediate pools, discovered hosts and empty pools are not modelled. Bank holidays are not learned.



Policies

Twenty-two built-in policies cover the receivers, the intermediate forwarders, the pools and the destinations; every policy is evaluated. Each policy has its severity, the runs it needs to open and to recover, a scope (**Pools**: empty means every pool and the hosts no pool claims), a bank holiday hold, and a **How it is evaluated** tab that shows the rule as configured, the data it reads with ready-to-run searches on the tenant's own source, and how to investigate and resolve.



The most useful policies to know first:

- **Receiver not accepting** (critical) — the receiver stopped its listening ports because its queues stayed blocked: every sender to it is refused.
- **Intermediate output blocked** (critical) — an intermediate paused its output: every sender behind it is held back. The finding counts the senders held and names the destinations.
- **Back pressure cascade** (critical) — in one window, a receiver pool backs up while intermediates are paused towards it: one finding names the origin and the intermediates held.
- **Pool capacity** (high, critical when no member is up) — fewer members up than expected.
- **Receiver back pressure** and **Intermediate back pressure** (high) — a queue of the path is saturated; the finding names the bottleneck, and on an intermediate whether the cause is downstream, local or an upstream surge.
- **Destination unreachable** (high) — many senders fail to reach one receiver for 15 minutes: one finding on the receiver, the senders listed in its evidence.

Every policy, its defaults and its settings are in *Built-in policies*.
